- Status indication

During reverse execution, characters "RVRS" blink on the screen. During forward reexecution, characters "RTRY" blink to indicate that forward reexecution is in progress. The "RTRY" indication is kept blinking until the block at which reverse execution started is reached and normal operation starts (until forward execution is restarted).
When a block to be executed is no longer present during reverse execution, or if an attempt is made to perform reverse execution for a block that cannot be executed by reverse execution, characters "RVED" blink, notifying the user that reverse execution can no longer be performed.

- Number of blocks that can be executed by reverse execution

Up to about 100 blocks can be executed by reverse execution. Depending on the specified program, the maximum number of executable blocks may decrease.

- Reset

A reset operation (the RESET key on the MDI unit, the external reset signal, or the reset & rewind signal) clears the blocks stored for reverse execution.

- Feedrate

A feedrate to be applied during reverse execution can be specified in parameter No. 1414. If this parameter is set to 0, the feedrate in reverse execution is assumed to be the same as that in forward execution. Rapid traverse, however, is performed always at the rapid traverse rate, regardless of the setting of this parameter.
The feedrate in forward reexecution is always the same as that in forward execution.
In reverse execution or forward reexecution, feedrate override, rapid traverse override, and dry run are allowed.

- Start of reverse execution or forward reexecution after the end of a block

In a block for rapid traverse (G00), linear interpolation (G01), circular interpolation (G02, G03), dwelling (G04), skip cutting (G31), or an auxiliary function in an automatic operation mode (memory operation, part program operation, or MDI operation), reverse execution or forward reexecution can be started. However, reverse execution and forward reexecution do not start as soon as the reverse execution signal status is changed. When the block has ended, that is, after a movement, dwelling, or an auxiliary function is completed, reverse execution or forward reexecution starts.

- Start of reverse execution or forward reexecution after feed hold stop

When a feed hold stop operation is performed during execution of rapid traverse (G00), linear interpolation (G01), circular interpolation (G02, G03), or skip cutting (G31), then the reverse execution signal status is changed and operation is restarted, reverse execution or forward reexecution can be started immediately from the stop position. This cannot be performed when dwelling (G04) or an auxiliary function is being executed.

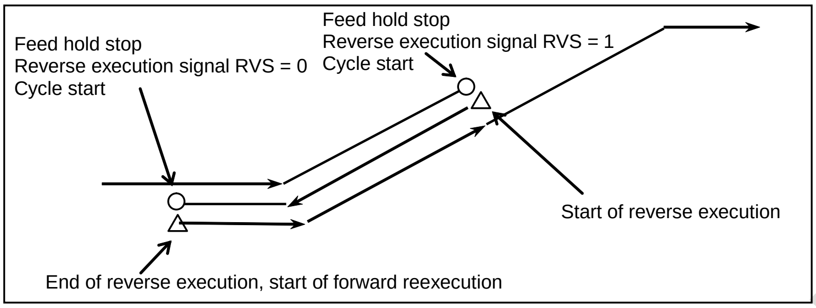

Fig. 5.10 (j)

When reverse execution is started after feed hold stop operation, the part from the start point of that block to the feed hold stop position is stored as one block. Therefore, when forward reexecution is performed with the single block switch set to 1, a single block stop takes place as soon as the position at which reverse execution started is reached.

- Start of reverse execution or forward reexecution after single block stop

After a single block stop takes place, reverse execution or forward reexecution can be started immediately when the reverse execution signal status is changed and restart operation is performed.

Limitation

- Blocks that cannot be executed by reverse execution

In the modes listed below, reverse execution cannot be performed.
When one of these commands appears during reverse execution, reverse execution ends immediately and "RVED" is displayed.

- Cylindrical interpolation (G07.1,G107)
- Polar coordinate command (G16)
- Functions related thread cutting (G33,G34,G35,G36)
- Polygon turning (G50.2, G51.2)
- Tool axis direction control (G53.1)
- Single direction positioning (G60)
- Tapping mode (G63)
- Tapping cycle (G84,G74)
- Rigid tapping cycle (G84,G74,G84.2,G84.3)
- Fine boring cycle (G76)
- Back boring cycle (G87)

It is impossible to perform reverse execution for blocks specifying the commands listed below. If one of these commands appears during reverse execution, reverse execution ends immediately and "RVED" is displayed.
Some of these commands turn a mode on and off. It is possible to start reverse execution and perform forward reexecution in a mode set by such a command. However, if a block that turns the mode on or off is reached during reverse execution, the reverse execution ends at that block, and "RVED" is displayed.

- Functions related AI contour control (G05,G05.1,G08)
- HRV3 on/off (G05.4)
- Inch/metric conversion (G20, G21)
- Stored stroke check on/off (G22, G23)
- Functions related reference position return (G27, G28, G29, G30)
- 3-dimensional coordinate system conversion (G68, G69)
- Feature coordinate system (G68.2)
- Figure copying (G72.1,G72.2)
- Index table indexing
- Cs contouring control

- Spindle positioning

- Switching of automatic operation mode

When a single block stop operation is performed during reverse execution or forward reexecution and the mode is changed from memory operation to MDI operation or vice versa, it becomes impossible to perform reverse execution, forward reexecution, and forward execution. To restart operation, restore the original mode, then perform a cycle start operation.

- Single block stop position

A block that is internally generated by the control unit is also treated as one block during reverse execution.

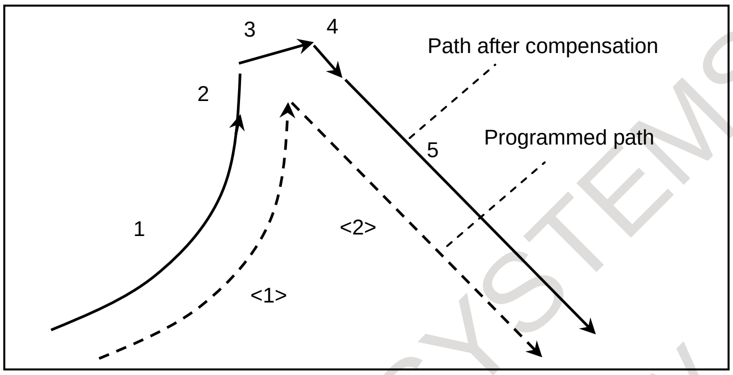

Fig. 5.10 (k) Path when cutter compensation is applied

In the above example, the program specifies two blocks, but in actual operation, move commands for five blocks are generated.
In such a case, positions at which a single block stop takes place may differ between forward execution and reverse execution.

- Positioning (G00)

When non-linear type positioning is performed (bit 1 (LRP) of parameter No. 1401 is set to 0), the tool path in reverse execution and that in forward execution do not match. The tool path in forward reexecution is the same as that in forward execution.
When linear type positioning is performed (bit 1 (LRP) of parameter No. 1401 is set to 1), the tool path in reverse execution is the same as that in forward execution.

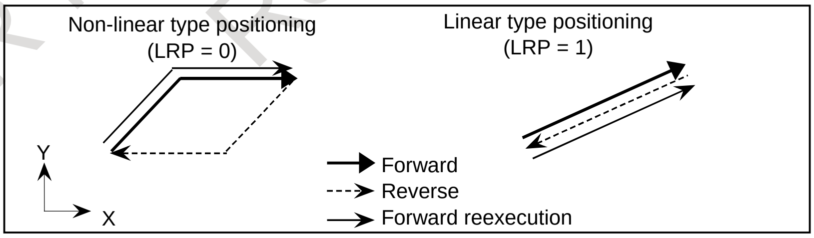

Fig. 5.10 (l)

- Dwell command (G04)

During reverse execution or forward reexecution, the dwell command (G04) is executed in the same way as in normal operation.

- Programmable data input (G10)

Tool compensation values, parameters, pitch error data, workpiece origin offsets, and tool life management values set or modified by programmable data input (G10) are ignored during reverse execution and forward reexecution.

- Skip function (G31) and automatic tool length measurement (G37)

The skip signal and the automatic tool length measurement signal are ignored during reverse execution and forward reexecution. During reverse execution and forward reexecution, the tool moves along the path that the tool has actually passed during forward execution.

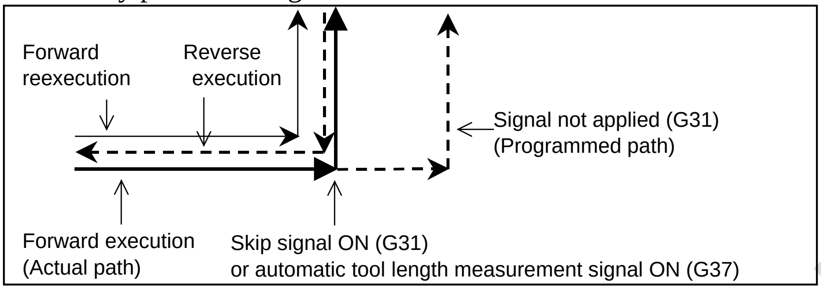

Fig. 5.10 (m)

- Setup of a coordinate system (G92, G54 to G59, G54.1P_, G52, and G92.1)

As for the display of the absolute coordinate value under reverse motion, the value in the work coordinate system when reverse motion begins is displayed. Therefore, when the command (G92, G54 to G59, G54.1P_, and G52) to which the work coordinate system is changed is passed, a different value might be displayed as forward movement. However, the actual machine position does not differ.

- Mirror image

When a block to which a mirror image is applied by programmable mirror image (G50.1, G51.1) is executed during reverse execution, the tool moves along the actual path resulting from the application of a mirror image in the reverse direction.
When a mirror image is applied to a block by setting or a machine signal, the block with the mirror image not applied is stored. Mirror image application by setting or a machine signal is enabled also during reverse execution and forward reexecution. Therefore, during reverse execution and forward reexecution, the mirror image by setting data or machine signal must be turned on and off so that this on/off status and the on/off status during forward execution match.

- Changing offsets

Even when cutter compensation offsets or tool length offsets are changed during reverse execution or forward reexecution, the change in compensation or offset data does not become valid until forward reexecution ends and normal operation starts. Until then, the tool moves with the offset data that was applied when the block was executed for the first time during forward execution.

- Feedrate clamp

During reverse execution or forward reexecution, feedrate clamp is not performed with parameter No. 1420 (rapid traverse rate) or parameters Nos. 1430 and 1432 (maximum cutting feedrate). It is executed with parameter No. 1414 or at the feedrate assumed during forward execution.
If, for example, the parameters above are set to smaller values during reverse execution or forward reexecution, clamp is not performed with these values, but with parameter No. 1414 or at the feedrate assumed during forward execution.
For clamp at the feedrate assumed during backward execution or forward reexecution, change the feedrate with the external deceleration or override signal.

- Interrupt type custom macro

(1) Do not initiate any interrupt during reverse execution.
(2) Do not execute an interrupted block and the interrupt program in reverse execution.

- Tool management function

The tool life is not counted during reverse execution and forward reexecution.

- Inverse time feed (G93)

If a nonzero value is set as the feedrate to be applied during reverse execution in parameter No. 1414, a block that moves the tool by inverse time feed during forward execution is executed at the parameter-set feedrate (feed per minute) during reverse execution.
If the feedrate during reverse execution (parameter No. 1414) is not set (= 0), the same feedrate as applied during forward execution is used.

- Maximum spindle speed clamp (G92Sxxxx)

Clamping at a maximum spindle speed specified during reverse execution becomes valid. This means that if G92Sxxxx appears during reverse execution, the spindle speed is clamped at Sxxxx in the subsequent reverse execution. As a result, the clamp speed may differ between reverse execution and forward execution even when the same block is executed. The spindle speed is clamped when the G96 mode is set.

- Auxiliary functions

M, S, T, and the second auxiliary function (B function) are output directly also during reverse execution and forward reexecution.
When specified together with a move command in the same block, M, S, T, and the second auxiliary function (B function) are output with the move command at the same time during forward execution, reverse execution, and forward reexecution. Therefore, the output positions of M, S, T, and the second auxiliary function (B function) during reverse execution differ from those during forward execution and forward reexecution.

- Custom macro

Custom macro operations are ignored during reverse execution and forward reexecution.

- Execution macro (macro executor)

Macro executor operations are ignored during reverse execution and forward reexecution.

- Tool retract and recover function

For retract operation and repositioning operation by the tool retract and recover function, reverse execution cannot be performed. Retract operation and repositioning operation are ignored during reverse execution and forward reexecution.

- AI contour control

When the reverse execution is started in AI contour control mode, a reverse execution ends immediately depending on a program then the reverse motion is not possible.
During reverse execution and forward reexecution, the feedrate clamp function by acceleration under AI contour control is disabled.

- Display

During reverse execution and forward reexecution, the modal display and the display of the currently executed program are not updated; information obtained at the start of reverse execution is maintained.

Signal

Reverse execution signal RVS<Gn007.0>

[Classification] Input signal

[Function] Requests the control unit during automatic operation (DNC operation and MDI operation except memory operation and binary operation) to return the tool by retracing the path the tool has passed so far.

[Operation] When this signal is set to “1” during forward execution, the machining path along which the tool has moved so far is retraced. Note that, however, reverse execution does not start as soon as this signal is set to “1”; reverse execution starts after the forward execution of the current block ends. When this signal is set to “0” during reverse execution, switching from reverse execution to forward reexecution takes place. Also in this case, forward reexecution does not start as soon as the signal is set to “0”, but forward reexecution starts after the reverse execution of the current block is completed.

To make swift switching from forward execution to reverse execution or from reverse execution to forward reexecution, set the automatic operation stop signal *SP to 0 to stop automatic operation, and after the automatic operation in-progress signal STL becomes “0” and the automatic operation stop state is entered, change the RVS signal status. Subsequently, after the automatic operation stop signal *SP is set to “1” and the status of the automatic operation in-progress signal ST is changed from “1” to “0” to start automatic operation, it becomes possible to change the execution mode to reverse execution or forward reexecution in the middle of a block.

Reverse execution in-progress signal RVSL<Fn082.2>

[Classification] Output signal

[Function] Posts that reverse execution is being performed.

[Output cond.] This signal is set to “1” when:

- The reverse execution signal RVS is set to “1” and reverse execution is being performed.

This signal is set to “0” when:

- The reverse execution signal RVS is set to “0” and forward reexecution or forward execution is being performed.
- Blocks to be executed are no longer present during reverse execution, and so execution is stopped.

During reverse execution, the M, S, T, and second auxiliary functions are executed in the same way as during forward execution. When these functions are not to be performed in the same way as during forward execution, use this signal to allow the PMC to perform appropriate processing.

In particular, when the M, S, T, or second auxiliary function and a move command are specified in the same block, the positions at which the code signal and strobe signal are output differ between forward execution and reverse execution. Therefore, use this signal and distribution completion signal DEN to allow the PMC to perform appropriate processing as necessary.

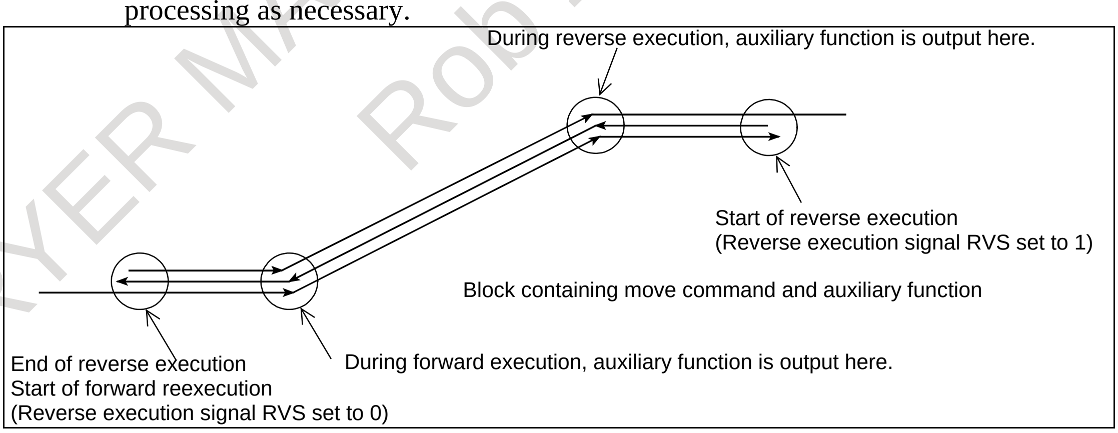

Fig. 5.10 (n)

Signal address

Parameter

1414	Cutting feedrate for reverse motion

[Input type] Parameter input
[Data type] Real path
[Unit of data] mm/min, inch/min, deg/min (machine unit)
[Min. unit of data] Depend on the increment system of the reference axis
[Valid data range] Refer to the standard parameter setting table (C)
(When the increment system is IS-B, 0.0 to +999000.0)
Set a cutting feedrate for retrace operation. When 0 is set, a retrace operation is performed at a programmed feedrate.

NOTE
This parameter has no effect on blocks that are in rapid traverse mode during reverse execution.

Warning

⚠ **WARNING**

1 Auxiliary functions are output directly even during reverse execution and forward reexecution. Accordingly, note that the execution status of an auxiliary function during forward execution may be reversed during reverse execution.
Example:
When forward rotation of the spindle(M03) and stop (M05) are specified.
When N3 is executed during reverse execution, M05 is output. So, when N2 and N1 are executed during reverse execution, operation is performed with the spindle stopped.
When N1 is executed during forward reexecution, M03 is output. So, when N1 and N2 are executed during forward reexecution, operation is performed with the spindle rotating in the forward direction.

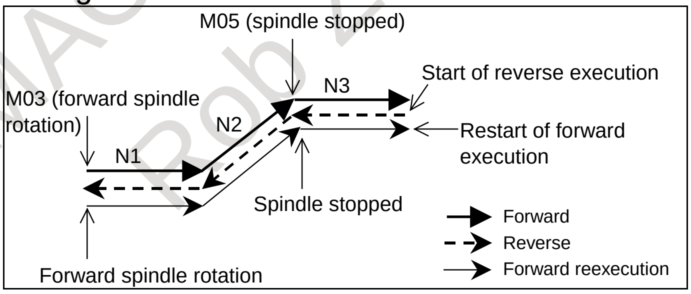

Fig. 5.10 (o)

2 To perform reverse execution after a feed hold stop or single block stop operation, be sure to restore the original position if manual intervention has been performed after the stop , then set the reverse execution signal to 1. Movements made by manual intervention are ignored during reverse execution and forward reexecution. (The same operation as in the manual absolute off state takes place.)
If manual intervention is performed during reverse execution or forward reexecution, the amount of manual intervention is added to the coordinate system at a restart after a stop due to a feed hold or single block during forward execution after the end of forward reexecution. Whether to add the amount of manual intervention follows the manual absolute signal *ABSM <Gn006.2>.

5.11 EXACT STOP / EXACT STOP MODE / TAPPING MODE / CUTTING MODE

Overview

NC commands can be used to control a feedrate in continuous cutting feed blocks as described below.

- Exact stop (G09)

The tool is decelerated in a block specifying G09, and an in-position check (*1) is performed. When the feed motor falls in-position, the tool is moved by the next block. This function may be used to produce a sharp edge at the corner of a workpiece at cutting feed.

- Exact Stop Mode (G61)

When G61 is commanded, deceleration of cutting feed command at the end point and in-position check is performed per block thereafter. This G61 is valid until G62 (automatic corner override), G63 (tapping mode), or G64 (cutting mode), is commanded.

- Tapping Mode (G63)

When G63 is commanded, feed rate override is ignored (always regarded as 100%), and feed hold also becomes invalid. Cutting feed does not decelerate at the end of block to transfer to the next block. Tapping signal TAP<Fn001.5> is set to "1" during tapping mode. This G63 is valid until G61 (exact stop mode), G62 (automatic corner override), or G64 (cutting mode) is commanded.

> **NOTE**
> Spindle override is enabled during tapping mode.

- Cutting Mode (G64)

When G64 is commanded, deceleration at the end point of each cutting feed block thereafter is not performed and cutting goes on to the next block. This command is valid until G61 (exact stop mode), G62 (automatic corner override), or G63 (tapping mode) is commanded. However, in G64 mode, feed rate is decelerated to zero and in-position check is performed in the following case;
1) Positioning mode (G00, G60)
2) Block with exact stop check (G09)
3) Next block is a block without movement command

*1 The term in-position indicates that the servo motor reaches in a range of positions specified by a parameter. See Section "In-position check" and "In-position check independently of feed/rapid traverse" for details.

> **NOTE**
> When the in-position check signal SMZ<Gn053.6> is set to "1", cutting feed decelerates at the end point of each block and an in-position check is performed even in tapping mode or cutting mode.

(Example) Tool paths from block <1> to block <2>

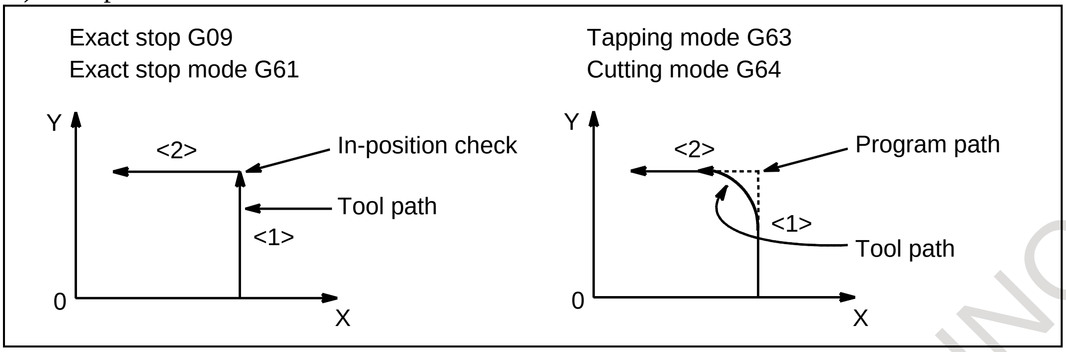

Fig. 5.11 (a)

- Restriction on tapping mode (G63)

There are restrictions when the following functions are used. Please refer to each function for detail.

- Retrace
- AI contour control

Signal

Tapping signal TAP<Fn001.5>

[Classification] Output signal

[Function] Reports that tapping is in progress.

[Output cond.] The signal is set to "1" when:

- The system is in tapping cycle mode.
  (G74,G84 : for M series)
  (G84,G88 : for T series)
- The system is in tapping mode.
  (G63)

The signal is set to "0" when:

- The system is in neither tapping cycle mode nor tapping mode.

> **NOTE**
> When a reset or emergency stop is specified in tapping cycle mode, if the system is not in tapping mode, this signal is set to "0".

5.12 RETRACTION FOR RIGID TAPPING / RETRACTION FOR 3-DIMENSIONAL RIGID TAPPING

Overview

When rigid tapping is stopped by a result of a power shutdown, emergency stop, or reset, the tap may cut into the workpiece. The tap can subsequently be drawn out by using a PMC signal or a program command. This function automatically stores information on tapping executed most recently. When a tap retraction

signal is input or G30 is specified, only retraction in the rigid tapping cycle is executed, based on the stored information, and the tap is removed and pulled toward the R point. When a retract value α is set in parameter No. 5382, the retraction distance can be increased by α.
The machining data for rigid tapping retraction is retained until the next rigid tapping command is specified, even after the power is turned off. Rigid tapping retraction can, therefore, be specified even after the power is turned off.
In retraction for 3-dimensional rigid tapping, the tap is removed and pulled when 3-dimensional rigid tapping or rigid tapping in tilted working plane indexing command mode is stopped.

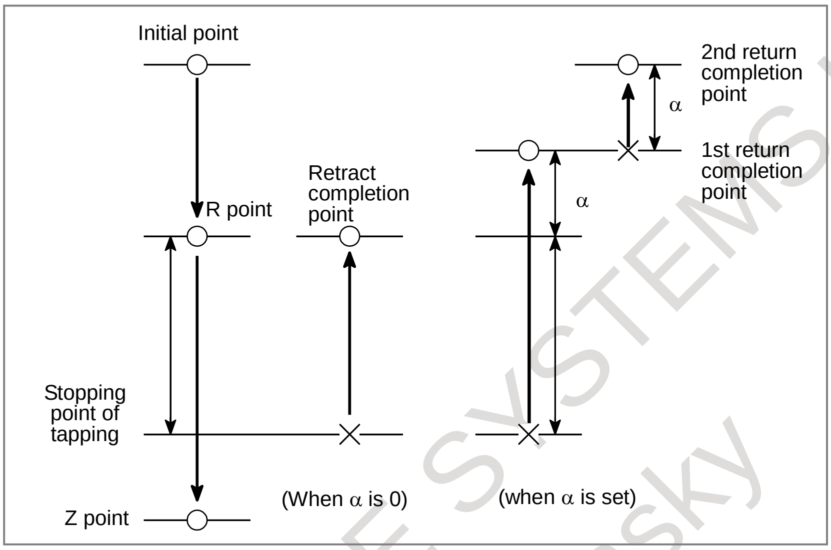

Fig. 5.12 (a)

> **NOTE**
> 1 Retraction for rigid tapping and 3-dimensional rigid tapping are optional functions.
> 2 To use retraction for rigid tapping, option of rigid tapping is also required.
> 3 To use 3-dimensional rigid tapping, option of retraction for rigid tapping is also required.

Basic procedure

- Retraction for rigid tapping by using a PMC signal

This method is used when bit 1 (RG3) of parameter No. 5202 is 0.

1 Start
Reset the CNC, then select MDI mode. Setting rigid tapping retraction start signal RTNT <Gn062.6> to “1” starts rigid tapping retraction.

2 Completion
Upon the completion of rigid tapping retraction, rigid tapping retraction completion signal RTPT <Fn066.1> is set to “1”, with which the CNC automatically enters the reset state. Setting rigid tapping retract start signal RTNT to “0” sets rigid tapping retraction completion signal RTPT to “0”.

3 Stop
During rigid tapping retraction, setting rigid tapping retraction start signal RTNT to “0” stops rigid tapping retraction, placing the CNC in the reset state. To resume rigid tapping retraction, set rigid tapping retraction start signal RTNT to “1”. Rigid tapping retraction can also be stopped by means of a reset or feed hold.

4 Resume
Once rigid tapping retraction has been stopped, it can be resumed by performing the same operation as that used for starting rigid tapping retraction. If rigid tapping retraction has been completed, however, the start operation does not restart rigid tapping retraction. If retract value α is set in parameter No. 5382, however, the start operation performs rigid tapping retraction using α only.

- Start and completion time chart

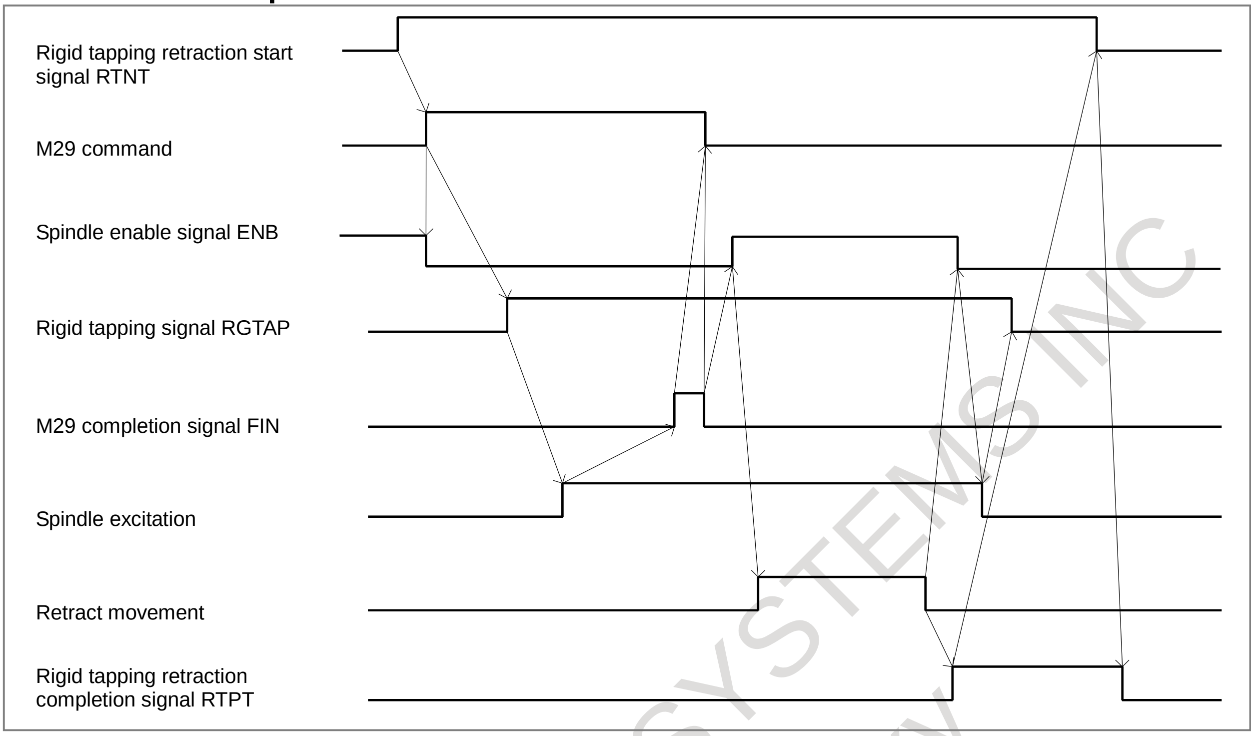

Fig. 5.12 (b) Start and completion time chart

In the reset state, setting rigid tapping retraction start signal RTNT to "1" in MDI mode causes the rigid tapping M command to be output. For rigid tapping retraction, specify neither gear switching nor orientation. Spindle function strobe signal SF is also output if no S command has been specified after power-on.
Upon the completion of rigid tapping retraction, spindle enable signal ENB <Fn001.4> is set to "0", in the same way as at the end of ordinary rigid tapping. Therefore, perform the sequence for canceling rigid tapping. Once rigid tapping retraction has been completed, rigid tapping retraction completion signal RTPT is set to 1 and the CNC enters the reset state.

- Time chart for stopping tapping retraction

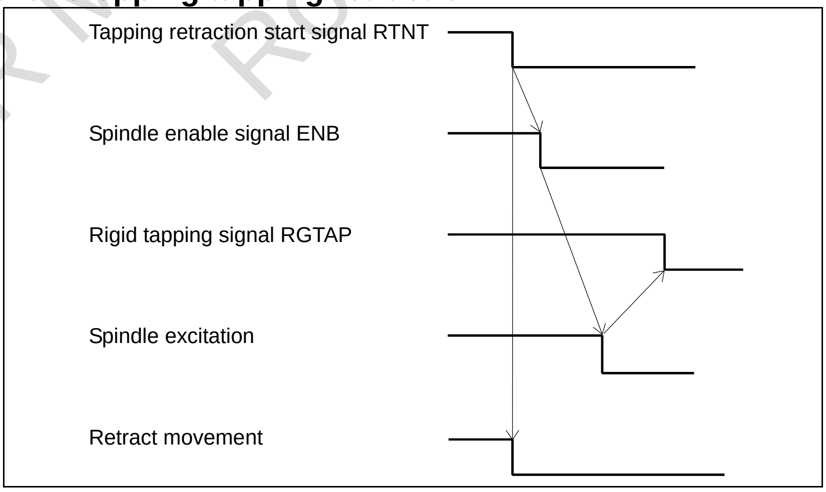

Fig. 5.12 (c)

When tapping retraction is stopped, spindle enable signal is set to "0", in the same way as for ordinary rigid tapping. Therefore, perform the sequence for canceling rigid tapping. The CNC also automatically enters the reset state when tapping retraction is stopped.

- Retraction for rigid tapping by using the G30 command

If bit 1 (RG3) of parameter No. 5202 is 1, it is possible to perform retraction for rigid tapping by using the G30 command.
If rigid tapping is interrupted due to a reset or emergency stop or if the power is turned off during rigid tapping, executing the command below in MEM or MDI operation causes the tapping axis to move to the initial point or the R point while synchronized with the spindle, based on the rigid tapping command information in the machining program.
The command for retraction for rigid tapping is a one shot command.

- Retraction for rigid tapping
  G30 P99 M29 S $\underline{\text{min}^{-1}}$;

(Example)

```
Machining program
----------
M29 S1000 ;
G84 X20.0 Y20.0 R-10.0 Z-30.0 F500 ;
X50.0 Y50.0 ;
X100.0 Y100.0 ;
G80
----------

Retraction program
----------
G30 P99 M29 S1000 ;
G00 Z-10.0 ;
----------
```

- Retraction for rigid tapping during 3-dimensional coordinate system conversion

G68 Xxx Yyy Zzz Iii Jjj Kkk Rrr ;	(3-dimensional coordinate system conversion) (NOTE 1)
G30 P99 M29 Sxxx ;	(Retraction for rigid tapping) (NOTE 2)

- Retraction for rigid tapping in tilted working plane indexing mode

G68.2 Xxx Yyy Zzz Iii Jjj Kkk Rrr ;	(Tilted working plane indexing) (NOTE 1)
G53.1 ;	(Tool axis direction control)
G30 P99 M29 Sxxx ;	(Retraction for rigid tapping) (NOTE 2)

NOTE
1. Specify arguments used when rigid tapping stops.Alarm PS5384 occurs if the specified arguments are different from those used at stopping.
2. M-code and S-code used when rigid tapping stops are executed regardless of the "M29 Sxxxx" command. "M29 Sxxxx" can be omitted from the G30 P99 command.
3. If a value other than 0 is set in parameter No. 5210, specify the value instead of M29 in the above program.
4. Be sure to set bit 0 (G84) of parameter No. 5200 to 0 before using this function.

Limitation

T

When G code system A is used for a lathe system, retraction for rigid tapping using Rigid tapping retraction start signal RTNT <Gn062.6> (parameter RG3(bit 1 of No.5202)=1), you may want to use an axis parallel to one of the basic three axes as a drilling axis. In this case, use the extended axis name function to specify X*, Y*, or Z* (* is an alphanumeric character) as the axis name of the axis parallel to one of the basic three axes.

Examples

Basic three axes: X, Y, and Z

Parallel axes: XA, YA, and ZA

Note

1. When retraction involves movement only for the retract value set in parameter No. 5382, the retraction operation is executed in the program coordinate system in 3-dimensional coordinate system conversion mode or tilted working plane indexing mode.
2. Retraction for rigid tapping by the G30 command results in alarm PS5384 if the program coordinate system used when rigid tapping is stopped is different from that used for retraction for rigid tapping. The program coordinate system is the coordinate system for the program after conversion is determined by the rotation center, the direction of rotation, and the rotation angle that was commanded by the arguments of the G68 or G68.2 command. In other words, the arguments of G68 or G68.2 command are different at the stop of rigid tapping and in retraction for rigid tapping.

Signal

Rigid tapping signal RGTAP <Gn061.0>

[Classification] Input signal

[Function] The M29 (rigid tapping mode ready auxiliary function) command causes the PMC to place itself in rigid tapping mode, turning this signal ON and notifying the CNC.

1 : The PMC is in rigid tapping mode.

0 : The PMC is not in rigid tapping mode.

For an explanation of the processing for placing the PMC in rigid tapping mode, see "Interface with the PMC", to be described later. This signal is a check signal used to determine whether the PMC is placed in rigid tapping mode. If M29 is specified, but this signal is not set to “1”, a PS alarm will be issued in a G84/G74 (machining center system) or G84/G88 (lathe system) block.

Rigid tapping retraction start signal RTNT <Gn062.6>

[Classification] Input signal

[Function] Starts rigid tapping retraction.

[Operation] When this signal is set to “1”, the control unit operates as follows:

- Starts rigid tapping retraction.

Rigid tapping retraction completion signal RTPT <Fn066.1>

[Classification] Output signal

[Function] Notifies the completion of rigid tapping retraction.

[Output cond.] This signal is set to “1” in the following case:

- Rigid tapping retraction has been completed.

This signal is set to “0” in the following case:

- Rigid tapping retraction start signal has been set to “0”.

Signal address

	#7	#6	#5	#4	#3	#2	#1	#0

Gn062		RTNT						
Fn066							RTPT	

Parameter

	#7	#6	#5	#4	#3	#2	#1	#0
5200				DOV				

[Input type] Parameter input
[Data type] Bit path

#4 DOV Override during extraction in rigid tapping:
0: Invalidated
1: Validated (The override value is set in parameter No. 5211. However, set an override value for rigid tapping return in parameter No. 5381.)

	#7	#6	#5	#4	#3	#2	#1	#0
5201					OVU			

[Input type] Parameter input
[Data type] Bit path

#3 OVU The increment unit of the override parameter No. 5211 for tool rigid tapping extraction and No. 5381 for tool rigid tapping return is:
0: 1%
1: 10%

	#7	#6	#5	#4	#3	#2	#1	#0
5202							RG3	

[Input type] Parameter input
[Data type] Bit path

> **NOTE**
> When this parameter is set, the power must be turned off before operation is continued.

#1 RG3 Retraction for rigid tapping is performed by:
0: Rigid tapping retraction start signal RTNT <Gn062.6>.
1: One-shot G code G30 command.

> **NOTE**
> 1 When this parameter is 1, retraction for rigid tapping using the rigid tapping retraction start signal RTNT <Gn062.6> cannot be performed.
> 2 When this parameter is 1, use the method to use the M code of rigid tapping mode. (Parameter G84(bit 0 of No.5200)=0)

5381	Override value during rigid tapping return

[Input type] Parameter input
[Data type] Word path
[Unit of data] % or 10% (The unit of this parameter depends on the parameters OVU (bit 3 of parameter No.5201))
[Valid data range] 0 to 200
This parameter is used to set the override value during rigid tapping return.
If the setting is 0, no override is applied.

NOTE
1. This parameter is valid when bit 4 (DOV) of parameter No. 5200 for enabling override at normal extraction time is set to 1.
2. When the parameter OVU (bit 3 of No.5201) is set to 1, the data unit of this parameter is 10%.
3. If the setting value is less than or equal to 0, it is treated as 100%. Also, if the setting value is greater than 200, it is treated as 2000% or 200%.

5382	Amount of return for rigid tapping return

[Input type] Parameter input
[Data type] Real path
[Unit of data] mm, inch (input unit)
[Min. unit of data] Depend on the increment system of the drilling axis
[Valid data range] 0 or positive 9 digit of minimum unit of data (refer to the standard parameter setting table (B))
(When the increment system is IS-B, 0.0 to +999999.999)

This parameter is used to set an extra amount of rigid tapping return. The tool is retracted additionally near point R by the distance set in this parameter. If the tool has already been retracted from rigid tapping, it will be retracted further only by the distance specified in this parameter.

NOTE
If a negative value is set in this parameter, it is treated as a positive value.

Warning

⚠ WARNING
1. For rigid tapping retraction, the CNC internally activates a return program. Rigid tapping retraction may, therefore, cause some G codes or M/F/S/L codes to be overwritten (G80/G84/G74, G94/G95).
2. During rigid tapping retraction, do not change any setting affecting the travel distance (such as the increment system, input unit 10 time multiply, or calculator-type decimal notation) that was made when machining data was stored for rigid tapping retraction.

Caution

⚠ CAUTION
1. If rigid tapping is stopped as a result of an emergency stop, the position on the tapping axis (Z-axis) is maintained but the spindle position is lost. In such a case, therefore, the positional relationship between the spindle and tapping axis is not guaranteed when operation is resumed.
2. Rigid tapping retraction is performed based on the tapping axis (Z-axis) commands accumulated for tapping. If rigid tapping is stopped as a result of an emergency stop, therefore, rigid tapping retraction may fail to draw the tapping tool completely out of the workpiece. In such a case, set retract value α (parameter No. 5382).
3. During rigid tapping retraction, switching the mode to the manual operation mode stops rigid tapping retraction, and decelerates and stops the machine.

> ⚠ **CAUTION**
> 4 If the power is turned off during rigid tapping motion by power failure or etc, when retraction for rigid tapping is executed after the power turned on, the tapping axis (Z-axis) may be retracted additionally by the accumulated distance of acceleration/deceleration.

Note

> **NOTE**
> 1 Setting rigid tapping retraction start signal RTNT <Gn062.6> to “1” starts rigid tapping retraction only when the CNC is placed in both the reset state and MDI mode.
> 2 Rigid tapping retraction is not performed if the input increment (inches or millimeters) selected when machining data is stored for rigid tapping retraction differs from that selected when rigid tapping retraction is executed.
> 3 Override can be applied to rigid tapping retraction when bit 4 (DOV) of parameter No. 5200 is set to 1.
> 4 Set each parameter before executing retract for rigid tapping.

Alarm and Message

Number	Message	Description
PS5384	RETRACT FOR RIGID CANNOT BE CMD.	In retraction for 3-dimensional rigid tapping by the G30 command, program coordinate used when rigid tapping is stopped and that used for retraction for rigid tapping are different. The program coordinate system is the coordinate system for the program after conversion is determined by the rotation center, the direction of rotation, and the rotation angle that was commanded by the arguments of the G68 or G68.2 command. In other words, the arguments of G68 or G68.2 command are different at the stop of rigid tapping and in retraction for rigid tapping. Modify the program.

5.13 DNC OPERATION

Overview

When automatic operation is performed in the DNC operation mode (RMT), machining (DNC operation) can be performed while a program is being read via the RS-232C interface, from the Embedded Ethernet or from a memory card.
Before performing DNC operation, set parameters relating to the RS-232C interface.

> **NOTE**
> DNC operation cannot be performed while a program is being read from a USB memory.

Signal

DNC operation select signal DNCI<Gn043.5>

[Classification] Input signal

[Function] Selects the DNC operation mode (RMT).
To select the DNC operation mode (RMT), the memory operation mode (MEM) must be selected, and the DNC operation selection signal must be set to “1” at the same time.

[Operation] When this signal is set to “1”, the control unit operates as follows:
- If the memory operation mode (MEM) is not selected, the control unit ignores this signal and does nothing.
- If the memory operation mode (MEM) is selected, the DNC operation mode (RMT) is selected, enabling DNC operation. At this time, DNC operation selection confirm signal MRMT is set to “1”.

DNC operation selection confirm signal MRMT<Fn003.4>

[Classification] Output signal

[Function] Indicates that the DNC operation mode (RMT) is selected.

[Output cond.] This signal is set to “1” when:
- The DNC operation mode (RMT) is selected.

This signal is set to “0” when:
- Selection of the DNC operation mode (RMT) ends.

External device program execution signal DVCPR<Fn531.6>

[Classification] Output signal

[Function] The external device program is notified to being executed.

[Output cond.] This signal is set to “1” when:
- DNC operation
- M198 is being executed in MEM/MDI mode.

This signal is set to “0” when:
- Reset
- Switching to other mode (MEM/MDI) while DNC mode.
- Switching to other mode (MDI/DNC) while executing M198 in MEM mode.
- Switching to other mode (MEM/DNC) while executing M198 in MDI mode.

Signal address

	#7	#6	#5	#4	#3	#2	#1	#0
Gn043			DNCI					
Fn003				MRMT				
Fn531		DVCPR						

Parameter

	#7	#6	#5	#4	#3	#2	#1	#0
0138	MNC							

[Input type] Parameter input
[Data type] Bit

#7 MNC DNC operation from the memory card and external device subprogram call from the memory card are:
0: Not performed.
1: Performed. (In addition, compact flash card adapter is necessary)

NOTE
1 The compact flash card must be inserted in the front PCMCIA slot by using a compact flash card adapter.
2 When a DNC operation using a memory card is being performed, the memory card cannot be accessed to, for example, display a list of data stored on the memory card.
3 DNC operation using a memory card cannot be performed when the system has multiple paths.
4 During DNC operation using a memory card, never remove the memory card.
5 A program being executed by DNC operation cannot call another program on the memory card.
6 The memory card utilities of the CNC screen display function cannot be used to perform DNC operation.

	#7	#6	#5	#4	#3	#2	#1	#0
14885E							EDE	ISO

[Input type] Parameter input
[Data type] Bit

#0 ISO When the embedded Ethernet is selected as an I/O device, data input/output is performed using
0: ASCII codes.
1: ISO codes.

⚠ **WARNING**
1 Unless data is input using ASCII codes, set this parameter to 1 to input or output data using ISO codes.
2 Data input/output with ASCII codes is dangerous because parity information is not included and a data error during the data input/output is not detected.
3 DNC operation from the embedded Ethernet also must set the parameter to 1, and execute DNC operation by ISO code. Data input/output with ASCII codes is dangerous because parity information is not included and a data error during the data input is not detected.

#1 EDE DNC operation from the embedded Ethernet and external device subprogram call from the embedded Ethernet are:
0: Not performed.
1: performed.

NOTE
1 When DNC operation, check that the valid device is the embedded Ethernet port.
2 When a DNC operation using the embedded Ethernet is being performed, the embedded Ethernet cannot be accessed to, for example, display the Embedded Ethernet host file list screen.
3 DNC operation cannot be performed concurrently on multiple paths. DNC operation can be performed on one path at a time.
4 Only one DNC operation file can be set as a system.

Alarm and message

Number	Message	Description
SR0086	DR OFF	During I/O process by RS232C interface 1, the data set ready input signal of the I/O device (DR) was 0. Possible causes are an I/O device not turn on, a broken cable, and a defective printed circuit board.
SR1830	DR OFF(2)	During I/O process by RS232C interface 2, the data set ready input signal of the I/O device (DR) was 0. Possible causes are an I/O device not turn on, a broken cable, and a defective printed circuit board.
PS0123	ILLEGAL MODE FOR GOTO/WHILE/ DO	A GOTO statement or WHILE–DO statement was found in the program in the MDI or DNC mode.
PS1081	EXT DEVICE SUB PROGRAM CALL MODE ERROR	The external device subprogram call is not possible in this mode.

5.14 DIRECT OPERATION BY PERSONAL COMPUTER FUNCTION

Overview

When automatic operation is started in the DNC operation mode (RMT), it becomes possible to perform machining (direct operation = DNC operation) while a program is being read from a personal computer function.

DNC operation

To perform direct operation using a personal computer function, the following settings are required:

1. Determine connection destination 1 or 2 according to the connection method as follows:

Connection method	Destination
First HSSB board inserted in an option slot of the LCD-mounted type FS0*i*-F (except the 15-/19-inch LCD type)	Destination 1
Stand-alone type FS0*i*-F (For the stand-alone type, connect the HSSB cable to COP21A.)	Destination 1
Second HSSB board inserted in an option slot of the LCD-mounted type FS0*i*-F	Destination 2
HSSB board inserted in an option slot of the Stand-alone type FS0*i*-F	Destination 2
First HSSB board inserted in an option slot of the LCD-mounted type FS0*i*-F (15-/19-inch LCD type)	Destination 2

2. Make settings according to the connection destination as listed below. There are two setting methods for connection destination 1.

Destination	Setting
Destination 1	DMMC<G0042.7>=1
	I/O CHANNEL (parameter No.0020))=15 DNCI<G043.5>=1
Destination 2	I/O CHANNEL (parameter No.0020))=16 DNCI<G043.5>=1

Signal

Direct operation select signal DMMC<Gn042.7>

[Classification] Input signal

[Function] Selects the mode (direct operation mode) for performing machining while reading a program from the personal computer function.

[Operation] When this signal is set to "1", the control unit operates as follows:

- If the memory operation mode (MEM) is not selected, the control unit ignores this signal and does nothing.
- If the memory operation mode (MEM) is selected, the direct operation mode is selected, enabling direct operation.

DNC operation select signal DNCI<Gn043.5>

[Classification] Input signal

[Function] Selects the DNC operation mode (RMT).
To select the DNC operation mode (RMT), the memory operation mode (MEM) must be selected, and the DNC operation selection signal must be set to "1" at the same time.

[Operation] When this signal is set to "1", the control unit operates as follows:

- If the memory operation mode (MEM) is not selected, the control unit ignores this signal and does nothing.
- If the memory operation mode (MEM) is selected, the DNC operation mode (RMT) is selected, enabling DNC operation. At this time, DNC operation selection confirm signal MRMT is set to "1".

DNC operation selection confirmation signal MRMT<Fn003.4>

[Classification] Output signal

[Function] Indicates that the DNC operation mode (RMT) is selected.

[Output cond.] This signal is set to "1" when:

- The DNC operation mode (RMT) is selected.

This signal is set to "0" when:

- Selection of the DNC operation mode (RMT) ends.

5.15 DIRECT OPERATION BY C LANGUAGE EXECUTOR

Overview

When the DNC operation mode (RMT) is set, and automatic operation is started, it becomes possible to perform machining (direct operation = DNC operation) while reading a program from the C Language Executor.

Signal

Direct operation select signal DMMC<Gn042.7>

[Classification] Input signal

[Function] Selects the mode (direct operation mode) for performing machining while reading a program from the C Language Executor.

[Operation] When this signal is set to “1”, the control unit operates as follows:

- If the memory operation mode (MEM) is not selected, the control unit ignores this signal and does nothing.
- If the memory operation mode (MEM) is selected, the direct operation mode is selected, enabling direct operation.

DNC operation selection confirm signal MRMT<Fn003.4>

[Classification] Output signal

[Function] Posts that the DNC operation mode (RMT) is selected.

[Output cond.] This signal is set to “1” when:

- The DNC operation mode (RMT) is selected.

This signal is set to “0” when:

- Selection of the DNC operation mode (RMT) ends.

Signal address

	#7	#6	#5	#4	#3	#2	#1	#0
Gn042	DMMC							
Fn003				MRMT				

NOTE

As direct operation select signal DMMC<Gn042.7>, the same signal as the signal used for direct operation by personal computer function is used. Direct operation by personal computer function and direct operation by C Language Executor cannot be performed at the same time. If an attempt is made to use these functions at the same time, an application that executes the cnc_dncstart2 function first becomes valid.

6 INTERPOLATION FUNCTION

6.1 POSITIONING

Overview

The G00 command moves a tool to the position in the workpiece system specified with an absolute or an incremental command at a rapid traverse rate. In the absolute command, coordinate value of the end point is programmed. In the incremental command the distance the tool moves is programmed.
The tool path is determined by selecting one of the following with bit 1 (LRP) of parameter No. 1401:

- Linear interpolation type positioning
  The tool is positioned using a straight path and a speed that is not higher than the rapid traverse of each axis but that assures the shortest positioning time. By changing the acceleration/ deceleration type from the constant acceleration/deceleration (inclination) type to the constant time (time constant) type with bit 4 (PRT) of parameter No. 1603, the tool can be moved along a specified path.
- Non-linear interpolation type positioning
  Positioning is performed with each axis independently at the rapid traverse rate. Generally, the tool path is not a straight line.

The rapid traverse rate in the G00 command is set to the parameter No.1420 for each axis independently by the machine tool builder. In the positioning mode actuated by G00, the tool is accelerated to a predetermined speed at the start of a block and is decelerated at the end of a block. Execution proceeds to the next block after confirming the in-position.

Parameter

	#7	#6	#5	#4	#3	#2	#1	#0
1401							LRP	

[Input type] Parameter input
[Data type] Bit path

#1 LRP Positioning (G00)
0: Positioning is performed with non-linear type positioning so that the tool moves along each axis independently at rapid traverse.
1: Positioning is performed with linear interpolation so that the tool moves in a straight line.
When using 3-dimensional coordinate system conversion, set this parameter to 1.

1420	Rapid traverse rate for each axis

[Input type] Parameter input
[Data type] Real axis
[Unit of data] mm/min, inch/min, deg/min (machine unit)
[Min. unit of data] Depend on the increment system of the applied axis
[Valid data range] Refer to the standard parameter setting table (C)
(When the increment system is IS-B, 0.0 to +999000.0)
Set the rapid traverse rate when the rapid traverse override is 100% for each axis.

	#7	#6	#5	#4	#3	#2	#1	#0
1603				PRT				

[Input type] Parameter input
[Data type] Bit path

#4 PRT For positioning of linear interpolation type:
0: Acceleration/deceleration of acceleration fixed type is used.
1: Acceleration/deceleration of time fixed type is used.

Note

NOTE
1. The rapid traverse rate cannot be specified in the address F.
2. In case of linear interpolation type positioning, set the parameters Nos. 1620 and 1621 to the same values for all axes. If the setting values are different in each axis, the positioning may not be straight path.
   If linear rapid traverse is acceleration/deceleration before interpolation (FRP(bit 5 of parameter No.19501) is set to 1), the positioning path is straight even if the setting values are different in each axes.

OPERATOR'S MANUAL (B-64694EN)	Positioning (G00)

6.2 SINGLE DIRECTION POSITIONING

Overview

For accurate positioning without play of the machine (backlash), final positioning from one direction is available.

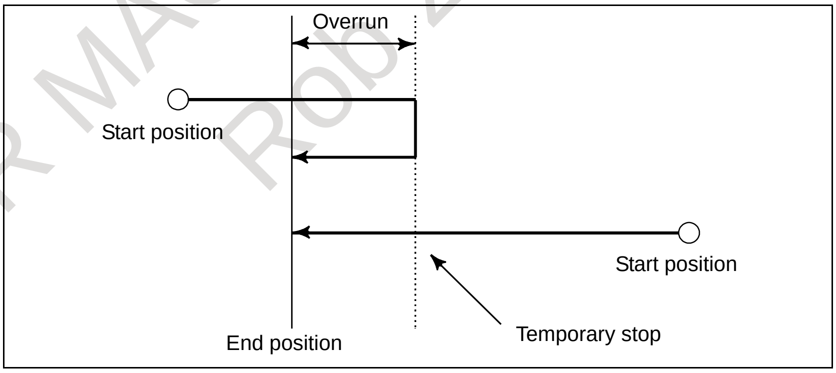

Fig. 6.2 (a) Example in which the positioning direction is the minus direction

An overrun and a positioning direction are set by the parameter No. 5440.
Even when a commanded positioning direction coincides with that set by the parameter, the tool stops once before the end point.
G60, which is an one-shot G-code, can be used as a modal G-code in group 01 by setting 1 to the bit 0 (MDL) of parameter No. 5431.
This setting can eliminate specifying a G60 command for every block. Other specifications are the same as those for an one-shot G60 command.
When an one-shot G code is specified in the single direction positioning mode, the one-shot G command is effective.

(Example)

When one-shot G60 commands are used.		When modal G60 command is used.	
:		:	
:		:	
G90;		G90 G60;	Single direction positioning mode start
G60 X0 Y0;	Single direction positioning	X0 Y0;	Single direction positioning
G60 X100;		X100;	
G60 Y100;		Y100;	
G04 X10;		G04 X10;	
G00 X0 Y0;		G00 X0 Y0;	Single direction positioning mode cancel

- Overview of operation

- In the case of positioning of non-linear interpolation type (bit 1 (LRP) of parameter No. 1401 = 0)

As shown Fig. 6.2(b), single direction positioning is performed independently along each axis.

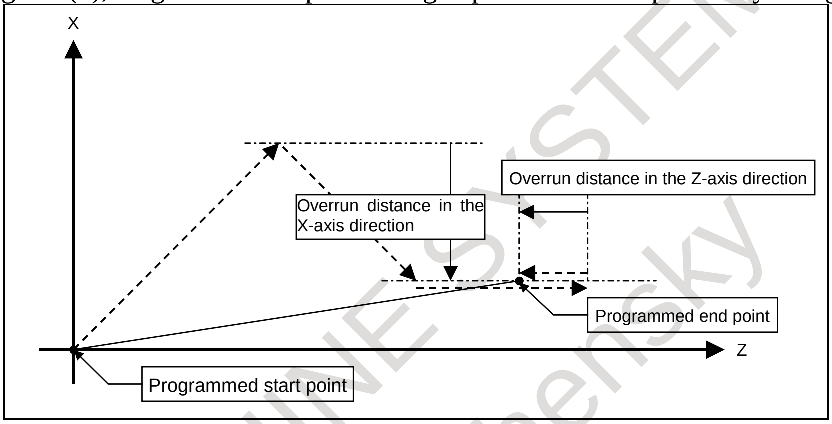

Fig. 6.2 (b)

- In the case of positioning of linear interpolation type (bit 1 (LRP) of parameter No. 1401 = 1)

Positioning of interpolation type is performed until the tool once stops before or after a specified end point. Then, the tool is positioned independently along each axis until the end point is reached.

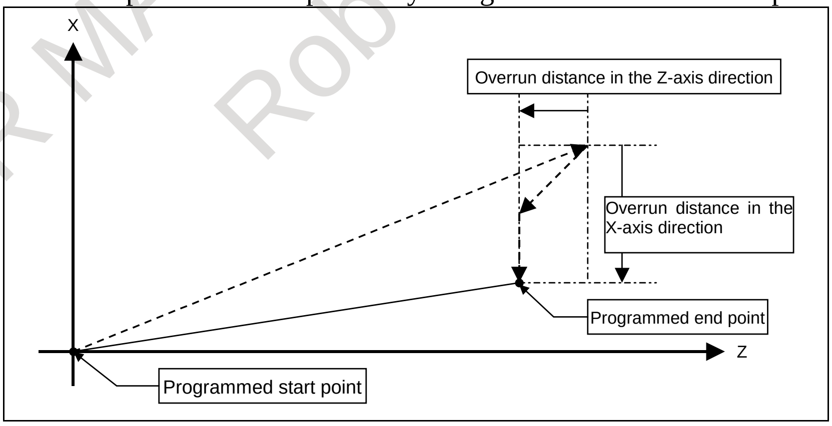

Fig. 6.2 (c)

Parameter

	#7	#6	#5	#4	#3	#2	#1	#0
5431							PDI	MDL

[Input type] Parameter input
[Data type] Bit

#0 MDL The G60 code (single direction positioning) is:
0: One-shot G code (group 00).
1: Modal G code (group 01).

#1 PDI In the G60 mode, an in-position check at a stop position is:
0: Not made. (Waiting for only the end of acceleration/deceleration)
1: Made.

5440	Positioning direction and overrun distance in single direction positioning

[Input type] Parameter input
[Data type] Real axis
[Unit of data] mm, inch, deg (machine unit)
[Min. unit of data] Depend on the increment system of the applied axis
[Valid data range] Refer to the standard parameter setting table (A)
(When the increment system is IS-B, -999999.999 to +999999.999)
This parameter sets the positioning direction and overrun distance in single direction positioning (G60) for each axis. The positioning direction is specified using a setting data sign, and the overrun distance using a value set here.
Overrun distance>0: The positioning direction is positive (+).
Overrun distance<0: The positioning direction is negative (-).
Overrun distance=0: Single direction positioning is not performed.

Alarm And message

Number	Message	Contents
DS0025	G60 CANNOT BE EXECUTED	The state of mirror image when a single direction positioning block is looked ahead differs from the state of mirror image when the execution of the block is started, so that single direction positioning cannot be executed. Correct the program.

Limitation

- Single direction positioning is not performed along an axis for which no overrun distance is set in parameter No. 5440.
- Single direction positioning is not performed along an axis for which travel distance 0 is specified.
- The mirror image function is not applied in a parameter-set direction. Even in the mirror image mode, the direction of single direction positioning remains unchanged. If positioning of linear interpolation type is used, and the state of mirror image when a single direction positioning block is looked ahead differs from the state of mirror image when the execution of the block is started, an alarm (DS0025)"G60 CANNOT BE EXECUTED" is issued. When switching mirror image in the middle of a program, disable looking ahead by specifying a non-buffering M code. Then, switch mirror image when there is no look-ahead block.
- In the cylindrical interpolation mode (G07.1), single direction positioning cannot be used.
- In the polar coordinate interpolation mode (G12.1), single direction positioning cannot be used.

- When specifying single direction positioning on a machine that uses angular axis control, first position the angular axis then specify the positioning of the Cartesian axis. If the reverse specification order is used, or the angular axis and Cartesian axis are specified in the same block, an incorrect positioning direction can result.
- In positioning at a restart position by program restart function, single direction positioning is not performed.

M

- Single direction positioning cannot be performed for a hole machining axis in a canned cycle for hole machining.
- Single direction positioning is not performed for an axis subject to shift value movement in a G76 or G87 canned cycle.

T

- The G code for single direction positioning is G60, regardless of whether the G code system is A, B, or C.
- In a multiple repetitive canned cycle (G70 to G76), single direction positioning cannot be used.
- Single direction positioning cannot be used for a hole machining axis in a canned cycle for hole machining (G83 to G89) and rigid tapping (G84 and G88). However, single direction positioning can be used for positioning operation.
- Single direction positioning cannot be used in a canned cycle (G90, G92, or G94).
- In the single direction positioning mode, G07.1, G12.1, G70 to G76, and G90 to G94 cannot be specified.

Manual name	Item name
OPERATOR'S MANUAL (B-64694EN)	Single direction positioning

6.3 LINEAR INTERPOLATION

Overview

Tools can move along a line. A tools move along a line to the specified position at the feedrate specified in F.

The feedrate specified in F is effective until a new value is specified. It need not be specified for each block.

The feedrate commanded by the F code is measured along the tool path. If the F code is not commanded, the feedrate is regarded as zero.

The feedrate of each axis direction is as follows.

G01 $\alpha\underline{\alpha}$ $\beta\underline{\beta}$ $\gamma\underline{\gamma}$ $\zeta\underline{\zeta}$;

Feed rate of α axis direction : $F\alpha=\alpha/L\times f$

Feed rate of β axis direction : $F\beta=\beta/L\times f$

Feed rate of γ axis direction : $F\gamma=\gamma/L\times f$

Feed rate of ζ axis direction : $F\zeta=\zeta/L\times f$

$$L=\sqrt{\alpha^2+\beta^2+\gamma^2+\zeta^2}$$

The feedrate of the rotary axis is commanded in the unit of deg/min (if the feedrate is 12 deg/min, F12.0 is commanded).

When the straight line axis α (such as X, Y, or Z) and the rotating axis β (such as A, B, or C) are linearly interpolated, the feed rate is that in which the tangential feed rate in the α and β cartesian coordinate system is commanded by F(mm/min).

β-axis feedrate is obtained ; at first, the time required for distribution is calculated by using the above formula, then the β-axis feedrate unit is changed to deg/min.
A calculation example is as follows.
(Example)

G91 G01 X20.0 C40.0 F300.0 ;
This changes the unit of the C axis from 40.0 deg to 40mm with metric input. The time required for distribution is calculated as follows:

$$\frac{\sqrt{20^2+40^2}}{300} \fallingdotseq 0.14907\ \mathrm{min}$$

The feed rate for the C axis is

$$\frac{40\ \mathrm{deg}}{0.14907\ \mathrm{min}} \fallingdotseq 268.3\mathrm{deg/min}$$

In simultaneous 3 axes control, the feed rate is calculated in cartesian coordinate system the same way as in simultaneous 2 axes control.

Parameter

1411	Cutting feedrate

NOTE
When this parameter is set, the power must be turned off before operation is continued.

[Input type] Setting input
[Data type] Real path
[Unit of data] mm/min, inch/min, deg/min (input unit)
[Min. unit of data] Depend on the increment system of the reference axis
[Valid data range] Refer to the standard parameter setting table (C)
(When the increment system is IS-B, 0.0 to +999000.0)
A cutting feedrate can be specified with this parameter for a machine which does not have to change the cutting feedrate frequently during machining. This eliminates the need to specify a cutting feedrate (F code) in the NC program.

1430	Maximum cutting feedrate for each axis

[Input type] Parameter input
[Data type] Real axis
[Unit of data] mm/min, inch/min, deg/min (machine unit)
[Min. unit of data] Depend on the increment system of the applied axis
[Valid data range] Refer to the standard parameter setting table (C)
(When the increment system is IS-B, 0.0 to +999000.0)
Specify the maximum cutting feedrate for each axis.

	#7	#6	#5	#4	#3	#2	#1	#0
3402								G01

[Input type] Parameter input
[Data type] Bit path

#0 G01 G01 Mode entered when the power is turned on or when the control is cleared
0: G00 mode (positioning)
1: G01 mode (linear interpolation)

Alarm and message

Number	Message	Description
PS0011	FEED ZERO (COMMAND)	The cutting feedrate instructed by an F code has been set to 0. This alarm is also generated if the F code instructed for the S code is set extremely small in a rigid tapping instruction as the tool cannot cut at the programmed lead.

Manual name	Item name
OPERATOR'S MANUAL (B-64694EN)	Linear interpolation (G01)

6.4 CIRCULAR INTERPOLATION

Overview

The command below can move a tool along a circular arc in the defined plane.
"Clockwise"(G02) and "counterclockwise"(G03) on the XpYp plane (ZpXp plane or YpZp plane) are defined when the XpYp plane is viewed in the positive-to-negative direction of the Zp axis (Yp axis or Xp axis, respectively) in the right-handed Cartesian coordinate system. See the Fig. 6.4 (a).

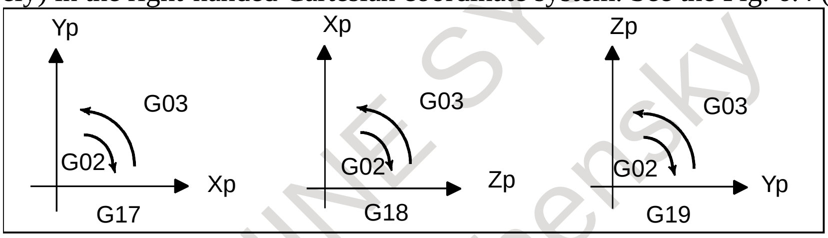

Fig. 6.4 (a)

The end point of an arc is specified by address Xp, Yp or Zp, and is expressed as an absolute or incremental value according to G90 or G91. For the incremental value, the distance of the end point which is viewed from the start point of the arc is specified with a sign.
The arc center is specified by addresses I, J, and K for the Xp, Yp, and Zp axes, respectively. The numerical value following I, J, or K, however, is a vector component in which the arc center is seen from the start point, and is always specified as an incremental value, as shown below (Fig. 6.4 (b)).
I, J, and K must be signed according to the direction.

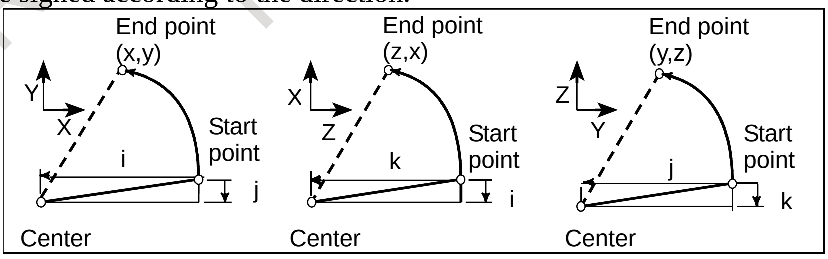

Fig. 6.4 (b)

I0,J0, and K0 can be omitted. When Xp, Yp , and Zp are omitted (the end point is the same as the start point) and the center is specified with I, J, and K, a 360° arc (circle) is specified.
G02 I; Command for a circle
If the difference between the radius at the start point and that at the end point exceeds the value in a parameter No. 3410, an alarm PS0020 occurs.
The distance between an arc and the center of a circle that contains the arc can be specified using the radius, R, of the circle instead of I, J, and K.
In this case, one arc is less than 180°, and the other is more than 180° are considered.

Specify an arc more than 180° with a negative radius value commanded.
If Xp, Yp, and Zp are all omitted, if the end point is located at the same position as the start point and when R is used, an arc of 05 is programmed.
G02R_ ; (The tool does not move.)

(Example)
For arc (1) (less than 180°)
G91 G02 X60.0 Y20.0 R50.0 F300.0 ;
For arc (2) (greater than 180°)
G91 G02 X60.0 Y20.0 R-50.0 F300.0 ;

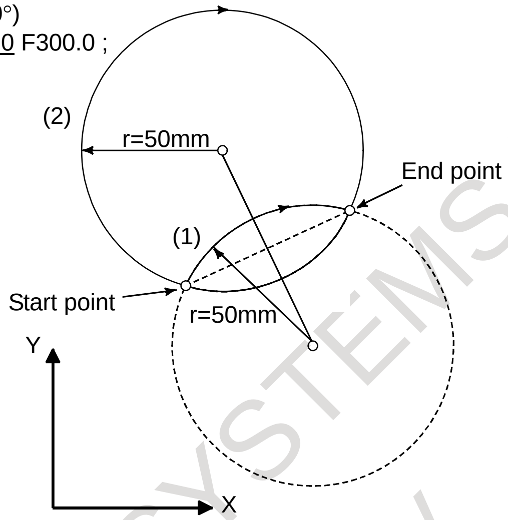

Fig. 6.4 (c)

The feedrate in circular interpolation is equal to the feedrate specified by the F code, and the feedrate along the arc (the tangential feedrate of the arc) is controlled to be the specified feedrate.

Parameter

1022	Setting of each axis in the basic coordinate system

[Input type] Parameter input
[Data type] Byte axis
[Valid data range] 0 to 7

To determine a plane for circular interpolation, cutter compensation, and so forth (G17: Xp-Yp plane, G18: Zp-Xp plane, G19: Yp-Zp plane), specify which of the basic three axes (X, Y, and Z) is used for each control axis, or a parallel axis of which basic axis is used for each control axis.
A basic axis (X, Y, or Z) can be specified only for one control axis.
Two or more control axes can be set as parallel axes for the same basic axis.

Table 6.4 (a)

Setting	Meaning
0	Rotary axis (Neither the basic three axes nor a parallel axis)
1	X axis of the basic three axes
2	Y axis of the basic three axes
3	Z axis of the basic three axes
5	Axis parallel to the X axis
6	Axis parallel to the Y axis
7	Axis parallel to the Z axis

In general, the increment system and diameter/radius specification of an axis set as a parallel axis are to be set in the same way as for the basic three axes.

0: The setting of bit 1 (G18) of parameter No. 3402 is followed.
1: G19 mode (plane YZ)
When this bit is set to 1, set bit 1 (G18) of parameter No. 3402 to 0.

3410	Tolerance of arc radius

[Input type] Setting input
[Data type] Real path
[Unit of data] mm, inch (input unit)
[Min. unit of data] Depend on the increment system of the reference axis
[Valid data range] 0 or positive 9 digit of minimum unit of data (refer to the standard parameter setting table (B))
(When the increment system is IS-B, 0.0 to +999999.999)
When a circular interpolation command is executed, the tolerance for the radius between the start point and the end point is set.

Alarm and message

Number	Message	Description
PS0011	FEED ZERO (COMMAND)	The cutting feedrate instructed by an F code has been set to 0. This alarm is also generated if the F code instructed for the S code is set extremely small in a rigid tapping instruction as the tool cannot cut at the programmed lead.
PS0020	OVER TOLERANCE OF RADIUS	An arc was specified for which the difference in the radius at the start and end points exceeds the value set in parameter No. 3410. Check arc center codes I, J and K in the program. The tool path when parameter No. 3410 is set to a large value is spiral.
PS0021	ILLEGAL PLANE SELECT	1) In the selected plane (by G17, G18 or G19 command), the basic axis(X,Y, or Z) and its parallel axis are commanded at the same time. Modify the program. 2) In the following functions, an axis not included in the selected plane was commanded,or the selected plane was not correct. Modify the program : - Circular interpolation - Multiple repetitive cycle (if parameter DSA(No.5109#0) is set to 1.) etc. 3) In the helical interpolation, the number of axes that can be commanded simultaneously is exceeded. Modify the program.
PS0025	CIRCLE CUT IN RAPID (F0)	F0 (rapid traverse in inverse feed or feed specified by an F code with 1–digit number) was specified during circular interpolation (G02, G03).

Note

NOTE

1. For T series, the U, V and W axes (parallel with the basic axis) can be used with G-code system B and C.
2. If I, J, K, and R addresses are specified simultaneously, the arc specified by address R takes precedence and the other are ignored.
3. If an axis not comprising the specified plane is commanded, an alarm is displayed.
   For example, when G code system B or C is used, if U axis with X axis is specified as a parallel axis to X axis when plane XY is specified, an alarm PS0021 is displayed.

OPERATOR'S MANUAL (B-64694EN)	Circular interpolation (G02, G03)

6.5 THREADING

6.5.1 Threading

Overview

Tool movement can be synchronized with spindle rotation when cutting threads.
The spindle speed is continuously read through the position coder attached to the spindle. Then, it is converted to a cutting feedrate (feed per minute) to feed the tool.

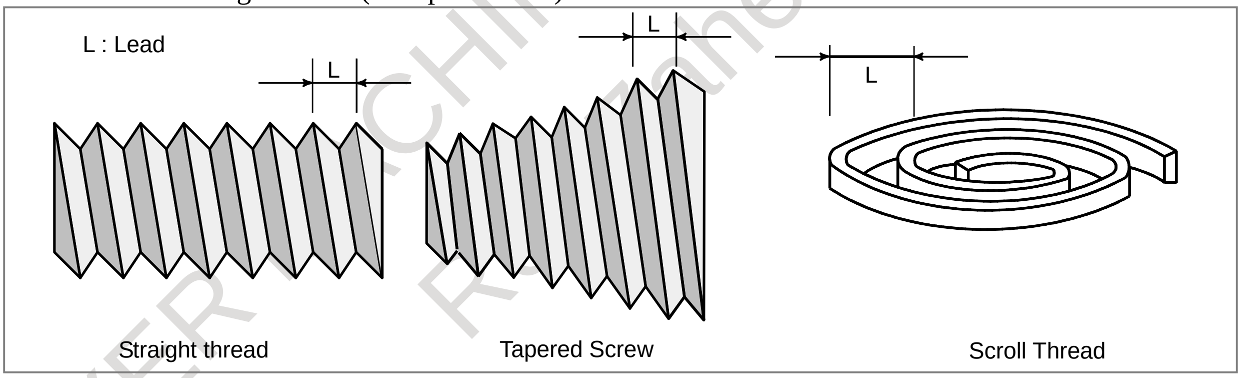

Fig. 6.5.1 (a)

In general, thread cutting is repeated along the same tool path in rough cutting through finish cutting for a screw. Since thread cutting starts when the position coder mounted on the spindle outputs a 1-turn signal, threading is started at a fixed point and the tool path on the workpiece is unchanged for repeated thread cutting. Note that the spindle speed must remain constant from rough cutting through finish cutting. If not, incorrect thread lead will occur.

⚠ **CAUTION**

Detector with one-rotation signal is required for threading, and it must be connected with spindle at a gear ratio of 1:1.
If detector is not connected correctly, the lead of threading may become wrong or start position of threading may become wrong.

- Serial spindle

Set the parameters correctly according to detector configuration. For detector configuration and the parameters, refer to FANUC AC SPINDLE MOTOR αi series PARAMETER MANUAL (B-65280EN).

- Analog spindle

Connect position coder with 4096 pulses per one rotation of the spindle.

It is enabled that feedback pulses of serial spindle or analog spindle is changed to high precision. For details, refer to "11.27 IMPROVEMENT OF SPINDLE FEEDBACK PULSES".

- When the maximum cutting feedrate is exceeded

If bit 4 (MTA) of parameter No.1612 is 0 and the maximum cutting feedrate (parameter No.1430) is exceeded, the alarm PS0530 “EXCESS VELOCITY IN THREADING” is issued as follows:

- When the maximum cutting feedrate is exceeded before threading start, the alarm is issued and the tool stops immediately.
- When the maximum cutting feedrate is exceeded after threading start, the alarm is issued and the tool stops after threading is finished.

This function can detect that the maximum cutting feedrate is exceeded. If the bit 4 (MTA) of parameter No.1612 is 0, the alarm is not issued.

NOTE
The alarm PS0530 is not issued during dry run.

Limitation

- Tool Retract and Recover

When the major axis for threading is specified as the retraction axis, retraction is not performed. In this case, after a block that does not specify threading is executed, an alarm PS0429, “ILLEGAL COMMAND IN G10.6” is issued and the tool stops.

T

- Chamfering and Corner R

Chamfering or corner R cannot be specified in a block in which thread cutting is specified. If chamfering or corner R is specified, alarm PS0050, “CHF/CNR NOT ALLOWED IN THRD BLK”, is issued.

- Tool offset

Tool offset cannot be specified in a block in which thread cutting is specified. If tool offset is specified, alarm PS0509, “TOOL OFFSET COMMAND IS NOT AVAILABLE”, is issued.

Signal

Spindle speed arrival signal SAR<Gn029.4>

[Classification] Input signal

[Function] The SAR signal initiates cutting feed. In other words, if the signal is logical “0”, cutting feed will not start.

[Operation] Generally, this signal is used to inform the CNC that the spindle has reached the specified speed. For this purpose, the signal must be set to “1” only after the actual speed of the spindle has reached the specified speed.
Setting parameter No. 3740 with a wait time before the start of checking the SAR signal inhibits cutting feed from starting under a condition of SAR = “1” specified before the change of the spindle command.
To use the SAR signal, it is necessary to set bit 0 (SAR) of parameter No. 3708 to 1. The CNC checks the SAR signal under the following conditions:
a. Bit 0 (SAR) of parameter No. 3708 is set to 1.

b. Before starting distribution of the first feed (move command) block after shifting from the rapid traverse mode to the cutting feed mode. This checking is performed after the time set by parameter No. 3740 has elapsed after the feed block is read.
c. Before starting distribution of the first feed command block after an S code is commanded. The wait time for checking is the same as in item b.
d. When an S code and feed are programmed in the same block, the S code (or command output to the spindle) is output, and the SAR signal is checked after a fixed time elapses. If the SAR signal is set to "1", feed begins.

> ⚠ **CAUTION**
> According to the conditions of item d above, note that if the circuit is so designed that SAR is turned to "0" simultaneously with the output of an S code and the change of spindle speed is initiated by the DEN signal, the operation will stop. That is, the spindle speed does not reach the commanded speed because the CNC is waiting for the DEN signal and distribution is not started because the CNC is waiting for the SAR signal.

Threading signal THRD<Fn002.3>

[Function] This signal indicates that threading is in progress.

[Output cond.] This signal turns to "1" in the following cases:
- Threading mode in progress
- Threading cycle for turning

This signal turns to "0" in the following case.
- Neither threading mode nor thread cutting cycle are in progress.

3713		MPC						

[Input type] Parameter input
[Data type] Bit

> **NOTE**
> When at least one of these parameters is set, the power must be turned off before operation is continued.

#6 MPC When a spindle is selected with address P in a program during multi-spindle control (bit 3 (MPP) of parameter No. 3703 is set to 1), position coder feedback used for thread cutting, feed per revolution, and so forth is:
0: Not changed automatically according to the selected spindle.
1: Changed automatically according to the selected spindle.

> **NOTE**
> Setting this parameter produces the same effects as when position coder select signals PC2SLC<Gn028.7>, PC3SLC<Gn026.0>, and PC4SLC<Gn026.1>, inter-path spindle feedback signals SLPCA<Gn064.2>, SLPCB<Gn064.3>, SLPCC<Gn403.4>, and SLPCD<Gn403.5> are set.
> At this time, even when an attempt to set these signals is made by a PMC ladder, these signal operations are ignored.

	#7	#6	#5	#4	#3	#2	#1	#0
11602			NCP					

[Input type] Parameter input
[Data type] Bit path

#5 NCP If there is a non-threading block between two threading blocks, the second threading block:
0: Waits until the spindle one-rotation signal and the spindle speed arrival signal SAR <Gn029.4> are detected.
1: Does not wait until the spindle one-rotation signal and the spindle speed arrival signal SAR <Gn029.4> are detected unless a G code in non-threading group 01 is issued. (FS16*i* compatible specification)

Alarm and message

Number	Message	Description
PS0050	CHF/CNR NOT ALLOWED IN THRD BLK	Chamfering or corner R is commanded in the thread cutting block. Modify the program.
PS0429	ILLEGAL COMMAND IN G10.6	When retraction was started in the threading block, the retract command was performed in the longitudinal direction of the threading.
PS0509	TOOL OFFSET COMMAND IS NOT AVAILABLE	- Tool offset (for the lathe system) was specified in the thread cutting block. - Tool offset was specified (lathe system) in the scaling mode, coordinate system rotation mode, or programmable mirror image mode.
PS0530	EXCESS VELOCITY IN THREADING	Feedrate exceeds the maximum cutting feedrate.

Warning

⚠ **WARNING**

During threading, stopping feed without stopping the spindle is dangerous because the cutting depth will abruptly increase. Feed hold is, therefore, disabled during threading. If attempted during threading, feed stops in the same way as single block stop upon the completion of the first non-threading block after the termination of threading mode. Feed hold lamp signal SPL <Fn000.4>, however, turns to “1” immediately after feed hold signal *SP <Gn008.5> is set to “1”. The signal SPL turns to “0” when feed stops (the CNC enters the single block stop state).

Caution

⚠ **CAUTION**

1 Detector with one-rotation signal is required for threading, and it must be connected with spindle at a gear ratio of 1:1.
2 Feedrate override is ignored during threading, 100% being assumed.
3 During threading, spindle override is ignored, 100% being assumed.
4 When the first non-threading block is executed after threading mode has been finished, and the feed hold button is pressed again (or the feed hold button has been held down), the execution of the non-threading block is stopped immediately.
5 When threading is executed in the single block status, the tool stops after execution of the first block not specifying threading.
6 When the previous block was a threading block, cutting will start immediately without waiting for detection of the 1-turn signal even if the present block is a threading block.
7 When a dry run operation is performed the dry run rate becomes the longitudinal axis feedrate.
8 The threading retract function is supported only for the threading cycle.

Note

NOTE

Even in the machine lock state, threading detects a one-rotation signal from the position coder mounted to the spindle.
If threading is specified, and the threading is to be performed without waiting for a one-rotation signal from the position coder, it is necessary to enable dry run (bit 5 (TDR) of parameter No. 1401 = 0) with the threading command and set the dry run signal DRN <Gn046.7> to ”1”.
The threading command remains the same regardless of whether the threading cycle is a canned cycle or a multiple repetitive cycle.
Even if "without position coder feed per revolution" is used (bit 0 (NPC) of parameter No. 1402 = 1), set the dry run signal DRN to ”1” for threading in the machine lock state.

6.5.2 Threading Cycle Retract

T

When feed hold is performed during threading, the tool immediately retracts while performing chamfering and then returns to the start point. This function is valid for only canned cycle and multiple repetitive canned cycle as following table. This function is invalid for threading, variable lead threading, and circular threading.

	Machining center system	Lathe system			Threading Cycle Retract
		G code system			
		A	B	C	
Canned Cycle	-	G92	G78	G21	Valid
Multiple Repetitive Canned Cycle	-	G76	G76	G78	Valid
Threading	G33	G32	G33	G33	Invalid
Variable Lead Threading	G34	G34	G34	G34	Invalid
Circular Threading	G35,G36	G35,G36	G35,G36	G35,G36	Invalid
Circular thread cutting B	G02.1, G03.1	-	-	-	Invalid

The detail of this function is described below.

6.5.2.1 Threading cycle retract (canned cycle)

T

Overview

When feed hold is performed during threading in threading cycle (G92), the tool immediately retracts while performing chamfering and then returns to the start point in the order of the plane second axis (X-axis) followed by the plane first axis (Z-axis).

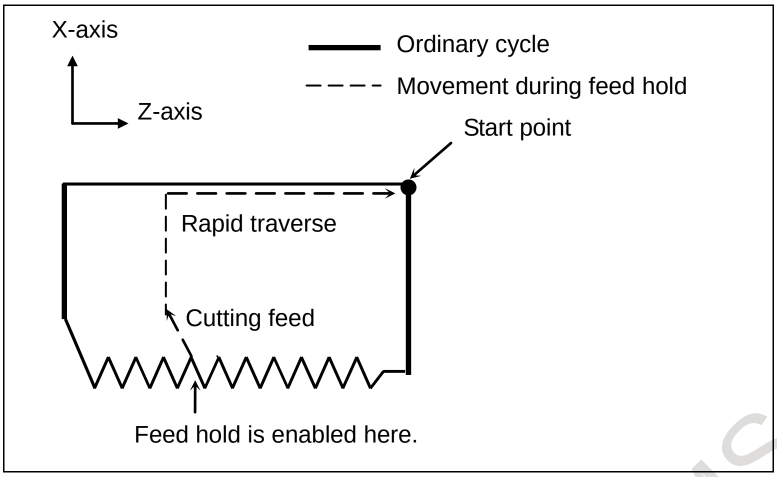

Fig. 6.5.2.1 (a)

The chamfering angle during retraction is the same as that at the end point.

- Thread chamfering

For the thread chamfering angle, 1° to 89° can be specified with parameter No. 5131. When the parameter value is 0, 45° is set.
The type of acceleration/deceleration after interpolation, time constant for acceleration/deceleration after interpolation, and FL feedrate used for thread chamfering are the same as those for threading.

- Retraction after chamfering

For retraction after chamfering, the feedrate, type of acceleration/deceleration after interpolation, and time constant are used as described in the Table 6.5.2.1 (a).

Table 6.5.2.1 (a)

Bit 0 (CFR) of parameter No.1611	Parameter No.1466	Description
0	Non-0	The type of acceleration/deceleration after interpolation for threading is used together with the threading time constant (parameter No.1626), FL feedrate (parameter No.1627), and feedrate for retraction (parameter No.1466).
0	0	The type of acceleration/deceleration after interpolation for threading is used together with the threading time constant (parameter No.1626), FL feedrate (parameter No.1627), and rapid traverse rate (parameter No.1420).
1		Before retraction a check is made to see that the specified feedrate has become 0 (delay in acceleration/deceleration is 0), and the type of acceleration/deceleration after interpolation for rapid traverse is used together with the rapid traverse time constant and the rapid traverse rate (parameter No. 1420).

For the feedrate for retraction after chamfering, the rapid traverse override can be disabled by setting 1 to bit 4 (ROC) of parameter No.1403.

> **NOTE**
> During retraction, the tool does not stop at cutting feedrate override of 0%, regardless of the setting of bit 4 (RF0) of parameter No.1401.

- Rapid traverse override

Rapid traverse override can be disabled during threading cycle retract by setting 1 to bit 7 (RTV) of parameter No.1403.

- Threading signal

Threading signal THRD<Fn002.3> turns to "1" in the block for returning to starting point of threading cycle by setting 1 to bit 1 (TRS) of parameter No.11223.

Signal

Threading signal THRD<Fn002.3>

[Function] This signal indicates that threading is in progress.

[Output cond.] This signal turns to "1" in the following cases:

- Threading mode in progress
- Threading cycle for turning

This signal turns to "0" in the following case.

- Neither threading mode nor thread cutting cycle are in progress.

Parameter

	#7	#6	#5	#4	#3	#2	#1	#0
1403	RTV			ROC				

[Input type] Parameter input
[Data type] Bit path

#4 ROC In the threading cycles G92 and G76 rapid traverse override for retraction after threading is finished is:
0: Effective
1: Not effective (Override of 100%)

#7 RTV Rapid traverse override while the tool is retracting in threading
0: Rapid traverse override is effective.
1: Rapid traverse override is not effective.

1466	Feedrate for retraction in threading cycle G92 or G76

[Input type] Parameter input
[Data type] Real path
[Unit of data] mm/min, inch/min (machine unit)
[Min. unit of data] Depend on the increment system of the reference axis
[Valid data range] Refer to the standard parameter setting table (C)
(When the increment system is IS-B, 0.0 to +999000.0)

When threading cycle G92 (T series) or G76 (T series) is specified, retraction is performed after threading. Set a feedrate for this retraction.

> ⚠ **WARNING**
> When the manual handle interruption is valid, set the same value as the parameter No.1430 to the parameter No.1466.

> **NOTE**
> When this parameter is set to 0 or bit 1 (CFR) of parameter No. 1611 is set to 1, the rapid traverse rate set in parameter No. 1420 is used.

	#7	#6	#5	#4	#3	#2	#1	#0
1610			THLx					

[Input type] Parameter input
[Data type] Bit axis

#5 THLx Acceleration/deceleration in threading cycles G92 and G76
0: Exponential acceleration/deceleration is applied.
1: The same acceleration/deceleration as for cutting feedrate is applied.
(Depending on the settings of bits 1 (CTBx) and 0 (CTLx) of parameter No. 1610)
As the time constant and FL rate, however, the settings of parameters Nos. 1626 and 1627 for threading cycles are used.

	#7	#6	#5	#4	#3	#2	#1	#0
1611								CFR

[Input type] Parameter input
[Data type] Bit path

#0 CFR For retraction after threading in the threading cycles G92 and G76:
0: The type of acceleration/deceleration after interpolation for threading is used together with the threading time constant (parameter No. 1626) and FL rate (parameter No. 1627).
1: The type of acceleration/deceleration after interpolation for rapid traverse is used together with the rapid traverse time constant.

NOTE
If this parameter is set to 1, a check is made before a retraction to see that the specified feedrate has become 0 (the delay in acceleration/deceleration has become 0). For retraction, the rapid traverse rate (parameter No. 1420) is used, regardless of the setting of parameter No. 1466. When this parameter is set to 0, parameter No. 1466 is used as the feedrate for retraction. As acceleration/deceleration used for retraction, only acceleration/deceleration after interpolation is used. Rapid traverse acceleration/deceleration before interpolation and optimum torque acceleration/deceleration are disabled.

1626	Acceleration/deceleration time constant in threading cycles for each axis

[Input type] Parameter input
[Data type] Word axis
[Unit of data] msec
[Valid data range] 0 to 4000
Set a time constant for acceleration/deceleration after interpolation in the threading cycles G92 and G76 for each axis.

1627	FL rate for acceleration/deceleration in threading cycles for each axis

[Input type] Parameter input

[Data type] Real axis
[Unit of data] mm/min, inch/min, deg/min (machine unit)
[Min. unit of data] Depend on the increment system of the applied axis
[Valid data range] Refer to the standard parameter setting table (C)
(When the increment system is IS-B, 0.0 to +999000.0)
Set an FL rate for acceleration/deceleration after interpolation in the threading cycles G92 and G76 for each axis. Set 0 at all times except in a special case.

5131	Cutting angle in thread cutting cycles G92 and G76

[Input type] Parameter input
[Data type] Byte path
[Unit of data] deg
[Valid data range] 1 to 89
This parameter sets a thread cutting angle in a thread cutting cycle (G92 (T series)/G76 (T series)).
When 0 is set, an angle of 45 degrees is specified.

	#7	#6	#5	#4	#3	#2	#1	#0
11223							TRS	

[Input type] Parameter input
[Data type] Bit path

#1 TRS In threading cycle retraction, when a block that specifies return to the start point of the threading cycle is executed, threading signal THRD <Fn002.3> is:
0: Set to “0”.
1: Set to “1”.

Caution

> ⚠ **CAUTION**
> Feed hold cannot be performed during retracting.

Note

> **NOTE**
> The chamfering angle for retraction is determined by the setting of parameter No. 5131.

Manual name	Item name
OPERATOR’S MANUAL (B-64694EN)	Threading cycle

6.5.2.2 Threading cycle retract (multiple repetitive canned cycle)

T

Overview

When feed hold is performed during threading in multiple repetitive threading cycle G76, threading is curtailed (chamfered) and then the tool returns to the start point in the threading cycle and stops.
At this time, if the cycle is started, it resumes from the threading cycle for which feed hold was applied.

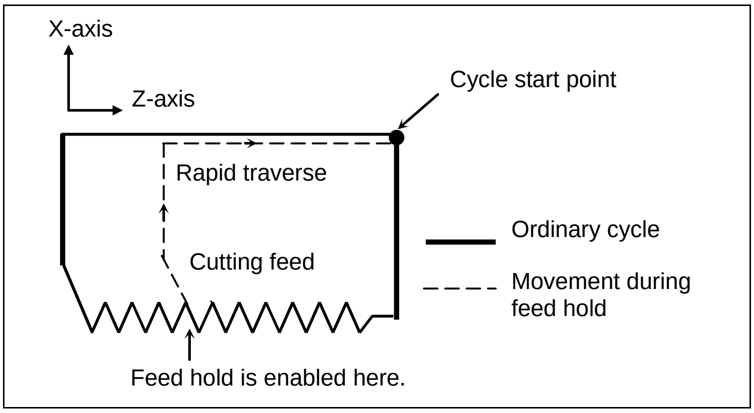

Fig. 6.5.2.2 (a)

The angle of chamfering during retracting is same as that at the end point.

- Thread chamfering

For the thread chamfering angle, 1° to 89° can be specified with parameter No. 5131. When the parameter value is 0, 45° is set.
The type of acceleration/deceleration after interpolation, time constant for acceleration/deceleration after interpolation, and FL feedrate used for thread chamfering are the same as those for threading.

- Retraction after chamfering

For retraction after chamfering, the feedrate, type of acceleration/deceleration after interpolation, and time constant are used as described in the Table 6.5.2.2(a).

Table 6.5.2.2 (a)

Bit 0 (CFR) of parameter No. 1611	Parameter No. 1466	Description
0	Non-0	The type of acceleration/deceleration after interpolation for threading is used together with the threading time constant (parameter No.1626), FL feedrate (parameter No.1627), and feedrate for retraction (parameter No.1466).
0	0	The type of acceleration/deceleration after interpolation for threading is used together with the threading time constant (parameter No.1626), FL feedrate (parameter No.1627), and rapid traverse rate (parameter No.1420).
1		Before retraction a check is made to see that the specified feedrate has become 0 (delay in acceleration/deceleration is 0), and the type of acceleration/deceleration after interpolation for rapid traverse is used together with the rapid traverse time constant and the rapid traverse rate (parameter No. 1420).

For the feedrate for retraction after chamfering, the rapid traverse override can be disabled by setting 1 to bit 4 (ROC) of parameter No.1403.

NOTE
During retraction, the tool does not stop at cutting feedrate override of 0%, regardless of the setting of bit 4 (RF0) of parameter No.1401.

Parameter

	#7	#6	#5	#4	#3	#2	#1	#0
1403	RTV			ROC				

[Input type] Parameter input
[Data type] Bit path

#4 ROC In the threading cycles G92 and G76, rapid traverse override for retraction after threading is finished is:
0: Effective
1: Not effective (Override of 100%)

#7 RTV Rapid traverse override while the tool is retracting in threading
0: Rapid traverse override is effective.
1: Rapid traverse override is not effective.

1466	Feedrate for retraction in threading cycle G92 or G76

[Input type] Parameter input
[Data type] Real path
[Unit of data] mm/min, inch/min (machine unit)
[Min. unit of data] Depend on the increment system of the reference axis
[Valid data range] Refer to the standard parameter setting table (C)
(When the increment system is IS-B, 0.0 to +999000.0)
When threading cycle G92 and G76 is specified, retraction is performed after threading. Set a feedrate for this retraction.

> ⚠ **WARNING**
> When the manual handle interruption is valid, set the same value as the parameter No.1430 to the parameter No.1466.

> **NOTE**
> When this parameter is set to 0 or bit 1 (CFR) of parameter No. 1611 is set to 1, the rapid traverse rate set in parameter No. 1420 is used.

	#7	#6	#5	#4	#3	#2	#1	#0
1610			THLx

#5 THLx Acceleration/deceleration in threading cycles G92 and G76
0: Exponential acceleration/deceleration is applied.
1: The same acceleration/deceleration as for cutting feedrate is applied.
(Depending on the settings of bits 1 (CTBx) and 0 (CTLx) of parameter No. 1610)
As the time constant and FL rate, however, the settings of parameters Nos. 1626 and 1627 for threading cycles are used.

	#7	#6	#5	#4	#3	#2	#1	#0
1611								CFR

[Input type] Parameter input
[Data type] Bit path

#0 CFR For retraction after threading in the threading cycles G92 and G76:

0: The type of acceleration/deceleration after interpolation for threading is used together with the threading time constant (parameter No. 1626) and FL rate (parameter No. 1627).
1: The type of acceleration/deceleration after interpolation for rapid traverse is used together with the rapid traverse time constant.

NOTE
If this parameter is set to 1, a check is made before a retraction to see that the specified feedrate has become 0 (the delay in acceleration/deceleration has become 0). For retraction, the rapid traverse rate (parameter No. 1420) is used, regardless of the setting of parameter No. 1466. When this parameter is set to 0, parameter No. 1466 is used as the feedrate for retraction. As acceleration/deceleration used for retraction, only acceleration/deceleration after interpolation is used. Rapid traverse acceleration/deceleration before interpolation and optimum torque acceleration/deceleration are disabled.

1626	Acceleration/deceleration time constant in threading cycles for each axis

[Input type] Parameter input
[Data type] Word axis
[Unit of data] msec
[Valid data range] 0 to 4000
Set a time constant for acceleration/deceleration after interpolation in the threading cycles G92 and G76 for each axis.

1627	FL rate for acceleration/deceleration in threading cycles for each axis

[Input type] Parameter input
[Data type] Real axis
[Unit of data] mm/min, inch/min, deg/min (machine unit)
[Min. unit of data] Depend on the increment system of the applied axis
[Valid data range] Refer to the standard parameter setting table (C)
(When the increment system is IS-B, 0.0 to +999000.0)
Set an FL rate for acceleration/deceleration after interpolation in the threading cycles G92 and G76 for each axis. Set 0 at all times except in a special case.

5131	Cutting angle in thread cutting cycles G92 and G76

[Input type] Parameter input
[Data type] Byte path
[Unit of data] deg
[Valid data range] 1 to 89
This parameter sets a thread cutting angle in a thread cutting cycle (G92 and G76).
When 0 is set, an angle of 45 degrees is specified.

	#7	#6	#5	#4	#3	#2	#1	#0
11223							TRS	

[Input type] Parameter input
[Data type] Bit path

#1 TRS In threading cycle retraction, when a block that specifies return to the start point of the threading cycle is executed, threading signal THRD <Fn002.3> is:
0: Set to “0”.
1: Set to “1”.

Caution

> ⚠ **CAUTION**
> Feed hold cannot be performed during retracting.

Note

> **NOTE**
> The chamfering angle for retraction is determined by the setting of parameter No. 5131.

Manual name	Item name
OPERATOR’S MANUAL (B-64694EN)	Variable lead threading

6.5.4 Continuous Threading

Overview

Threading blocks can be programmed successively to eliminate a discontinuity due to a discontinuous movement in machining by adjacent blocks.

Since the system is controlled in such a manner that the synchronism with the spindle does not deviate in the joint between blocks wherever possible, it is possible to performed special threading operation in which the lead and shape change midway.

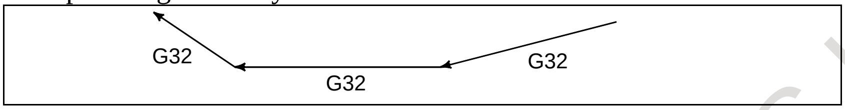

Fig. 6.5.4 (a)

Even when the same section is repeated for thread cutting while changing the depth of cut, this system allows a correct machining without impairing the threads.

Reference item

Manual name	Item name
OPERATOR'S MANUAL (B-64694EN)	Continuous treading

6.5.5 Multiple Threading

Overview

Using the Q address to specify an angle between the one-spindle-rotation signal and the start of threading shifts the threading start angle, making it possible to produce multiple-thread screws with ease.

M

Set the bit 0 (GQS) of parameter No. 3451 to 1 for using this function.

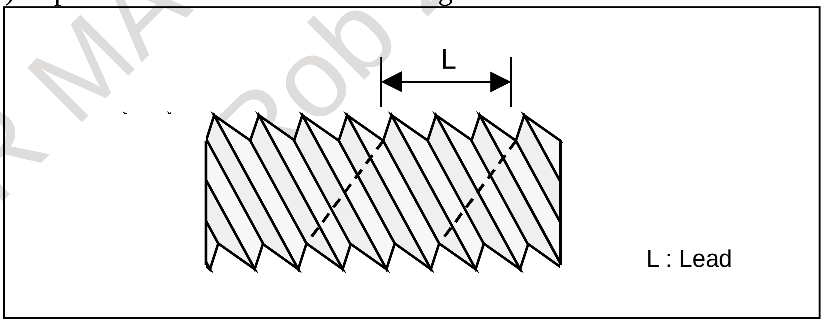

Fig. 6.5.5 (a)

Limitation

- Threading start angle

The threading start angle is not a continuous state (modal) value. It must be specified each time it is used. If a value is not specified, 0 is assumed.

- Threading start angle increment

The threading start angle (Q) increment is 0.001 degrees. Note that no decimal point can be specified.
Example:

For a shift angle of 180 degrees, specify Q180000.
Q180.000 cannot be specified, because it contains a decimal point.

Note: Q1 is the command of 0.001 degree for the angle for shifting the threading start angle, regardless of the setting of the followings.

- Increment system IS-A/B/C (Parameter No.1013#3-#0)
- Pocket calculator type decimal point programming (Bit 0(DPI) of parameter No.3401)
- The least input increment is 10 times greater than the least command increment (Bit 7(IPR) of parameter No.1004)

- Specifiable threading start angle range

The threading start angle (Q) of between 0 and 360000 (in 0.001-degree units) can be specified. If a value greater than 360000 (360 degrees) is specified, it is rounded down to 360000 (360 degrees).
If a minus value is specified, it works as a plus value.
Example:

If Q-90000 (-90 degrees) is specified, it works as Q90000 (90 degrees).

T

- Multiple threading cycle (G76 (G code system A/B)) (G78 (G code system C))

The address Q of the G76/G78 multiple threading cycle command is used for the minimum cutting depth or the depth of cut in 1st cut. For this reason, the angle for shifting the threading start angle can not be commanded.
However, if the FS15 tape format is used, in G76/G78 multiple threading cycle, the address Q is possible to specify the angle for shifting the threading start angle.

6.5.7 Arbitrary Speed Threading

6.5.7.1 Arbitrary speed threading

Overview

In conventional threading, spindle speed could not be changed because tool movement could not synchronize with spindle rotation, and machining accuracy of a screw is decreased. This function makes it possible to change spindle speed during threading. This function can be used with threading, threading cycle, and multiple threading cycle. Changing spindle speed can prevent the vibration that occurs during threading at the specific spindle speed for a large size machine. Besides, for repetitive machining, the same thread shape can be machined even if spindle speed is changed between rough machining and finishing machining. Cs contour control is required for this function.

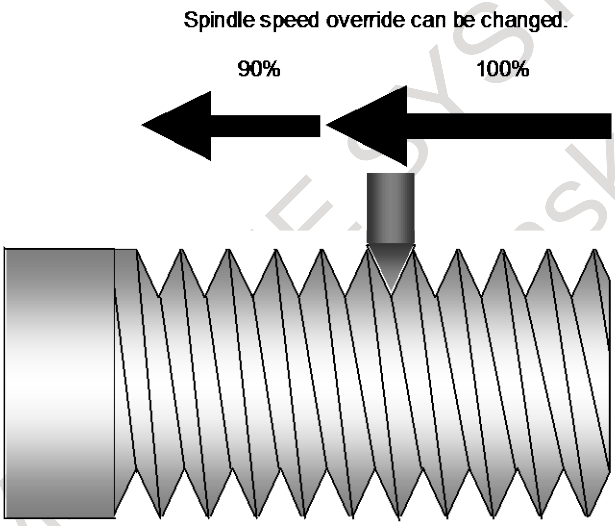

Fig.6.5.7.1 (a) Arbitrary speed threading

Furthermore, even if a workpiece is removed from a chuck before threading is not finished, re-machining of this workpiece can be achieved. Refer to the section "6.5.7.2 Re-machining thread" for details.

Format

Mxx ;	**Start of arbitrary speed threading**
G32IP_F_;	**Threading command**
Myy ;	**Cancel of arbitrary speed threading**

xx : M code set in parameter No.11487
yy : M code set in parameter No.11488

Explanation

The system enters arbitrary speed threading mode according to the sequence of arbitrary speed threading mode change by specifying the M code set in parameter No.11487 (start of arbitrary speed threading). Then, threading (threading, threading cycle, or multiple threading cycle) is specified. Arbitrary speed threading mode is canceled by specifying the M code set in parameter No.11488 (cancel of arbitrary speed threading). Arbitrary speed threading is enabled by setting bit 0 (AST) of parameter No.11485 to 1.
Example of machining program

```
N1G00 X10.Z50.;
N2S_;                         : specifying the spindle speed
N3Mxx;                        : start of arbitrary speed threading
N4G92X151.0Z-200.F10.;        : start of threading cycle
N5X150.0;
N6X149.0;
N7X148.0;
N8G00;                        : cancel of threading cycle
N9Myy;                        : cancel of arbitrary speed threading
```

The same thread shape can be machined in threading cycle specified N4 to N7 blocks, even if the spindle speed is changed.

NOTE
1 M code for arbitrary speed threading must be specified alone in a block.
2 M code for arbitrary speed threading prevents buffering.
3 Start command of arbitrary speed threading must be specified in canned cycle cancel mode for drilling. .
4 M code of arbitrary speed threading cancel must be specified after canceling threading mode. If the M code is specified in threading mode, the alarm PS0529, “THREADING COMMAND IMPOSSIBLE” is issued.
5 During arbitrary speed threading mode, feedback pulse of a position coder must be the one from the spindle which is commanded Mxx (xx is set in parameter No.11487).
6 If threading, threading cycle, or multiple threading cycle is specified when arbitrary speed threading mode is canceled, usual threading is executed.

- Command in arbitrary speed threading mode

Arbitrary speed threading can be used with the following threading commands.

Table 6.5.7.1 (a) Threading commands used with arbitrary speed threading

	Machining center system	Lathe system		
		G code system		
		A	B	C
Threading	G33	G32	G33	G33
Threading cycle	–	G92	G78	G21
Multiple threading cycle	–	G76	G76	G78

NOTE

1. When continuous threading is executed, the lead along the feed axis (the first axis on the plane) must not be changed between threading blocks.
2. If the next block of threading command (G32: lathe system in G code system A, G33: machining center system) does not include threading, the feedrate is decelerated at the end point of threading command.
3. If a taper angle is lower than that of the previous block in continuous threading, or if a chamfering angle is lower than the taper angle in threading cycle, the alarm PS0529 is issued. Machining program must be created as the direction of chamfering during arbitrary speed threading is in the hatching area of Fig. 6.5.7.1 (b).

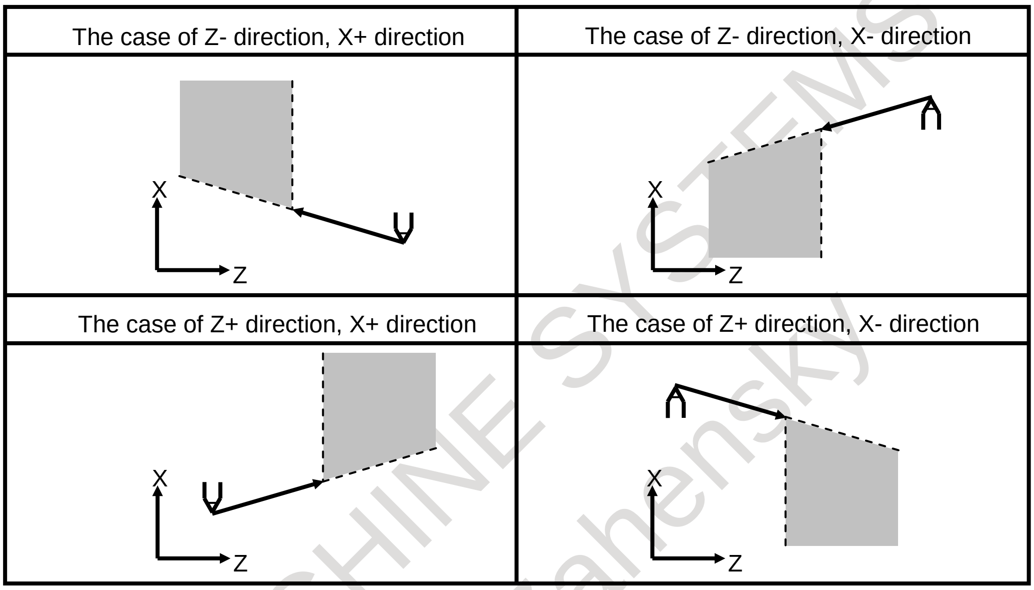

Fig. 6.5.7.1 (b) Chamfering during arbitrary speed threading

- Change of arbitrary speed threading mode

Cs contour control high speed switching signals are used for arbitrary speed threading. The spindle control mode is switched from spindle rotation control to Cs contour control without stopping spindle rotation when arbitrary speed threading mode is selected. To cancel arbitrary speed threading mode, Cs contour control change signal CON <Gn027.7> or Cs contour control change signals in each axis CONS <Gn274.0 to 3> is set to "0" in M code of canceling arbitrary speed threading, then, spindle control mode is switched from Cs contour control to spindle rotation control without stopping spindle rotation. The following parameter setting is required to change arbitrary speed threading mode.

Table 6.5.7.1 (b) Parameters to set for change of arbitrary speed threading mode

Parameter number	Description
ROT(No.1006#0)	Type of rotary axis(Please set to 1)
ROS(No.1006#1)	Type of rotary axis(Please set to 0)
ROAx(No.1008#0)	Whether to use the roll-over function of a rotary axis(Please set to 1)
RRLx(No.1008#2)	Whether Relative coordinates to be rounded by the amount of shift per rotation(Please set to 1)
CSDRCT(No.4002#4)	Whether to use the rotation direction signal (SFR/SRV) on Cs contouring control(Please set to 1)
No.4504	Cs contour control high speed switching : Reference position establishment speed
No.4505	Cs contour control high speed switching : Reference position establishment acceleration

Parameter number	Description
No.4506	Cs contour control high speed switching : Bell shaped acceleration/deceleration time constant for the reference position establishment
No.4507	Cs contour control high speed switching : Reference position establishment completion level
AST(No.11485#0)	Whether to use the function of arbitrary speed threading
No.11487	M code to start arbitrary speed threading mode
No.11488	M code to cancel arbitrary speed threading mode
No.11489	Acceleration in arbitrary speed threading

Rotation direction in Cs contour control may be different from that in spindle rotation control according to machine configuration or parameter setting. In this case, SV reverse signals SVRVS1 to SVRVS8 <Gn523> are set to “1” before changing to the arbitrary speed threading mode. Also when the arbitrary speed threading mode is canceled, SV reverse signal is set to “0”.

Example of reverse rotation direction in Cs contour control

-The case of the following machine configuration:

When the motor rotation direction is plus, the spindle rotation direction is minus owing to the gear between the motor and the spindle.

Forward rotation/Reverse rotation command signal SFR/SRV specifies the motor rotation direction in spindle rotation control, on the other hand these signals specify the spindle rotation direction in Cs contour control. Therefore, the relationship between command, motor rotation direction, and spindle rotation direction is as follows.

Spindle rotation control:
Command (+) – Motor rotation direction (+) – Spindle rotation direction (-)

Cs contour control:
Command (+) – Motor rotation direction (-) – Spindle rotation direction (+)

NOTE

1 When bit 1 (ART) of parameter No.11486 is set to 0, if reset operation is executed in arbitrary speed threading mode, Cs contour control change signal CON <Gn027.7> or Cs contour control change signals in each axis CONS <Gn274.0 to 3> must be set to “0” to cancel arbitrary speed threading mode. If an automatic operation is restarted without performing this operation, alarm PS0529 “THREADING COMMAND IMPOSSIBLE” is issued. When bit 1 (ART) of parameter No.11486 is set to 1, if reset operation is executed, arbitrary speed threading mode is maintained. To cancel arbitrary speed threading mode, the arbitrary speed threading mode cancellation M code (parameter No.11488) is specified, and Cs contour control change signal CON <Gn027.7> or Cs contour control change signals in each axis CONS <Gn274.0 to 3> must be set to “0”.

2 Cs contour control change signal CON must be set to “1” after the speed arrival signal SARA to SARD <Fn045.3, Fn049.3, Fn168.3, Fn266.3> become “1” when arbitrary speed threading mode is changed.

3 SV reverse signal setting must be decided after checking the rotation direction in spindle rotation control and that in Cs contour control by changing arbitrary speed threading mode with a speed of 0[min-1] (S0) once.

4 Reference position return of Cs contour control axis must be performed once after power-on to detect one-rotation signal of a spindle.

- Sequence of arbitrary speed threading mode change

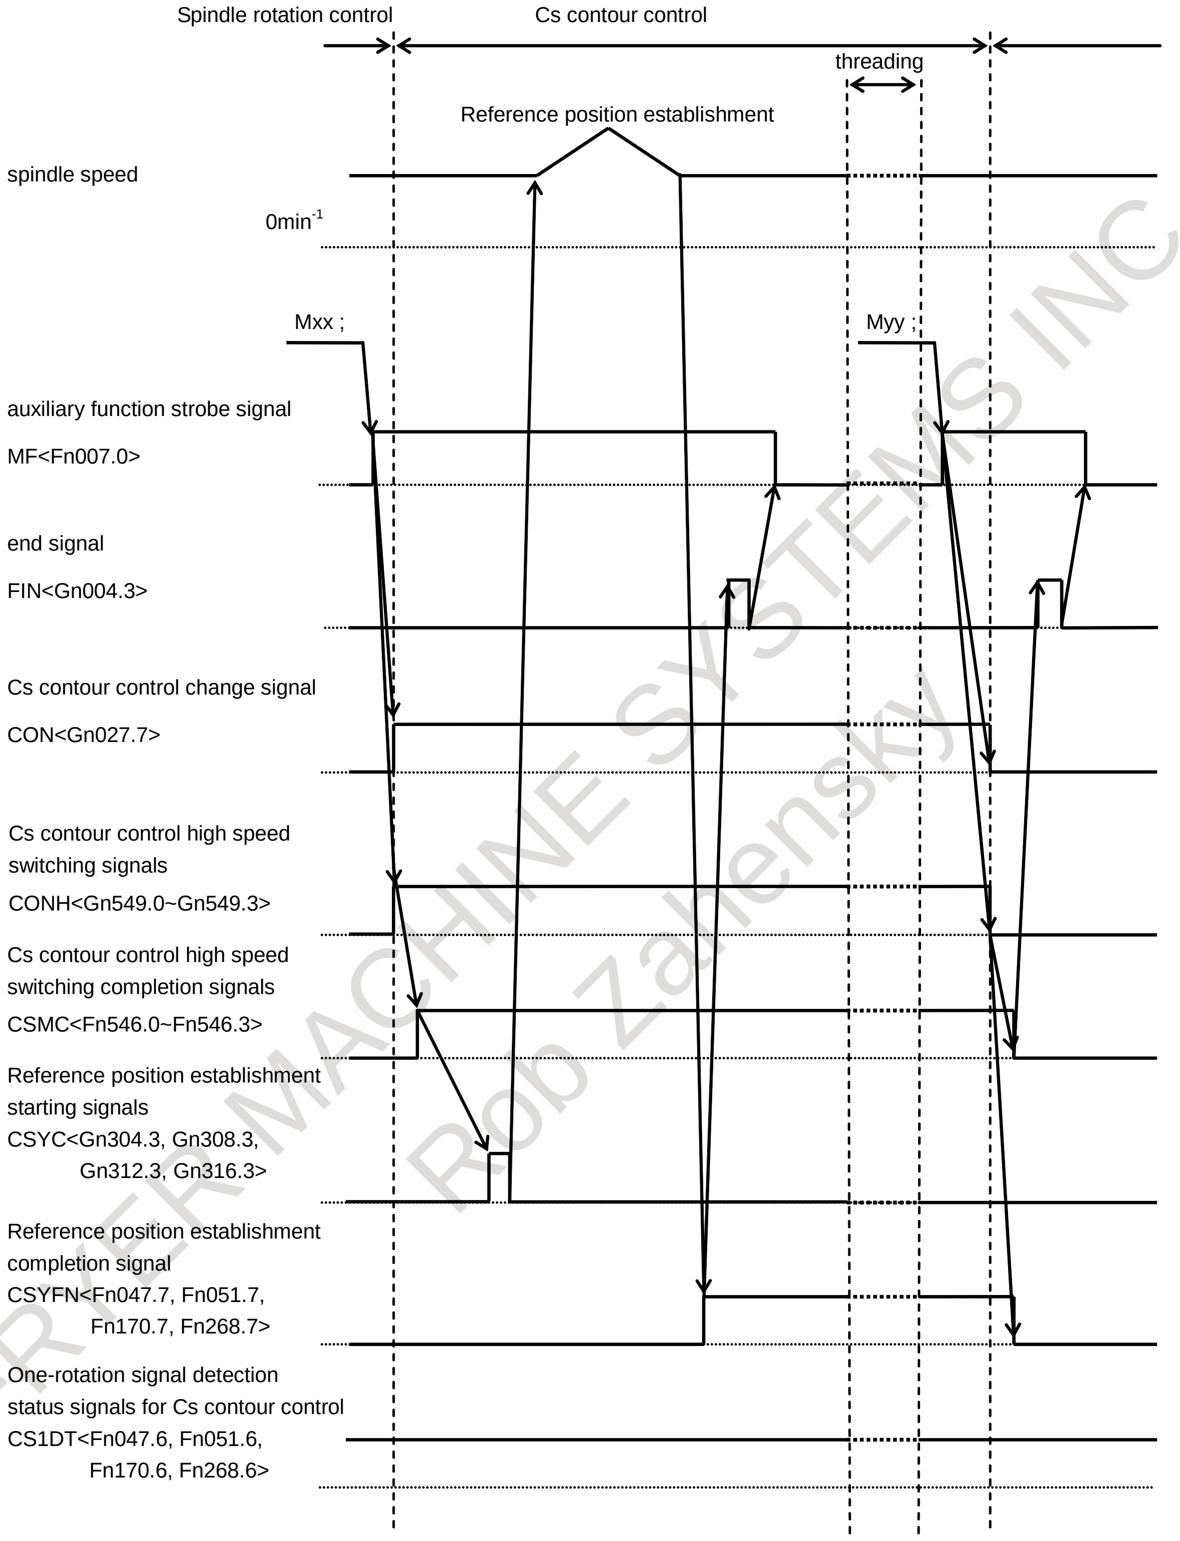

Fig.6.5.7.1 (c) sequence of arbitrary speed threading mode change

- Spindle speed override

Spindle speed override signals SOV0 to SOV7 <Gn030> are available. If the override for individual spindles is enabled, SOV20 to SOV27 <Gn376> (second spindle), SOV30 to SOV37 <Gn377> (third spindle), SOV40 to SOV47 <Gn378> (forth spindle) are available, too.
However, changing the spindle speed override is disabled during the following period.

- After the Cs contour control change signal CON is set to “1” until the reference position establishment completion signal CYSFN becomes “1”.
- After threading starts until the feedrate of feed axis (the first axis on the plane) arrives at the commanded speed.

NOTE

1 If spindle speed override in each path is used, not only the spindle speed of the spindle in arbitrary speed threading mode but also the spindle speed of spindles in the same path is not changed according to spindle speed override signals.

2 As the spindle speed gets higher, the incorrect thread length is longer. Machining program must be created considering the incorrect thread length which is changed according to the range of spindle speed override in arbitrary speed threading mode.

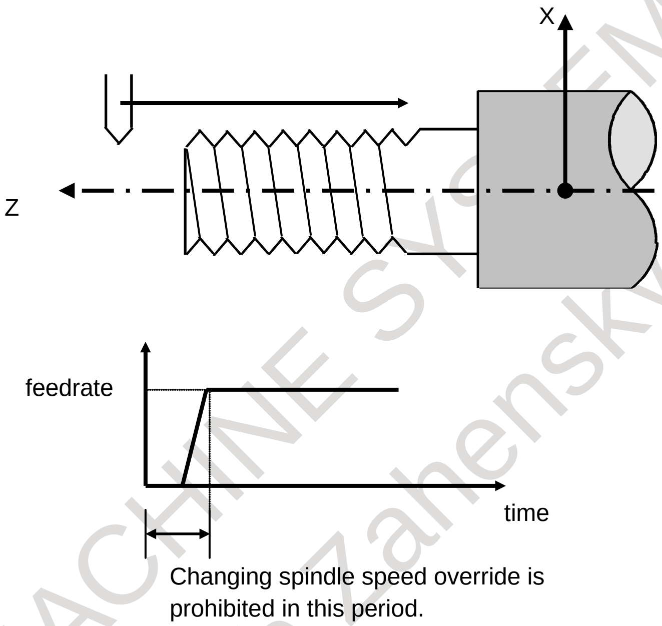

Fig.6.5.7.1 (d) Period in which changing spindle speed override is prohibited

- Acceleration/Deceleration of spindle in arbitrary speed threading

It is possible to switch the acceleration of a spindle according to spindle speed when the spindle speed override is changed in arbitrary speed threading. There are two switching points, which is set in parameter No.11020 and No.11021. Besides, acceleration of each section is set in parameter No.11030, No.11031, and No.11032.

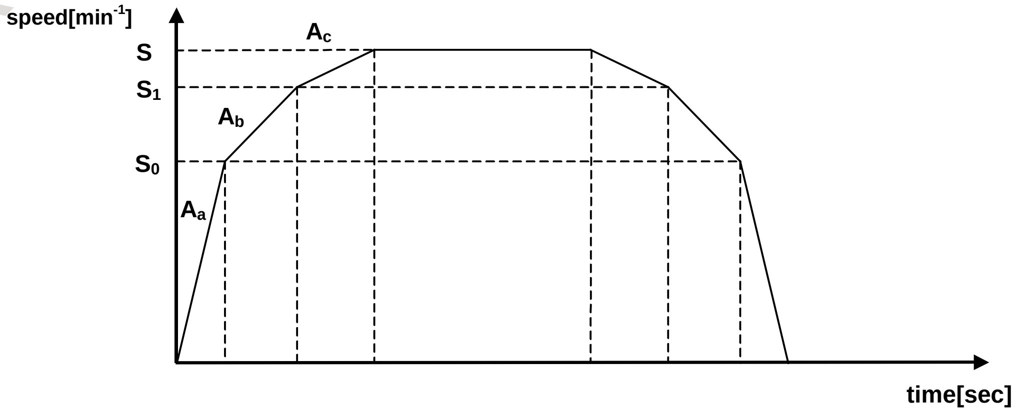

Fig.6.5.7.1 (e) Acceleration/deceleration of spindle in arbitrary speed threading

S_0: value set in parameter No.11020 (Acceleration is switched at S_0[min^{-1}].)

S_1: value set in parameter No.11021 (Acceleration is switched at S_1[min^{-1}].)
S : specified rotation speed[min^{-1}]
A_a : value set in parameter No.11030 (Acceleration [min^{-1}/s] applied from 0[min^{-1}] to S_0[min^{-1}] (section 1))
A_b : value set in parameter No.11031 (Acceleration [min^{-1}/s] applied from S_0[min^{-1}] to S_1[min^{-1}] (section 2))
A_c : value set in parameter No.11032 (Acceleration [min^{-1}/s] applied from S_1[min^{-1}] to maximum speed (section 3))

In addition, the deceleration can be set in other parameter by setting bit 6 (DCS) of parameter No.11001 to 1.

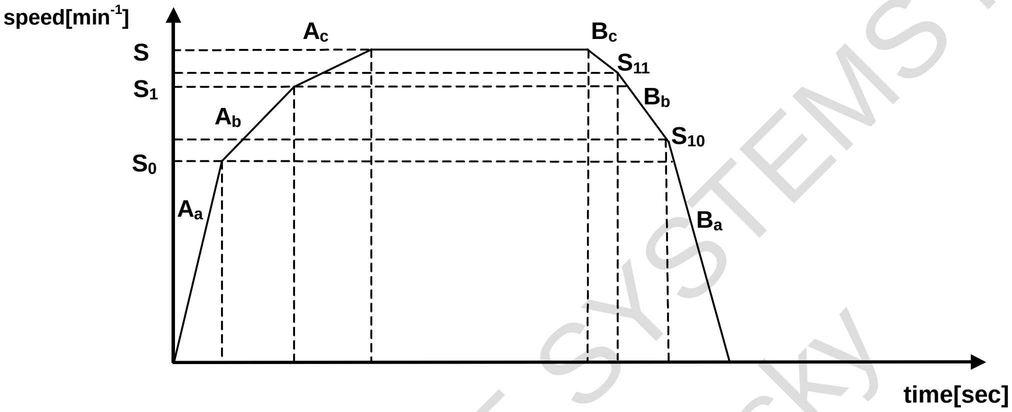

Fig.6.5.7.1 (f) Acceleration/deceleration of spindle in arbitrary speed threading (exclusive parameter for deceleration)

S_{10} : value set in parameter No.25700 (Deceleration is switched at S_{10}[min^{-1}].)
S_{11} : value set in parameter No.25701 (Deceleration is switched at S_{11}[min^{-1}].)
B_a : value set in parameter No.25710 (Deceleration [min^{-1}/s] applied from 0[min^{-1}] to S_{10} [min^{-1}] (section 1))
B_b : value set in parameter No.25711 (Deceleration [min^{-1}/s] applied from S_{10} [min^{-1}] to S_{11} [min^{-1}] (section 2))
B_c : value set in parameter No.25712 (Deceleration [min^{-1}/s] applied from S_{11} [min^{-1}] to maximum speed (section 3))

Determine the value of each parameter considering the torque characteristic of the motor and so on.

- Spindle speed at the start of threading

Spindle speed at the start of threading must be arrived at the specified speed in arbitrary speed threading. Therefore, threading can be started in the mode if the difference between specified speed and feedback pulse from a position coder is smaller than the level set in parameter No.11490.

> **NOTE**
> Speed arrival signals SARA to SARD <Fn045.3, Fn049.3, Fn168.3, Fn266.3> are always “1” while Cs contour control high speed switching completion signal is “1”.

- Acceleration/Deceleration of feed axis and infeed axis in threading

In threading, the axis whose travel distance is the longest is called a major axis. Thread is machined so that the specified lead would be applied in the direction of the major axis. In arbitrary speed threading, exclusive linear acceleration/deceleration is executed. Acceleration for the major axis is set in parameter No.11489. As for infeed axis (the second axis on the plane) performing taper threading and chamfering, acceleration is calculated from that of the major axis automatically. In continuous threading, acceleration of the major axis is applied from the first threading block to the last threading block. If the spindle speed override is changed, the spindle acceleration/deceleration is executed according to the switching point set in parameter No.11020, No.11021, and acceleration set in parameter No.11030 to No.11032, then, the major axis acceleration/deceleration is executed according to the spindle acceleration/deceleration.

Example: continuous threading
In block 1, acceleration for Z axis (major axis) is applied whose value is set in parameter No.11489, acceleration for X axis is calculated automatically. In block 2, the major axis is changed from Z axis to X axis because the chamfering angle is 60 degrees. But acceleration for Z axis is not changed (same as block 1), and acceleration for X axis is calculated automatically.

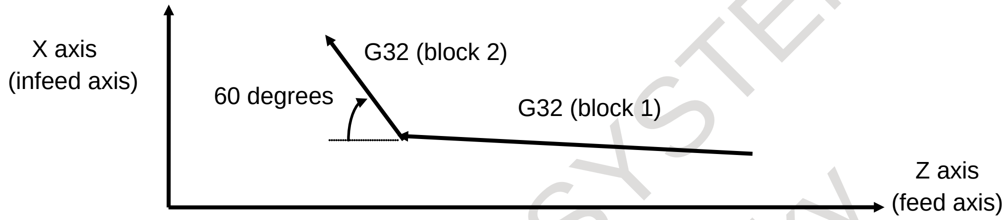

Fig. 6.5.7.1 (g) Acceleration/Deceleration of feed axis and infeed axis in threading

NOTE

1 Acceleration of a major axis must be higher than that of a spindle in order to machine without breaking the thread even if the spindle speed is changed. Acceleration of a major axis (parameter No.11489) must be set so that the acceleration would satisfy the following inequality.

$A_{ax}>(A_{sp}/60)*F$

Where,

A_{ax} : acceleration of major axis set in parameter No.11489

A_{sp} : maximum acceleration of spindle set in parameters No.11030 to No.11032, No.25710 to No.25712

F : maximum lead specified in a machining program

If the above condition is not satisfied, alarm PS0531 “THREADING PARAMETER ERROR” is issued.

2 In continuous threading, if the feedrate of infeed axis (the second axis on the plane) cannot be decelerated to 0 with automatically calculated acceleration, alarm PS0529 is issued (For example when the major axis of block 1 and block 2 is the second axis on the plane, and travel distance of block 2 is short.).

Chamfering value and angle in thread cutting cycles

In usual threading, parameter No.5130 for chamfering value in thread cutting cycles and parameter No.5131 for chamfering angle in thread cutting cycles are used. In arbitrary speed threading, the parameter is selected to use in chamfering by chamfering for arbitrary speed threading signal ASTC<Gn549.6>.

- Chamfering value and angle in usual thread cutting cycles (Parameters No.5130, No.5131)
- Chamfering value and angle in thread cutting cycles for arbitrary speed threading (Parameters No.11497, No.11498).

NOTE
Use M code without buffering when ASTC <Gn549.6> is changed during arbitrary speed threading mode.

- Retraction after chamfering for threading cycle and multiple threading cycle

Feedrate, type of acceleration/deceleration, and time constant of retraction after chamfering (3. retraction of Fig. 6.5.7.1 (h) threading cycle) are as usual, as shown in Table 6.5.7.1 (c).

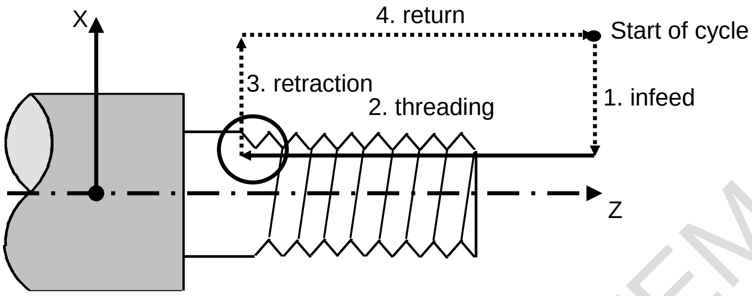

Fig. 6.5.7.1 (h) threading cycle

Table 6.5.7.1 (c) setting of acceleration/deceleration for retraction after chamfering

Parameter CFR (No.1611#0)	Parameter (No.1466)	Description
0	Other than 0	Uses the type of acceleration/deceleration after interpolation for threading, time constant for threading (parameter No.1626), FL feedrate (parameter No.1627), and retraction feedrate specified in parameter No.1466.
0	0	Uses the type of acceleration/deceleration after interpolation for threading, time constant for threading (parameter No.1626), FL feedrate (parameter No.1627), and rapid traverse rate specified in parameter No.1420.
1		Before retraction, a check is made to see that the specified feedrate has become 0 (delay in acceleration/deceleration is 0), and the type of acceleration/deceleration after interpolation for rapid traverse is used together with the rapid traverse time constant and the rapid traverse rate (parameter No.1420).

When the type of acceleration/deceleration after interpolation for threading is used as the acceleration / deceleration for retraction after chamfering (bit 0 (CFRx) of parameter No.1611 is 1), acceleration / deceleration after interpolation for threading is acceleration/deceleration of exponential interpolation type. By setting bit 5 (THLx) of parameter No.1610, the same acceleration/deceleration for cutting feed can be selected (Followed by the setting of bits 1 (CTBx) and 0 (CTLx) of parameter No.1610). However, as a time constant and FL feedrate, the settings of parameter No.1626 and No.1627 for the threading cycle are used.

NOTE
Acceleration/deceleration after interpolation is invalid during arbitrary speed threading (2.threading in Fig. 6.5.7.1 (h) threading cycle), and acceleration/deceleration is controlled according to the exclusive acceleration. Retraction is started after finishing the deceleration of feed axis and infeed axis.

- Maximum cutting feedrate

If the cutting feedrate of feed axis or infeed axis exceeds the maximum cutting feedrate (parameter No.1430), cutting feedrate is clamped to the limit set in parameter No.1430, and the alarm PS0530 “EXCESS VELOCITY IN THREADING” is issued. Threading is continued even if the alarm is issued.

Automatic operation is stopped after retracting in the case of threading cycle and multiple threading cycle. Automatic operation is stopped at the end of a block in the case of threading.

- Acceleration/Deceleration after interpolation

Acceleration/Deceleration after interpolation is ineffective in threading and chamfering.

- Dry run

Dry run is available according to the setting of bit 5 (TDR) of parameter No.1401.

- Position gain

Position gain of spindle (Cs contour control axis), position gain of feed axis, and position gain of infeed axis must be set the same value.

- feed axis, infeed axis
  parameter No.1825
- spindle (Cs contour control axis)
  parameter No.4069 (HIGH gear)
  parameter No.4070 (MEDIUM HIGH gear)
  parameter No.4071 (MEDIUM LOW gear)
  parameter No.4072 (LOW gear)

- Gear change system

T type gear selection method must be selected for the path which is applied arbitrary speed threading.

- Path spindle control

Start and cancel command of arbitrary speed threading must be specified in the same path. The path specified M code of starting arbitrary speed threading and the path to which a spindle for arbitrary speed threading must be set bit 0 (AST) of parameter No.11485 to 1. When the setting of bit 0 (AST) of parameter No.11485 is different because of the path specified M code of starting arbitrary speed threading and the path to which a spindle for arbitrary speed threading, it operates as follows.

- When the path specified M code is valid and the path to which a spindle is invalid:
  An alarm PS0531 "THREADING PARAMETER ERROR" occurs. M code is not output.
- When the path specified M code is invalid and the path to which a spindle is valid:
  It is not processed as M code for arbitrary speed threading. M code is output.

It is not able to specify the same spindle as the axis performing arbitrary speed threading among multiple paths. When the spindle is already used in arbitrary speed threading mode at one path, if the command of starting arbitrary speed threading is specified to the same spindle at other path, the alarm PS0529 "THREADING COMMAND IMPOSSIBLE" is issued.

Set parameters for arbitrary speed threading as follows.
Path A: The path specified M code of starting arbitrary speed threading
Path B: The path to which a spindle for arbitrary speed threading

Necessary parameters both path A and path B to set	
Parameter No.	**Explanation**
No.11485#0	Arbitrary speed threading is valid

Necessary parameter for path A to set	
Parameter No.	**Explanation**
No.11486#0	Command for shifting the threading start angle by address Q in re-machining thread is invalid (0) / valid (1)
No.11486#1	Arbitrary speed threading mode is canceled (0) / not canceled (1) by reset
No.11486#2	In arbitrary speed threading mode, M code to start arbitrary speed threading mode is invalid (0) / valid (1) to command
No.11489	Acceleration of major axis in arbitrary speed threading (set to major axis)

Necessary parameter for path A to set	
Parameter No.	**Explanation**
No.11490	Spindle speed arrival level in arbitrary speed threading
No.11492	Adjusting parameter 1 for arbitrary speed threading (position error of servo)
No.11493	Adjusting parameter 2 for arbitrary speed threading (position error of spindle)

Necessary parameter for path B to set	
Parameter No.	**Explanation**
No.11487	M code to start arbitrary speed threading mode
No.11488	M code to cancel arbitrary speed threading mode
No.11030	Individual acceleration/deceleration
No.11031	Individual acceleration/deceleration
No.11032	Individual acceleration/deceleration
No.4002#4	In Cs contour control, the rotation direction signal (SFR/SRV) function is used / not used. (Please set to 1)
No.4069	Position gain in Cs contour control (HIGH gear)
No.4070	Position gain in Cs contour control (MEDIUM HIGH gear)
No.4071	Position gain in Cs contour control (MEDIUM LOW gear)
No.4072	Position gain in Cs contour control (LOW gear)
No.4504	Cs contour control high speed switching: Reference position establishment speed
No.4505	Cs contour control high speed switching: Reference position establishment acceleration
No.4506	Cs contour control high speed switching: Bell-shaped acceleration/deceleration time constant for the reference position establishment
No.4507	Cs contour control high speed switching: Reference position establishment completion level

Note

- Emergency stop

A spindle (Cs contour control axis) is stopped by emergency stop *ESP <X008.4> (for the first machine group), <X008.0> (for the second machine group), <X008.1> (for the third machine group), and <Gn008.4> during arbitrary speed threading.

- Spindle stop

A spindle can be stopped by the following operations during arbitrary speed threading.

- Spindle stop signal *SSTP<Gn029.6>, individual spindle stop signal *SSTP1 to *SSTP4<Gn027.3 to Gn027.5, Gn026.6> (using multi-spindle control)
- Spindle speed override signal, individual spindle speed signal
- S0 command

Arbitrary speed threading must be canceled when a spindle is stopped by an operation except above during arbitrary speed threading. Besides, a spindle is stopped by servo alarm or servo-off differently from usual spindle control.

- Machine lock

All-axis machine lock signal MLK<Gn044.1> and each-axis machine lock signals MLK1 to MLK8<Gn0108> are ineffective for a spindle during arbitrary speed threading. These signals are effective before threading. But these signals are ineffective during threading including chamfering.

- Interlock

All axes interlock signal *IT<Gn008.0> and interlock signals for each axis *IT1 to *IT8<Gn130> are ineffective for a spindle during arbitrary speed threading.

- Stored stroke check

Stored stroke check is ineffective for a spindle during arbitrary speed threading.

- Arbitrary speed threading in Cs contour control

If the M code for start of arbitrary speed threading is specified in Cs contour control mode, the alarm (PS0529) ” THREADING COMMAND IMPOSSIBLE” is issued. Changing to arbitrary speed threading mode is permitted in only spindle rotation control mode.

- Simple spindle electronic gear box

The slave axis synchronizes by following to the master axis, therefore, the slave axis is required a higher acceleration ability than that of the master axis. If the acceleration ability of the master axis is higher than that of the slave axis, the acceleration/deceleration of the master axis should be set in consideration of the acceleration ability of the slave axis. Moreover, the spindle which is commanded in arbitrary speed threading mode should be a master axis.

- Spindle speed

When bit 3 (IRC) of parameter No.1408 is set to 0, the malfunction prevent function may work at a rotation speed of about 2778 min^{-1}. When the motor rotates at a rotation speed of 2778 min^{-1} or more, set bit 3 (IRC) of parameter No.1408 to 1. If bit 3 (IRC) of parameter No.1408 is set to 1, a rotation speed can be specified up to about 27778 min^{-1}.

Limitation

- Reference position return

As a rule, in order to use this function, reference position return must be performed in Cs contour control once after power-on to detect the one-rotation signal of the spindle. If arbitrary speed threading mode change is executed without performing reference position return, the spindle decelerates to the reference position return speed (parameter No.4074) in order to detect the one-rotation signal. After detecting the one-rotation signal, one-rotation signal detection status signal for Cs contour control CS1DTx (<Fn047.6> (1st spindle), <Fn051.6> (2nd spindle), <Fn170.6> (3rd spindle), <Fn268.6> (4th spindle)) become “1”.

- Unavailable functions for arbitrary speed threading

- Pitch error compensation
  Pitch error compensation is not available for spindle in arbitrary speed threading.
- Synchronous control and composite control
  Synchronous control and composite control are not available for the first axis on the plane, the second axis on the plane, and the spindle during arbitrary speed threading. Alarm PS0529 “THREADING COMMAND IMPOSSIBLE” is issued.
- Superimposed control
  Superimposed control is not available for the first axis on the plane, the second axis on the plane, and the spindle during arbitrary speed threading. Alarm PS0529 “THREADING COMMAND IMPOSSIBLE” is issued.
- Spindle synchronous control
- Spindle command synchronous control
  Both spindle synchronous control and spindle command synchronous control are not available for the spindle during arbitrary speed threading. Alarm PS0529 “THREADING COMMAND IMPOSSIBLE” is issued.
- Manual reference position return
  If manual reference position return for spindle is performed in arbitrary speed threading mode, alarm PS0529 “THREADING COMMAND IMPOSSIBLE” is issued.
- Arbitrary reference position setting function
- Cs contour control axis coordinate establishment
  Both arbitrary reference position setting function and Cs contour control axis coordinate establishment are not available for a spindle during arbitrary speed threading.
- Spindle control with a servo motor
  Arbitrary speed threading is not available for a spindle which is controlled with a servo motor.
- Spindle analog output

Arbitrary speed threading is not available for analog spindle.

- Usual threading
  Usual threading is not available during arbitrary speed threading mode. Arbitrary speed threading must be canceled to enable usual threading.
- Manual handle retrace
- Spindle output control by the PMC
- Balance cutting
- Mirror image for double turret
  Arbitrary speed threading is not available during double turret mirror image mode.
- Flexible path axis assignment
  Arbitrary speed threading is not available for a spindle which is assigned/exchanged by flexible path axis assignment.
- Constant surface speed control
  Arbitrary speed threading is not available in constant surface speed control.

- Spindle software functions

The following functions cannot be used with arbitrary speed threading.

- Spindle electronic gear box (spindle EGB)
- Dual position feedback function

6.5.7.2 Re-machining thread

Overview

This function makes it possible to re-machine the same thread even if the workpiece which is not finished threading is removed from a chuck once. In order to re-machine the thread, groove of thread is measured after mounting the workpiece on a chuck. Then, the thread is re-machined by the same machining program. This function is included in “Arbitrary speed threading”.

Explanation

In order to re-machine the thread, the groove of thread is measured. Then, re-machining thread signal RMTC<Gn549.5> is set to “1”, and re-machining thread is executed in arbitrary speed threading mode. This function is enabled by setting bit 1 (RMT) of parameter No.11485 to 1.

Measurement of thread groove

- Measurement of thread groove in arbitrary speed threading mode

1.) Change to arbitrary speed threading mode by specifying M code on condition that the spindle is stopped (S0).
2.) In manual operation, touch the tool to a groove of thread.
3.) In order to measure the groove of thread, groove of thread measurement signal GTMSR <Gn549.4> is set to “1”. Groove of thread measurement signal GTMSR <Gn549.4> is set to “0” after groove of thread measurement completion signal GTMC <Fn546.4> becomes “1”. Machine coordinates of each axis are stored in parameter No.11496 by measuring the groove of thread.
4.) Retract the tool.
5.) Cancel arbitrary speed threading by specifying M code.

> ⚠ **CAUTION**
> 1 In changing to arbitrary speed threading mode, the spindle rotates at a speed of parameter No.4504 to No.4506, and reference position establishment is performed.
> 2 Spindle should not be rotated from the end of reference position establishment to the end of measurement of thread groove.

- Measurement of thread groove with reference position return in Cs contour control mode

In case that a spindle used in re-machining thread is in Cs contour control mode (Cs contour control change completion signal FSCSL <Fn044.1> or Cs contour control change completion signals in each axis FCSSx <Fn274.0 to 3 = “1”) and reference position return is completed (reference position return end signals ZPx<Fn094.0 to 8>=”1”), measuring thread groove is possible. By this way, measuring thread groove can be performed only by operating signals without executing automatic operation.

1) Change to Cs contour control mode on condition that the spindle used in re-machining thread is stopped (S0), and reference position return must be performed. At this time, feedback pulse from this spindle position coder must be selected during measurement of thread groove.
2) In manual operation, touch the tool to a groove of thread.
3) In order to measure the groove of thread, groove of thread measurement signal GTMSR <Gn549.4> is set to “1”. Groove of thread measurement signal GTMSR <Gn549.4> is set to “0” after groove of thread measurement completion signal GTMC <Fn546.4> becomes “1”. Machine coordinates of each axis are stored in parameter No.11496 by measuring the groove of thread.
4) Retract the tool.
5) Cancel Cs contour control mode

> ⚠ **CAUTION**
> 1 The spindle whose feedback pulse from position coder is effective is recognized as a spindle used in re-machining thread. So if another spindle is selected by mistake, groove of thread measurement error (groove of thread measurement error signal GTME<Fn546.5>=”1”) occurs or thread cutting is not performed correctly, so be careful to select the proper spindle.
> 2 If the spindle whose feedback pulse from position coder is effective is not in the state of reference position return end, groove of thread measurement error (groove of thread measurement error signal GTME<Fn546.5>=”1”) occurs.

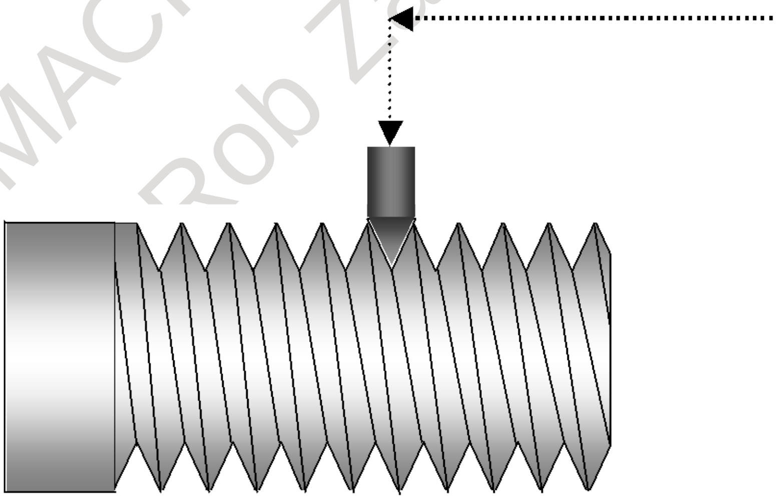

Fig. 6.5.7.2 (a) measurement of thread groove

> ⚠ **CAUTION**
> 1 The groove of thread must be measured when axes except for PMC axis, and spindle for arbitrary speed threading are stopped.
> 2 The groove of thread must be measured with the same tool which is used for re-machining thread. Besides, tool offset should not be changed from measurement of thread groove to re-machining.

> **NOTE**
> The groove of thread cannot be measured in servo-off state.

Re-machining thread

Re-machining thread signal GTMC<Gn549.5> is set to “1”, then arbitrary speed threading is specified. If the re-machining is finished, re-machining thread signal GTMC<Gn549.5> is set to “0”.

<Re-machining thread signal GTMC<Gn549.5> is set to “1”>

```
S_;                     : specifying the spindle speed
Mxx;                    : start of arbitrary speed threading
N1G92 X151.0Z-200.F10.;
N2X150.0;
N3X149.0;
N4X148.0;
G00;
Myy;                    : cancel of arbitrary speed threading
```

<Re-machining thread signal GTMC<Gn549.5> is set to “0”>

> **NOTE**
> 1 If arbitrary speed threading is executed with re-machining thread signal GTMC<Gn549.5> setting to “1”, the timing of threading start is changed according to the measured data of thread groove. Therefore, re-machining thread signal GTMC<Gn549.5> should be set to “0” while re-machining thread is not executed.
> 2 If re-machining thread is executed without measuring the groove of thread after power-on, the alarm PS0532 ”RE-MACHINING OF THREAD CUTTING IMPOSSIBLE” is issued.

- Available threading commands for re-machining thread

Threading commands which are available for re-machining are as follows.

Table 6.5.7.2 (a) Available threading commands for re-machining thread

	Machining center system	Lathe system		
		G code system		
		A	B	C
Threading	G33	G32	G33	G33
Threading cycle	−	G92	G78	G21
Multiple threading cycle	−	G76	G76	G78

Note

- Measurement of thread groove

Measurement position must be the groove except for chamfering part in the case of threading cycle, or the first block groove in the case of continuous threading.

- Re-machining thread

The workpiece which is machined by usual threading can be re-machined. Since re-machining is controlled in arbitrary speed threading mode, re-machined thread may not have the same thread shape completely due to the difference of acceleration/deceleration method. The difference of thread shape may occur at chamfering part of threading cycle or taper part for chamfering of continuous threading.

- Re-machining thread signal

If arbitrary speed threading is executed with re-machining thread signal GTMC<Gn549.5> setting to “1”, the timing of threading start is changed according to the measured data of thread groove. Therefore, re-machining thread signal GTMC<Gn549.5> should be set to “0” while re-machining thread is not executed.

- Command for shifting the threading start angle by address Q

Whether the command for shifting the threading start angle by address Q is enabled or not is selected according to bit 0 (ADQ) of parameter No.11486.

- Bit 0 (ADQ) of parameter No.11486 is set to 0
  The command for shifting the threading start angle by address Q is disabled for re-machining thread. The tool passes the measured groove of thread regardless of Q command.

- Bit 0 (ADQ) of parameter No.11486 is set to 1
  The command for shifting the threading start angle by address Q is enabled for re-machining thread. The measured position of thread groove is assumed to be standard angle (Q=0), and the shift of the threading start angle commanded by address Q is added.

⚠ **CAUTION**

- When bit 0 (ADQ) of parameter No.11486 is set to 1:

  In re-machining the thread which is machined the following program, the groove of thread which is machined by address Q=0 must be measured.

  Example)

  ```
  G32 Z-200.0 F10.0 Q0 ;
        :
  G32 Z-200.0 F10.0 Q90000 ;
        :
  ```

  If the groove of thread which is machined by address Q=90000 is measured, and re-machining is executed by above program, thread is re-machined as shown in Fig. 6.5.7.2 (b).

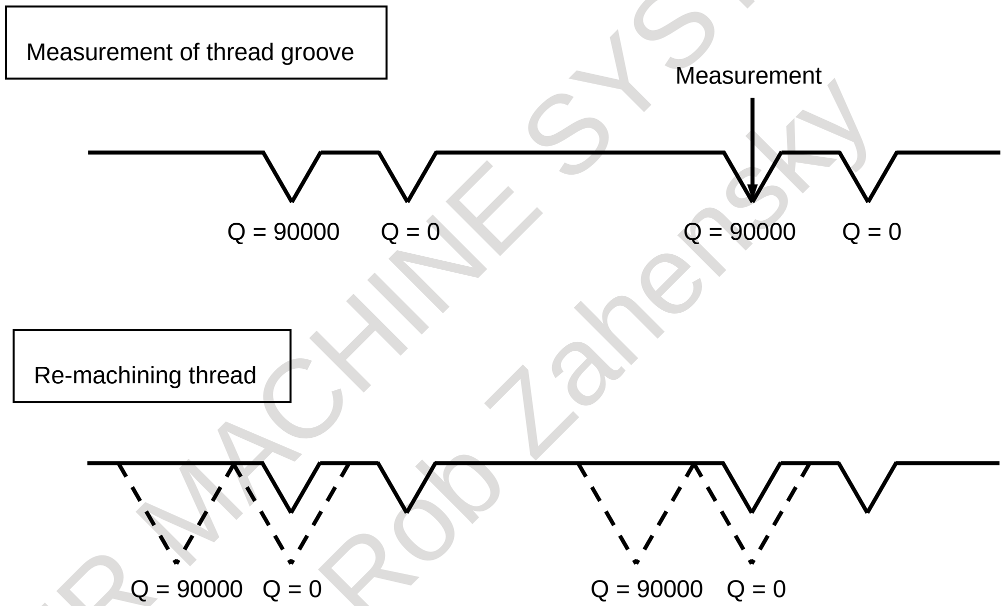

Fig. 6.5.7.2 (b) Example of re-machining thread in bit 0 (ADQ) of parameter No.11486 is set to 1.

Limitation

- Multiple threading cycle

Cutting method of multiple threading cycle is usually one-edge threading with constant cutting amount as shown in Fig. 6.5.7.2 (c) (1). Re-machining of multiple threading cycle is executed so that the groove of thread would be machined at the stored position by measurement as shown in Fig. 6.5.7.2 (c) (2).

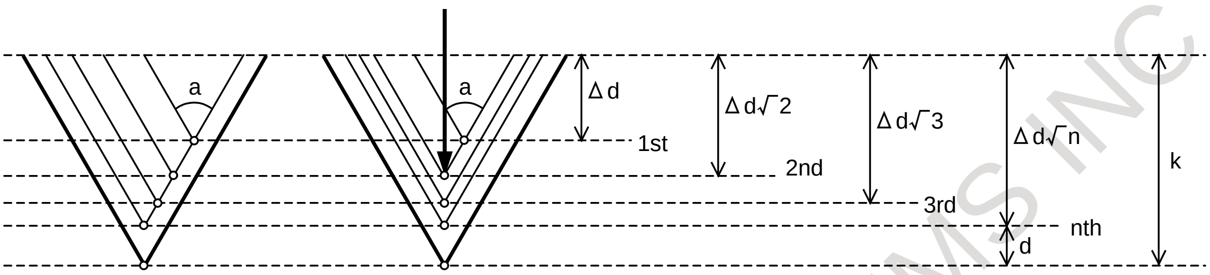

Fig. 6.5.7.2 (c) cutting method of multiple threading cycle re-machining

In the case of memory operation using Series 15 format, even if the following cutting method is selected, re-machining of multiple threading cycle is executed as shown in Fig. 6.5.7.2 (c) (2), too.

P1 : one-edge threading with constant cutting amount
P2 : both-edge zigzag threading with constant cutting amount
P3 : one-edge threading with constant depth of cut
P4 : both-edge zigzag threading with constant depth of cut

- Mirror image

Thread cannot be re-machined with mirror image applied.

Signal

1st spindle speed override signal SOV0 to SOV7<Gn030>
2nd spindle speed override signal SOV20 to SOV27<Gn376>
3rd spindle speed override signal SOV30 to SOV37<Gn377>
4th spindle speed override signal SOV40 to SOV47<Gn378>

[Classification] Input signal

[Function] If bit 3 (MSC) of parameter No.3713 = 1, and bit 4 (EOV) of parameter No.3713 = 1, an override of 0% to 254% of the rotation speed specified by the CNC can be applied to individual spindles separately.

[Operation] Specify an override value, using an 8-bit binary number.
If all bits are “1”, however, an override of 0% is assumed.

> **NOTE**
> If both bit 3 (MSC) and bit 4 (EOV) of parameter No.3713 are not 1, the override signals SOV0 to SOV7 are applied to all spindles that receive speed commands.
> The signals SOV20 to SOV27, SOV30 to SOV37, and SOV40 to SOV47 are invalid.

Cs contour control high speed switching signals
CONH1 to CONH4<Gn549.0 to Gn549.3>

[Classification] Input signal

[Function] These signals specify high speed switching from spindle rotation control to Cs contour control.
When these signals are set to “1”, setting the Cs contour control change signal CON <Gn027.7> (or the Cs contour control change signal in each axis CONSx <Gn274.0 to Gn274.3>) from “0” to “1” starts Cs contour control high speed switching.
When these signals are set to “0”, setting CON (or CONS) from “0” to “1” starts ordinary switching to Cs contour control.
Setting CON (or CONS) from “1” to “0” switches to spindle rotation control. The type of switching is the same as of switching to Cs contour control.
These signals are valid when bit 0 (AST) of parameter No.11485 is set to 1.

Cs contour control high speed switching completion signals
CSMC1 to CSMC4<Fn546.0 to Fn546.3>

[Classification] Output signal

[Function] These signals notify the PMC that the system is put in the Cs contour control mode by Cs contour control high speed switching.

[Output cond.] These signals become “1” under the following condition:

- The system is put in the Cs contour control mode by Cs contour control high speed switching.

These signals become “0” under the following condition:

- The system is put in the Cs contour control mode by ordinary switching to Cs contour control.
- The system is not in the Cs contour control mode.

Forward rotation / Reverse rotation command signal (serial spindle)
SFRA/SRVA<Gn070.5/Gn070.4> : First spindle
SFRB/SRVB<Gn074.5/Gn074.4> : Second spindle
SFRC/SRVC<Gn204.5/Gn204.4> : Third spindle
SFRD/SRVD<Gn266.5/Gn266.4> : Fourth spindle

[Classification] Input signal

[Function] These signals switch between on and off of motor excitation in Cs contour control.

[Operation] When this function is used, in Cs contour control, keep SFRx or SRVx to “1” during:
Mode switching from spindle rotation control to Cs contour control
Mode switching from Cs contour control to spindle rotation control

> **NOTE**
> When SFRx (or SRVx) is set to “0” during mode switching from spindle rotation control to Cs contour control, the spindle decelerates, then reference position establishment is performed.

Reference position establishment starting signal (serial spindle)
CSYCA<Gn304.3> : First spindle
CSYCB<Gn308.3> : Second spindle
CSYCC<Gn312.3> : Third spindle
CSYCD<Gn316.3> : Fourth spindle

[Classification] Input signal

[Function] These signals establish the reference position while the spindle is rotating.

[Operation] Setting these signals to “0” after the reference position establishment starting signal CSYCx is set to “1” starts to establish the reference position while the spindle is rotating.

Reference position establishment completion signal (serial spindle)
CSYFNA<Fn047.7> : First spindle
CSYFNB<Fn051.7> : Second spindle
CSYFNC<Fn170.7> : Third spindle
CSYFND<Fn268.7> : Fourth spindle

[Classification] Output signal

[Function] These signals indicate that reference position establishment while the spindle is rotating is completed.

[Output cond.] These signals become "1" under the following condition:
- Reference position establishment while the spindle is rotating is completed.

These signals become "0" under the following condition:
- Reference position establishment while the spindle is rotating is not completed.
- The system is in the spindle rotation control mode.

One-rotation signal detection status signal for Cs contour control (serial spindle)
CS1DTA<Fn047.6> : First spindle
CS1DTB<Fn051.6> : Second spindle
CS1DTC<Fn170.6> : Third spindle
CS1DTD<Fn268.6> : Fourth spindle

[Classification] Output signal

[Function] These signals indicate that the one-rotation signal has been detected in Cs contour control.

[Output cond.] These signals become "1" under the following condition:
- The one-rotation signal has been detected in Cs contour control.

These signals become "0" under the following condition:
- The one-rotation signal has not been detected in Cs contour control.

SV reverse signals SVRVS1 to SVRVS8<Gn523>
[Classification] Input signal

[Function] These signals cause the respective axes to reverse their rotation direction in the arbitrary speed threading mode.

[Operation] Setting these signals to "1" cause the respective axes to reverse their rotation direction. Resetting these signals to "0" cause the respective axes to resume their normal rotation direction.

> **NOTE**
> In this function, because spindle rotation control mode is switched to arbitrary speed threading mode (position control) immediately while the spindle is rotating, rotation direction in arbitrary speed threading might be switched from that in spindle rotation control due to machine configuration or parameter setting. For this case, SV reverse signal SVRVS1 to SVRVS8 <Gn523> is set to "1" before changing to arbitrary speed threading mode so that the rotation direction in arbitrary speed threading would be the same as that in spindle rotation control. Besides, SV reverse signal SVRVS1 to SVRVS8 <Gn523> is set to "0" after canceling the arbitrary speed threading mode.

Groove of thread measurement signal GTMSR<Gn549.4>
[Classification] Input signal

[Function] The groove of thread is measured.

[Operation] When groove of thread measurement signal is set to “1”, the groove of thread is measured.

Groove of thread measurement completion signal GTMC<Fn546.4>

[Classification] Output signal

[Function] Completion of thread groove measurement is indicated.

[Output cond.] This signal becomes “1” when:

- Groove of thread measurement signal is set to “1”, then the measurement of thread groove is completed.

This signal becomes “0” when:

- Groove of thread measurement signal is set from “1” to “0”.

Groove of thread measurement error signal GTME<Fn546.5>

[Classification] Output signal

[Function] It indicates that error is detected while measurement of thread groove.

[Output cond.] This signal becomes “1” when:

- The groove of thread is measured when axes except for PMC axis, and spindle (for arbitrary speed threading) are not stopped. This signal becomes “1” when the groove of thread measurement completion signal becomes “1” at the same time. This signal becomes “0” when:
- Groove of thread measurement signal is set from “1” to “0”.

Sequence of thread groove measurement

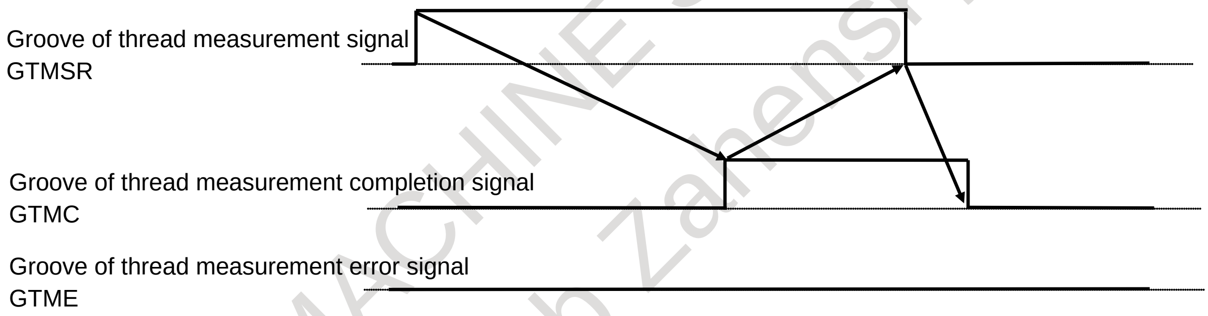

Fig. 6.5.7.2 (d) completion of thread groove measurement

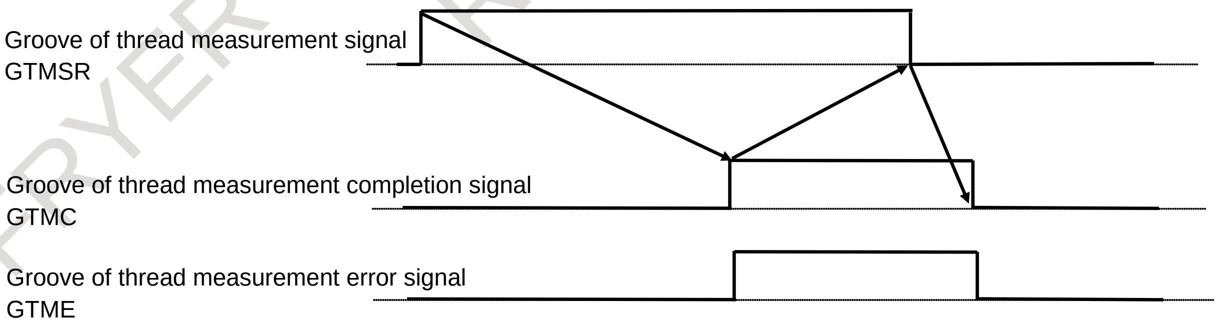

Fig. 6.5.7.2 (e) error of thread groove measurement

Re-machining thread signal RMTC<Gn549.5>

[Classification] Input signal

[Function] Re-machining thread is executed.

[Operation] In order to re-machine the thread, arbitrary speed threading is executed with setting this signal to “1”.

If re-machining thread is executed without measuring the groove of thread after power-on, the alarm PS0532 “RE-MACHINING OF THREAD CUTTING IMPOSSIBLE” is issued. This signal may be set to “1” in arbitrary speed threading. However, in this case, this signal must be set to “1” while the buffering is prevented by specifying M code of preventing buffering.

Chamfering for arbitrary speed threading signal ASTC<Gn549.6>

[Classification] Input signal

[Function] In arbitrary speed threading, the parameter is selected to use with chamfering value and angle in thread cutting cycles.

[Operation] When ASTC is “0”, chamfering value and angle in usual thread cutting cycles (Parameters No.5130, No.5131) are used.
When ASTC is “1“, chamfering value and angle in thread cutting cycles for arbitrary speed threading (Parameters No.11497, No.11498) are used.

Parameter

Parameters which are used for this function are as follows.

	#7	#6	#5	#4	#3	#2	#1	#0
11485							RMT	AST

[Input type] Parameter input
[Data type] Bit path

> **NOTE**
> When this parameter is set, the power must be turned off before operation is continued.

#0 AST Arbitrary speed threading is:
0: Disabled.
1: Enabled.

#1 RMT Re-machining thread is:
0: Disabled.
1: Enabled.

	#7	#6	#5	#4	#3	#2	#1	#0
11486						AMM	ART	ADQ

[Input type] Parameter input
[Data type] Bit path

#0 ADQ Command for shifting the threading start angle by address Q in re-machining thread is:
0: Disabled.
1: Enabled.

#1 ART Arbitrary speed threading mode is:

0: Canceled by reset.
1: Not canceled by reset.

NOTE
1 In case of this parameter is 0, if reset operation is executed in arbitrary speed threading mode, Cs contour control change signal CON <Gn027.7> or Cs contour control change signals in each axis CONS <Gn274.0 to 3> must be set to “0”.
2 In case of this parameter is 1, if reset operation is executed in arbitrary speed threading mode, Cs contour control change signal CON <Gn027.7> or Cs contour control change signals in each axis CONS <Gn274.0 to 3> must be maintained to “1”. If it cancels the arbitrary speed threading mode, M code of cancel the arbitrary speed threading (No.11488) must be specified and Cs contour control change signal CON <Gn027.7> or Cs contour control change signals in each axis CONS <Gn274.0 to 3> must be set to “0”.

#2 AMM In arbitrary speed threading mode, M code to start arbitrary speed threading mode is
0: Disable to command (Alarm (PS0529) "THREADING COMMAND IMPOSSIBLE" occurs).
1: Enabled to command.

NOTE
In case of this parameter is 1, M code to start arbitrary speed threading can be re-commanded in arbitrary speed threading mode. Arbitrary speed threading mode is already selected. So process to change to arbitrary speed threading is not performed, but M code is output. Please operate properly with PMC ladder.

11487	M code to start arbitrary speed threading mode

[Input type] Parameter input
[Data type] 2-word spindle
[Unit of data] None
[Valid data range] 0 to 99999999
This parameter sets the M code to start arbitrary speed threading mode.

NOTE
1 The parameter setting must not be the same as the M code used for any other function.
2 When this parameter is set to 0, this function is invalid.
3 If the same value is set for two or more Cs contour control axes, the alarm PS0531, “THREADING PARAMETER ERROR” is issued.
4 The M code set in this parameter prevents buffering.

11488	M code to cancel arbitrary speed threading mode

[Input type] Parameter input
[Data type] 2-word spindle
[Unit of data] None
[Valid data range] 0 to 99999999

This parameter sets the M code to cancel arbitrary speed threading mode.

> **NOTE**
> 1 The parameter setting must not be the same as the M code used for any other function.
> 2 When this parameter is set to 0, this function is invalid.
> 3 If the same value is set for two or more Cs contour control axes, the alarm PS0531, "THREADING PARAMETER ERROR" is issued.
> 4 The M code set in this parameter prevents buffering.

11489	Acceleration in arbitrary speed threading

[Input type] Parameter input
[Data type] Real axes
[Unit of data] mm/sec^2, inch/sec^2, deg/sec^2 (machine unit)
[Min. unit of data] Depend on the increment system of the applied axis
[Valid data range] Refer to the standard parameter setting table (D)
(When the machine system is metric system, 0.0 to +100000.0. When the machine system is inch system, 0.0 to +10000.0.)
This parameter sets acceleration of major axis in arbitrary speed threading.
If this parameter is set to 0, acceleration is assumed to 100000.0.

11490	Spindle speed arrival level in arbitrary speed threading

[Input type] Parameter input
[Data type] word path
[Unit of data] min^{-1}
[Valid data range] 0 to 32767
Threading is started if the spindle speed is arrived within the level set in this parameter.

> **NOTE**
> Threading is not started if the spindle speed is not arrived within the level set in this parameter.

11496	Measurement result of thread groove

[Input type] Parameter input
[Data type] Real axis

[Unit of data] mm, inch, deg (machine unit)
[Min. unit of data] Depend on the increment system of the applied axis
[Valid data range] 9 digit of minimum unit of data (refer to standard parameter setting table (A))
(When the increment system is IS-B, -999999.999 to +999999.999)
Measurement result of thread groove is stored.

> **NOTE**
> This parameter stores measurement result of thread groove. Don't input this parameter.

11497	Chamfering value in thread cutting cycles G92 and G76 for arbitrary speed threading

[Input type] Parameter input

[Data type] Byte path
[Unit of data] 0.1
[Valid data range] 0 to 127

This parameter sets a chamfering value in the thread cutting cycle (G76) of a multiple repetitive canned cycle and in the thread cutting cycle (G92) of a canned cycle for arbitrary speed threading.
Let L be a lead. Then, a chamfering value range from 0.1L to 12.7L is allowed.
To specify a chamfering value of 10.0L, for example, specify 100 in this parameter.

11498	Chamfering angle in thread cutting cycles G92 and G76 for arbitrary speed threading

[Input type] Parameter input
[Data type] Byte path
[Unit of data] deg
[Valid data range] 1 to 89

This parameter sets a thread chamfering angle in a thread cutting cycle (G92/G76) for arbitrary speed threading. When 0 is set, an angle of 45 degrees is specified.

	#7	#6	#5	#4	#3	#2	#1	#0
11001		DCS						

[Input type] Parameter input
[Data type] Bit axis

#6 DCS Special acceleration for deceleration is:
0: Disabled.
1: Enabled.

11020	Acceleration/deceleration switching speed (S_0) for each axis
11021	Acceleration/deceleration switching speed (S_1) for each axis
25700	Acceleration/deceleration switching speed (S_{10}) for deceleration
25701	Acceleration/deceleration switching speed (S_{11}) for deceleration

[Input type] Parameter input
[Data type] 2-word axis
[Unit of data] min^{-1}
[Valid data range] 0 to 99999999

These parameter set the speed at which acceleration/deceleration is changed for each axis (S_0, S_1, S_{10}, S_{11}).

NOTE
If this parameter is set the following values, the subsequent acceleration/deceleration is disabled.
- Over the maximum speed
- 0
- The value of upper step is smaller than that of lower step

11030	Individual acceleration/deceleration 1 (0 to S_0)
11031	Individual acceleration/deceleration 2 (S_0 to S_1)

11032	Individual acceleration/deceleration 3 (S_1 to maximum speed)
25710	Special acceleration for deceleration (0 to S_{10})
25711	Special acceleration for deceleration (S_{10} to S_{11})
25712	Special acceleration for deceleration (S_{11} to maximum speed)

[Input type] Parameter input
[Data type] 2-word axis
[Unit of data] min^{-1}/s
[Valid data range] 0 to 99999999

This parameters set acceleration/deceleration of sections 0 to S_0, S_0 to S_1, $S_1$to maximum speed, 0 to S_{10}, S_{10} to S_{11}, S_{11} to maximum speed for each axis.

	#7	#6	#5	#4	#3	#2	#1	#0
1006							ROSx	ROTx

[Input type] Parameter input
[Data type] Bit axis

NOTE
When at least one of these parameters is set, the power must be turned off before operation is continued.

#0 ROTx
#1 ROSx Setting linear or rotary axis.

ROSx	ROTx	Meaning
0	0	Linear axis (1) Inch/metric conversion is done. (2) All coordinate values are linear axis type. (Is not rounded in 0 to 360°) (3) Stored pitch error compensation is linear axis type (Refer to parameter No.3624)
0	1	Rotary axis (A type) (1) Inch/metric conversion is not done. (2) Machine coordinate values are rounded in 0 to 360°. Absolute coordinate values are rounded or not rounded by bits 0 (ROAx) and 2 (RRLx) of parameter No.1008. (3) Stored pitch error compensation is the rotation type. (Refer to parameter No.3624) (4) Automatic reference position return (G28, G30) is done in the reference position return direction and the move amount does not exceed one rotation.
1	1	Rotary axis (B type) (1) Inch/metric conversion is not done. (2) Machine coordinate values, absolute coordinate values and relative coordinate values are linear axis type. (Is not rounded in 0 to 360°). (3) Stored pitch error compensation is linear axis type. (Refer to parameter No.3624) (4) Cannot be used with the rotary axis roll-over function and the index table indexing function (M series)
Except for the above.		Setting is invalid (unused)

	#7	#6	#5	#4	#3	#2	#1	#0
1008						RRLx		ROAx

[Input type] Parameter input
[Data type] Bit axis

> **NOTE**
> When at least one of these parameters is set, the power must be turned off before operation is continued.

#0 ROAx The rotary axis roll-over is
0: Invalid
1: Valid

> **NOTE**
> ROAx specifies the function only for a rotary axis (for which bit 0 (ROTx) of parameter No.1006 is set to 1)

#2 RRLx Relative coordinates are
0: Not rounded by the amount of the shift per one rotation
1: Rounded by the amount of the shift per one rotation

> **NOTE**
> 1 RRLx is valid only when ROAx is 1.
> 2 Assign the amount of the shift per one rotation in parameter No.1260.

	#7	#6	#5	#4	#3	#2	#1	#0
1408					IRCx			

[Input type] Parameter input
[Data type] Bit axis

#3 IRCx The least input increment of the maximum cutting feedrates set in parameter No.1430 and 1432 and the maximum servo motor speed set in parameter No.12255 is:
0: Not multiplied by ten.
1: Multiplied by ten.

Set this parameter for the following axes, which are operated by the following functions:
- Spindle control axis by servo motor
- Tool rotary axis in the polygon turning function

The maximum cutting feedrates parameter (No.1430/No.1432) is not checked in the undermentioned function.
When this parameter is set, only the least input increment of the servo motor maximum speed parameter (No.12255) is multiplied by ten.
- Arbitrary speed threading

If a rotation speed of 1000 (1/min) (=360000 (deg/min)) is to be used when this parameter is set to 1, set 36000.0 in parameter No. 1430/1432.

1430	Maximum cutting feedrate for each axis

[Input type] Parameter input
[Data type] Real axis
[Unit of data] mm/min, inch/min, deg/min (machine unit)
[Min. unit of data] Depend on the increment system of the applied axis

[Valid data range] Refer to the standard parameter setting table (C)
(When the increment system is IS-B, 0.0 to +999000.0)
Specify the maximum cutting feedrate for each axis.

1825	Servo loop gain for each axis

[Input type] Parameter input
[Data type] Word axis
[Unit of data] 0.01/sec
[Valid data range] 1 to 32767

Set the loop gain for position control for each axis.
When the machine performs linear and circular interpolation (cutting), the same value must be set for all axes. When the machine requires positioning only, the values set for the axes may differ from one another. As the loop gain increases, the response by position control is improved. A too large loop gain, however, makes the servo system unstable. The relationship between the positioning deviation (the number of pulses counted by the error counter) and the feedrate is expressed as follows:

Positioning deviation = Feedrate / (60 * Loop gain)
Unit : Positioning deviation mm, inch or deg
Feedrate mm/min, inch/min, or deg/min
Loop gain 1/sec

	#7	#6	#5	#4	#3	#2	#1	#0
1610			THLx	JGLx			CTBx	CTLx

[Input type] Parameter input
[Data type] Bit axis

#0 CTLx Acceleration/deceleration in cutting feed or dry run during cutting feed
0: Exponential acceleration/deceleration is applied.
1: Linear acceleration/deceleration after interpolation is applied.

NOTE
This parameter is initial setting parameter. For details, refer to the appendix "Automatic setting / Initial setting parameter" in this manual.

#1 CTBx Acceleration/deceleration in cutting feed or dry run during cutting feed
0: Exponential acceleration/deceleration or linear acceleration/deceleration is applied. (depending on the setting in bit 0 (CTLx) of parameter No.1610)
1: Bell-shaped acceleration/deceleration is applied.

NOTE
This parameter is initial setting parameter. For details, refer to the appendix "Automatic setting / Initial setting parameter" in this manual.

#4 JGLx Acceleration/deceleration in jog feed
0: Exponential acceleration/deceleration is applied.
1: The same acceleration/deceleration as for cutting feedrate is applied.
(Depending on the settings of bits 1 (CTBx) and 0 (CTLx) of parameter No.1610)

> **NOTE**
> This parameter is initial setting parameter. For details, refer to the appendix "Automatic setting / Initial setting parameter" in this manual.

#5 THLx Acceleration/deceleration in threading cycles
0: Exponential acceleration/deceleration is applied.
1: The same acceleration/deceleration as for cutting feedrate is applied.
(Depending on the settings of bits 1 (CTBx) and 0 (CTLx) of parameter No.1610)
As the time constant and FL rate, however, the settings of parameters Nos.1626 and 1627 for threading cycles are used.

	#7	#6	#5	#4	#3	#2	#1	#0
1611								CFR

[Input type] Parameter input
[Data type] Bit path

#0 CFR For retraction after threading in the threading cycles G92 and G76:
0: The type of acceleration/deceleration after interpolation for threading is used together with the threading time constant (parameter No.1626) and FL rate (parameter No.1627).
1: The type of acceleration/deceleration after interpolation for rapid traverse is used together with the rapid traverse time constant.

> **NOTE**
> If this parameter is set to 1, a check is made before a retraction to see that the specified feedrate has become 0 (the delay in acceleration/deceleration has become 0). For retraction, the rapid traverse rate (parameter No.1420) is used, regardless of the setting of parameter No.1466. When this parameter is set to 0, parameter No.1466 is used as the feedrate for retraction. As acceleration/deceleration used for retraction, only acceleration/deceleration after interpolation is used. Rapid traverse acceleration/deceleration before interpolation and optimum torque acceleration/deceleration are disabled.

1626	Acceleration/deceleration time constant in threading cycles for each axis

[Input type] Parameter input
[Data type] Word axis
[Unit of data] msec
[Valid data range] 0 to 4000
Set a time constant for acceleration/deceleration after interpolation in the threading cycles G92 and G76 for each axis.

1627	FL rate for acceleration/deceleration in threading cycles for each axis

[Input type] Parameter input
[Data type] Real axis

[Unit of data] mm/min, inch/min, deg/min (machine unit)
[Min. unit of data] Depend on the increment system of the applied axis
[Valid data range] Refer to the standard parameter setting table (C)
(When the increment system is IS-B, 0.0 to +999000.0)
Set an FL rate for acceleration/deceleration after interpolation in the threading cycles G92 and G76 for each axis. Set 0 at all times except in a special case.

	#7	#6	#5	#4	#3	#2	#1	#0
4002				CSDRCT				

[Input type] Parameter input
[Data type] Bit spindle

#4 CSDRCT In Cs contour control, the rotation direction signal (SFR/SRV) function is:
0: Used.
1: Not used.
When using this function, setting to 1 (the rotation direction signal function is not used) is recommended.
When this parameter is set to 0, keep SFRx or SRVx to “1” during the following operation.
- Mode switching from spindle rotation control to Cs contour control
- Mode switching from Cs contour control to spindle rotation control
- Arbitrary speed threading
- Measurement of thread groove
- Re-machining thread

4069	Position gain in Cs contour control (HIGH gear)

4070	Position gain in Cs contour control (MEDIUM HIGH gear)

4071	Position gain in Cs contour control (MEDIUM LOW gear)

4072	Position gain in Cs contour control (LOW gear)

[Input type] Parameter input
[Data type] Integral word spindle
[Unit of data] 0.01/sec
[Valid data range] 0 to 32767
Set the position gain in Cs contour control.

4504	Cs contour control high speed switching: Reference position establishment speed

[Input type] Parameter input
[Data type] Word spindle
[Unit of data] min^{-1}
[Valid data range] 0 to 1000
This parameter sets the spindle speed during reference position establishment.

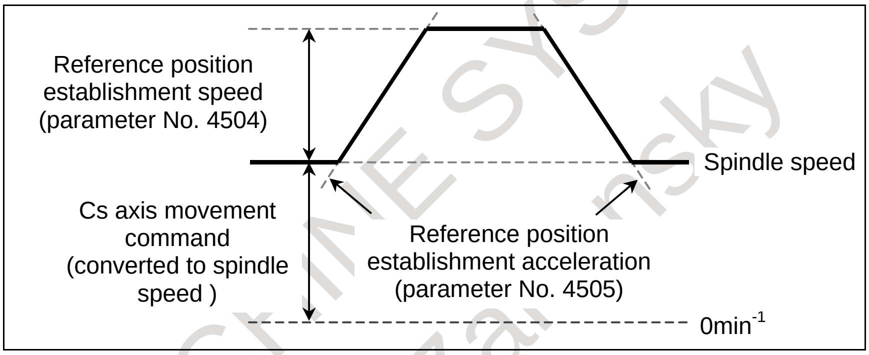
NOTE

Set a value in this parameter so that the absolute value of "Cs axis move command (converted to the spindle speed) ± setting" does not exceed the maximum spindle speed in Cs contour control (set in parameter No.4021). If the value exceeds the maximum spindle speed, a symptom including the following may occur:
- Reference position establishment is not completed.
- Positional deviation increases and a large acceleration/deceleration shock occurs.

4505	Cs contour control high speed switching: Reference position establishment acceleration

[Input type] Parameter input
[Data type] Word spindle
[Unit of data] min^{-1}/sec
[Valid data range] 3 to 32767

This parameter sets the acceleration rate applied to the spindle during reference position establishment.



NOTE

Set a value so that the spindle acceleration/deceleration capacity is not exceeded. If the capacity is exceeded, positional deviation may increase, a large acceleration/deceleration may occur, or another symptom may occur.

4506	Cs contour control high speed switching: Bell-shaped acceleration/deceleration time constant for the reference position establishment

[Input type] Parameter input
[Data type] Word spindle
[Unit of data] msec
[Valid data range] 8 to 64

This parameter sets the bell-shaped acceleration/deceleration time constant for reference position establishment. If a value outside the valid data range is input, the setting is clamped to the upper or lower limit.

4507	Cs contour control high speed switching: Reference position establishment completion level

[Input type] Parameter input
[Data type] Word spindle
[Unit of data] detection unit
[Valid data range] 0 to 32767

This parameter sets the completion level for reference position establishment. When the absolute value of spindle positional deviation becomes within the setting after the move command for reference position establishment has been distributed, the reference position establishment completion signal CSYFNx becomes 1. When this parameter is set to 0, CSYFNx becomes 1 immediately after the move command for reference position establishment has been distributed.

Alarm and message

Number	Message	Description
PS0528	THREADING FORMAT ERROR	The format of arbitrary speed threading is invalid.
PS0529	THREADING COMMAND IMPOSSIBLE	1) The following commands cannot be specified in arbitrary speed threading mode. - Threading command except for threading (G32), threading cycle (G92), and multiple threading cycle (G76). - Taper angle is smaller than that of the last block in the case of continuous threading. Chamfering angle is smaller than the taper angle in the case of threading cycle. - Infeed axis cannot be decelerated to 0 with acceleration which is calculated automatically in continuous threading. - Synchronous control, composite control, and superimposed control - Manual reference position return - Spindle command synchronous control - Simple spindle electronic gear box 2) Arbitrary speed threading is specified in Cs contour control. 3) Spindle software does not support arbitrary speed threading. Cs contour control change signal is not set to “0” after resetting CNC in arbitrary speed threading mode.
PS0530	EXCESS VELOCITY IN THREADING	Feedrate exceeds the maximum cutting feedrate.
PS0531	THREADING PARAMETER ERROR	Parameter setting for arbitrary speed threading is invalid. Possible causes are: - An M code value to start arbitrary speed threading is used for multiple Cs contour control axes. - An M code value to cancel arbitrary speed threading is used for multiple Cs contour control axes. - Acceleration of feed axis (parameter No.11489) is smaller than that of spindle (Cs contour control axis) (parameter No.11030 to No.11032, No.25710 to No.25712).

Number	Message	Description
DS0083	THREADING SIGNAL ERROR	Signal setting is invalid. Possible causes are: - Reference position establishment starting signal CSYC is set to “1” before the Cs contour control high speed switching completion signal CSMCx becomes “1”. - FIN for start of arbitrary speed threading is returned before the reference position establishment completion signal becomes “1”. - FIN for cancel of arbitrary speed threading is returned before the Cs contour control high speed switching completion signal CSMCx becomes “0”. - Spindle which is commanded M code for arbitrary speed threading is not specified to get the feedback pulse from position coder. - State of signal (the Cs contour control high speed switching completion signal CSMCx and the reference position establishment completion signal) is not corresponding to arbitrary speed threading mode.
PS0532	RE-MACHINING OF THREAD CUTTING IMPOSSIBLE	Re-machining thread cannot be executed. Possible causes are: - Groove of thread is not measured. - Measured data is outside of threading path. - Mirror image is applied to the first axis on the plane or the second axis on the plane.

6.5.8 Rapid Traverse Overlap in Threading Cycle

T

Overview

In threading cycle of canned cycle, a cycle time can be shortened with rapid traverse overlap between blocks.

> **NOTE**
> This function is invalid in “Multiple repetitive cycle”.

Explanation

To use this function, set the following parameters.

- Bit 2 (TOD) of parameter No.1612 = 1
  Rapid traverse overlap is valid in threading cycle.
- Bit 0 (CFR) of parameter No.1611 = 1
  For retraction after threading, the type of acceleration/deceleration after interpolation for rapid traverse is used.
- Bit 4 (PRT) of parameter No.1603 = 0
  Acceleration/deceleration of acceleration fixed type is used for positioning of linear interpolation type.

> **NOTE**
> 1 It is not necessary to set bit 4 (RTO) of parameter No.1601 for this function.
> 2 On condition that both standard rapid traverse blocks overlap and this function are available, this function is valid in threading cycle. And, standard rapid traverse block overlap is valid in other cases.

Rapid traverse overlap is executed at the following corners.
- Between the retraction of X-axis (3) and the return to the cycle start point of Z-axis (4)
- Between the return to the cycle start point of Z-axis (4) and positioning to the threading start point of X-axis (1)

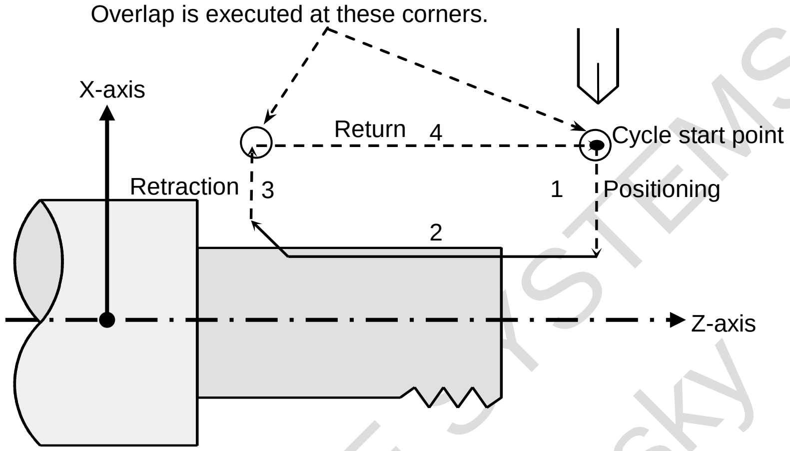


Fig. 6.5.8 (a) Rapid traverse overlap in threading cycle

Overlap is executed as the following figure.
After interpolation is completed, the next block starts when the delay by acceleration/deceleration control is the distance of overlap or below.

Example : Overlap between retraction and return

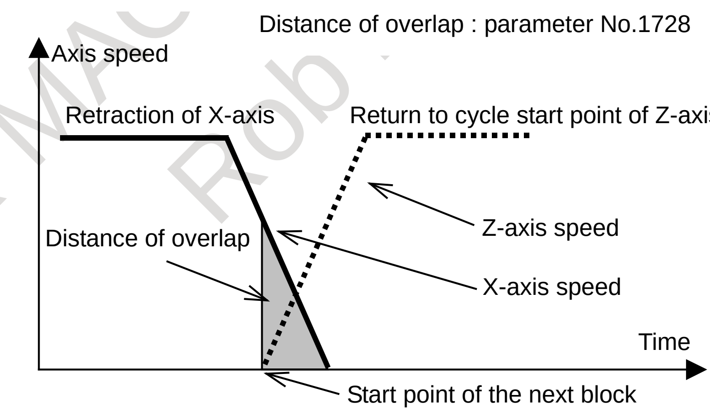

Fig. 6.5.8 (b) Overlap between retraction and return

Distances of overlap are specified with the following parameters.
- Parameter No.1728
  Distance of overlap between retraction (3) and return (4) in threading cycle
- Parameter No.1729
  Distance of overlap between return (4) and positioning of the next threading cycle (1)

Threading cycle retract can be used for this function.

Restrictions

This function is invalid in the following cases.

- Acceleration/deceleration before raid traverse interpolation is used.
- The bit 6 (RDR) of parameter No.1401 = 1 (dry run for rapid traverse is valid), and the dry run signal DRN<Gn046.7> is "1" and the manual rapid traverse selection signal RT<Gn019.7> is set to "0".
- The bit 1 (LRP) of parameter No.1401 = 1 (positioning is performed with linear interpolation) and bit 4 (PRT) of parameter No.1603 = 1 (acceleration/deceleration of time fixed type is used).

Besides, there are the following restrictions.
- The threading cycle must be commanded in G40 mode (Tool nose radius compensation cancel mode).
- Rapid traverse block overlap disable signal ROVLP<Gn053.5> is invalid in this function.

Parameter

	#7	#6	#5	#4	#3	#2	#1	#0
1612						TOD		

[Input type] Parameter input
[Data type] Bit path

#2 TOD Rapid traverse overlap in threading cycle is
0: Invalid.
1: Valid.
In threading cycle of canned cycle, rapid traverse overlap at the following corners.
- Between the retraction of X-axis and the return to the cycle start point of Z-axis
- Between the return to the cycle start of Z-axis and positioning to the threading start point of X-axis

Distances of overlap are specified with parameter No.1728 and No.1729.

1728	Distance of rapid traverse overlap between retraction and return in threading cycle

[Input type] Parameter input
[Data type] Real path
[Unit of data] mm, inch (input unit)
[Min. unit of data] Depend on the increment system of the applied axis
[Valid data range] 0 or positive 9 digit of minimum unit of data (refer to the standard parameter setting table (B)) (When the increment system is IS-B, 0.0 to +999999.999)
In threading cycle of canned cycle, return to the cycle start point of Z-axis starts when the delay of X-axis by acceleration/deceleration control is the distance of this parameter or below.

NOTE
1 Set radius value in this parameter.
2 This parameter is valid on condition that parameter TOD (bit 2 of No.1612) is "1".

1729	Distance of rapid traverse overlap between return and positioning of the next block in threading cycle

[Input type] Parameter input
[Data type] Real path
[Unit of data] mm, inch (input unit)
[Min. unit of data] Depend on the increment system of the applied axis
[Valid data range] 0 or positive 9 digit of minimum unit of data (refer to the standard parameter setting table (B)) (When the increment system is IS-B, 0.0 to +999999.999)
In threading cycle of canned cycle, positioning to the threading start point of X-axis starts when the delay of Z-axis by acceleration/deceleration control is the distance of this parameter or below.

> **NOTE**
> 1 Set radius value in this parameter.
> 2 This parameter is valid on condition that parameter TOD (bit 2 of No.1612) is “1”.

6.6 HELICAL INTERPOLATION

Overview

Helical interpolation that moved tool on the helically is enabled by specifying up to two other axes which move synchronously with the circular interpolation by circular commands.
The feedrate command can select whether to specify tangential velocity of an arc or to specify tangential velocity including a helical axis by the setting of bit 5 (HTG) of parameter No.1403.

An F command specifies a feed rate along a circular arc, when HTG is specified to 0. Therefore, the feed rate of the helical axis is as follows:

$$F \times \frac{\text{Length of helical axis}}{\text{Length of circular arc}}$$

Determine the feed rate so the helical axis feed rate does not exceed any of the various limit values.

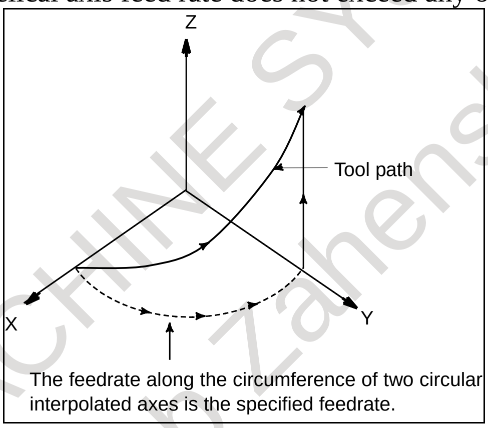

Fig. 6.6 (a)

If HTG is set to 1, specify a feedrate along the tool path including the helical axis. Therefore, the tangential velocity of the arc is expressed as follows:

$$F \times \frac{\text{Length of arc}}{\sqrt{(\text{Length of arc})^2 + (\text{Length of helical axis})^2}}$$

The velocity along the linear axis is expressed as follows:

$$F \times \frac{\text{Length of linear axis}}{\sqrt{(\text{Length of arc})^2 + (\text{Length of helical axis})^2}}$$

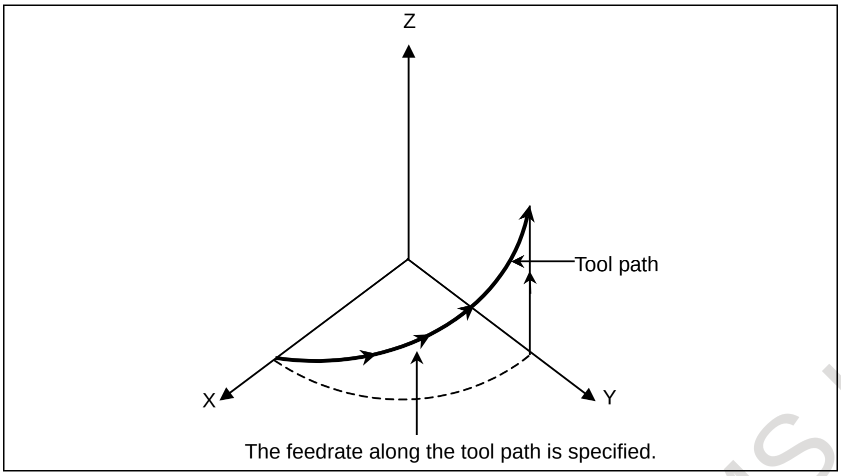

Fig. 6.6 (b)

If three or more axes were specified as helical axes in the helical interpolation mode, alarm (PS0232)"TOO MANY HELICAL AXIS COMMAND" is issued.

Parameter

	#7	#6	#5	#4	#3	#2	#1	#0
1403			HTG					

[Input type] Parameter input
[Data type] Bit path

#5 HTG The feedrate for helical interpolation is:
0: Specified using the feedrate along the tangent to an arc
1: Specified using the feedrate along axes including a helical axis

Alarm and message

Number	Message	Description
PS0232	TOO MANY HELICAL AXIS COMMAND	Three or more axes were specified as helical axes in the helical interpolation mode.

6.7 POLAR COORDINATE INTERPOLATION

T

Overview

Polar coordinate interpolation is a function that exercises contour control in converting a command programmed in a Cartesian coordinate system to the movement of a linear axis (movement of a tool) and the movement of a rotary axis (rotation of a workpiece). This function is useful for grinding a cam shaft.

Explanation

G12.1 starts the polar coordinate interpolation mode and selects a polar coordinate interpolation plane (Fig. 6.7). Polar coordinate interpolation is performed on this plane.

- Polar coordinate interpolation plane

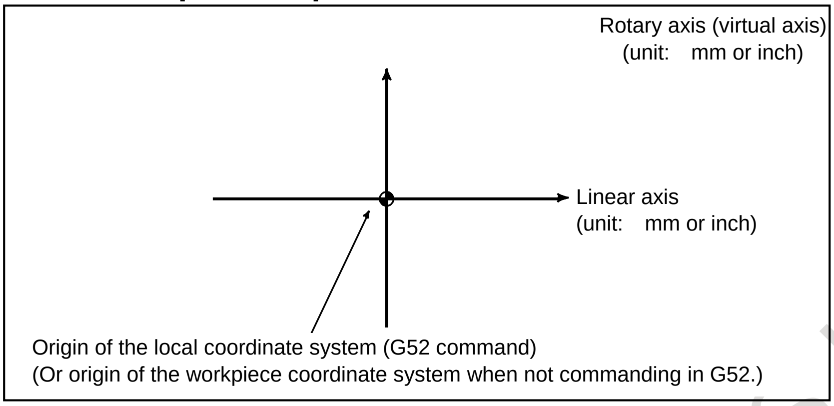

Fig. 6.7 (a) Polar coordinate interpolation plane

When the power is turned on or the system is reset, polar coordinate interpolation is canceled (G13.1).
The linear and rotation axes for polar coordinate interpolation must be set in parameters Nos. 5460 and 5461 beforehand.

> ⚠ **CAUTION**
> The plane used before G12.1 is specified (plane selected by G17, G18, or G19) is canceled. It is restored when G13.1 (canceling polar coordinate interpolation) is specified.
> When the system is reset, polar coordinate interpolation is canceled and the plane specified by G17, G18, or G19 is used.

Parameter

1430	Maximum cutting feedrate for each axis

[Input type] Parameter input
[Data type] Real axis
[Unit of data] mm/min, inch/min, deg/min (machine unit)
[Min. unit of data] Depend on the increment system of the applied axis
[Valid data range] Refer to the standard parameter setting table (C)
(When the increment system is IS-B, 0.0 to +999000.0)
Specify the maximum cutting feedrate for each axis.

	#7	#6	#5	#4	#3	#2	#1	#0
5450		PRD	PIC			PLS		PDI

[Input type] Parameter input
[Data type] Bit path

#0 PDI When the second axis on the plane in the polar coordinate interpolation mode is based on radius specification:
0: Radius specification is used.
1: Diameter specification is used.

#2 PLS The polar coordinate interpolation shift function is:
0: Not used.
1: Used.
This enables machining using the workpiece coordinate system with a desired point which is not the center of the rotation axis set as the origin of the coordinate system in polar coordinate interpolation.

#5 PIC The initial display type of the absolute position of the linear and rotary axes to be used in the polar coordinate interpolation is:
0: Actual position.
1: Cartesian coordinates in the polar coordinate interpolation plane.

> **NOTE**
> 1 The display type can be switched via the soft key [CARTES ON] / [CARTES OFF] in the absolute position display screen.
> 2 This parameter does not change if switching the display type via the soft key.

#6 PRD When the first axis on the plane in the polar coordinate interpolation mode is based on diameter specification:
0: Diameter specification is used.
1: Radius specification is used.

5460	Axis (linear axis) specification for polar coordinate interpolation

[Input type] Parameter input
[Data type] Byte path
[Valid data range] 1 to number of controlled axes
This parameter sets control axis numbers of linear axis to execute polar interpolation.

5461	Axis (rotation axis) specification for polar coordinate interpolation

[Input type] Parameter input
[Data type] Byte path
[Valid data range] 1 to number of controlled axes
This parameter sets control axis numbers of rotation axis to execute polar interpolation.

5463	Automatic override tolerance ratio for polar coordinate interpolation

[Input type] Parameter input
[Data type] Byte path
[Unit of data] %
[Valid data range] 0 to 100
Typical setting: 90% (treated as 90% when set to 0)
Set the tolerance ratio of the fastest cutting feedrate to the speed of the rotation axis during automatic override of polar coordinate interpolation.

5464	Compensation for error on hypothetical axis of polar coordinate interpolation

[Input type] Parameter input
[Data type] Byte path
[Unit of data] mm, inch (input unit)
[Min. unit of data] Depend on the increment system of the reference axis
[Valid data range] 9 digit of minimum unit of data (refer to standard parameter setting table (A))
(For IS-B, -999999.999 to +999999.999)
This parameter is used to set the error if the center of the rotation axis on which polar coordinate interpolation is performed is not on the X-axis.
If the setting of the parameter is 0, regular polar coordinate interpolation is performed.

Alarm and message

Number	Message	Description
PS0145	ILLEGAL USE OF G12.1/G13.1	The axis No. of plane selection parameter No. 5460 (linear axis) and No. 5461(axis of rotation) in the polar coordinate interpolation mode is out of range (1 to number of controlled axes).
PS0146	ILLEGAL USE OF G-CODE	The modal G code group contains an illegal G code in the polar coordinate interpolation mode or when a mode was canceled. Only the following G codes are allowed: G40, G50, G69.1 An illegal G code was specified while in the polar coordinate interpolation mode. The following C codes are not allowed: G27, G28, G30, G31 to G31.4, G37 to G37.3, G52, G92, G53, G17 to G19, G81 to G89, G68 In the 01 group, G codes other than G01, G02 and G03 cannot be specified.
DS1512	EXCESS VELOCITY	The feedrate of the linear axis during polar coordinate interpolation exceeded the maximum cutting feedrate.
DS1514	ILLEGAL MOTION IN G12.1 MODE	In a hypothetical axis direction compensation during the polar coordinate interpolation mode, an attempt is made to travel to the area in which the travel cannot be made.

6.8 CYLINDRICAL INTERPOLATION

6.8.1 Cylindrical Interpolation

Overview

The cylindrical interpolation function performs linear interpolation or arc interpolation with another axis by converting the travel distance of a rotation axis specified in degrees to the travel distance on the circumference.
Since programming is allowed with the side of a cylinder developed, a program for cylinder cam grooving or other machining can easily be created.

Explanation

- Plane selection (G17, G18, G19)

To specify a G code for plane selection, set the rotary axis in parameter No. 1022 as a linear axis that is one of the basic three axes of the basic coordinate system or an axis parallel to one of the basic axes. For example, when rotary axis C-axis is assumed to be parallel to the X-axis, specifying G17, axis address C, and Y at the same time can select a plane formed by the C-axis and Y-axis (the Xp-Yp plane).
Only an axis can be set to the rotary axis of cylindrical interpolation.

6.8.2 Cylindrical Interpolation by Plane Distance Command

Overview

In the conventional rotary axis command in cylindrical interpolation, the angle of the rotary axis is specified.
This function enables the rotary axis command in cylindrical interpolation to be specified by distance on the developed plane by setting bit 2(DTO) of parameter No.3454.

NOTE
1. Do not change the parameter DTO while cylindrical interpolation mode.
2. To use the function, enable "cylindrical interpolation" (bit 6 (NCL) of parameter No.8137#6 is 0).

6.8.3 Cylindrical Interpolation Cutting Point Compensation

Overview

The conventional cylindrical interpolation function controls the movement of the tool center so that the tool axis moves along a specified path on the cylindrical surface to always face toward the rotation axis of the workpiece (cylindrical axis).
On the other hand, the cylindrical interpolation cutting point control function controls the tool so that the tangent from the tool to the cutting face of a contour figure passes the rotation center of the workpiece at all times.
That is, the cutting face of a contour figure is always perpendicular to the cylinder. Therefore, the figure of the cutting face can be kept identical regardless of the cutter compensation.

NOTE
To use the function, enable "cylindrical interpolation" (bit 6 (NCL) of parameter No.8137#6 is 0).

Parameter

- **Settings common to cylindrical interpolation, cylindrical interpolation by plane distance command, and cylindrical interpolation cutting point compensation**

	#7	#6	#5	#4	#3	#2	#1	#0
1006							ROSx	ROTx

[Input type] Parameter input
[Data type] Bit axis

NOTE
When at least one of these parameters is set, the power must be turned off before operation is continued.

#0 ROTx
#1 ROSx Setting linear or rotary axis.

ROSx	ROTx	Meaning
0	0	Linear axis (1) Inch/metric conversion is done. (2) All coordinate values are linear axis type. (Is not rounded in 0 to 360°) (3) Stored pitch error compensation is linear axis type (Refer to parameter No. 3624)
0	1	Rotary axis (A type) (1) Inch/metric conversion is not done. (2) Machine coordinate values are rounded in 0 to 360°. Absolute coordinate values are rounded or not rounded by bits 0 (ROAx) and 2 (RRLx) of parameter No. 1008. (3) Stored pitch error compensation is the rotation type. (Refer to parameter No. 3624) (4) Automatic reference position return (G28, G30) is done in the reference position return direction and the move amount does not exceed one rotation.

ROSx	ROTx	Meaning
1	1	Rotary axis (B type) (1) Inch/metric conversion is not done. (2) Machine coordinate values, absolute coordinate values and relative coordinate values are linear axis type. (Is not rounded in 0 to 360°). (3) Stored pitch error compensation is linear axis type (Refer to parameter No. 3624) (4) Cannot be used with the rotary axis roll-over function and the index table indexing function (M series)
Except for the above.		Setting is invalid (unused)

1022	Setting of each axis in the basic coordinate system

[Input type] Parameter input
[Data type] Byte axis
[Valid data range] 0 to 7

To determine a plane for circular interpolation, cutter compensation, and so forth (G17: Xp-Yp plane, G18: Zp-Xp plane, G19: Yp-Zp plane) and a 3-dimensional tool compensation space (XpYpZp), specify which of the basic three axes (X, Y, and Z) is used for each control axis, or a parallel axis of which basic axis is used for each control axis.
A basic axis (X, Y, or Z) can be specified only for one control axis.
Two or more control axes can be set as parallel axes for the same basic axis.

Setting	Meaning
0	Rotary axis (Neither the basic three axes nor a parallel axis)
1	X axis of the basic three axes
2	Y axis of the basic three axes
3	Z axis of the basic three axes
5	Axis parallel to the X axis
6	Axis parallel to the Y axis
7	Axis parallel to the Z axis

In general, the increment system and diameter/radius specification of an axis set as a parallel axis are to be set in the same way as for the basic three axes.

1260	The shift amount per one rotation of a rotary axis

NOTE
When this parameter is set, the power must be turned off before operation is continued.

[Input type] Parameter input
[Data type] Real axis
[Unit of data] deg
[Min. unit of data] Depend on the increment system of the applied axis
[Valid data range] 0 or positive 9 digit of minimum unit of data (refer to the standard parameter setting table (B))
(When the increment system is IS-B, 0.0 to +999999.999)
Set the shift amount per one rotation of a rotary axis.
For the rotary axis used for cylindrical interpolation, set the standard value.

- Parameters required for cylindrical interpolation by plane distance command

	#7	#6	#5	#4	#3	#2	#1	#0
3454						**DTO**		

[Input type] Parameter input
[Data type] Bit path

#2 DTO The method of specifying a rotation axis in cylindrical interpolation mode is set.
0: In cylindrical interpolation mode, the rotation axis is specified by angle.
1: In cylindrical interpolation mode, the rotation axis is specified by distance on an expanded plane.

- Parameters required for cylindrical interpolation cutting point compensation

	#7	#6	#5	#4	#3	#2	#1	#0
19530		**CYS**	**CYA**					

[Input type] Parameter input
[Data type] Bit path

#5 CYA Specifies whether to perform cylindrical interpolation cutting point compensation in the cylindrical interpolation command (G07.1).
0: Perform.
1: Do not perform.

#6 CYS Specifies whether when the cylindrical interpolation cutting point compensation function is used, cutting point compensation is performed between blocks or together with a block movement if the cutting point compensation value is less than the setting of parameter No. 19534.
0: Performed between blocks.
1: Performed together with a block movement if the cutting point compensation value is less than the setting of parameter No. 19534.

19531	**Tool offset axis number for the XY plane**
19532	**Tool offset axis number for the ZX plane**
19533	**Tool offset axis number for the YZ plane**

[Input type] Parameter input
[Data type] Byte path
[Valid data range] 1 to number of controlled axes
Specify a tool offset axis that intersects the cylindrical rotation axis at right angles.

19534	**Limit for changing cylindrical interpolation cutting point compensation in a single block**

[Input type] Parameter input
[Data type] Real path
[Unit of data] mm, inch (input unit)
[Min. unit of data] Depend on the increment system of the reference axis
[Valid data range] 1 to 999999999
The following operation is performed, depending on the setting of parameter No. 19530:
(1) Bit 6 (CYS) of parameter No. 19530) is set to 0

If the amount of cylindrical interpolation cutting point compensation is smaller than the value set in this parameter, cylindrical interpolation cutting point compensation is not performed. Instead, this ignored amount of cylindrical interpolation cutting point compensation is added to the next amount of cylindrical interpolation cutting point compensation to determine whether to perform cylindrical interpolation cutting point compensation.

(2) Bit 6 (CYS) of parameter No. 19530) is set to 1
If the amount of cylindrical interpolation cutting point compensation is smaller than the value set in this parameter, cylindrical interpolation cutting point compensation is performed together with the movement of the specified block.

> **NOTE**
> Set this parameter as follows:
> Setting < (setting for a rotation axis in parameter No. 1430) × 4/3
> where 4/3 is a constant for internal processing.

19535	**Limit of travel distance moved with the cylindrical interpolation cutting point compensation in the previous block unchanged.**

[Input type] Parameter input
[Data type] Real path
[Unit of data] mm, inch (input unit)
[Min. unit of data] Depend on the increment system of the reference axis
[Valid data range] 1 to 999999999

The following operation is performed, depending on the type of interpolation:

(1) For linear interpolation
If the travel distance in a specified block is smaller than the value set in this parameter, machining is performed without changing the cylindrical interpolation cutting point compensation in the previous block.

(2) For circular interpolation
If the diameter of a specified arc is smaller than the value set in this parameter, machining is performed without changing the cylindrical interpolation cutting point compensation in the previous block. Cylindrical interpolation cutting point compensation is not performed according to a circular movement.

Alarm and message

Number	Message	Description
PS0015	TOO MANY SIMULTANEOUS AXES	A move command was specified for more axes than can be controlled by simultaneous axis control. Divide the number of programmed move axes into two blocks.
PS0175	ILLEGAL G07.1 AXIS	An axis which cannot perform cylindrical interpolation was specified. More than one axis was specified in a G07.1 block. An attempt was made to cancel cylindrical interpolation for an axis that was not in the cylindrical interpolation mode. For the cylindrical interpolation axis, set not 0 but one of 5, 6 or 7 (parallel axis specification) to parameter No. 1022 to instruct the arc with axis of rotation (bit 0 (ROT) of parameter No. 1006 is set to 1 and parameter No. 1260 is set) ON.
PS0176	ILLEGAL G-CODE USE(G07.1 MODE)	A G code was specified that cannot be specified in the cylindrical interpolation mode. This alarm also is generated when an 01 group G code was in the G00 mode or code G00 was instructed. Cancel the cylindrical interpolation mode before instructing code G00.

6.9 POLYGON TURNING

T

Polygon turning means machining a workpiece to a polygonal figure by rotating the workpiece and tool at a certain ratio.

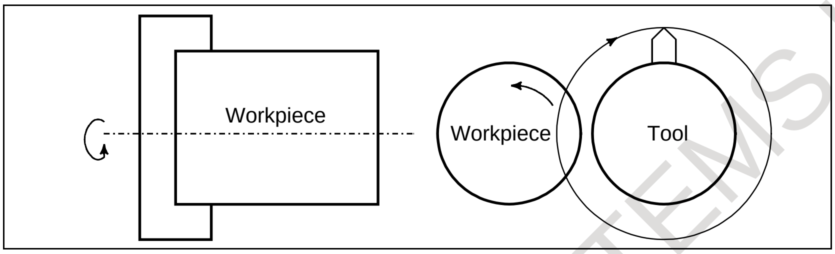

Fig. 6.9 (a)

By changing conditions which are rotation ratio of workpiece and tool and number of cutters, the workpiece can be machined to a square or hexagon. The machining time can be reduced as compared with polygonal figure machining using the polar coordinate interpolation.
The machined figure, however, is not exactly polygonal. Generally, polygon turning is used for the heads of square and/or hexagon bolts or hexagon nuts.
As the tool rotary axis, one of the following can be used:

- CNC controlled axis (servo axis)
- Second spindle (Two serial spindles are connected.)

Polygon turning performed using a servo axis as the tool rotary axis is referred to as polygon turning. Polygon turning performed using the second spindle as the tool rotary axis is referred to as polygon turning with two spindles.

Table 6.9 (a)

Function name	Workpiece axis	Tool rotary axis
Polygon turning	Spindle (Either an analog spindle or serial spindle is usable. However, a detector equivalent to a position coder is required.)	Servo axis
Polygon turning with two spindles	Spindle (Serial spindle)	Spindle (Serial spindle)

The specifications of polygon turning are described below.
For details of polygon turning with two spindles, see the specifications of polygon turning with two spindles.

6.9.1 Polygon Turning

Overview

A CNC controlled axis (servo axis) is assigned to the tool rotary axis.
This rotary axis of tool is called Y-axis in the following description. As the workpiece axis (spindle), either a serial spindle or analog spindle can be used.
The Y-axis is controlled by the G51.2 command, so that the ratio of the rotation speeds of the spindle (previously specified by S-command) and the tool becomes the specified ratio.
When simultaneous start is specified by G51.2, the one-rotation signal sent from the position codes set on the spindle is detected. After one-rotation signal detection, the Y-axis is controlled using the rotation ratio

of the spindle and Y-axis specified by P and Q. So, a position coder needs to be attached to the spindle. This control will be maintained until the polygon turning cancel command is executed (G50.2). Polygon turning is cancelled by any of the following in addition to the G50.2 command:

(1) Power off
(2) Emergency stop
(3) Servo alarm
(4) Reset (external reset signal ERS <Gn008.7>, reset/rewind signal RRW <Gn008.6>, and  key on the MDI panel)
(5) Occurrence of alarm PS0217 to PS0221, PS0314, and PS5018

NOTE

1 Before polygon turning, reference position return operation on the Y-axis needs to be specified to determine the rotation start position of the tool. This reference position return operation is performed by detecting a deceleration limit as in the case of manual reference position return operation. (By setting bit 7 (PLZ) of parameter No. 7600, reference position return operation can be performed without detecting a deceleration limit.)
2 The rotation direction on the Y-axis is determined by the sign of Q, and is not affected by the rotation direction of the position coder.
3 Among Y-axis position indications, the indication of a machine coordinate (MACHINE) changes within the amount of movement for 0 to 1 revolution as a movement is made on the Y-axis. The absolute coordinate and relative coordinate are not updated. So, when specifying an absolute-position command for the Y-axis after polygon turning mode cancellation, set a workpiece coordinate system after reference position return operation.
4 For the Y-axis engaged in polygon turning, jog feed and handle feed are disabled.
5 For the Y-axis not engaged in polygon turning, a move command can be specified as in the case of other controlled axes.
6 The Y-axis engaged in polygon turning is not counted in the number of simultaneously controlled axes.
7 One workpiece must be machined using a fixed spindle speed until the workpiece is finished.
8 G50.2 is the G code for suppressing buffering.
9 The following functions must be commanded with polygon turning cancel mode.
   - Inch/metric conversion
   - AI contour control
   - Tilted working plane indexing
   - Flexible path axis assignment

- Spindle connection

A position coder must be mounted on the spindle. However, polygon turning requires no additional changes to the spindle connection.

Polygon turning uses the position coder feedback signal to control the positional relationship (cutting position) between the spindle and tool rotation axis, and the ratio of speed.

- Tool rotation axis (servo axis) connection

Parameter No. 7610 specifies the controlled axis (servo axis) to be used as the tool rotation axis.

The same parameter setting as for ordinary servo axes applies to the servo axis connection for polygon turning except for some parameters.

When the machine is not in the polygon turning mode, the servo axis specified as the rotation tool axis functions as a feed axis. So, the servo axis can be:

- Used as a subspindle under PMC axis control
- Positioned by a move command from a machining program.

However, be careful about the angle to rotate through and feedrate.
Refer to the concrete example of the following a parameter setting.

- Principle of polygon turning

The principle of polygon turning is explained below. In the Fig. 6.9.1 (a), the radius of tool and workpiece are A and B, and the angular speeds of tool and workpiece are α and β. The origin of XY Cartesian coordinates is assumed to be the center of the workpiece.
Simplifying the explanation, consider that the tool center exists at the position Po (A, 0) on the workpiece periphery, and the tool nose starts from position Pto (A-B, 0).

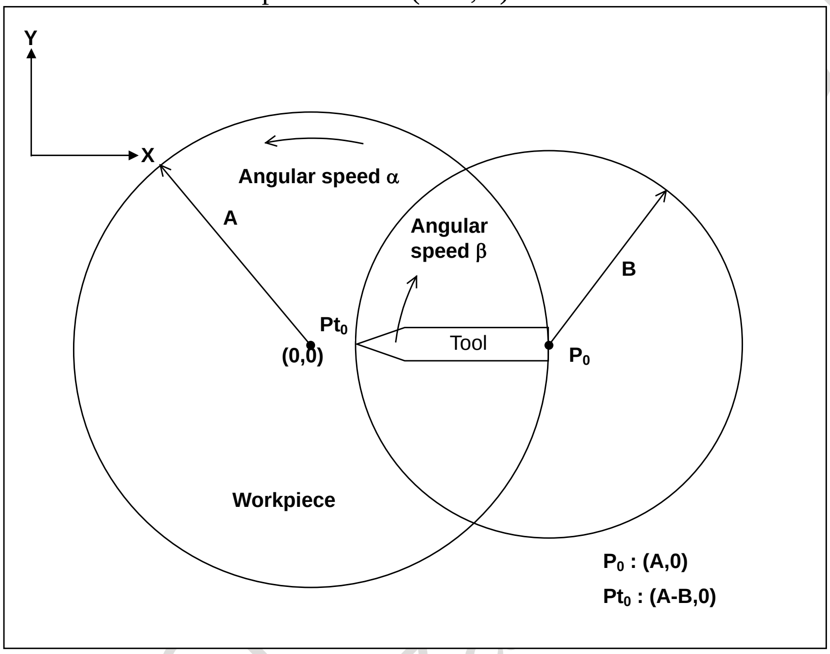

Fig. 6.9.1 (a)

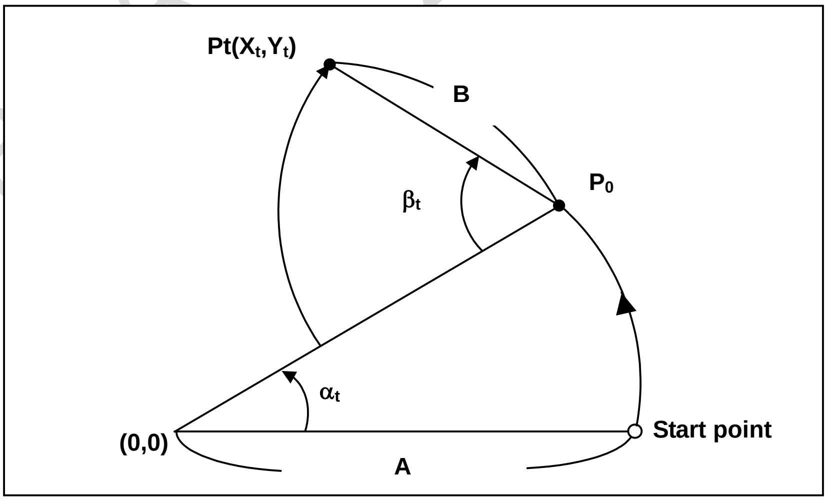

Fig. 6.9.1 (b)

In this case, the tool nose position Pt (Xt, Yt) after time t is expressed by equations 1 and 2:

$Xt=A\cos\alpha t-B\cos(\beta-\alpha)t$ (Equation 1)

$Yt=A\sin\alpha t+B\sin(\beta-\alpha)t$ (Equation 2)

Assuming that the rotation ration of workpiece to tool is 1:2, namely, β=2α, equations 1 and 2 are modified as follows:

$Xt=A\cos\alpha t-B\cos\alpha t=(A-B)\cos\alpha t$ (Equation 1)'

$Yt=A\sin\alpha t+B\sin\alpha t=(A+B)\sin\alpha t$ (Equation 2)'

These equations indicate that the tool nose path draws an ellipse with longer diameter A+B and shorter diameter A-B.

Then consider the case when one tool is set at 180° symmetrical positions, for a total of two. A square can be machined with these tools as shown Fig. 6.9.1 (c).

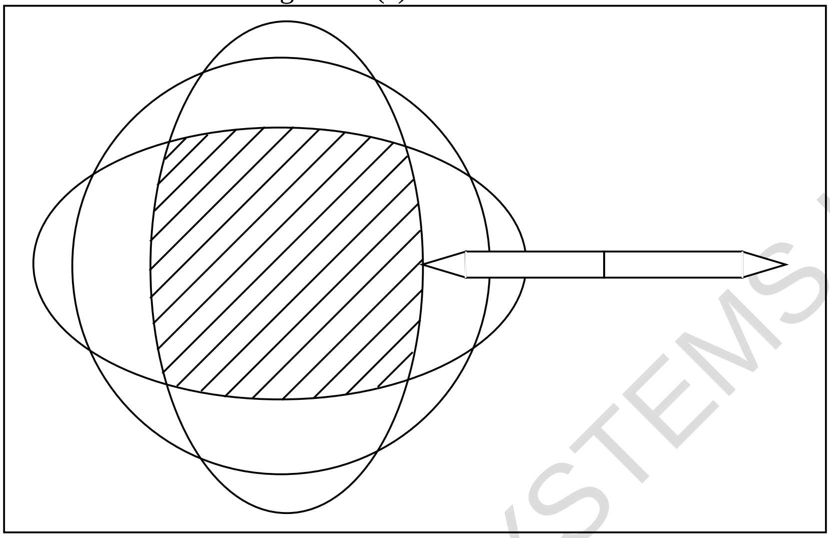

Fig. 6.9.1 (c)

If three tools are set at every 120°, the machining figure will be a hexagon as shown Fig. 6.9.1 (d).

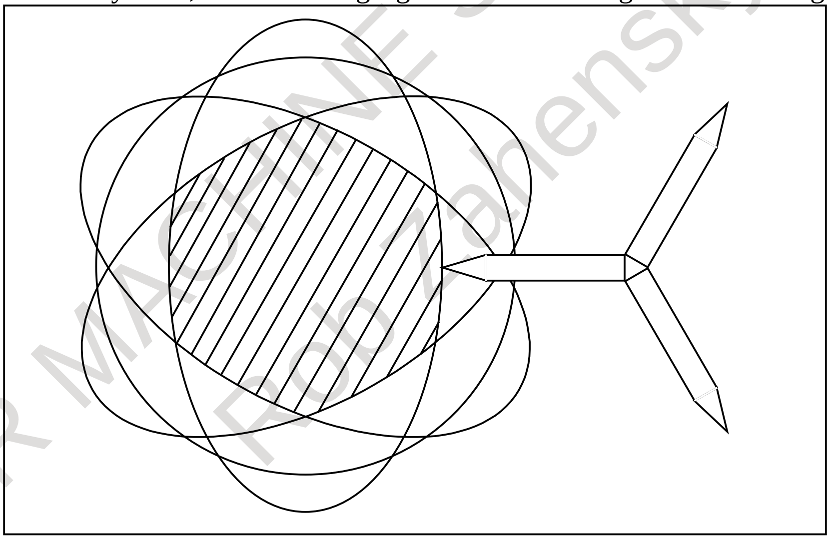

Fig. 6.9.1 (d)

> ⚠ **WARNING**
> For the maximum rotation speed of the tool, see the instruction manual supplied with the machine. Do not specify a spindle speed higher than the maximum tool speed or a ratio to the spindle speed that results in a speed higher than the maximum tool speed.

- Examples of parameter setting

The following descriptions exemplify typical parameter setting for polygon turning using a serial pulse coder (with a million pulse capability).

(1) Tool rotation axis setting

This example uses the CNC's fourth axis (connected as the Y-axis) as a rotation tool axis for polygon turning.

Parameter No. 7610 = 4 (controlled axis number for the tool rotation axis)

The following description assumes that the axis type parameter is set to the fourth axis.

(2) Servo parameter setting

Set the servo parameters as listed below:
CMR=1
DMR=36/100
(With the above setting, the reference counter capacity is 360000.)

Parameter No.1820=2	(CMR)
Parameter No.1821=360000	(reference counter capacity)
Parameter No.2084=36	(DMR numerator)
Parameter No.2085=100	(DMR denominator)

For the other servo parameters, specify typical values.

(3) Parameter setting for polygon turning

The least command increment, detection unit, the angle to rotate through per rotation for the Y axis are as follows:

Least command increment= $\dfrac{L \times \mathrm{CMR}}{\mathrm{Q} \times \mathrm{DMR}}$

Detection unit= $\dfrac{\text{Least command increment}}{\mathrm{CMR}} = \dfrac{\mathrm{L}}{\mathrm{Q} \times \mathrm{DMR}}$

Angle to rotate through per tool axis rotation=

$\dfrac{360}{\text{Least command increment}}$

where

L: Tool axis rotation angle per motor rotation (degrees),
(360 × speed increment ratio)

When the servo motor is connected directly to the rotation tool, for example, L = 360. When the tool speed is doubled, L = 720.

Q: Number of pulses per pulse coder rotation
(For a serial pulse coder, Q = 1000000.)

The least command increment specified here is specific to the Y axis. It is determined regardless of what is specified in parameter No. 1013#0,#1 (ISA/ISC). However, both ISA and ISC must be set to 0 for IS-B setting.

If the servo motor is connected directly to the rotation tool:

Least command increment= $\dfrac{360 \times 1}{1000000 \times 36/100} = 0.001$ [deg]

Detection unit=0.001 [deg]

Angle to rotate through per tool axis rotation= $\dfrac{360}{0.001} = 360000$

The upper limit to the tool rotation axis speed is:
Maximum servo motor speed × speed increment ratio

Therefore, if the maximum servo motor speed is 1000 [min^{-1}], and the servo motor is directly connected to the servo motor:

Upper limit to the tool rotation axis speed = 1000 × 1 = 1000 [min^{-1}]

This means the parameters must be set as follows:
Parameter No. 7620 = 360000 (angle to rotate through per tool axis rotation)
Parameter No. 7621 = 1000 (upper limit to tool rotation axis speed)

(4) Feedrate parameter setting

Because the least command increment is 0.01 [deg], the input unit for the feedrate is 1 [deg/min].
To obtain a rapid traverse speed of 1000 [min^{-1}], for example, specify as follows:
Parameter No. 1420 = 360000 (= 1000 × 360)
Other feedrate parameters must be set in degrees per minute.

(5) Commands from the NC program

When the machine is not performing polygon turning, the machining program can issue move commands to the Y-axis.

Such commands can be issued in the same way as for ordinary axes. However, note the travel increment and feedrate.
The Y-axis rotates through 0.003[deg] by the following command:
V3;
Likewise, the polygon axis rotates through 1.000[deg] by the following command:
V1.0;
The current position of the Y-axis in the machine coordinate system is normalized according to the value specified by parameter No. 7620.
Typical values range from 0.000 to 359.999.

Signal

Polygon synchronization under way signal PSYN<Fn063.7>

[Classification] Output signal
[Function] Informs the PMC that the machine is in the polygon turning mode.
[Output cond.] The polygon synchronization signal is set to logical “1” by the polygon turning mode command (G51.2) and stays at 1 during the polygon turning mode.
The signal is reset to logical “0” by the polygon turning mode reset command (G50.2) or a reset. It stays at logical 0 when the machine is not in the polygon turning mode.

> **NOTE**
> This signal uses the same address for both polygon turning (using the servo axis) and polygon turning with two spindles.

Other signals

Some signals related to the CNC controlled axis used as the tool rotation axis may be made ineffective depending on whether the machine is in the polygon turning mode.

Signal	Valid / invalid for the Y-axis of polygon turning mode
All-axis machine lock signal MLK<Gn044.1> Each-axis machine lock signal MLK1~MLK8 <Gn108>	Valid
Servo off signal SVF1~SVF8<Gn126>	Valid
Automatic operation stop signal *SP<Gn008.5>	Invalid
Interlock signal for all axes *IT <Gn008.0> Interlock signal for each axis *IT1~*IT8 <Gn130> Interlock signal for each axis direction +MIT1~+MIT8<Gn132>, -MIT1~-MIT8<Gn134>	Invalid
Feedrate override signal *FV0~*FV7 <Gn012>	Invalid
Dry run signal DRN<Gn046.7>	Invalid

Diagnosis data

478	Speed of the tool rotating axis during polygon turning (1/min)

This indication is the speed of the tool rotating axis during polygon turning.

Parameter

	#7	#6	#5	#4	#3	#2	#1	#0
7600	PLZ							PFF

[Input type] Parameter input

[Data type] Bit path

#0 PFF In spindle-servo polygon turning, feed forward for the tool rotation axis (servo axis) during polygon turning is always:
0: Disabled.
1: Enabled.

#7 PLZ Reference position return based on a G28 command on the tool rotation axis for polygon turning is:
0: Performed in the same sequence as manual reference position return.
1: Performed by positioning using the rapid traverse rate.
The synchronous axis returns to the reference position in the same sequence as the manual reference position return when no return-to-reference position is performed after the power is turned on.

	#7	#6	#5	#4	#3	#2	#1	#0
7603					PLROT			RPL

[Input type] Parameter input
[Data type] Bit path

#0 RPL Upon reset, polygon turning mode is:
0: Released.
1: Not released.

> **NOTE**
> 1 When an emergency stop occurs, the polygon turning mode is released regardless of whether this parameter is set to 0 or 1.
> 2 When any of the following PS alarms is issued, the polygon turning mode is released regardless of whether this parameter is set to 0 or 1:
> - Alarm PS0217, "DUPLICATE G51.2(COMMANDS)"
> - Alarm PS0219, "COMMAND G51.2/G50.2 INDEPENDENTLY"
> - Alarm PS0220, "ILLEGAL COMMAND IN SYNCHR-MODE"
> - Alarm PS0221, "ILLEGAL COMMAND IN SYNCHR-MODE"
> - Alarm PS5018, "POLYGON SPINDLE SPEED ERROR"
> 3 If an SV alarm is issued, the polygon turning mode is released regardless of whether this parameter is set to 0 or 1.
> 4 When this parameter is set to 1, polygon turning modal information is kept regardless of whether bit 6 (CLR) of parameter No. 3402 is set to 0 or 1.
> 5 Set bit 4 (C20) of parameter No. 3408 to 0.

#3 PLROT The machine coordinates of a tool rotation axis for polygon turning are:
0: Rounded by the setting in parameter No.7620.
1: Rounded by 360° (or the setting in parameter No. 1260 when bit 0 (ROA) of parameter No. 1008 is set to 1).

7610	Control axis number of tool rotation axis for polygon turning

NOTE
When this parameter is set, the power must be turned off before operation is continued.

[Input type] Parameter input
[Data type] Byte path
[Valid data range] 1 to number of controlled axes

This parameter sets the control axis number of a rotation tool axis used for polygon turning.
However, when a G51.2 command is executed by setting 0 in this parameter, operation stops with the alarm PS0314.

7620	Movement of tool rotation axis per revolution for polygon turning

NOTE
When this parameter is set, the power must be turned off before operation is continued.

[Input type] Parameter input
[Data type] Real path
[Unit of data] deg
[Min. unit of data] Depend on the increment system of the applied axis
[Valid data range] 0 or positive 9 digit of minimum unit of data (refer to the standard parameter setting table (B))
(When the increment system is IS-B, 0.0 to +999999.999)

This parameter sets the movement of a tool rotation axis per revolution.

7621	Maximum allowable speed for the tool rotation axis for polygon turning

[Input type] Parameter input
[Data type] 2-word path
[Unit of data] min^{-1}
[Valid data range] 0 or positive 9 digit of minimum unit of data (refer to the standard parameter setting table (B))
(When the increment system is IS-B, 0.0 to +999999.999)

This parameter sets the maximum allowable speed of the tool rotation axis.

NOTE
If the speed of the tool rotation axis exceeds the set maximum allowable speed during polygon turning, the synchronization between the spindle and tool rotation axis is lost, and operation stops with alarm PS5018.

Alarm and message

Number	Message	Description
PS0217	DUPLICATE G51.2(COMMANDS)	G51.2 is further commanded in the G51.2 mode. Modify the program.
PS0218	NOT FOUND P/Q COMMAND	P or Q is not commanded in the G51.2 block, or the command value is out of the range. Modify the program. For a polygon turning between spindles, more information as to why this alarm occurred is indicated in diagnosis data No. 471.

Number	Message	Description
PS0219	COMMAND G51.2/G50.2 INDEPENDENTLY	G51.2 and 50.2 were specified in the same block for other commands. Modify the program in another block.
PS0220	ILLEGAL COMMAND IN SYNCHR-MODE	In polygon turning, movement is commanded by the NC program or PMC axis control interface for the polygon axis. Modify the program or check the PMC ladder.
PS0221	ILLEGAL COMMAND IN SYNCHR-MODE	Polygon turning and Cs contour control or balance cutting are executed at a time. Modify the program.
PS0314	ILLEGAL SETTING OF POLYGONAL AXIS	An axis was specified invalidly in polygon turning. For polygon turning: A tool rotation axis is not specified. (Parameter No. 7610) For polygon turning with two spindles: Valid spindles are not specified. (Parameter Nos. 7640 to 7643) - A spindle other tan the serial spindle. - A spindle is not connected. For concurrent use of polygon turning and polygon turning with two spindles: - In the polygon turning mode, the value of parameter No. 7605 (selecting the type of polygon turning) was changed. - An attempt is made to use a spindle used for polygon turning also for polygon turning with two spindles.
PS5018	POLYGON SPINDLE SPEED ERROR	In G51.2 mode, the speed of the spindle or polygon synchronous axis either exceeds the clamp value or is too small. The specified rotation speed ratio thus cannot be maintained. For polygon turning with two spindles: More information as to why this alarm occurred is indicated in diagnosis data No. 471.

OPERATOR’S MANUAL (B-64694EN)	Polygon turning

6.9.2 Polygon Turning with Two Spindles

Overview

When two or more serial spindles are used, the workpiece rotation axis (master axis) and tool rotation axis (polygon synchronization axis) are synchronized at a certain speed ratio.
With this function, it is also possible to specify the phase difference between the master and polygon synchronization axes.

The polygon turning with two spindles can use different spindle speeds for the same workpiece, because it performs automatic phase compensation when a polygon synchronization mode command is issued or the S command is changed during polygon synchronization mode.

With a multiple path system, polygon turning is possible on each path.

By default, the first and second spindles in each system are selected as the master axis and polygon synchronization axis for each system. By setting parameters No. 7640 and No. 7641, however, any spindles belonging to the same system can be selected as the master axis and polygon synchronization axis. By setting parameters No. 7642 and No. 7643, however, any spindles belonging to different systems can be selected as the master axis and polygon synchronization axis.

- Command format

The following shows the program command format for polygon turning with two spindles. This is the same as the program command format for polygon turning except for the following points.

1) The command position (R) can be used.
2) Repeated specification in polygon synchronization mode is allowed.

For polygon turning, see also the section about polygon turning.

- Mode command and command value change

The G51.2 command is modal. Once specified, the P, Q, and R values stay unchanged until another G51.2 is issued to change them or polygon synchronized mode is released.

In polygon synchronized mode, the S command for the master axis controls the polygon synchronization axis so that it rotates at a speed of S × Q/P and its phase is R.

- Release command

G50.2 command releases the polygon synchronization mode. This mode is released also when:

<1> Reset and emergency stop
(Setting bit 0 (RPL) of parameter No.7603 to 1 prevents polygon synchronization mode from being released.)
<2> Power is turning off.
<3> An alarm condition occurs in the spindle control unit, and the serial spindle control unit stops in an emergency on the PMC signals *ESPA<Gn071.1> and *ESPB<Gn075.1>.
<4> Alarm PS0218, PS0219, PS0221, PS0314, or PS5018 occurs

NOTE
1 G51.2 and G50.2 must be issued separately from other commands.
2 In a G51.2 issued to enter the polygon synchronization mode, R is omissible, but P and Q are required.
3 When G51.2 is specified to change the P, Q, and R settings during the polygon synchronization mode, R can be specified independently. When P and Q are changed, however, be sure to specify both P and Q.
4 When bit 0 (RPL) of parameter No.7603 = 0 regardless of the setting of bit 6 (CLR) of parameter No.3402, a reset issues G50.2 (polygon synchronization release mode). When bit 0 (RPL) of parameter No. 7603 = 1, a reset does not clear G51.2 (polygon synchronization mode) in polygon synchronization mode.
5 The following functions must be commanded with polygon turning cancel mode.
- Inch/metric conversion
- AI contour control
- Tilted working plane indexing
- Flexible path axis assignment

- Spindle operation during the polygon synchronization mode with two spindles

When the start of polygon synchronization is specified by G51.2, the polygon synchronization axis speed is adjusted to Q/P times the master axis speed based on spindle speed command value for the master axis and then phase matching is performed.

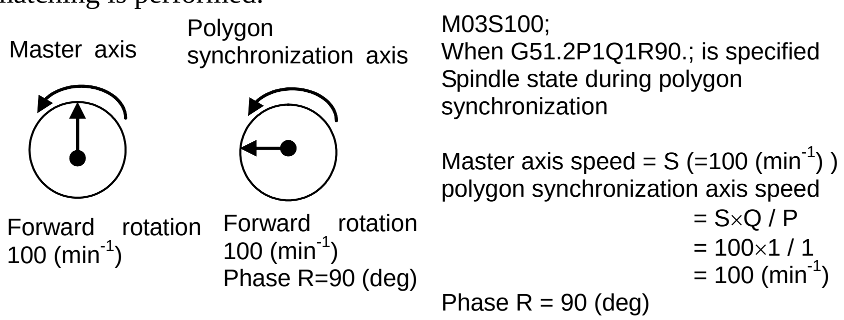

Fig. 6.9.2 (a)

When the spindle is accelerated or decelerated or when phase matching is being performed, the synchronization state of rotation ratio of P to Q is not guaranteed. Therefore, in an actual cutting block command, control the spindle speed arrival signal SAR<Gn029.4> after checking that the signal state of the polygon spindle speed arrival signal for polygon turning with two spindles PSAR<Fn063.2> is 1 or take sufficient wait time in the program.

Each time any of the following changes is made during polygon synchronization, control the speed and then perform phase matching.

1) The spindle speed command for the master axis is changed.
2) The speed ratio commands P and Q are specified by G51.2 again.
3) The phase command value R is specified by G51.2 again.
4) The polygon spindle stop signal *PLSST <Gn038.0> is changed from “0” to “1”.

How to specify the spindle speed for the master axis (multi-spindle control or spindle output control by PMC) does not change regardless of whether polygon synchronization mode or normal operation is selected. Spindle speed specification for the polygon synchronization axis is disabled in polygon synchronization mode.

If the speed of the polygon synchronization axis (S × Q / P(min^{-1}): where S is the master axis speed) exceeds the clamp speed set in parameter No. 7621 after the command is executed, an alarm (PS5018) occurs and the polygon synchronization state is cleared.

The diagnostic display bit 2 (QCL) of No. 471 can be used to check whether the clamp speed is exceeded after the command is executed.

- PMC sequence

Although this function is based on the G-code system, it is necessary to add or change PMC ladder sequences because control on the part of the spindle is also required.
(See the description of the PMC sequence in this section.)

- Example of polygon turning with two spindles

This example of polygon turning with two spindles produces a square using single-edged cutting tools (for roughing and finishing).

.		
Mxy; Txxyy;	Step 1.	Mount a roughing tool on the polygon synchronization axis (tool rotation axis).
G00 X100. Z20. M03 S1000 ;	Step 2.	Start rotating the workpiece (with the master axis at 1000 (min^{-1}))
.		
G51.2 P1 Q2 R0 ;	Step 3.	Start rotating the tool. In the PMC ladder, the polygon synchronization axis is energized by polygon synchronization under way signal PSYC<Fn063.7>. After acceleration to 2000 (min^{-1}) is performed as the polygon synchronization axis, positioning is performed. The phase is 0. In the PMC ladder, the spindle speed arrival signal SAR<Gn029.4> is controlled based on the polygon spindle speed arrival signal PSAR<Fn063.2> during the polygon synchronization mode.
G01 X80. F10. ;	Step 4.	Starts cutting along the X-axis after SAR<Gn029.4> becomes logical 1 in signal control at step 3.
.		
G04 P4000 ;	Step 5.	Polygonal turning (roughing 1)
.		
G00 X100. ;	Step 6.	Retract the tool along the X-axis.
.		
G51.2 R180.;	Step 7.	Change the phase by 180 degrees.
.		
[Repeat steps 4, 5, and 6.]	Step 8.	Polygonal turning (roughing 2)
.		
G50.2 ; Myz; Tyyzz;	Step 9.	Release the polygon synchronization mode. Change to a finishing tool.
.		
S2000; G51.2 P1 Q2 R0 ; . .	Step 10.	Change the spindle speed for finishing Start rotating the tool. (master axis at 2000 min^{-1} and polygon synchronization axis at 4000 min^{-1} with a phase difference of 0).
[Repeat steps 4, 5, and 6.]	Step 11.	Polygonal turning (finishing 1)
.		
[Repeat step 7.]	Step 12.	Change the phase by 180 degrees.
.		
[Repeat steps 4, 5, and 6.]	Step 13.	Polygonal turning (finishing 2)
.		
G50.2 ; . . .	Step 14.	Release the polygon synchronization mode. The polygon synchronization axis (tool rotation axis) stops. The master axis rotates at 2000 (min^{-1}).
M05S0; . .	Step 15.	The master axis stops.

Diagnosis data

For polygon turning with two spindles, the following information is displayed on the diagnosis screen.

	#7	#6	#5	#4	#3	#2	#1	#0
470	SC0	LGE		SCF	PSC	PEN	PSU	SPL

Polygon turning with two spindles
Indication of information about the polygon synchronization mode

SPL Polygon synchronization with two spindles under way
PSU Polygon synchronization mode with two spindles being activated

> **NOTE**
> If only PSU becomes 1, but no change occurs, and the program stops in a block containing a G51.2 command, the speed of an spindle does not reach the targeted polygon synchronization speed, for example, because bit 7 (PST) of parameter No. 7603 = 0 keeps the spindle from being energized.

PEN Polygon synchronization mode with two spindles released
PSC Spindle speed being changed during polygon synchronization mode with two spindles
SCF Spindle speed has been changed during polygon synchronization mode with two spindles
LGE The loop gain is different between the spindles during polygon synchronization mode with two spindles.

> **NOTE**
> When the speed is changed during polygon synchronization mode, LGE is set to 1 if the spindle synchronization control loop gain used by the serial spindle control unit is different between the master spindle and polygon synchronization axis.
> Diagnosis display indicates the loop gain because this function requires that both spindles be controlled with the same loop gain. However, no alarm is issued even if the loop gain is different between the spindles.
> (For the serial spindle control unit, the parameters used are changed according to the state of the CTH1 and CTH2 signals.)

SC0 Actual speed command is 0 during polygon synchronization mode with two spindles.

> **NOTE**
> Signal SC0 is not a value specified by the program. It is set to 1 under any of the following conditions:
> 1. When the S command value is adjusted according to the signals related to spindle control, SSTP<Gn029.6> and SOV0-SOV7<Gn030> and the signal related to multi-spindle control <Gn027>, the result is 0.
> 2. The S command value is smaller than the spindle control resolution (the result of multiplying the S command value by a value of 4095/(maximum spindle speed) is less than 1).
>   The S command value is specified by SIND control <Gn032, Gn033>, and it is 0.
>
> If SC0 = 1, the spindle speed becomes 0 and bit 0 (SCU) of diagnosis data No. 471 becomes 1. In this case, the polygon synchronization rotation ratio is impractical, but alarm PS5018 does not occurs, because it is regarded as the result of the command.

If the following status is indicated during the polygon synchronization mode, there are no abnormalities.

	#7	#6	#5	#4	#3	#2	#1	#0
470	0	0	0	1	-	0	0	1

	#7	#6	#5	#4	#3	#2	#1	#0
471	NPQ	PQE	QMS	NSP	SUO	QCL		SCU

Polygon turning with two spindles
Indication of causes for alarms PS5018, PS0314, and PS0218

#0 to #3 Causes for alarm PS5018
Alarm PS5018 is cleared by a reset, but the indication of its causes remains until the causes are cleared or the polygon synchronization mode is released.

SCU The specified speed is too low during polygon synchronization mode with two spindles.
(The unit of speed calculated internally becomes 0.)

NOTE
SCU becomes 1 also when the specified spindle speed is 0 (bit 7(SC0) of diagnosis data No.470 is 1). In this case, however, alarm PS5018 is not issued (because the command is 0). When bit 7(SC0) of diagnosis data No.470 is 0 and bit 0(SCU) of diagnosis data No.471 is 1, alarm PS5018 occurs. Normally this does not occur with speed at which the spindle can rotate.

QCL The polygon synchronization axis is clamped.

NOTE
QCL becomes 1, when the polygon synchronization axis receives a command with a polygon synchronization speed that is higher than the value specified in parameter No. 7621 and is clamped at that speed.

SUO The specified speed is too high during the polygon synchronization mode with two spindles.
(It is clamped to the upper limit calculated internally.)

NOTE
SUO occurs, if a result of (speed specified for the master spindle)/(value specified at P) is higher than 59998. In other words, the master spindle must rotate at a speed lower than 59998 min^{-1} assuming P = 1.

#4 Causes for alarm PS0314
When alarm PS0314 occurs, the polygon synchronization mode is released, but the indication of its causes remains until the alarm PS0314 is cleared by a reset.

NSP A spindle necessary for control is not connected.
(For example, there is not a serial spindle or the second spindle.)
The axis settings for polygon turning are not correct.

#5 to #7 Causes for alarm PS0218
When alarm PS0218 occurs, the polygon synchronization mode is released, but the indication of its causes remains until the alarm PS0218 is cleared by a reset.

QMS When bit 1 (QDR) of parameter No. 7603 = 1, a negative value is specified at Q.

PQE In a G51.2, either P or Q has a value out of the specifiable range.
Or, P and Q are not specified as a pair.

NPQ In a G51.2, R is specified when P and Q have not been specified at all, or none of P, Q, and R has been specified.

Indication of values specified during the polygon synchronization mode with two spindles

474	Rotation ratio for the master axis during the polygon synchronization mode with two spindles (P command value)

This indication is the current rotation ratio (P command value) of the master axis during the polygon synchronization mode with two spindles.

475	Rotation ratio for the polygon synchronization axis during the polygon synchronization mode with two spindles (Q command value)

This indication is the current rotation ratio (Q command value) of the polygon synchronization axis during the polygon synchronization mode with two spindles.

476	Phase difference between the two spindles under polygon synchronization control with two spindles(R command value)

This indication is the current phase value (R command value) specified during the polygon synchronization mode with two spindles. (The increment system for the reference axis used.)

However, if bit 5 (RDG) of parameter No. 7603 = 1, the indication is the amount of shifting specified for the serial spindle (number of pulses after conversion is performed assuming 360 degrees = 4096 pulses).
Indication of the actual speed of each spindle during the polygon synchronization mode with two spindles

477	Actual master axis speed (min^{-1}) during the polygon synchronization mode with two spindles

This indication is the actual speed of the master axis during the polygon synchronization mode with two spindles.

478	Actual polygon synchronization axis speed (min^{-1}) during the polygon synchronization mode with two spindles

This indication is the actual speed of the polygon synchronization axis during the polygon synchronization mode with two spindles.

Spindle tuning screen

During the polygon synchronization mode with two spindles, information for the spindle synchronization control mode is displayed.

The following information is displayed on the spindle tuning screen.
”Positional deviation” indicates the positional deviation of the spindle currently being displayed.
”Synchronous deviation” indicates the absolute value of a synchronization error in polygon synchronization during polygon turning with two spindles. The synchronization error value is displayed on the spindle tuning screen for the spindle used as the polygon synchronization axis.
For details, please refer to Spindle tuning screen of MAINTENANCE MANUAL (B-64695EN).

Motor speed
Spindle speed
Positional deviation S1
Positional deviation S2
Synchronous deviation

Signal

Polygon spindle stop signal *PLSST<Gn038.0>

[Classification] Input signal

[Function] This function is enabled when bit 7 (PST) of parameter No. 7603 is set to 1. This signal is used to stop the spindle during the polygon synchronization mode with two spindles.
0 = polygon spindle stop
1 = polygon spindle operable
During the polygon synchronous mode with two spindles, the rotation of the spindle is controlled with a position loop created.
The spindle is rotated by move command pulses based on the polygon synchronization speed.
When the activated spindle is turned off by the spindle stop (for example, M05) command, move command pulses are generated even when activation is off unless the spindle speed command is set to 0 using the spindle stop signal *SSTP<Gn029.6> or the like, some error pulses being accumulated. When activation is turned on at this time, the spindle may rotates at high speed because the accumulated error pulses are moved at a time.
This signal can be used to stop the delivery to the polygon spindle only during the polygon synchronous mode with two spindles. The signal must be controlled according to the activation status (on/off) of the polygon spindle.

For details on usage, see the section that describes PMC sequences.

Polygon synchronization under way signal PSYN<Fn063.7>

[Classification] Output signal

[Function] Informs the PMC that the system is in the polygon synchronization mode.

[Output cond.] The polygon synchronization mode command (G51.2) sets this signal to logical “1”. It stays at 1 as long as the system is in the polygon synchronization mode. It is turned to 0 when the polygon synchronization mode is cleared (G50.2 command or a reset). It stays at 0 when the system is not in the polygon synchronization mode.

> **NOTE**
> The same address is used for this signal in both polygon turning (using the servo axis) and the polygon turning with two spindles.

Polygon spindle speed arrival signal PSAR<Fn063.2>

[Classification] Output signal

[Function] Informs the PMC that the spindle has reached its constant-speed for polygon synchronization during polygon turning with two spindles.

[Output cond.] During polygon synchronization mode with two spindles, whether the constant-speed is reached for polygon synchronization is output as shown below:

0 = not reached (during phase change or acceleration/deceleration under way)

1 = reached

During the polygon synchronization mode, this signal becomes logical 1 when the speed of each spindle reaches the acceptable level specified in parameter No. 7631 and remains there for a period specified in parameter No. 7632.

If the speed of either spindle goes off the acceptable level, or a change is made to the S command, the signal returns to logical “0” and begins monitoring the above condition.

When this signal is “0”, the specified speed ratio and phase are not guaranteed for polygon turning. If the signal is confirmed before actual turning is started, however, the operation is more efficient than when a dwell command (like G04) is used to allow wait time.

Polygon master axis not arrival signal PSE1<Fn063.0>
Polygon synchronization axis not arrival signal PSE2<Fn063.1>

[Classification] Output signal

[Function] Informs the PMC whether the actual speed of each spindle has reached the specified speed during polygon turning mode with two spindles.

[Output cond.] During the polygon synchronization mode with two spindles, whether each spindle has reached the polygon synchronization speed is output as shown below:

0 = reached

1 = not reached (during phase change or acceleration/deceleration under way)

During the polygon synchronization mode with two spindles, this signal becomes logical 1 when the speed of master axis and polygon synchronization axis does not reach the acceptable level specified in parameter No. 7631.

PMC sequence

The following shows the signal status time chart when the polygon synchronization mode is on and off.

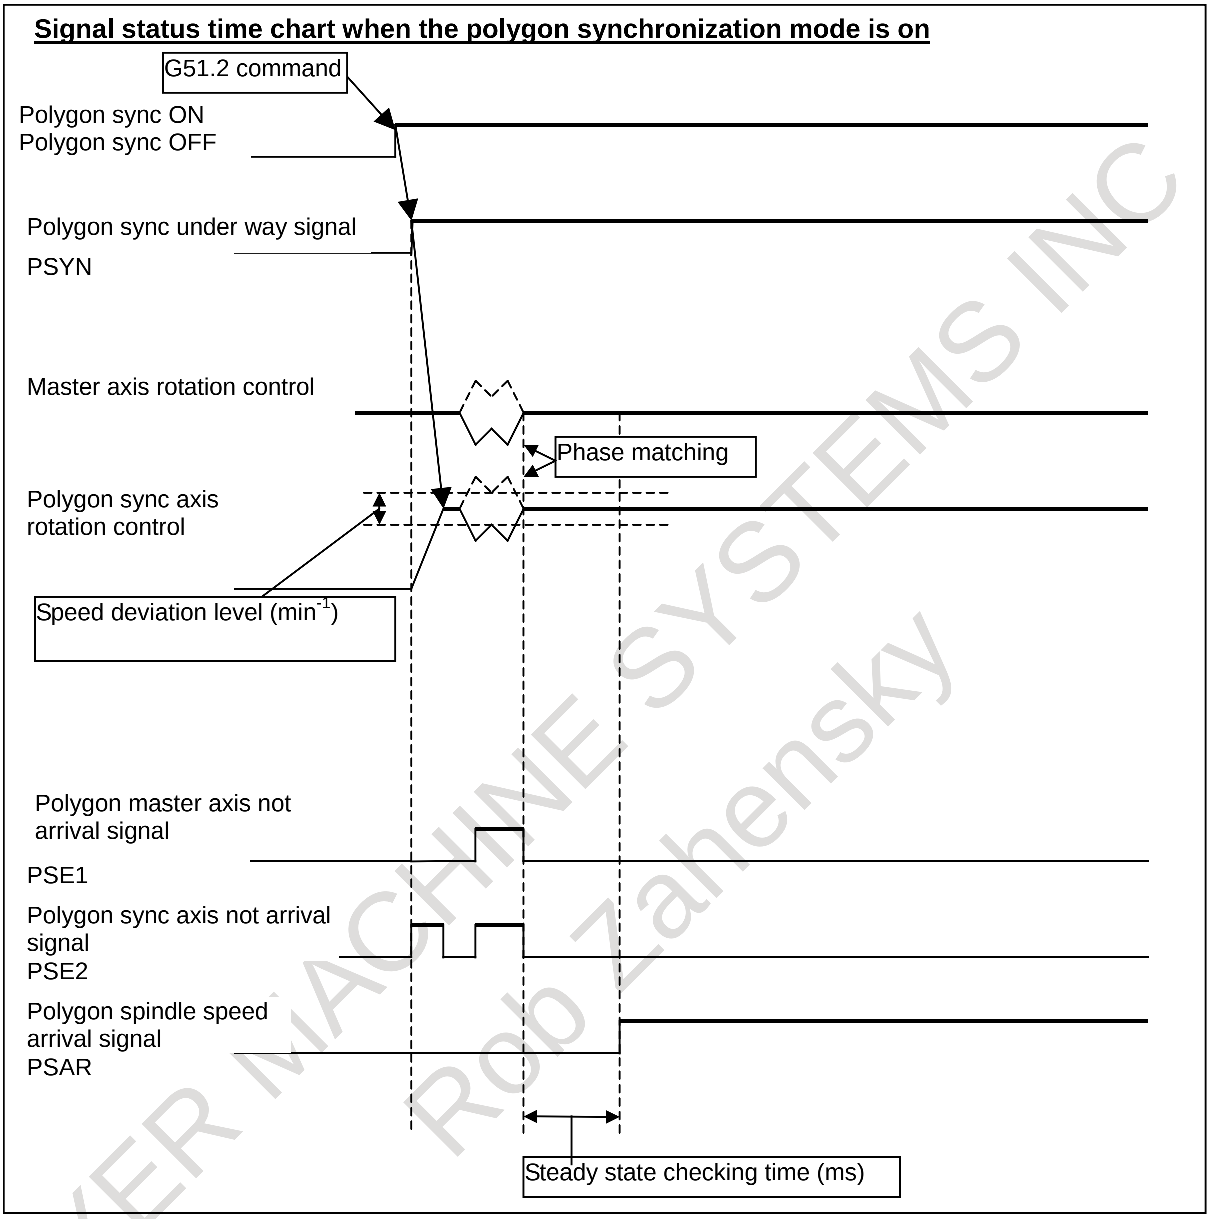

Fig. 6.9.2 (b)

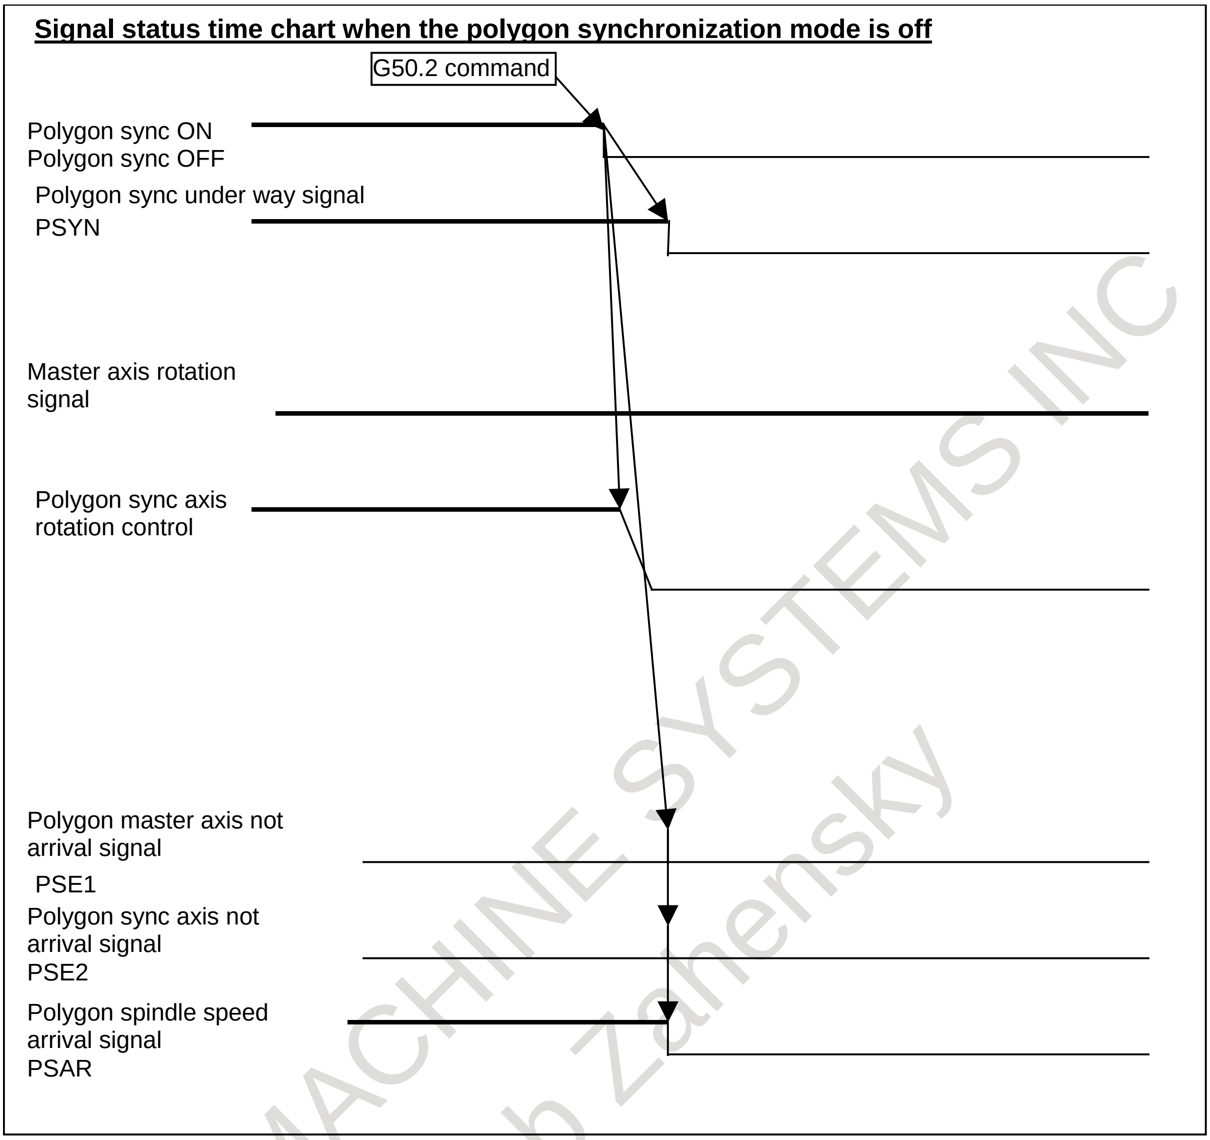

Fig. 6.9.2 (c)

When the polygon synchronization mode is started by the G51.2 command, the polygon synchronization under way signal PSYN<Fn063.7> is set to “1”.
Create a PMC sequence during the polygon synchronization mode by checking the polygon synchronization under way signal with the PMC ladder.

First, select one method of controlling spindle activation used during the polygon synchronization mode from methods A and B. Then create a PMC sequence according to the selected method.

- Method A

During the polygon synchronization mode, activation of the master axis and polygon synchronization axis is automatically turned on.
During this mode, activation of the spindle is not turned off.

For method A, set bit 7 (PST) of parameter No. 7603 to 0.
In a PMC sequence, activation of the master axis and polygon synchronization axis must be turned on when the polygon synchronization under way signal PSYN<Fn063.7> changes from “0” to “1”.

In addition, while the polygon synchronization under way signal is 1, prevent the activation of the master axis and polygon synchronization axis from being turned off by, for example, prohibiting the acceptance of spindle stop (for example M05) during normal control.

When the polygon synchronization under way signal PSYN<Fn063.7> changes from “1” to “0”, basically turn off activation.

The NC stops at the G51.2 command block for entering the polygon synchronization mode and does not proceed to the next block until the spindle speed reaches the polygon synchronization speed.

- Method B

Even during the polygon synchronization mode, another M code or the like is used to turn on or off activation of the spindle.
Or, even during the polygon synchronization mode, activation of the spindle may be turned off.

For method B, set bit 7 (PST) of parameter No. 7603 to 1.
This parameter setting enables the polygon spindle stop signal *PLSST<Gn038.0> and makes the NC proceed to the next block without waiting for the spindle speed to reach the polygon synchronization speed in the G51.2 command block for starting the polygon synchronization mode.

In a PMC sequence, during the polygon synchronization mode (the polygon synchronization under way signal PSYN<Fn063.7> is “1”), set the polygon spindle stop signal *PLSST<Gn038.0> to “1” after confirming that activation of the master axis and polygon synchronization axis is turned on.
When the polygon synchronization mode is not entered (the polygon synchronization under way signal PSYN<Fn063.7> is “0”), set the polygon spindle stop signal *PLSST<Gn038.0> to “0”.

When the polygon spindle stop signal *PLSST<Gn038.0> is changed from “0” to “1” during the polygon synchronization mode, phase control is performed after acceleration from the spindle stop state to the polygon synchronization speed is performed.

- Sequences common to methods A and B

During the polygon synchronization mode, observe the follow rules to create a PMC sequence regardless of whether method A or method B is used.

(1) The rotation direction of the master axis during the polygon synchronization mode is fixed to the forward direction rather than being switched by the forward/reverse rotation specification signal (SFR/SRV). When changing the rotation direction, use a command.
   - When using the S command in the program
     Specify M03/M04 by setting bit 7 (TCW) of parameter No. 3706 to 1.
   - When using a command by the spindle output control by the PMC
     Switch the rotation direction by setting the polarity selection signal SSIN<Gn033.6> to “1” to control the polarity specification signal SGN<Gn033.5>.
     The rotation direction of the polygon synchronization axis must also be fixed to the forward direction rather than being switched by the SFR/SRV signal.

(2) During the polygon synchronization mode, phase control is performed after the polygon synchronization speed is reached. Therefore, the speed arrival signal of each spindle (SARA<Fn045.3> and SARB<Fn049.3>) is insufficient for determining the start condition of the cutting feed command.
To confirm that the spindle speed is reached during the polygon synchronization mode, use the polygon spindle speed arrival signal PSAR<Fn063.2> to control the spindle speed arrival signal SAR<Gn029.4>.
The polygon spindle speed arrival signal PSAR<Fn063.2> can be used to check whether both spindles meet the settings of parameters No. 7631 and 7632 after phase control is performed in the polygon synchronization mode.

The set time (parameter No. 3740) that elapses before the spindle speed arrival signal is checked is also valid for the execution of the cutting feed command during the polygon synchronization mode.

If the spindle speed arrival signal SAR<Gn029.4> is not used as the start condition for the cutting feed command, the time required for the master axis and polygon synchronization axis to rotate at steady-state speed must be reserved during start of the polygon synchronization mode, change of the spindle speed, or change of the machining condition by a program command (for example, G04) before cutting by polygon turning is started.

(3) During the spindle polygon synchronization mode, the polygon synchronization axis cannot be rotated independently of the master axis.
Since the spindle orientation function (ORCMA <Gn070.6> and ORCMB<Gn074.6>) cannot also be used, the polygon synchronization mode must be released before shifting gears or changing tools or workpieces.
If necessary, take such an action that displays a message requesting the release of the polygon synchronization mode when an unavailable command is used during the polygon synchronization mode.

Parameter

	#7	#6	#5	#4	#3	#2	#1	#0
7603	PST		RDG				QDR	RPL

[Input type] Parameter input
[Data type] Bit path

#0 RPL Upon reset, polygon turning with two spindles mode is:
0: Released.
1: Not released.

#1 QDR The rotational direction of the polygon synchronization axis:
0: Depends on the sign (+/-) of a specified value for Q.
1: Depends on the rotational direction of the first spindle.
If a negative value is specified for Q when QDR = 1, the alarm PS0218 is issued.

#5 RDG On the diagnosis data No. 476, for spindle-spindle polygon phase command value (R), displays:
0: The specified value (in the increment system for the rotation axis).
1: The actual number of shift pulses.

> **NOTE**
> A phase command is specified in address R, in units of degrees. For control, the actual shift amount is converted to a number of pulses according to the conversion formula: 360 degrees = 4096 pulses. This parameter switches the display of a specified value to that of a converted value.

#7 PST The polygon spindle stop signal *PLSST <Gn038.0> is:
0: Not used.
1: Used.

7621	Maximum allowable speed for the tool rotation axis for polygon turning

[Input type] Parameter input
[Data type] 2-word path

[Unit of data] min^{-1}
[Valid data range] 0 or positive 9 digit of minimum unit of data (refer to the standard parameter setting table (B))
(When the increment system is IS-B, 0.0 to +999999.999)
This parameter sets the maximum allowable speed of the tool rotation axis.

> **NOTE**
> If the speed of the tool rotation axis exceeds the set maximum allowable speed during polygon turning, the synchronization between the spindle and tool rotation axis is lost, and operation stops with alarm PS5018.

7631	Allowable spindle speed deviation level in polygon turning with two spindles

[Input type] Parameter input
[Data type] Word path
[Unit of data] min^{-1}
[Valid data range] 0 to 99999999
This parameter sets the allowable level of deviation between the actual speed and specified speed of each spindle in polygon turning with two spindles. The value set with this parameter is used for both the master axis and polygon synchronization axis.
When 0 is set in this parameter, the specification of 8 [min^{-1}] is assumed.

7632	Steady state confirmation time duration in spindle polygon turning

[Input type] Parameter input
[Data type] Word path
[Unit of data] msec
[Valid data range] 0 to 32767
This parameter sets the duration required to confirm that both spindles have reached their specified speeds in polygon turning with two spindles.
If the state where the speed of each spindle is within the range set with parameter No.7631, and has lasted at least for the duration specified with parameter No.7632, the spindle polygon speed arrival signal PSAR <Fn063.2> is set to "1".
When 0 is set in this parameter, the specification of 64 [msec] is assumed.

7640	Master axis in polygon turning with two spindles

[Input type] Parameter input
[Data type] Byte path
[Valid data range] 0 to Maximum number of controlled axes (Within a path)
This parameter sets the master axis in polygon turning with two spindles.

> **NOTE**
> 1 Polygon turning with two spindles is enabled only for serial spindles.
> 2 When any one of parameters No. 7642 and 7643 is set to 0 and any one of parameters No. 7640 and 7641 is set to 0, polygon turning is performed using the first spindle (master axis) and the second spindle (polygon synchronous axis) in the path to which the parameter belongs.

> **NOTE**
> 3 When a spindle other than the first serial spindle is used as a master axis, the multi-spindle control is required to specify an S command for the master axis.
> 4 When the PMC window function or G10 command is used to rewrite this parameter, rewrite this parameter before the block specifying the spindle-spindle polygon command G51.2. When the PMC window function is used to rewrite this parameter in the block immediately before G51.2, specify the rewriting of this parameter by using an M code (parameter No. 3411 and up) without buffering.
> 5 When this parameter is used, set the parameters No.7642 and No.7643 to 0.

7641	Polygon synchronous axis in polygon turning with two spindles

[Input type] Parameter input
[Data type] Byte path
[Valid data range] 0 to Maximum number of controlled axes (Within a path)
This parameter sets the polygon synchronous (slave) axis in polygon turning with two spindles.

> **NOTE**
> 1 Polygon turning with two spindles is enabled only for serial spindles.
> 2 When any one of parameters No. 7642 and No. 7643 is set to 0 and any one of parameter No. 7640 and No. 7641 is set to 0, polygon turning is performed using the first spindle (master axis) and the second spindle (polygon synchronous axis) in the path to which the parameter belongs.
> 3 When a spindle other than the first serial spindle is used as a master axis, the multi-spindle control is required to specify an S command for the master axis.
> 4 When the PMC window function or G10 command is used to rewrite this parameter, rewrite this parameter before the block specifying the spindle-spindle polygon command G51.2. When the PMC window function is used to rewrite this parameter in the block immediately before G51.2, specify the rewriting of this parameter by using an M code (parameter No. 3411 and up) without buffering.
> 5 When this parameter is used, set the parameters No.7642 and No.7643 to 0.

7642	Master axis in polygon turning with two spindles (spindle number common to the system)

[Input type] Parameter input
[Data type] Byte path
[Valid data range] 0 to Maximum number of controlled axes (Common to the system)
This parameter sets the master axis in polygon turning with two spindles.

NOTE

1 Polygon turning with two spindles is enabled only for serial spindles.
2 This parameter is invalid if either parameter No. 7642 or No.7643 is set to 0. In this case, the settings of parameter No. 7640 and No.7641 are valid.
3 When a spindle other than the first serial spindle is used as a master axis, the multi-spindle control is required to specify an S command for the master axis.
4 When the PMC window function or G10 command is used to rewrite this parameter, rewrite this parameter before the block specifying the spindle-spindle polygon command G51.2. When the PMC window function is used to rewrite this parameter in the block immediately before G51.2, specify the rewriting of this parameter by using an M code (parameter No. 3411 and up) without buffering.
5 A spindle number common to the system is to be set in this parameter. When using this parameter, set 0 in parameter No. 7640 and No. 7641.

7643	Polygon synchronous axis in polygon turning with two spindles (spindle number common to the system)

[Input type] Parameter input
[Data type] Byte path
[Valid data range] 0 to Maximum number of controlled axes (Common to the system)

This parameter sets the polygon synchronous (slave) axis in polygon turning with two spindles.

NOTE

1 Polygon turning with two spindles is enabled only for serial spindles.
2 This parameter is invalid if either parameter No. 7642 or No.7643 is set to 0. In this case, the settings of parameter No. 7640 and No.7641 are valid.
3 When a spindle other than the first serial spindle is used as a master axis, the multi-spindle control is required to specify an S command for the master axis.
4 When the PMC window function or G10 command is used to rewrite this parameter, rewrite this parameter before the block specifying the spindle-spindle polygon command G51.2. When the PMC window function is used to rewrite this parameter in the block immediately before G51.2, specify the rewriting of this parameter by using an M code (parameter No. 3411 and up) without buffering.
5 A spindle number common to the system is to be set in this parameter. When using this parameter, set 0 in parameter No. 7640 and No. 7641.

4032	Acceleration at spindle synchronous control

[Input type] Parameter input
[Data type] Word spindle
[Data unit] 1min^{-1}/sec
[Valid data range] 0 to 32767

This parameter sets an acceleration value for linear acceleration/deceleration when the synchronous speed command for spindle synchronous control is changed.
For polygon machining with two spindles, when bit 1 (POLYM) of parameter No. 4001 is 1, the allowable data range is not limited.

	Data range		
Spindle synchronous control	0-23767		
Polygon turning with two spindles	POLYM=0		POLYM=1
	SPDUNT=0	SPDUNT=1	0-32767
	0, 916-32767	0, 92-32767	

NOTE
1. Set exactly the same data for a master axis spindle and a slave axis. When different data is set, synchronization between the two spindles is not guaranteed.
2. When this parameter is set to 0, acceleration/deceleration of a spindle is not applied. Set an appropriate value.

4065	Position gain in servo mode (HIGH)
4066	Position gain in servo mode (MEDIUM HIGH)
4067	Position gain in servo mode (MEDIUM LOW)
4068	Position gain in servo mode (LOW)

[Data type] Word spindle
[Unit of data] 0.01 sec^{-1}
[Valid data range] 0 to 32767
These parameters set a servo loop gain on servo mode. (spindle positioning, rigid tapping, etc.)

NOTE
When the spindle positioning by a serial spindle is performed, set the position control loop gain in place of parameter No. 4970. For which gear is used, it depends on the clutch/gear signal (serial spindle) CTH1s, CTH1s.

Alarm and message

Number	Message	Description
PS0194	SPINDLE COMMAND IN SYNCHRO-MODE	A Cs contour control mode, spindle positioning command, or rigid tapping mode was specified during the spindle synchronous control mode or spindle command synchronous control mode.
PS0218	NOT FOUND P/Q COMMAND	P or Q is not commanded in the G51.2 block, or the command value is out of the range. Modify the program. For a polygon turning between spindles, more information as to why this alarm occurred is indicated in diagnosis data No. 471.
PS0219	COMMAND G51.2/G50.2 INDEPENDENTLY	G51.2 and 50.2 were specified in the same block for other commands. Modify the program in another block.
PS0221	ILLEGAL COMMAND IN SYNCHR-MODE	Polygon turning synchronous operation and Cs contour control or balance cutting are executed at a time. Modify the program.

Number	Message	Description
PS0314	ILLEGAL SETTING OF POLYGONAL AXIS	An axis was specified invalidly in polygon turning. For polygon turning: A tool rotation axis is not specified. (Parameter No. 7610) For polygon turning with two spindles: Valid spindles are not specified. (Parameter Nos. 7640 to 7643) - A spindle other than the serial spindle. - A spindle is not connected. For concurrent use of polygon turning and polygon turning with two spindles: - In the polygon turning mode, the value of parameter No. 7605 (selecting the type of polygon turning) was changed. - An attempt is made to use a spindle used for polygon turning also for polygon turning with two spindles.
PS5018	POLYGON SPINDLE SPEED ERROR	In G51.2 mode, the speed of the spindle or polygon synchronous axis either exceeds the clamp value or is too small. The specified rotation speed ratio thus cannot be maintained. For polygon turning with two spindles: More information as to why this alarm occurred is indicated in diagnosis data No. 471.

Caution

⚠ **CAUTION**

1. The maximum spindle speed for each gear stage (Parameters No. 3741 to 3744) must be specified correctly according to the model of the machine. In addition, ordinary spindle connections must have been terminated.
2. This function uses the one-rotation signal for the spindle as a reference point for phase adjustment.
   When a built-in sensor is used, and there are gears between the spindle and spindle motor, it is necessary to install a detector on the spindle separately to take a one-rotation signal from the spindle. If the detector does not guarantee detection of a correct position from arbitrary speed, set bit 4 (HST) of parameter No. 7602 and bit 7 (RFCHK3) of serial spindle parameter No. 4016 to 1. This setting reduces the spindle speed automatically down to 0 for spindle position detection each time the polygon turning mode with two spindles is entered, thus guaranteeing a correct phase relationship during polygon synchronization mode with two spindles.
3. This function uses the spindle synchronization function for serial spindles. (However, it does not require the spindle synchronization for the CNC.) You may need to specify the relevant serial spindle parameters (such as Nos. 4032 to 4035 and Nos. 4065 to 4068).
   Specify the same serial spindle loop gain (parameters Nos. 4065 to 4068) for both spindles.
   If the same serial spindle loop gain is not used for both spindles, polygon turning may not be accurate.
   If an attempt is made to perform polygon turning with two spindles using different loop gain, bit 6(LGE) of diagnosis data No.470 becomes 1. (No alarm is issued.)
4. Before using the polygon synchronization mode, place both master axis and polygon synchronization axis in the spindle control mode. If the polygon synchronization mode starts during another mode (Cs contour control mode, spindle orientation, or the like), an alarm occurs.

⚠ **CAUTION**

5 During the polygon synchronization mode, no command cannot be executed for the polygon synchronization axis.
During the polygon synchronization mode, the spindle orientation function cannot be used for either the master axis and polygon synchronization axis. Therefore, gear, tool or workpiece change is basically unusable during the polygon synchronization mode.

6 During polygon synchronization mode, speed change and phase adjustment are performed each time the spindle speed is changed. Therefore, this mode cannot be used together with a function that causes continuous spindle speed change (such as G96 constant surface speed control)

7 During the polygon synchronization mode, the rotation ratio between the master axis and polygon synchronization axis is controlled with priority. Therefore, the difference between the master axis speed and S command value may become larger than during ordinary spindle control.

Note

NOTE

During the polygon synchronization mode, phase control is performed in the least command increment of 360/4096 = 0.08789...(degrees) in reference to the one-rotation signal for each spindle. A setting less that the least command increment is actually invalid.
Since phase control covers relative phase of both spindles within a turn, a setting greater than 360 degrees has no meaning.
This function does not limit the range of valid R settings. A setting greater than 360 degrees is assumed as the remainder of division by 360.

Manual name	Item name
OPERATOR'S MANUAL (B-64694EN)	Polygon turning with two spindles

6.9.3 Concurrent Use of Polygon Turning and Polygon Turning with Two Spindles

Overview

When both of polygon turning and polygon turning with two spindles are specified, which polygon turning option is used for each path can be selected using a parameter.

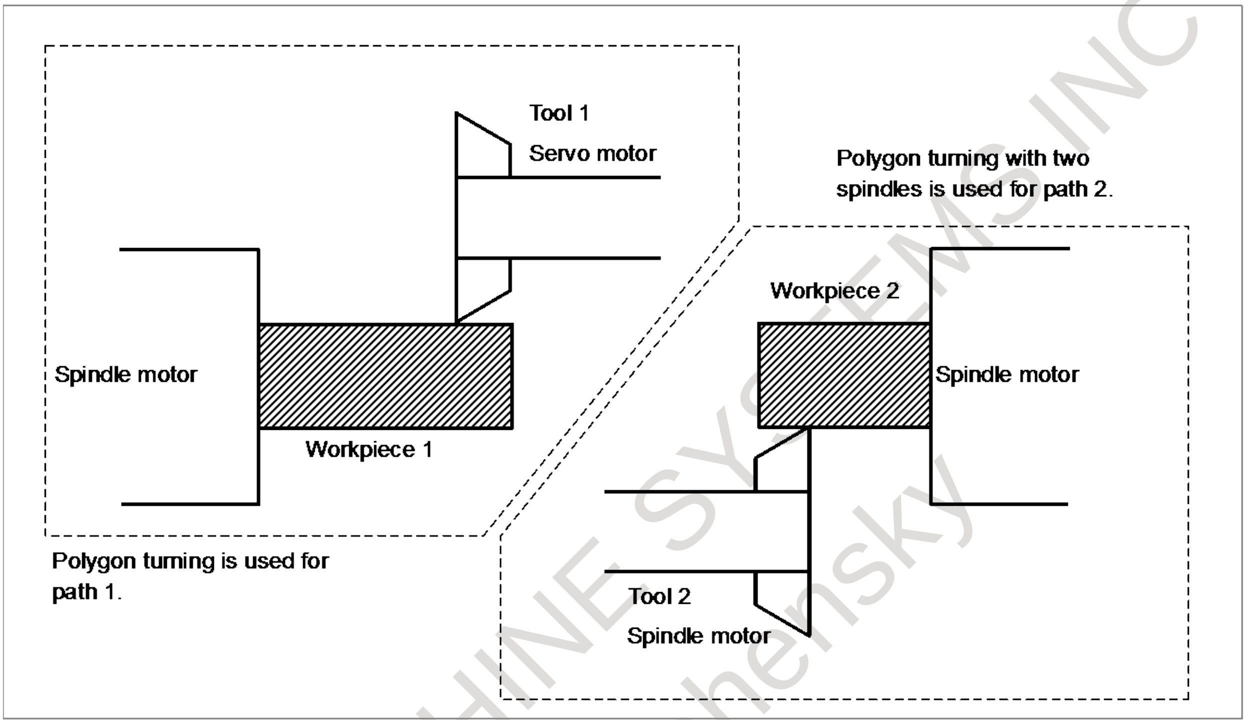

Fig. 6.9.3 (a) Example of performing polygon turning for path 1 and polygon turning with two spindles for path 2

Explanation

- Setting parameters

For a path for which bit 7 (PCG) of parameter No. 7604 is set to 1, whether to perform polygon turning or polygon turning with two spindles can be selected by setting parameter No. 7605. For a path for which bit 7 (PCG) of parameter No. 7604 is set to 0, only polygon turning with two spindles can be performed.

- Alarm

If the parameter for selecting the type of polygon turning is rewritten in the polygon turning mode, alarm PS0314, "ILLEGAL SETTING OF POLYGONAL AXIS", occurs. If an attempt is made to use a spindle used for polygon turning also used for polygon turning with two spindles, alarm PS0314 occurs.

Example)

When polygon turning is performed in path 1, if polygon turning with two spindles with using the same spindle is specified from path 2, alarm PS0314, "ILLEGAL SETTING OF POLYGONAL AXIS", occurs.

Parameter

	#7	#6	#5	#4	#3	#2	#1	#0
7604	PCG							

[Input type] Parameter input
[Data type] Bit path

> **NOTE**
> When this parameter is set, the power must be turned off before operation is continued.

#7 PCG If both polygon turning with two spindles and polygon turning are specified:
0: Polygon turning with two spindles is performed.
1: Either of the options is enabled depending on the setting of parameter No. 7605.

7605	Polygon turning type selection

[Input type] Parameter input
[Data type] Byte path
[Valid data range] 0, 1

If both polygon turning with two spindles and polygon turning are specified, this parameter can be used to select one of the options for use. A type of polygon turning is selected according to the setting as follows:
0: Polygon turning with two spindles
1: Polygon turning
If a value other than 0 or 1 is specified, 0 is assumed.

> **NOTE**
> Before re-setting this parameter, using the PMC window function or the G10 command, cancel polygon turning (G50.2). In addition, when re-setting this parameter, using the PMC window function, use the M code preventing buffering.

Alarm and message

Number	Message	Description
PS0314	ILLEGAL SETTING OF POLYGONAL AXIS	An axis was specified invalidly in polygon turning. For polygon turning: A tool rotation axis is not specified. (Parameter No. 7610) For polygon turning with two spindles: Valid spindles are not specified. (Parameter Nos. 7640 to 7643) - A spindle other than the serial spindle. - A spindle is not connected. For concurrent use of polygon turning and polygon turning with two spindles: - In the polygon turning mode, the value of parameter No. 7605 (selecting the type of polygon turning) was changed. - An attempt is made to use a spindle used for polygon turning also for polygon turning with two spindles.

6.10 NORMAL DIRECTION CONTROL

Overview

When a tool with a rotation axis (C-axis) is moved in the XY plane during cutting, the normal direction control function can control the tool so that the C-axis is always perpendicular to the tool path (Fig. 6.10 (a): Sample Movement of the tool).

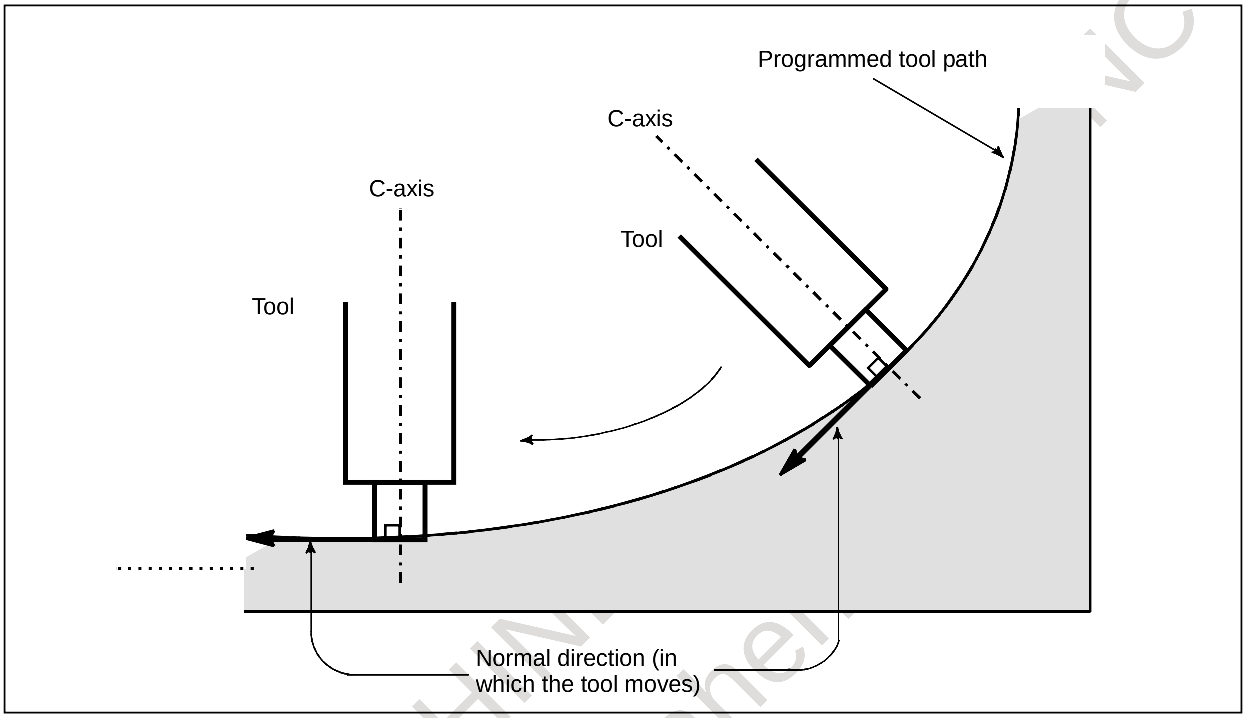

Fig. 6.10 (a) Sample Movement of the tool

Movement of the tool inserted at the beginning of each block is executed at the feedrate set in parameter No. 5481. If dry run mode is on at that time, the dry run feedrate is applied. If the tool is to be moved along the X-and Y-axes in rapid traverse (G00) mode, the rapid traverse rate is applied.
If the feedrate of the C axis exceeds the maximum cutting feedrate of the C axis specified to parameter No. 1430, the feedrate of each of the other axes is clamped to keep the feedrate of the C axis below the maximum cutting feedrate of the C axis.

Parameter

	#7	#6	#5	#4	#3	#2	#1	#0
1006							ROSx	ROTx

[Input type] Parameter input
[Data type] Bit axis

NOTE
When at least one of these parameters is set, the power must be turned off before operation is continued.

#0 ROTx
#1 ROSx Setting linear or rotary axis.

ROSx	ROTx	Meaning
0	0	Linear axis (1) Inch/metric conversion is done. (2) All coordinate values are linear axis type. (Is not rounded in 0 to 360°) (3) Stored pitch error compensation is linear axis type (Refer to parameter No. 3624)
0	1	Rotary axis (A type) (1) Inch/metric conversion is not done. (2) Machine coordinate values are rounded in 0 to 360°. Absolute coordinate values are rounded or not rounded by bits 0 (ROAx) and 2 (RRLx) of parameter No. 1008. (3) Stored pitch error compensation is the rotation type. (Refer to parameter No. 3624) (4) Automatic reference position return (G28, G30) is done in the reference position return direction and the move amount does not exceed one rotation.
1	1	Rotary axis (B type) (1) Inch/metric conversion is not done. (2) Machine coordinate values, absolute coordinate values and relative coordinate values are linear axis type. (Is not rounded in 0 to 360°). (3) Stored pitch error compensation is linear axis type (Refer to parameter No. 3624) (4) Cannot be used with the rotary axis roll-over function and the index table indexing function (M series)
Except for the above.		Setting is invalid (unused)

NOTE
Just a rotation axis can be subjected to normal direction control.

5480	Number of the axis for controlling the normal direction

[Input type] Parameter input
[Data type] Byte path
[Valid data range] 1 to the maximum controlled axis number

This parameter sets the controlled axis number of the axis for controlling the normal direction.

5481	Feedrate of rotation of the normal direction controlled axis

[Input type] Parameter input
[Data type] Real axis
[Unit of data] deg/min
[Min. unit of data] Depend on the increment system of the applied axis
[Valid data range] Refer to the standard parameter setting table (C)

This parameter sets the feedrate of the movement along the normal direction controlled axis that is inserted at the start point of a block during normal direction control.

5482	Limit value used to determine whether to ignore the rotation insertion of the normal direction controlled axis

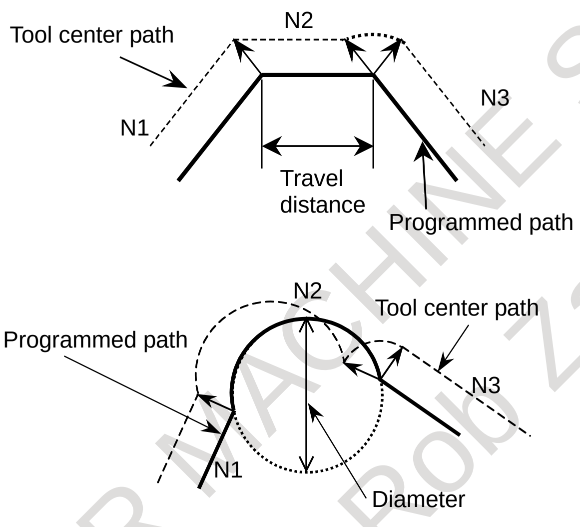
[Input type] Parameter input
[Data type] Real path
[Unit of data] deg
[Min. unit of data] Depend on the increment system of the reference axis

[Valid data range] 0 or positive 9 digit of minimum unit of data (refer to the standard parameter setting table (B))
The rotation block of the normal direction controlled axis is not inserted when the rotation insertion angle calculated during normal direction control does not exceed this setting.
The ignored rotation angle is added to the next rotation insertion angle, and the block insertion is then judged.

> **NOTE**
> 1 No rotation block is inserted when 360 or more degrees are set.
> 2 If 180 or more degrees are set, a rotation block is inserted only when the circular interpolation setting is 180 or more degrees.

5483	Limit value of movement that is executed at the normal direction angle of a preceding block

[Input type] Parameter input
[Data type] Real path
[Unit of data] mm, inch (input unit)
[Min. unit of data] Depend on the increment system of the reference axis
[Valid data range] 0 or positive 9 digit of minimum unit of data (refer to standard parameter setting table (B)



For straight line
When the travel distance of N2 in the figure on the left does not exceed the setting, block N2 is machined with the tool being normal to block N1.

For arc
When the arc diameter of N2 in the figure on the left does not exceed the setting, arc N2 is machined with the tool being normal to block N1. A normal direction axis is not controlled to move in the normal direction according to the arc movement.

Fig. 6.10 (b)

1430	Maximum cutting feedrate for each axis

[Input type] Parameter input
[Data type] Real axis
[Unit of data] mm/min, inch/min, deg/min (machine unit)
[Min. unit of data] Depend on the increment system of the applied axis
[Valid data range] Refer to the standard parameter setting table (C)
(When the increment system is IS-B, 0.0 to +999000.0)
Specify the maximum cutting feedrate for each axis.
The cutting feed rate is clamped so that the feedrate in the tangent direction does not exceed the parameter setting.

Alarm and message

Number	Message	Description
PS1470	G40.1 –G42.1 PARAMETER MISS	A parameter setting related to normal direction control is illegal. The axis number of a normal direction controlled axis is set in parameter No. 5480, but that axis number is in the range of the number of controlled axes. The axis set as a normal direction controlled axis is not set as a rotation axis (bit 0 (ROTx) of parameter No. 1006) = 1 and No.1022=0).
PS1471	ILLEGAL COMMAND IN G40.1 –G42.1	An invalid G code was specified in the normal direction control mode.

Limitation

NOTE

1 Do not specify any command to the C axis during normal direction control. Any command specified at this time is ignored.
2 Before processing starts, it is necessary to correlate the workpiece coordinate of the C axis with the actual position of the C axis on the machine using the coordinate system setting (G92) or the like.
3 Helical cutting cannot be specified in the normal direction control mode.
4 Normal direction control cannot be performed by the G53 move command.
5 The C-axis must be a rotation axis.
6 The following functions must be commanded with normal direction control cancel mode.
 - Plane selection command
 - Spiral interpolation
 - Conical interpolation
 - AI contour control

T

NOTE

In the normal direction control mode, the following commands cannot be issued. An attempt to issue any of them results in alarm PS1471 being raised.
- Plane selection command (G17, G18, G19)
- Automatic reference position return(G28)
- 2nd/3rd/4th reference position return(G30)
- Move from the reference position (G29)

6.11 LINEAR INTERPOLATION (G28, G30, G53)

Overview

When positioning operation of linear interpolation type is specified (bit 1 (LRP) of parameter No. 1401 = 1), the following operations can also be set as operations of linear interpolation type by setting bit 4 (ZRL) of parameter No. 1015 to 1:

- Movement from an intermediate point to a reference position in automatic reference position return operation (G28)
- Movement from an intermediate point to a reference position in second, third, or fourth reference position return operation (G30)
- Positioning by machine coordinate system selection (G53)

When any of the operations above is set as an operation of linear interpolation type, acceleration/deceleration control follows the setting of bit 4 (PRT) of parameter No. 1603.

Parameter

	#7	#6	#5	#4	#3	#2	#1	#0
1015				**ZRL**				

[Input type] Parameter input
[Data type] Bit path

#4 ZRL When a reference position is established, the tool path from the middle point to the reference position and machine coordinate positioning (G53) in automatic reference position return (G28) or 2nd/3rd/4th reference position return (G30) are based on:
0: Positioning of nonlinear interpolation type
1: Positioning of linear interpolation type

> **NOTE**
> This parameter is valid when bit 1 (LRP) of parameter No. 1401 is set to 1.

	#7	#6	#5	#4	#3	#2	#1	#0
1603				**PRT**				

[Input type] Parameter input
[Data type] Bit path

#4 PRT For positioning of linear interpolation type:
0: Acceleration/deceleration of acceleration fixed type is used.
1: Acceleration/deceleration of time fixed type is used.

Note

> **NOTE**
> Automatic reference position return operation of low-speed type (G28)
> If reference position return operation is not performed for a specified axis even once after the power is turned on in automatic reference position return operation (G28), a reference position return operation of low-speed type is performed for the axis.
> At this time, positioning of non-linear interpolation type is performed.
> For example, if G28X0Y0Z0; is specified when reference position return operation is completed for the X-axis and Y-axis, and is not completed for the Z-axis, positioning of non-linear interpolation type is performed.

6.12 SMOOTH TOLERANCE+ CONTROL

M

Overview

Smooth tolerance+ control is a function that generates smooth machining path within specified tolerance. In the case of die mold machining program that consists of small line segments, this function acts as smoothing function and makes joints of blocks smooth. As the result, machining surface gets high quality.

Smoothing small line segments

This function smooths small line segments. If the length of linear blocks is less than the value set at parameter No. 19595, those blocks are treated as small line segment blocks, and smooth curves not depending on commanded points are generated, which are within tolerance from commanded points. Machining gets smoother even if there are small discontinuous blocks in a program.
Tolerance is set as same value as CAM tolerance which generating small line segments. Tolerance is specified by parameters (No.11786, 11787) or NC program (G10.8L4Q_R_).

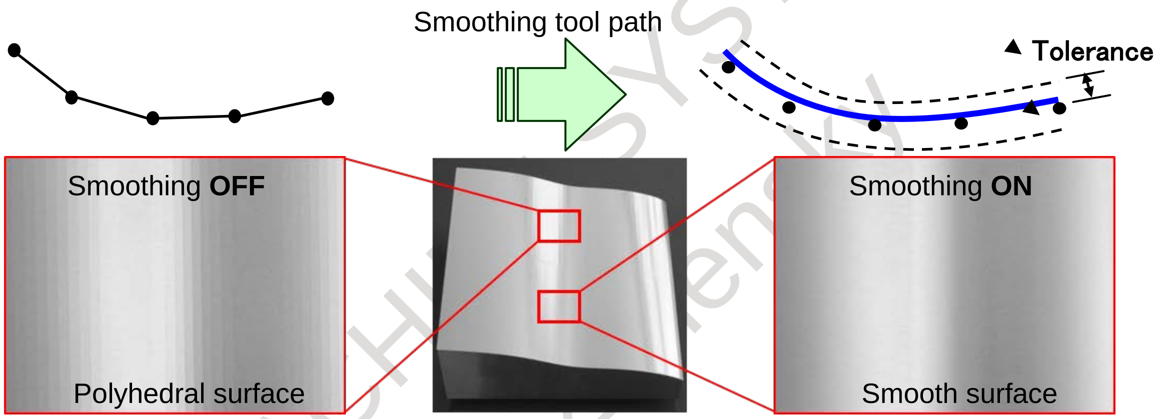


Fig. 6.12 (a) Smoothing small line segments

Command format (In Case of 3-axis Machining)

G05.1 Q3 Xp0 Yp0 Zp0;	**Smooth tolerance+ control mode on**
G10.8 L4 Q_;	**Specify tolerance**
:	
G05.1 Q0;	**Smooth tolerance+ control mode off**

Xp: X-axis or an axis parallel to the X-axis
Yp: Y-axis or an axis parallel to the Y-axis
Zp: Z-axis or an axis parallel to the Z-axis
Q: Tolerance for linear axis on curves

NOTE
1 Specify G05.1 Q3 alone in a block.
(To avoid specifying any other G code in the same block)
2 Unit of "Q" in G10.8 command depends on the increment system of the basic axis.
3 The value of parameter No. 11786 is effective as tolerance between G05.1 Q3 command and G10.8 L4 command.

4 Smooth tolerance^{+} control is disabled when the tolerance for linear axis is set to 0.
5 Smooth tolerance^{+} control mode is activated at the start of automatic operation by setting bit 0 (CAT) of parameter No. 11785.

Description of the Function

- Automatically turning on AI contour control with Smooth tolerance^{+} control

Specifying G5.1 Q3 also enables Smooth tolerance^{+} control and AI contour control to be turned on at the same time.
The automatic velocity control by AI contour control reduces impacts on the mechanical system.

- Conditions for enabling Smooth tolerance^{+} control

Smooth tolerance^{+} control is enabled when the following conditions are satisfied.
In a block that does not satisfy the conditions for enabling it, Smooth tolerance^{+} control is canceled, and it is judged
in the next block whether to perform Smooth tolerance^{+} control again.

- The mode is all of the following:
  - Cutting mode (G64)
  - Linear interpolation (G01)
  - Feed per minute (G94, however G98 in G code system A of T series)
    or Feed per revolution(G95, however G99 in G code system A of T series)
  - Constant surface speed control cancel (G97)
  - Normal direction control cancel (G40.1)
  - Polar coordinate command cancel (G15)
  - Polar coordinate interpolation cancel (G13.1)
  - Polygon turning cancel (G50.2)
- The block does not contain a one shot G code command.
- The block does not contain MST command.
- The block does not suppress look ahead (buffering).
- The block contains a move for at least a linear axis.
- The block contains a move command for only axes subject to Smooth tolerance^{+} control.
- The difference between a radius at the beginning point and a radius at the end point is less than 20µm.
- Smooth tolerance^{+} control disable signal STCD <Gn599.2> is “0”.
- Block length is less than the value of parameter No. 19595.

- Interlock

When an axis for Smooth tolerance^{+} control is interlocked, all axes are interlocked in the block which Smooth tolerance^{+} control is enabled, even if the interlocked axis is not commanded in the block.

- Axis moving signals

In the block which Smooth tolerance^{+} control is enabled, axis moving signals MV1 to MV8 <Fn102> for axes for Smooth tolerance^{+} control are set to one regardless of the movement.

- Use with other functions

In the case Smooth tolerance^{+} control is used with the following functions, it controls paths which each function is applied.

- Cutter compensation and tool nose radius compensation
- Tool length compensation
- Programmable mirror image
- Scaling
- Coordinate system rotation

Use with cutter compensation and tool nose radius compensation

In case using cutter compensation and tool nose radius compensation, Smooth tolerance+ control works for paths cutter compensation and tool nose radius compensation applied.

- Status display in the Smooth Tolerance+ control mode

Character string “TOLCON” blinks in the status bar when Smooth tolerance+ control mode is enabled.

Fig. 6.12 (b) Status display in the Smooth Tolerance+ control mode

6.12.1 Change Tolerance in Smooth Tolerance+ Control Mode

The tolerance in smooth tolerance+ control mode can be changed any time by specifying G10.8 L4. The appropriate tolerance can be used which depends on situations in a program.

Format

Change Tolerance in Smooth Tolerance+ Control Mode

G10.8 L4 Q_ R_;	Directly specify tolerance
G10.8 L4;	Use paramter (No.11786, No.11787) as default tolerance

Q: Tolerance for linear axis on curves
R: Tolerance for rotary axis on curves

NOTE

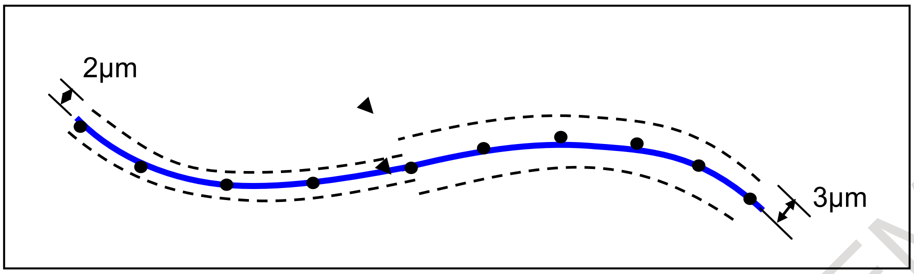
1. Specify G10.8 alone in a block. (Avoid specifying any other G code in the same block)
2. G10.8 L4 is a one-shot G code.
3. Unit of “Q” and “R” in G10.8 command depends on the increment system of the basic axis.
4. Specifying a negative value to “Q” or “R” causes alarm PS2010, “ILL. COMMAND IN TOLERANCE CON.”.
5. When G10.8 L4 specified not in smooth tolerance+ control mode (G05.1 Q3), alarm PS0412, “ILLEGAL G CODE” is issued.
6. The value of parameter No. 11786 and No. 11787 do not change by specifying G10.8 L4.

Example (1)

Here is an example for changing tolerance in smooth tolerance+ control mode.

```
O0012;
G28 G91 X0 Y0;
G05.1 Q3 X0 Y0 Z0;              (Smooth tolerance+ control mode on)
G10.8 L4 Q0.002;                (Tolerance is set.)
G00 G90 X100.0 Y100.0 Z100.0;
G01 X100.121 Y100.321 F1000;
X100.121 Y100.321;
X100.321 Y100.881;
X100.721 Y101.365;              Smoothing (Tolerance = 2μm)
  :
  :
```

```
G10.8 L4 Q0.003;          (Tolerance is changed.)
X110.121 Y120.321;  ┐
X110.321 Y120.881;  │
X110.721 Y121.365;  ├  Smoothing (Tolerance = 3µm)
   :                │
   :                ┘
G05.1 Q0;                 (Smooth tolerance+ control mode off)
M30;
```



Signal

Smooth tolerance^{+} control disable signal STCD <Gn599.2>

[Classification] Input signal

[Function] Switches Smooth tolerance^{+} control mode on / off.

[Operation] When a signal is set to "1", Smooth tolerance^{+} control is disabled.
This signal is effective for blocks analyzed after the signal switched.

> **Note**
> 1 Do not change this signal in the feed hold stop state. If this signal is changed, alarm PS2012 "ILL. OPERATION IN TOLERANCE CON." is issued in restarting operation.
> 2 Switching this signal does not mean switching Smooth tolerance^{+} control mode immediately. Actual switch takes place when Smooth tolerance^{+} control mode can be changed.

Signal address

	#7	#6	#5	#4	#3	#2	#1	#0
Gn599						STCD		

Parameter

	#7	#6	#5	#4	#3	#2	#1	#0
11785								CAT

[Input type] Parameter input
[Data type] Bit axis

#0 CAT On start up of automatic operation, smooth tolerance^{+} control is:
0: Ineffective on an axis.
1: Effective on an axis.

11786	Smoothing tolerance for linear axis in smooth tolerance^{+} control mode

[Input type] Parameter input
[Data type] Real path

[Unit of data] mm, inch (input unit)
[Min. unit of data] Depend on the increment system of the reference axis
[Valid data range] 0 or positive 9 digit of minimum unit of data (refer to the standard parameter setting table (B))
(When the increment system is IS-B, 0.000 to +999999.999)
Set tolerance for linear axes for curves generated in smooth tolerance^{+} control mode. If tolerance is not specified in tolerance mode, machining path is controlled so that the machining accuracy on curves represented by small segment is within the tolerance set to this parameter.
When this parameter is set to 0 or less, the smoothing is not effective.

11787	Smoothing tolerance for rotary axis in smooth tolerance^{+} control mode

[Input type] Parameter input
[Data type] Real path
[Unit of data] deg (machine unit)
[Min. unit of data] Depend on the increment system of the reference axis
[Valid data range] 0 or positive 9 digit of minimum unit of data (refer to the standard parameter setting table (B))
(When the increment system is IS-B, 0.000 to +999999.999)
Set tolerance for rotary axes for curves generated in smooth tolerance^{+} control mode. If tolerance is not specified in tolerance mode, machining path is controlled so that the machining accuracy on curves represented by small segment is within the tolerance set to this parameter.
When this parameter is set to 0 or less, it operates as 0.05° is set.

	#7	#6	#5	#4	#3	#2	#1	#0
11790					SMC			

[Input type] Parameter input
[Data type] Bit path

#3 SMC When smooth tolerance^{+} control is used with macro modal call, smooth tolerance^{+} control is,
0: Effective.
1: Disabled. (Temporary disabled while macro modal call is effective)

11791	Angle for breaking smoothing in smooth tolerance^{+} control mode

[Input type] Parameter input
[Data type] Real path
[Unit of data] deg
[Min. unit of data] Depend on the increment system of the reference axis
[Valid data range] 0 to 90
Set the angle to judge if smoothing of smooth tolerance^{+} control is effective or not.
When this parameter is set to 0, the smoothing is not disabled.

19595	Maximum block length for small line segments in smooth tolerance^{+} control mode

[Input type] Parameter input
[Data type] Real path
[Unit of data] mm, inch (input unit)
[Min. unit of data] Depend on the increment system of the reference axis

[Valid data range] 0 or positive 9 digit of minimum unit of data (refer to the standard parameter setting table (B))
(When the increment system is IS-B, 0.000 to +999999.999)
Set maximum block length for regarding a linear block as a small line segment in smooth tolerance+ control mode. If the block length is less than the value of this parameter, smoothing of small line segments is applied to the block.
When this parameter is set to 0 or less, smoothing is applied to any block.

19599	Maximum allowable acceleration rate for the deceleration function based on acceleration in smooth tolerance+ control mode for each axis

[Input type] Parameter input
[Data type] Real axis
[Unit of data] mm/sec2, inch/sec2, deg/sec2 (machine unit)
[Min. unit of data] Depend on the increment system of the applied axis
[Valid data range] Refer to the standard parameter setting table (D)
(When the machine system is metric system, 0.0 to +100000.0. When the machine system is inch system, machine, 0.0 to +10000.0.)
Feedrate is controlled so that acceleration produced by changing the move direction does not exceed the value specified to this parameter in smooth tolerance+ control mode.
This parameter is valid for basic 3-axes (the axes that 1, 2, 3 are set in the parameter No.1022). This parameter of the other axes is invalid, and not necessary to be set.
For an axis with 0 set in this parameter, the deceleration function based on acceleration in smooth tolerance+ control mode is disabled.
If a different value is set to this parameter for each axis, a feedrate is determined from the smallest of the acceleration rates specified for the moving axes.

Diagnosis data

5000	The index number of the spindle axis that synchronizes with each servo axis

[Data Type] Bit
TOLERANCE ON

When smooth tolerance+ control G5.1 Q3 is specified and all conditions are satisfied, "1" is indicated. G5.1 Q3 command turns on AI contour control at the same time. Therefore, the AI contour control mode signal AICC<Fn062.0> turns on.

5006	Tolerance for linear axes for curves generated in smooth tolerance+ control mode

[Data type] Real path
[Unit of data] mm/inch
[Valid data range] 0 or positive 9 digit of minimum unit of data
[Meaning] Tolerance for linear axes for curves generated in smooth tolerance+ control mode is displayed.
In the beginning of smooth tolerance+ control mode, the value of a parameter No.11786 is displayed.
When the tolerance is changed by G10.8L4, the changed tolerance is displayed.

5007	Tolerance for rotary axes for curves generated in smooth tolerance+ control mode

[Data type] Real path
[Unit of data] deg
[Valid data range] 0 or positive 9 digit of minimum unit of data
[Meaning] Tolerance for rotary axes for curves generated in smooth tolerance+ control mode is displayed.
In the beginning of smooth tolerance+ control mode, the value of a parameter No.11787 is displayed.
When the tolerance is changed by G10.8L4, the changed tolerance is displayed.

Alarm

Number	Message	Description
PS0412	ILLEGAL G CODE	Illegal G code is specified. - G10.8L4 is specified not in smooth tolerance+ control mode.
PS2010	ILL. COMMAND IN TOLERANCE CON.	Illegal command is specified in smooth tolerance+ control mode. Check the program.
PS2011	ILL. PARAMETER IN TOLERANCE CON.	Illegal parameter is set, which is related to smooth tolerance+ control. Check the parameter settings.
PS2012	ILL. OPERATION IN TOLERANCE CON.	Illegal operation is done in smooth tolerance+ control mode.

Note

- Functions Which Smooth tolerance$^+$ control Is Temporary Disabled

This function is temporary disabled when the following functions are used together.

Functions
Any kind of interpolations except liner interpolation.
Inverse time feed
Constant surface speed control cancel
Normal direction control
Polar coordinate command
Polar coordinate interpolation
Polygon turning
Tool length compensation command block
Canned cycle

- Background graphic display

The background graphic display function draws the path in Smooth tolerance+ control mode by linear interpolation.

- Functions Which Does Not Work with Smooth Tolerance$^+$ Control

This function doesn't work with the following functions.

Functions	Alarm (1)
Interruption type custom macro	PS2012

(1) Functions which issue alarms in case using with Smooth tolerance$^+$ control.

6.13 GENERAL PURPOSE RETRACT

Overview

In automatic operation mode or in manual operation mode, setting the retract signal RTRCT <Gn066.4> to 1 causes this function to capture the rise of this signal, causing the tool to move (retract) along the axis for which a retract amount is specified for parameter No. 7741. After the end of retraction, the retract completion signal RTRCTF <Fn065.4> is output. This function is intended to retract the tool from the workpiece immediately when a tool breakage is detected.

- The feedrate assumed during retract is the same as that set in parameter No. 7740. A feedrate override is invalid.
- A feed hold is invalid to movement during retraction.
- If the retract signal is set to 1 during automatic operation, a retract operation is performed and automatic operation is stopped.
- The retract completion signal becomes 0 when the tool has moved along one of the retract axes.

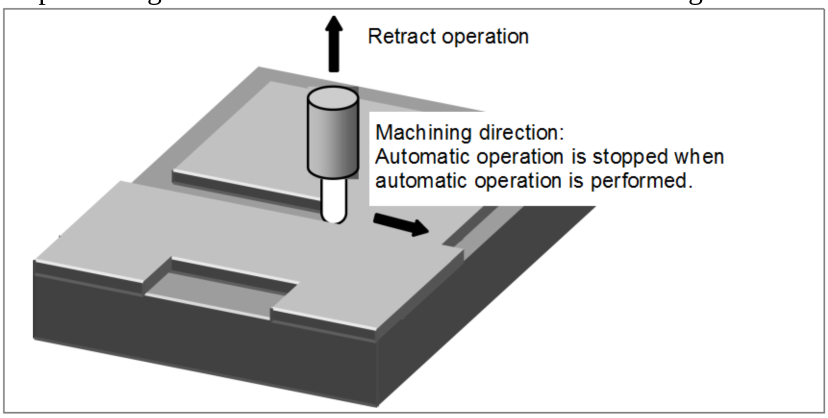


Fig. 6.13 (a)

Signal

Retract signal RTRCT<Gn066.4>

[Classification] Input signal

[Function] Causes the tool to retract along the axis for which a retract amount is set in the parameter.

[Operation] When this signal becomes 1, the CNC operates as described below.

- Captures the rise of the signal and causes the tool to retract along the axis for which a retract amount is set in parameter No. 7741. The retract amount and the retract speed assume the values previously set in parameters Nos. 7741 and 7740.
  After the end of retraction, the retract completion signal RTRCTF becomes 1.
  The retract signal is effective in either automatic operation mode (MEM, MDI) or manual mode (HNDL, JOG, etc.).
  If the retract signal is set to 1 during automatic operation, a retract operation is performed and automatic operation is stopped.

Retract completion signal RTRCTF<Fn065.4>

[Classification] Output signal

[Function] Notifies that retraction is completed.

[Output cond.] This signal becomes 1 when:

- A retract operation is completed.
  If a retract operation is performed on two or more axes, the operation is completed on all retract axes.

It becomes 0 when:

- After the end of a retract operation, a move command is issued for one of the retract axes.
- Follow-up occurs due to a servo-off, emergency stop, or other conditions.

> **NOTE**
> While the retract completion signal is 1, the retract signal cannot be accepted.

Fig. 6.13 (d)

Parameter

7740	Feedrate during retraction

[Input type] Parameter input
[Data type] Real axis
[Unit of data] mm/min, inch/min, deg/min (machine unit)
[Min. unit of data] Depend on the increment system of the applied axis
[Valid data range] Refer to the standard parameter setting table (C)
(When the increment system is IS-B, 0.0 to +999000.0)
This parameter sets the feedrate during retraction for each axis.

7741	Retract amount

[Input type] Parameter input
[Data type] Real axis
[Unit of data] mm, inch, deg (machine unit)
[Min. unit of data] Depend on the increment system of the applied axis
[Valid data range] 9 digit of minimum unit of data (refer to standard parameter setting table (A))
(When the increment system is IS-B, -999999.999 to +999999.999)
This parameter sets the retract amount for each axis.

> **NOTE**
> The tool moves (is retracted) by the specified amount regardless of whether diameter or radius programming is specified.

	#7	#6	#5	#4	#3	#2	#1	#0
7704								ACR

[Input type] Parameter input
[Data type] Bit path

#0 ACR In the AI contour control mode, general purpose retract operation is:
0: Not Used.
1: Used.

7745	Time constant for linear acceleration/deceleration in retract operation for each axis

[Input type] Parameter input
[Data type] word axis
[Unit of data] msec
[Valid data range] 0 to 1000

This parameter sets an acceleration rate for linear acceleration/deceleration in retract operation based on the general-purpose retract function. Set a time (Time constant) used to reach the federate set in parameter No.7740 for each axis.

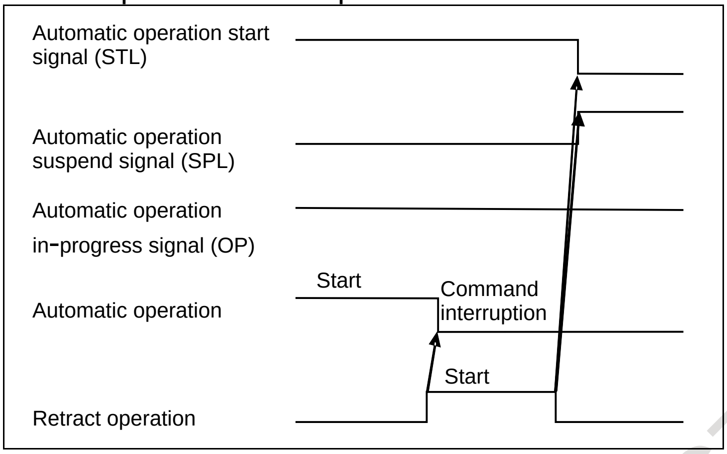
> **NOTE**
> This parameter is valid when bit 0 (ACR) of parameter No. 7704 is set to 1 to perform a retract operation in the AI contour control mode.

Caution

> ⚠ **CAUTION**
> 1 A feedrate override is invalid to the retract speed.
> 2 During a retract operation, an interlock to a retract axis is effective.
> 3 During a retract operation, a machine lock to a retract axis is effective. The retract operation is completed in the machine lock state, and the retract completion signal is output.
> 4 During retraction, a feed hold is invalid.
> 5 The retract direction is the movement direction of the machine regardless of whether a mirrored image (signal and setting) is valid or not. (A mirror image is not applied to the updating of absolute coordinates.)

⚠ CAUTION

6 When retraction is performed during automatic operation, the execution of a command is interrupted as soon as a retract operation starts. However, the operation state is switched to the automatic operation stopped state when the retract operation is completed.



7 Retract movement is effected with non-linear type positioning.

8 During a retract operation, acceleration/deceleration assumes the acceleration/deceleration state at the start of retraction. In AI contour control mode, acceleration/deceleration before interpolation is not applied to a retract operation. By setting 1 in ACR, bit 0 of parameter No. 7704, and setting a retract time constant in parameter No. 7745, it is possible to apply linear acceleration/deceleration to a retract operation in AI contour control mode.

9 During a retract operation, performing a reset or emergency stop causes the operation to be interrupted. In this case, the retract completion signal does not become 1.

10 If, during following alarms are generated, the retract operation is interrupted. In this case, the retract completion signal does not become 1.
With alarms other than following alarms, the retract operation is not interrupted
- Servo alarm
- Retract axis OT alarm
- PW alarm
- Alarm DS0001 or DS0002

11 After the start of a retract operation, setting the retract signal RTRCT to 0 does not cause the retract operation to be interrupted.

12 While the retract completion signal RTRCTF is 1, the retract signal RTRCT cannot be accepted.

13 Even while a threading command is being executed, the retract function is effective. When the retract function is executed, the threading operation is stopped immediately, and a retract operation is started.

14 Even in a canned cycle (during tapping), the retract function is effective. When the retract function is executed, the cycle operation is stopped immediately, and a retract operation is started.

15 When retraction is performed on an axis on which movement is effected with PMC axis control, the move command for the PMC axis is not canceled. If, therefore, retraction is to be performed on a PMC axis on which movement is effected, set the retract signal RTRCT to 1 and use the PMC axis reset signal ECLRg to cancel PMC axis control.

⚠ **CAUTION**

16 If an electronic gear box is attached, this function is invalid.

17 If a group that has selected flexible synchronization control wishes to perform a retract operation when a sync mode is valid, the group must set the retract function for the master axis only. If the retract function is set for the slave axis, a retract operation is not performed normally.

18 If general purpose retract is executed on an axis for which axis synchronous control is enabled, the parameters below causes a retract operation to be performed according to the settings of the master axis.
- Feedrate during retraction (parameter No. 7740)
- Retracted distance (parameter No. 7741)
- Time constant during retraction in AI contour control (parameter No. 7745)

Do not perform general purpose retract while the grid positioning automatic setup of axis synchronous control is being executed.

19 This function cannot be used for axes related to 3-dimensional coordinate system conversion.

20 When this function is used in the axis involved with Synchronous, Composite, or Superimposed control, alarm DS1934, “RETRACT CANNOT BE USED” is issued. Retract operation is not performed in the path including this axis.

7 FEEDRATE CONTROL/ACCELERATION AND DECELERATION CONTROL

7.1 FEEDRATE CONTROL

The feed functions control the feedrate of the tool. The following two feed functions are available:

1. Rapid traverse
   When the positioning command (G00) is specified, the tool moves at a rapid traverse rate set in the CNC (parameter No. 1420).
2. Cutting feed
   The tool moves at a programmed cutting feedrate.

Override can be applied to a rapid traverse rate or cutting feedrate using the override signal.

7.1.1 Rapid Traverse Rate

Overview

The positioning command (G00) positions the tool by rapid traverse.

G00 IP_ ;

G00 : G code (group 01) for positioning (rapid traverse)
IP_ : Dimension word for the end point

In rapid traverse, the next block is executed after each axis stops at the end point and the servo motor reaches a certain range set by the parameter No. 1826 (in-position check).
A rapid traverse rate is set for each axis by parameter No. 1420 or No. 1428 (before reference position establishment), so no rapid traverse rate need be programmed.
The following overrides can be applied to a rapid traverse rate with the rapid traverse override signals ROV1, ROV2<Gn014.0, 1>: F0, 25, 50, 100%
F0: Allows a fixed feedrate to be set for each axis by parameter No. 1421.
The 1% step rapid traverse override selection signal HROV<Gn096.7> or 0.1% step rapid traverse override selection signal FHROV<Gn353.7> enables a rapid traverse override to be applied in steps of 1% or 0.1% over a range of 0% to 100%.
In case that bit 4 (RF0) of parameter No. 1401 is set to 1, the machine tool stops moving when cutting feedrate override is 0% during rapid traverse.
Positioning (G00) is performed with either non-linear or linear interpolation can be specified by bit 1 (LRP) of parameter No. 1401.
Dry run for rapid traverse command is enabled by setting bit 6 (RDR) of parameter No. 1401 to 1.
For details of override, refer to “Rapid traverse override”.
For details of manual rapid traverse, refer to “JOG FEED/INCREMENTAL FEED”.

Signal

Rapid traversing signal RPDO<Fn002.1>

[Function] This signal indicates that a move command is executed at rapid traverse.
[Output cond.] 1 indicates that an axis starts moving after rapid traverse has been selected in automatic operation mode or manual operation mode.
0 indicates that an axis starts moving after a feedrate other than rapid traverse has been selected in automatic operation mode or manual operation mode.

NOTE

1 The rapid traverse in automatic operation includes all rapid traverses in canned cycle positioning, automatic reference point return, etc., as well as the move command G00. The manual rapid traverse also includes the rapid traverse in reference position return.

2 This signal may be 1 when not only during axis movement but also when the axis is stopped.Once rapid traverse has been selected and movement is started, this signal remains 1, including during a stop, until another feedrate has been selected and movement is started.

Signal address

	#7	#6	#5	#4	#3	#2	#1	#0
Fn002							RPDO	

Parameter

	#7	#6	#5	#4	#3	#2	#1	#0
1401		RDR		RF0			LRP	

[Input type] Parameter input
[Data type] Bit path

#1 LRP Positioning (G00)
0: Positioning is performed with non-linear type positioning so that the tool moves along each axis independently at rapid traverse.
1: Positioning is performed with linear interpolation so that the tool moves in a straight line.
When using 3-dimensional coordinate system conversion, set this parameter to 1.

#4 RF0 When cutting feedrate override is 0% during rapid traverse,
0: The machine tool does not stop moving.
1: The machine tool stops moving.

#6 RDR Dry run for rapid traverse command
0: Disabled
1: Enabled

1420	Rapid traverse rate for each axis

[Input type] Parameter input
[Data type] Real axis
[Unit of data] mm/min, inch/min, deg/min (machine unit)
[Min. unit of data] Depend on the increment system of the applied axis
[Valid data range] Refer to the standard parameter setting table (C)
(When the increment system is IS-B, 0.0 to +999000.0)
Set the rapid traverse rate when the rapid traverse override is 100% for each axis.

1421	F0 rate of rapid traverse override for each axis

[Input type] Parameter input
[Data type] Real axis
[Unit of data] mm/min, inch/min, deg/min (machine unit)

[Min. unit of data] Depend on the increment system of the applied axis
[Valid data range] Refer to the standard parameter setting table (C)
(When the increment system is IS-B, 0.0 to +999000.0)
Set the F0 rate of the rapid traverse override for each axis.

1826	In-position width for each axis

[Input type] Parameter input
[Data type] 2-word axis
[Unit of data] Detection unit
[Valid data range] 0 to 99999999
The in-position width is set for each axis.
When the deviation of the machine position from the specified position (the absolute value of the positioning deviation) is smaller than the in-position width, the machine is assumed to have reached the specified position. (The machine is in the in-position state.)

OPERATOR'S MANUAL (B-64694EN)	Rapid traverse

7.1.2 Cutting Feedrate Clamp

Overview

An upper limit can be set on the cutting feedrate along each axis (parameter No. 1430). If an actual cutting feedrate (with an override applied) exceeds a specified upper limit, it is clamped to the upper limit.

Parameter

1430	Maximum cutting feedrate for each axis

[Input type] Parameter input
[Data type] Real axis
[Unit of data] mm/min, inch/min, deg/min (machine unit)
[Min. unit of data] Depend on the increment system of the applied axis
[Valid data range] Refer to the standard parameter setting table (C)
(When the increment system is IS-B, 0.0 to +999000.0)
Specify the maximum cutting feedrate for each axis.

Alarm and message

Number	Message	Description
PS5009	PARAMETER ZERO (DRY RUN)	The dry run rate parameter No. 1410 or the parameter for the maximum cutting feedrate for each axis is 0. The parameter for the maximum cutting feedrate for each axis is No. 1432 if look-ahead acceleration/deceleration before interpolation is enabled and No. 1430 otherwise. Functions that cause look-ahead acceleration/deceleration before interpolation include AI contour control.

Number	Message	Description
PS5011	PARAMETER ZERO (CUT MAX)	The setting of the parameter for the maximum cutting feedrate is 0. The parameter is No. 1432 if look-ahead acceleration/deceleration before interpolation is enabled and No. 1430 otherwise. Functions that cause look-ahead acceleration/deceleration before interpolation include AI contour control.

Warning

⚠ WARNING

CNC calculation may involve a feedrate error of ±2% with respect to a specified value. However, this is not true for acceleration/deceleration. To be more specific, this error is calculated with respect to a measurement on the time the tool takes to move 500 mm or more in the steady state.

Reference item

Manual name	Item name
OPERATOR'S MANUAL (B-64694EN)	Cutting feed

7.1.3 Feed per Minute

Overview

- Feed per minute

After specifying G94 (G98 for G code system A in lathe system) (in the feed per minute mode), the amount of feed of the tool per minute is specified by setting a number after F. G94 (G98 for G code system A in lathe system) is a modal code. Once a G94 (G98 for G code system A in lathe system) is specified, it is valid until another G code belonging to the group 05, such as G95 (G99 for G code system A in lathe system) (feed per revolution) is specified. At power-on, the feed per minute mode (feed per revolution mode for lathe system and bit 4(FPM) of parameter No.3402 is set to 0) is set.

An override from 0% to 254% (in 1% steps) can be applied to feed per minute with the feedrate override signals *FV0 to *FV7 <Gn012>.

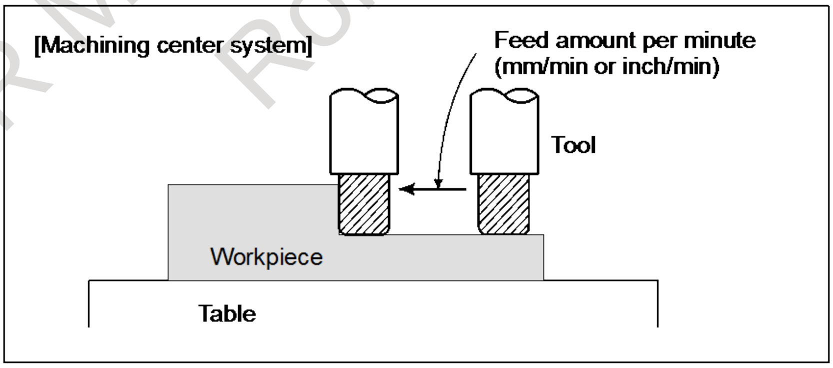

Fig. 7.1.3 Feed per minute

⚠ CAUTION

No override can be used for any commands such as for threading.

Format

M

Feed per minute

G94; **G code for feed per minute (Group 05)**
F_; **Feed rate (mm/min or inch/min)**

T

G code system A

Feed per minute

G98; **G code for feed per minute (Group 05)**
F_; **Feed rate (mm/min or inch/min)**

G code system B/C

Feed per minute

G94; **G code for feed per minute (Group 05)**
F_; **Feed rate (mm/min or inch/min)**

Note

- Feedrate (F) at the switching of feed mode

If a modal code in group 05 is switched with a feed selection command, the feedrate (F) is inherited as modal information, which means that cutting may be performed at an unintended feedrate. If switching a modal code in group 05, be sure to specify a feedrate (F).
If bit 4 (MFC) of parameter No. 13450 is set to 1, the feedrate (F) is cleared if a modal code in group 05 is switched. This causes alarm PS0011, "FEED ZERO (COMMAND)", to be issued. By inheriting the feedrate (F) as modal information, it is possible to prevent cutting from being performed at an unintended feedrate.

Example)

Execute the program below by setting bit 4 (MFC) of parameter No. 13450 to 1.
At the block for switching from G94 to G95 (N06), alarm PS0011 is issued.

```
O0001 ;
N01 G90 G00 X0.0 Y0.0 ;
N02 M03 S100 ;
N03 G91 G01 ;
N04 G94 X10.0 F100.0 ;
N05 Y10.0 ;
N06 G95 X10.0 ; ⇒ Alarm PS0011 is issued.
N07 Y10.0;
```

M

Feed selection commands are the following G codes in group 05.
G93 (inverse time feed) /G94 (feed per minute) / G95 (feed per revolution)

T

Feed selection commands are the following G codes in group 05.
G code system A
G93 (inverse time feed) /G98 (feed per minute) /G99 (feed per revolution)

G code system B/C

G93 (inverse time feed) /G94 (feed per minute) /G95（ (feed per revolution)

- Increment system of F command

The increment system of an F command in the feed per minute mode is as follows:

M

Table 7.1.3 (a) Increment system of F command (for the machining center system)

Decimal point	Metric input	Inch input
With decimal point	Depend on the increment system of the reference axis (IS-A, B, C)	
With no decimal point	1 mm/min	0.01 inch/mm

T

Table 7.1.3 (b) Increment system of F command (for the lathe system)

Decimal point	Bit 2 (FM3) of parameter No.1404	Metric input	Inch input
With decimal point	-	Depend on the increment system of the reference axis (IS-A, B, C)	
With no decimal point	0	1 mm/min	0.01 inch/min
	1	0.001 mm/min	0.00001 inch/min

Parameter

	#7	#6	#5	#4	#3	#2	#1	#0
13450				MFC				

[Input type] Parameter input
[Data type] Bit path

#4 MFC When the cutting is executed without specifying a feedrate (F) after the modal G code of group 05 was changed by G93(inverse time feed) / G94(feed per minute) / G95(feed per revolution) command,

0: The feedrate (F) is inherited as a modal.
1: Alarm PS0011, “FEED ZERO (COMMAND)” is issued.

NOTE

1 In G93 mode, if the axis command and the feedrate (F) command are not in the same block, alarm PS1202, "NO F COMMAND AT G93" is issued regardless of the setting of this parameter.

2 If this parameter bit is set to 1, and if the G code of group 05 is cleared due to a reset, by setting bit 6 (CLR) of parameter No. 3402 to 1 and bit 5 (C05) of parameter No. 3406 to 0, so that the modal G code is switched, the feedrate (F) will be cleared even if bit 7 (CFH) of parameter No. 3409 is set to 1.

3 If this parameter bit is 1, and bit 7 (FC0) of parameter No. 1404 is set to 1, alarm PS0011 is not issued and the block is executed with a feedrate of 0 even if the feed selection command is used to switch the modal code of group 05 and the axis command is executed in cutting feed mode without specifying a feedrate (F). In G93 mode, alarm PS1202 is issued regardless of the setting of the parameter bit FC0.

NOTE
4 If this parameter bit is 1, alarm PS0011 or PS1202 is not used even if the feed selection command is used to switch the modal code of group 05 and the axis command is executed in cutting feed mode without specifying a feedrate (F), provided that the travel distance is 0.
5 If this parameter bit is 1, alarms PS0011 and PS1202 are issued if the feed selection command is used to switch the modal code of group 05 and the axis command is executed in cutting feed mode without specifying a feedrate (F), even if cutting feedrate (parameter No. 1411) during automatic operation is set. (This is true of the M series.)

	#7	#6	#5	#4	#3	#2	#1	#0
1404	FC0					FM3		
	FC0							

[Input type] Parameter input
[Data type] Bit path

#2 FM3 The increment system of an F command without a decimal point in feed per minute is:
0: 1 mm/min (0.01 inch/min for inch input)
1: 0.001 mm/min (0.00001 inch/min for inch input)

#7 FC0 Specifies the behavior of the machine tool when a block (G01, G02, G03, etc.) containing a feedrate command (F command) that is 0 is issued during automatic operation, as follows:
0: An alarm PS0011, “FEED ZERO (COMMAND)” occurs.
1: An alarm PS0011 does not occur, and the block is executed at feedrate 0.

NOTE
1 In inverse time feed (G93) mode, the alarm PS1202, "NO F COMMAND AT G93" is issued irrespective of the setting of this parameter.
2 This parameter is set from 1 to 0, if a bit 6 (CLR) of parameter No. 3402 is 1, reset the CNC. Or if CLR is 0, turn off and on the CNC.

1411	Cutting feedrate

NOTE
When this parameter is set, the power must be turned off before operation is continued.

[Input type] Setting input
[Data type] Real path
[Unit of data] mm/min, inch/min, deg/min (input unit)
[Min. unit of data] Depend on the increment system of the reference axis
[Valid data range] Refer to the standard parameter setting table (C)
(When the increment system is IS-B, 0.0 to +999000.0)

A cutting feedrate can be specified with this parameter for a machine which does not have to change the cutting feedrate frequently during machining. This eliminates the need to specify a cutting feedrate (F code) in the NC program.

	#7	#6	#5	#4	#3	#2	#1	#0
3402		CLR		FPM				
		CLR						

[Input type] Parameter input
[Data type] Bit path

#4 FPM At power-on time or in the cleared state:
0: G99 or G95 mode (feed per revolution) is set.
1: G98 or G94 mode (feed per minute) is set.

#6 CLR RESET key on the MDI unit, external reset signal ERS<Gn008.7>, reset and rewind signal RRW<Gn008.6>, and emergency stop signal
0: Cause reset state.
1: Cause clear state.
For the reset and clear states, refer to Appendix in the OPERATOR'S MANUAL.

	#7	#6	#5	#4	#3	#2	#1	#0
3406			C05					

[Input type] Parameter input
[Data type] Bit

#5 C05 If bit 6 (CLR) of parameter No. 3402 is set to 1, set a G code of group 05 to be placed in the cleared state when the CNC is reset by the RESET key of the MDI unit, the external reset signal ERS<Gn008.7>, the reset and rewind signal RRW<Gn008.6>, or the emergency stop signal.
The table below indicates the correspondence between bits and G code groups
The setting of a bit has the following meaning:
0: Places the G code group in the cleared state.
1: Does not place G code group in the cleared state.

	#7	#6	#5	#4	#3	#2	#1	#0
3409	CFH							

[Input type] Parameter input
[Data type] Bit

#7 CFH When bit 6 (CLR) of parameter No. 3402 is 1, the RESET key on the MDI unit, the external reset signal ERS<Gn008.7>, the reset and rewind signal RRW<Gn008.6>, or emergency stop will,
0: Clear F codes, H codes (for the M series), D codes (for the M series), and T codes (for the T series).
1: Not clear F codes, H codes (for the M series), D codes (for the M series), and T codes (for the T series).

Alarm and message

Number	Message	Description
PS0011	FEED ZERO (COMMAND)	The cutting feedrate instructed by an F code has been set to 0. This alarm is also generated if the F code instructed for the S code is set extremely small in a rigid tapping instruction as the tool cannot cut at the programmed lead.
PS1202	NO F COMMAND AT G93	The F code in inverse time feed mode (G93) is not regarded as being modal. It must be specified for each block.

OPERATOR'S MANUAL (B-64694EN)	Cutting feed

7.1.4 Feed per Revolution/Manual Feed per Revolution

Overview

- Feed per revolution

After specifying G95 (G99 for lathe system) (in the feed per revolution mode), the amount of feed of the tool per spindle revolution is to be directly specified by setting a number after F. G95 (G99 for lathe system) is a modal code. Once a G95 is specified, it is valid until G94 (G98 for lathe system) (feed per minute) is specified.
An override of between 0 and 254% (in steps of 1%) can be applied to feed per revolution, using the feedrate override signals *FV0 to *FV7 <Gn012>.

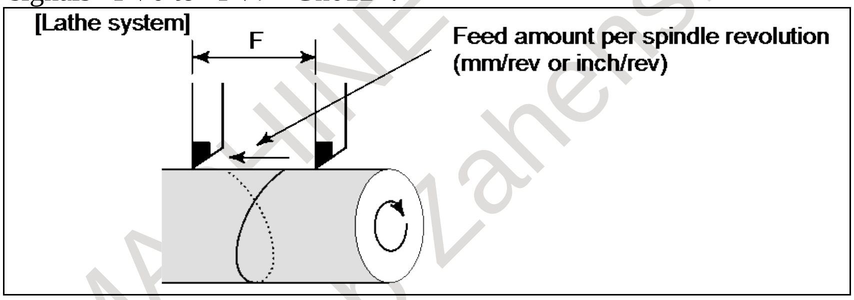

Fig. 7.1.4 (a) Feed per revolution

- Feed per revolution without the position coder

If bit 0 (NPC) of parameter No. 1402 has been set to 1, feed per revolution commands can be specified even when a position coder is not being used. (The CNC converts feed per revolution commands to feed per minute commands.)

- Manual feed per revolution

Jog feedrate can be specified by feed per revolution. An override from 0% to 655.34% (in 0.01% steps) can be applied to manual feed per revolution with the feedrate override signals *JV0 to *JV15 <Gn010,Gn011>.

> **NOTE**
> 1 Manual per revolution feed is not available at the setting of without the position coder (setting bit 0 (NPC) of parameter No.1402 to 1 or bit 1 (FPR) of parameter No.3729 to 1).

NOTE

2 When multi spindle control is enabled and the multiple position coders are used, the target feedback pulses from the position coder for manual per revolution feed is selected with a position coder select signal (PC2SLC<Gn028.7>, PC3SLC<Gn026.0>, PC4SLC <Gn026.1>). And in addition, when multi path control is enabled, an arbitrary position coder can be selected by combining a path spindle feedback selection signals (SLPCA<Gn064.2>, SLPCB<Gn064.3>, SLPCC<Gn403.4>, SLPCD<Gn403.5>). For the selection of a position coder, see the section of "Multi spindle" and "Path spindle control".

3 The command G95 (G99 for lathe system) is not necessary to validate the manual feed per revolution.

Parameter

	#7	#6	#5	#4	#3	#2	#1	#0
1402				JRV				NPC

[Input type] Parameter input
[Data type] Bit path

#0 NPC Feed per revolution without the position coder (function for converting feed per revolution F to feed per minute F in the feed per revolution mode (G95)) is:
0: Not used
1: Used

#4 JRV Jog feed or incremental feed is
0: Performed at feed per minute.
1: Performed at feed per rotation.

NOTE
Specify a feedrate in parameter No. 1423.

1423	Feedrate in manual continuous feed (jog feed) for each axis

[Input type] Parameter input
[Data type] Real axis
[Unit of data] mm/min, inch/min, deg/min (machine unit)
[Min. unit of data] Depend on the increment system of the applied axis
[Valid data range] Refer to the standard parameter setting table (C)
(When the increment system is IS-B, 0.0 to +999000.0)
(1) When bit 4 (JRV) of parameter No. 1402 is set to 0 (feed per minute), specify a jog feedrate (feed per minute) under an override of 100%.
(2) When bit 4 (JRV) of parameter No. 1402 is set to 1 (feed per revolution), specify a jog feedrate (feed per revolution) under an override of 100%.

NOTE
This parameter is clamped to the axis-by-axis manual rapid traverse rate (parameter No. 1424).

	#7	#6	#5	#4	#3	#2	#1	#0
3107					GSC			

[Input type] Setting input

[Data type] Bit path

#3 GSC The feedrate to be displayed:
0: Is a feedrate per minute.
1: Follows the setting of bit 5 (FSS) of parameter No. 3191.

	#7	#6	#5	#4	#3	#2	#1	#0
3191			**FSS**					

[Input type] Parameter input
[Data type] Bit path

#5 FSS Feedrate display is:
0: When it meets the following all requirements, display is feedrate per revolution. Besides, display is feedrate per minute.
- Group 05 G-code is feedrate per revolution.
- Other than manual feed, rapid traverse, dry run.
- During axis movement.
1: Fixed to feedrate per revolution.

> **NOTE**
> This parameter is valid only when bit 3 (GSC) of parameter No.3107 is 1.

	#7	#6	#5	#4	#3	#2	#1	#0
3729							**FPRs**	

[Input type] Parameter input
[Data type] Bit spindle

#1 FPRs Feed per revolution (without a position coder) is:
0: Not used for a spindle.
1: Used for a spindle.
In a machine that does not use a position coder, when FPRs is set to 1 for each spindle, feed per revolution can be performed with a spindle command. A feed per revolution is specified with G95 (G99 for lathe systems) in the same way as for normal operation.
When multispindle control is performed, the target spindle for feed per revolution is selected with a position coder select signal (PC2SLC<Gn028.7>, PC3SLC<Gn026.0>, PC4SLC <Gn026.1>).

> **NOTE**
> Enable constant surface speed control (bit 0 (SSC) of parameter No.8133 is 1).

Caution

> ⚠ **CAUTION**
> When the speed of the spindle is low, feedrate fluctuation may occur.
> The slower the spindle rotates, the more frequently feedrate fluctuation occurs.

OPERATOR'S MANUAL (B-64694EN)	Cutting feed

7.1.5 One-digit F Code Feed

M

Overview

- One-digit F code feed

When a one-digit number from 1 to 9 is specified after F, the feedrate set for that number in a parameters Nos. 1451 to 1459 is used. When F0 is specified, the rapid traverse rate is applied.
Acceleration/deceleration of the one-digit F code feed is same as cutting feed.
By setting the one-digit F code feed signal F1D <Gn016.7> to 1 and rotating the manual pulse generator, the feedrate of the currently selected number is decreased or increased.
The increment/decrement, ΔF, in feedrate per scale of the manual pulse generator is as follows:

$$\Delta F = \frac{Fmax}{100n}$$

Fmax : Feedrate upper limit for F1-F4 set by parameter 1460, or feedrate upper limit for F5-F9 set by parameter 1461
n : Any value of 1 to 127 set by parameter 1450
The feedrate set or altered is kept even while the power is off. The current feedrate is displayed on the screen.

- Cutting feed override during one-digit F code feed

In case bit 7 (F1O) of parameter No. 1406 is set to 1, the following functions are enabled for a cutting feedrate during one-digit F code feed:

- Feedrate override
- Second feedrate override
- Override cancel

Even during machining using one-digit F code feed, the feedrate can be freely changed, within an applicable override range, from the parameter-set value by changing the override switch.

Signal

One-digit F code feed signal F1D<Gn016.7>

[Classification] Input signal
[Function] Increases or decreases one-digit F speed set by the parameters Nos. 1451 to 1459 using the manual pulse generator.
Since the manual pulse generator may also be used for axis feeding, signal F1D <G016.7> designates which function may be used.
[Operation] When the signal is 1, the one-digit F speed can be increased/decreased using the manual pulse generator.

Signal address

	#7	#6	#5	#4	#3	#2	#1	#0
G016	F1D							

Parameter

	#7	#6	#5	#4	#3	#2	#1	#0
1406								
	F1O							

[Input type] Parameter input
[Data type] Bit path

#7 F1O For the cutting feedrate specified by a single-digit F code (F1 to F9), feedrate override, second feedrate override, and override cancellation are:
0: Disabled.
1: Enabled.

> **NOTE**
> For the F0 feedrate, rapid traverse override is enabled regardless of the setting of this parameter.

1450	
	Change of feedrate for one graduation on the manual pulse generator during one-digit F feed code

[Input type] Parameter input
[Data type] Byte path
[Valid data range] 1 to 127

Set the constant that determines the change in feedrate as the manual pulse generator is rotated one graduation during one-digit F feed code.

$$\Delta F = \frac{F\max i}{100n} \quad \text{(where, i=1 or 2)}$$

In the above equation, set n. That is, the number of revolutions of the manual pulse generator, required to reach feedrate Fmaxi is obtained. Fmaxi refers to the upper limit of the feedrate for a one-digit F code feed command, and set it in parameter No. 1460 or 1461.
Fmax1: Upper limit of the feedrate for F1 to F4 (parameter No. 1460)
Fmax2: Upper limit of the feedrate for F5 to F9 (parameter No. 1461)

1451	
	Feedrate for F1
to	to
1459	
	Feedrate for F9

[Input type] Setting input
[Data type] Real path
[Unit of data] mm/min, inch/min, deg/min (machine unit)
[Min. unit of data] Depend on the increment system of the reference axis
[Valid data range] Refer to the standard parameter setting table (C)
(When the increment system is IS-B, 0.0 to +999000.0)

These parameters set the feedrates for one-digit F code feed commands F1 to F9. When a one-digit F code feed command is specified, and the feedrate is changed by turning the manual pulse generator, the parameter-set value also changes accordingly.

1460	Upper limit of feedrate for F1 to F4

1461	Upper limit of feedrate for F5 to F9

[Input type] Parameter input
[Data type] Real path
[Unit of data] mm/min, inch/min, deg/min (machine unit)
[Min. unit of data] Depend on the increment system of the reference axis
[Valid data range] Refer to the standard parameter setting table (C)
(When the increment system is IS-B, 0.0 to +999000.0)
Set the upper limit of feedrate for the one-digit F code feed command.
As the feedrate increases by turning the manual pulse generator, the feedrate is clamped when it reaches the upper limit set. If a one-digit F feed command F1 to F4 is executed, the upper limit is that set in parameter No. 1460. If a one-digit F code feed command F5 to F9 is executed, the upper limit is that set in parameter No. 1461.

Manual name	Item name
OPERATOR'S MANUAL (B-64694EN)	Cutting feed

7.1.6 Inverse Time Feed

Overview

Feedrate of the tool can be specified by the move distance of the block and inverse time (FRN).

- Linear interpolation (G01)

FRN=1/Time (min) = Speed/Distance
Speed : mm/ min (metric input)
inch/ min (inch input)
Distance : mm (metric input)
inch (inch input)

- Circular interpolation (G02, G03)

FRN=1/Time (min) = Speed/Circle radius
Speed : mm/ min (metric input)
inch/ min (inch input)
Circle radius : mm (metric input)
inch (inch input)

A value from 0.001 to 9999.999 can be specified as FRN, regardless of whether the input mode is inches or metric, or the increment system is IS-B or IS-C.

F code specification value	FRN
F1	0.001
F1 (*1)	1.000
F1.0	1.000
F9999999	9999.999
F9999 (*1)	9999.000
F9999.999	9999.999

(NOTE)*1: Value specified in fixed-point format with bit 0 (DPI) of parameter No. 3401 set to 1

G code for inverse time feed is a modal G code and belongs to group 05 (includes G code for feed per revolution and G code for feed per minute).
When an F value is specified in inverse time specification mode and the feedrate exceeds the maximum cutting feedrate, the feedrate is clamped to the maximum cutting feedrate.
In the case of circular interpolation, the feedrate is calculated not from the actual amount of movement in the block but from the arc radius. This means that actual machining time is longer when the arc radius is longer than the arc distance and shorter when the arc radius is shorter than the arc distance. Inverse time feed can also be used for cutting feed in a canned cycle.

NOTE

1. In the inverse time specification mode, an F code is not handled as a modal code and therefore needs to be specified in each block. If an F code is not specified, alarm PS1202, "NO F COMMAND AT G93 " is issued.
2. When F0 is specified in inverse time specification mode, alarm PS0011, "FEED ZERO (COMMAND)" is issued.
3. Inverse time feed cannot be used when PMC axis control is in effect.
4. If the calculated cutting feedrate is smaller than the allowable range, alarm PS0011, "FEED ZERO (COMMAND)" is issued.

Example

- For linear interpolation (G01)

$$FRN = \frac{1}{time(min)} = \frac{feedrate}{distance}$$

Feedrate: mm/min (for metric input)
inch/min (for inch input)
Distance: mm (for metric input)
inch (for inch input)

- To end a block in 1 (min)

$$FRN = \frac{1}{time(\text{min})} = \frac{1}{1(\text{min})} = 1$$ Specify F1.0.

- To end a block in 10 (sec)

$$FRN = \frac{1}{time(\text{sec})/60} = \frac{1}{10/60(\text{sec})} = 6$$ Specify F6.0.

- To find the movement time required when F0.5 is specified

$$TIME(\text{min}) = \frac{1}{FRN} = \frac{1}{0.5} = 2$$ 2 (min) is required.

- To find the movement time required when F10.0 is specified

$$TIME(\text{min}) = \frac{1\times 60}{FRN} = \frac{60}{10} = 6$$ 6 (sec) is required.

- For circular interpolation (G02, G03)

$$FRN = \frac{1}{time(\text{min})} = \frac{feedrate}{arcradius}$$

Feedrate: mm/min (for metric input)
inch/min (for inch input)
Arc radius: mm (for metric input)
inch (for inch input)

⚠ **CAUTION**
In circular interpolation, the distance is not an actual distance of the block but the speed is calculated from the circle radius.

Alarm and message

Number	Message	Description
PS0011	FEED ZERO (COMMAND)	The cutting feedrate instructed by an F code has been set to 0. If the calculated cutting feedrate is smaller than the allowable range, this alarm is issued.
PS1202	NO F COMMAND AT G93	The F code in inverse time feed mode (G93) is not regarded as being modal. It must be specified for each block.

OPERATOR'S MANUAL (B-64694EN)	Cutting feed

7.1.7 Override

7.1.7.1 Rapid traverse override

Overview

An override of four steps (F0, 25%, 50%, and 100%) can be applied to the rapid traverse rate. F0 is set by a parameter No. 1421.
The 1% step rapid traverse override selection signal HROV<Gn096.7> or 0.1% step rapid traverse override selection signal FHROV<Gn353.7> enables a rapid traverse override to be selected in steps of 1% or 0.1% over a range of 0% to 100%.

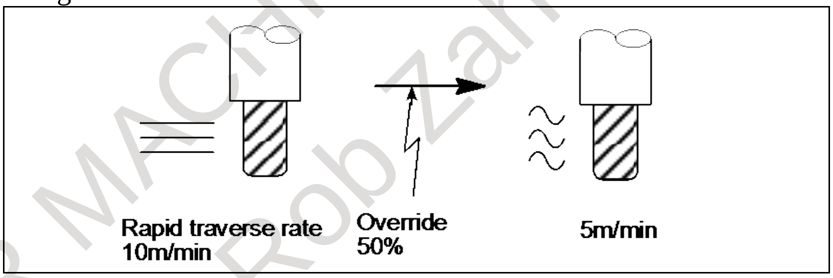

Fig. 7.1.7.1 Rapid traverse override

- Feedrate

Actual feedrate is obtained by multiplying the rapid traverse rate preset by parameter No. 1420 by the override value determined by this signal, whether in automatic or manual operation (including manual reference position return).

- F0 rate

For F0 value, an absolute value is set by parameter No. 1421 within a range of 0 to rapid traverse rate (for each axis).

- 1% step rapid traverse override

1% step rapid traverse override selection signal HROV determines whether rapid traverse override specified with rapid traverse override signals ROV1 and ROV2<Gn014.0,.1> is used or 1% step rapid traverse override is used.
When signal HROV is 0, override is applied to the rapid traverse rate using signals ROV1 and ROV2.
When signal HROV is 1, ROV1 and ROV2 are ignored, 1% step rapid traverse override signals *HROV0 to *HROV6<Gn096.0 to .6> being used to override the rapid traverse rate.

- 0.1% step rapid traverse override

With the 0.1% step rapid traverse override selection signal FHROV, a 1% step rapid traverse override or 0.1% step rapid traverse override can be selected for use.
When the HROV signal is set to 1 and the FHROV signal is set to 0, a 1% step rapid traverse override is applied.
When the HROV and FHROV signals are both set to 1, the 1% step rapid traverse override is disabled, and the rapid traverse override specified by the 0.1% step rapid traverse override signals *FHRO0 to *FHRO9<Gn352.0 to .7,Gn353.0 to .1> is enabled.

- PMC axis control

The rapid traverse override is enabled even in the PMC axis control. The rapid traverse override signals EROV1, EROV2 <Gn150.0,1> or the 1% step rapid traverse override signals *EROV0g to *EROV7g<Gn151> for PMC axis control is enabled even in case that a bit 2 (OVE) of parameter No.8001 is set to 1. The valid signal for PMC axis control follows the setting of bit 1 (OVR) of parameter No. 8013.

- Cutting feedrate override 0%

In case that the RF0 bit (bit 4 of parameter No.1401) is set to 1, when cutting feedrate override is 0% during rapid traverse, the machine tool stops moving.

Signal

Rapid traverse override signal ROV1,ROV2<Gn014.0 to 1>

[Classification] Input signal
[Function] These signals override the rapid traverse rate
[Operation] These two code signals correspond to the rates as follows (Table 7.1.15 (a)):

Table 7.1.7.1 Signals ROV1 to ROV2 and override value

Rapid traverse override		Override value
ROV2	ROV1	
0	0	100%
0	1	50%
1	0	25%
1	1	F0

F0 : Set in parameter No. 1421

1% step rapid traverse override selection signal HROV<Gn096.7>

[Classification] Input signal
[Function] Selects the rapid traverse override signals or the 1% step rapid traverse override signals.
[Operation] When this signal is set to 1, the values of *HROV0 to *HROV6 are enabled. (Rapid traverse override by signals ROV1 and ROV2 is disabled.)
When this signal is set to 0, Rapid traverse override by signals ROV1 and ROV2 is enabled. (the values of *HROV0 to *HROV6 are disabled.)

1% step rapid traverse override signals *HROV0 to *HROV6<Gn096.0 to 6>

[Classification] Input signal
[Function] Applies override to the rapid traverse rate in the range of 0% to 100% in steps of 1%.
[Operation] These seven signals give a binary code indicating an override value applied to the rapid traverse rate.

- When a binary code corresponding to an override value of 101% to 127% is specified, the applied override is clamped at 100%.
- Signals *HROV0 to *HROV6 are inverted signals.

To set an override value of 1%, set signals *HROV0 to *HROV6 to 1111110, which corresponds to a binary code of 0000001.

0.1% step rapid traverse override selection signal FHROV<Gn353.7>

[Classification] Input signal

[Function] Selects whether 1% rapid traverse override signals or 0.1% step rapid traverse override signals are enabled when the HROV signal is set to 1.

[Operation] When this signal is set to 1, the values of *FHRO0 to *FHRO9 are enabled. (The values of the *HROV0 to *HROV6 signals are invalidated.)
When this signal is set to 0, the values of *HROV0 to *HROV6 are enabled. (The values of the *FHRO0 to *FHRO9 signals are invalidated.)

0.1% step rapid traverse override signals *FHRO0 to *FHRO9<Gn352.0 to 7, Gn353.0 to 1>

[Classification] Input signal

[Function] Applies override to the rapid traverse rate in the range of 0% to 100% in steps of 0.1%.

[Operation] These ten signals give a binary code indicating an override value applied to the rapid traverse rate.

- When a binary code corresponding to an override value of 100.1 to 102.3% is specified, the applied override is clamped at 100%.
- Signals *FHRO0 to *FHRO9 are inverted signals.
  To set an override value of 0.1%, set signals *FHRO0 to *FHRO9 to 1111111110, which corresponds to a binary code of 0000000001.

Rapid traverse override signals EROV1, EROV2 <Gn150.0,1>

[Classification] Input signal, path-by-path signal

[Function] Applies rapid traverse override.

[Operation] These signals can be used to select the override for the rapid traverse rate, independently of the CNC, by setting of the bit 2 (OVE) of parameter No. 8001.

Rapid traverse override signals		Override value
EROV2	EROV1	
0	0	100%
0	1	50%
1	0	25%
1	1	F0

F0 is the minimum feedrate specified with parameter No. 1421.

1% step rapid traverse override signals *EROV0g to *EROV7g<Gn151 (, G163, G175, G187)>

[Classification] Input signal, path-by-path signal (group-by-group signal)

[Function] These signals use the same addresses as the feedrate override signals. When bit 1 (OVR) of parameter No. 8013 is set to 1, these signals are used for rapid traverse override.

[Operation] When bit 2 (OVE) of parameter No. 8001 is set to 1 and bit 1 (OVR) of parameter No. 8013 is set to 1, these signals can be used to select the override for the rapid traverse rate, in steps of 1% from 0% to 100%, independently of the CNC. The override is clamped to 100%.
Each corresponding signal has the following significance:

*EROV7 = 100%	*EROV3 = 8%
*EROV6 = 64%	*EROV2 = 4%
*EROV5 = 32%	*EROV1 = 2%
*EROV4 = 16%	*EROV0 = 1%

For example, to set an override of 5%, set signals *EFOV7 to *EFOV0 to 11111010, which corresponds to a binary code of 00000101.

When bit 7 (IFH) of parameter No. 11850 is set to 0, these signals are used as path-by-path signals. When the bit is set to 1, they are used as group-by-group signals.

> **NOTE**
> When all signals are set to “0”, an override of 100% is assumed, while an override of 0% is assumed for *EFOVg.

7.1.7.2 Feedrate override

Overview

A programmed feedrate can be reduced or increased by a percentage (%) selected by the override dial. This feature is used to check a program.
For example, if the programmed feedrate is 100 mm/min, by setting the override value to 50% by using the feedrate override signals *FV0 to *FV7 <Gn012>, it is possible to move the tool at 50 mm/min.

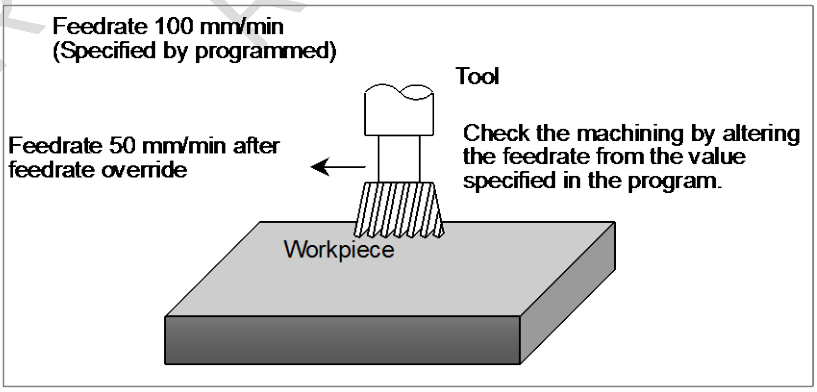

Fig. 7.1.7.2 Feedrate override

Limitation

M

- Cutting feed override during one-digit F code feed

The feedrate override, the second feedrate override and the override cancel are disabled for a cutting feedrate during one-digit F code feed. However, they are enabled in case that a bit 7 (F1O) of parameter No.1406 is set to 1.

- Cutting feed override during rigid tapping

The feedrate override, the second feedrate override and the override cancel are disabled for cutting/extraction operation in rigid tapping. However, they are enabled in case that a bit 4 (OVS) of parameter No.5203 is set to 1.

- Cutting feed override in PMC axis control

The feedrate override and the override cancel are enabled even in the PMC axis control. However, signals specific to PMC are enabled in case that a bit 2 (OVE) of parameter No.8001 is set to 1.

Signal

Feedrate Override signal *FV0 to *FV7<Gn012>

[Classification] Input signal

[Function] These signals override the cutting feedrate. Eight binary code signals correspond to override values as follows:

Override value= $\sum_{i=0}^{7} | 2^{i} \times Vi | \%$

Vi=0 when *FVi is 1 and
Vi=1 when *FVi is 0

These signals have the following weight.

*FV0 : 1% *FV1 : 2%
*FV2 : 4% *FV3 : 8%
*FV4 : 16% *FV5 : 32%
*FV6 : 64% *FV7 : 128 %

When all signals are 0, they are regarded as overriding 0% in the same way as when all signals are 1 .

Thus, the override is selectable in steps over a range of 0 to 254%.

[Operation] Actual feedrate is obtained by multiplying the specified speed by the override value selected by this signal.

The override is regarded as 100%, regardless of this signal, in the following cases:

- Override cancel signal OVC<Gn006.4> is 1.
- During cutting in tap cycle of canned cycle;
- Tapping mode (G63)
- Thread cutting is in progress.

Some examples are listed below.

Table 7.1.7.2 Example of feedrate override

*FV0 to *FV7								Override vlue (%)
7	6	5	4	3	2	1	0	
1	1	1	1	1	1	1	1	0

OPERATOR'S MANUAL (B-64694EN)	Cutting feed

7.1.7.3 Second feedrate override

Overview

An override can be applied to the cutting feedrate. The override is applied to the feedrate to which an override has been applied with the first feedrate override signals *FV0 to *FV7 <Gn012>.

(Actual feedrate) = F × FV_1 × FV_2

F: Specified cutting feedrate
FV_1: Feedrate override (%)
FV_2: Second feedrate override (%)

A percentage from 0 to 254 % can be selected in steps of 1% as the second feedrate override.
In case that a bit 3 (OV2) of parameter No.1402 is set to 1, a percentage from 0 to 655.34% can be selected in steps 0.01% as the second feedrate override.

Limitation

M

- Cutting feed override during one-digit F code feed

The feedrate override, the second feedrate override and the override cancel are disabled for a cutting feedrate during one-digit F code feed. However, they are enabled in case that a bit 7 (F1O) of parameter No.1406 is set to 1.

- Cutting feed override during rigid tapping

The feedrate override, the second feedrate override and the override cancel are disabled for cutting/extraction operation in rigid tapping. However, they are enabled in case that a bit 4 (OVS) of parameter No.5203 is set to 1.

- Cutting feed override in PMC axis control

The second feedrate override is disabled in the PMC axis control.

Signal

Second feedrate override signals *AFV0 to *AFV7<Gn013>

[Classification] Input signal
[Function] The cutting feedrate is multiplied by the second feedrate override. These eight binary code signals correspond to the override values as follows.

$$\text{Override value}=\sum_{i=0}^{7}|2^{i}\times Vi|\,\%$$

Vi=0 when *AFVi is 1 and

Vi=1 when *AFVi is 0
These signals have the following weight.
*AFV0 : 1%   *AFV1 : 2%
*AFV2 : 4%   *AFV3 : 8%
*AFV4 : 16%   *AFV5 : 32%
*AFV6 : 64%   *AFV7 : 128 %
If all signals are 0 or 1, the override is regarded as 0%. The override is selectable in steps of 1% over a range of 0 to 254%.

[Operation] In case that a bit 3 (OV2) of parameter No.1402 is set to 0, those signals are enabled.
In cutting feed during automatic operation, the actual feedrate is obtained as follows.
Actual feedrate = (Specified speed) × (First override) × (Override value specified by this signal)
Since the condition under which the first override is ignored and is set to 100% remains valid, the second feedrate override is also assumed to 100%.
Some examples are listed below.

Table 7.1.7.3 (a) Example of second feedrate override

*AFV0 to *AFV7								Override vlue (%)
7	**6**	**5**	**4**	**3**	**2**	**1**	**0**	
1	1	1	1	1	1	1	1	0
1	1	1	1	1	1	1	0	1
1	1	1	1	1	1	0	1	2
1	1	1	1	1	1	0	0	3
1	1	1	1	1	0	1	1	4
1	1	1	1	1	0	1	0	5
1	1	1	1	0	1	0	1	10
1	1	1	1	0	0	0	0	15
1	1	1	0	1	0	1	1	20
1	1	1	0	0	1	1	0	25
1	1	1	0	0	0	0	1	30
1	1	0	1	1	1	0	0	35
1	1	0	1	0	1	1	1	40
1	1	0	1	0	0	1	0	45
1	1	0	0	1	1	0	1	50
1	1	0	0	0	0	1	1	60
1	0	1	1	1	0	0	1	70
1	0	1	0	1	1	1	1	80
1	0	1	0	0	1	0	1	90
1	0	0	1	1	0	1	1	100
0	1	1	0	1	0	0	1	150
0	0	1	1	0	1	1	1	200
0	0	0	0	0	0	0	1	254
0	0	0	0	0	0	0	0	0

The value is calculated as follows.

1. In case that the override is 2%,
   (1) Convert to binary data.   0000 0010
   (2) Do logical NOT of binary data.   1111 1101
2. In case that the input signal is “1110 1110”,
   (1) Do logical NOT of binary data.   0001 0001
   (2) Convert to decimal data.   17%

> **NOTE**
> In case that the second feedrate override is enabled and the second feedrate override is not used, those signals must be set so that the override value is set to 100%.

0.01% step second feedrate override signals *APF00 to *APF15<Gn094, Gn095>

[Classification] Input signal

[Function] The cutting feedrate is multiplied by the second feedrate override. These sixteen binary code signals correspond to the override values as follows.

$$\text{Override value}=\sum_{i=0}^{15}|\,2^{i}\times Vi\,|\times 0.01\%$$

Vi=0 when *APFi is 1 and
Vi=1 when *APFi is 0
These signals have the following weight.
*APF00=0.01%, *APF01=0.02%, *APF02=0.04%, *APF03=0.08%
*APF04=0.16%, *APF05=0.32%, *APF06=0.64%, *APF07=1.28%
*APF08=2.56%, *APF09=5.12%, *APF10=10.24%, *APF11=20.48%
*APF12=40.96%, *APF13=81.92%, *APF14=163.84%, *APF15=327.68%
If all signals are 0 or 1, the override is regarded as 0%. The override is selectable in steps of 0.01% over a range of 0 to 655.34%.

[Operation] In case that a bit 3 (OV2) of parameter No.1402 is set to 1, those signals are enabled.
In cutting feed during automatic operation, the actual feedrate is obtained as follows.
Actual feedrate = (Specified speed) × (First override) × (Override value specified by this signal)
Since the condition under which the first override is ignored and is set to 100% remains valid, the second feedrate override is also assumed to 100%.
Some examples are listed below.

Table 7.1.7.3 (b) Example of 0.01% step second feedrate override

*APF00～*APF15																Override value (%)
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	
1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	0.00
1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	0	0.01
1	1	1	1	1	1	1	1	1	1	1	1	1	1	0	1	0.02
1	1	1	1	1	1	1	1	1	1	1	1	1	0	1	0	0.05
1	1	1	1	1	1	1	1	1	1	1	1	0	1	0	1	0.10
1	1	1	1	1	1	1	1	1	1	1	0	1	0	1	1	0.20
1	1	1	1	1	1	1	1	1	1	0	0	1	1	0	1	0.50
1	1	1	1	1	1	1	1	1	0	0	1	1	0	1	1	1.00

[Data type] Bit path

#4 OVS In rigid tapping, override by the feedrate override signals *FV0 to *FV7 <Gn012> and the second feedrate override signals *AFV0 to *AFV7 <Gn013> (or 0.01% step second feedrate override signals *APF00 to *APF15 <Gn094, Gn095>), and the cancellation of override by the override cancel signal OVC <Gn006.4> is:

0: Disabled.

1: Enabled.

When feedrate override is enabled, extraction override is disabled.
The spindle override is clamped to 100% during rigid tapping, regardless of the setting of this parameter.

7.1.7.4 Override cancel

Overview

The override cancel signal OVC<Gn006.4> fixes the feedrate override to 100%.

Limitation

M

- Cutting feed override during one-digit F code feed

The feedrate override, the second feedrate override and the override cancel are disabled for a cutting feedrate during one-digit F code feed. However, they are enabled in case that a bit 7 (F1O) of parameter No.1406 is set to 1.

- Cutting feed override during rigid tapping

The feedrate override, the second feedrate override and the override cancel are disabled for cutting/extraction operation in rigid tapping. However, they are enabled in case that a bit 4 (OVS) of parameter No.5203 is set to 1.

- Cutting feed override in PMC axis control

The feedrate override and the override cancel are enabled even in the PMC axis control. However, signals specific to PMC are enabled in case that a bit 2 (OVE) of parameter No.8001 is set to 1.

Signal

Override cancel signal OVC<Gn006.4>

[Classification] Input signal

[Function] Feedrate override is fixed to 100%.

[Operation] When the signal is 1, the CNC operates as follows:

- The feedrate override is fixed to 100% regardless of the feedrate override signals *FV0 to *FV7 <Gn012> or second feedrate override signals *AFV0 to *AFV7 <Gn013> (or 0.01% step second feedrate override signals *APF00 to *APF15 <Gn094, Gn095>). That is, the specified feedrate is used as is.
- Rapid traverse override and spindle speed override are not affected.

7.1.8 Automatic Corner Override

M

The movement of a tool in an inner corner or an inner arc is automatically decelerated during cutter compensation, so that the load on the tool is reduced, and a surface obtained by cutting becomes smooth.

7.1.8.1 Inner corner automatic override (G62)

Explanation

- Overriding conditions

When G62 is specified, and the tool path with cutter compensation applied forms an inner corner, the feedrate is automatically overridden at both ends of the corner.

There are four types of inner corners (Fig. 7.1.8.1 (a)).

$2° \leq \theta \leq \theta p \leq 178°$ in Fig. 7.1.8.1 (a)

θp is a value set with parameter No. 1711. When θ is approximately equal to θp, the inner corner is determined with an error of 0.001° or less.

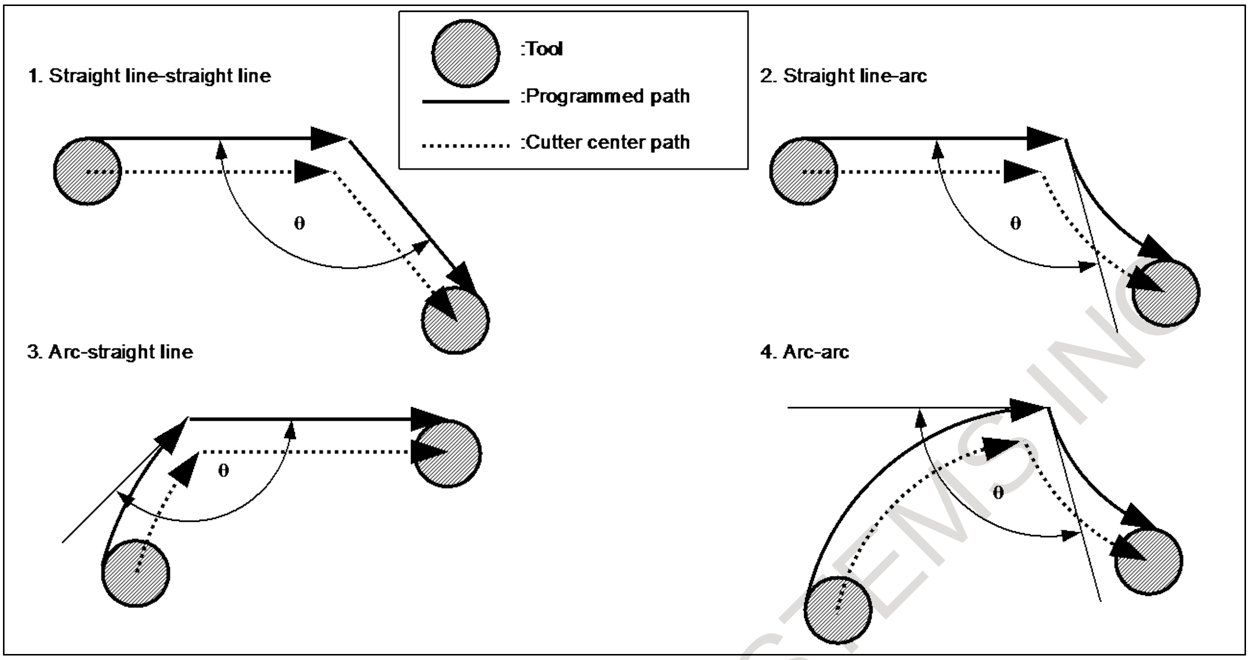

Fig. 7.1.8.1 (a) Inner corner

- Overriding range

When an inner corner is found, the feedrate is overridden before and after the intersection of the corresponding tool paths. Feedrate override distances Le and Ls are linear dimensions between the intersection of the tool paths and a point on either cutter center path (Fig. 7.1.8.1 (b), Fig. 7.1.8.1 (c), Fig. 7.1.8.1 (d)). Le and Ls are specified in parameters Nos.1713 and 1714.

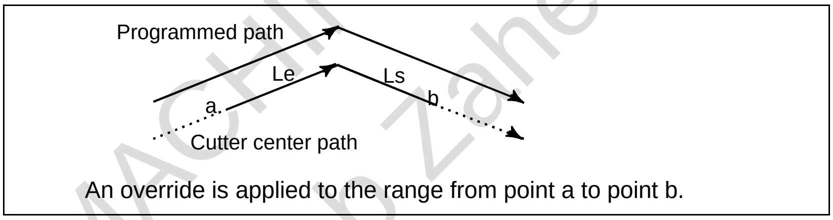

Fig. 7.1.8.1 (b) Overriding range (straight line - straight line)

An arc-shaped path is overridden if the start point and end point of the arc is in the same quadrant or in two adjacent quadrants (Fig. 7.1.8.1 (c)).

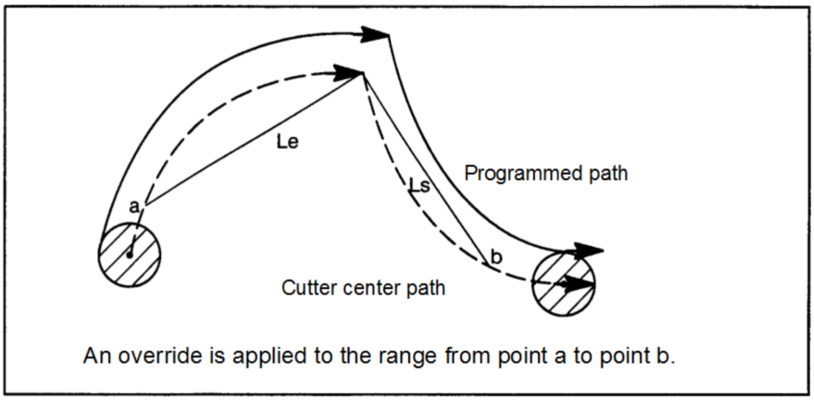

Fig. 7.1.8.1 (c) Overriding range (arc - arc)

On arc-shaped path <2> programmed as indicated below, an override occurs between points a and b and between points c and d (Fig. 7.1.8.1 (d)).

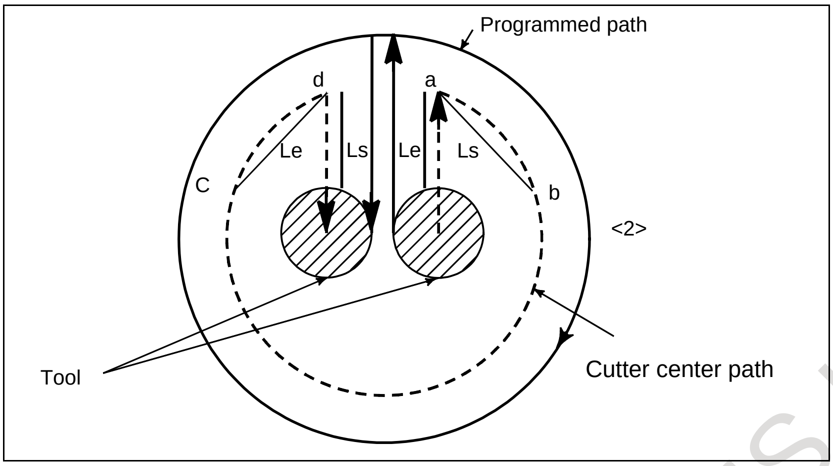

Fig. 7.1.8.1 (d) Overriding range (straight line - arc, arc - straight line)

- Override value

An override value is set with parameter No. 1712. An override value is valid even for dry run and F1-digit feed specification.
In the feed per minute mode, the actual feedrate is as follows:
F × (inner corner automatic override) × (feedrate override)

Limitation

- Look-ahead acceleration/deceleration before interpolation

The inner corner override function is disabled during look-ahead acceleration/deceleration before interpolation.

- Start-up, G41, G42

The inner corner override function is not carried out for a corner preceded by a cutter compensation start-up block or a corner followed by a block containing G41 or G42,.

- Offset value

If the offset value is zero, the inner corner override function is not executed.

7.1.8.2 Internal circular cutting feedrate change

For internally offset circular cutting, the feedrate on a programmed path is set to a specified feedrate (F) by specifying the circular cutting feedrate with respect to F, as indicated below (Fig. 7.1.8.2). This function is valid in the cutter compensation mode, regardless of the G62 code.

$$F \times \frac{Rc}{Rp}$$

Rc: Cutter center path radius
Rp: Programmed tool path radius

It is also valid for the dry run and the one digit F cord feed.

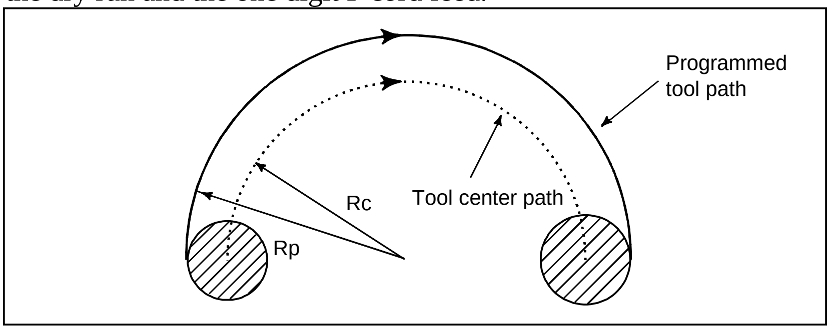

Fig. 7.1.8.2 Internal circular cutting feedrate change

If Rc is much smaller than Rp, Rc/Rp≒0; the tool stops. A minimum deceleration ratio (MDR) is to be specified with parameter No. 1710. When Rc/Rp≤MDR, the feedrate of the tool is (F×MDR).
If parameter No. 1710 is 0, the minimum deceleration ratio (MDR) is 100%.

> ⚠ **CAUTION**
> When internal circular cutting must be performed together with automatic override for inner corners, the feedrate of the tool is as follows:
> F×Rc/Rp×(inner corner override)×(feedrate override)

Parameter

	#7	#6	#5	#4	#3	#2	#1	#0
1602						**CAF**		

[Input type] Parameter input
[Data type] Bit path

#2 CAF In cutter compensation mode or tool nose radius compensation mode, the circular cutting feedrate change is;
0: Performed on the inner arc only.
1: Performed on the inner and outer arcs.

1710	Minimum deceleration ratio (MDR) for inner circular cutting feedrate change by automatic corner override

[Input type] Parameter input
[Data type] Byte path
[Unit of data] %
[Valid data range] 0 to 100

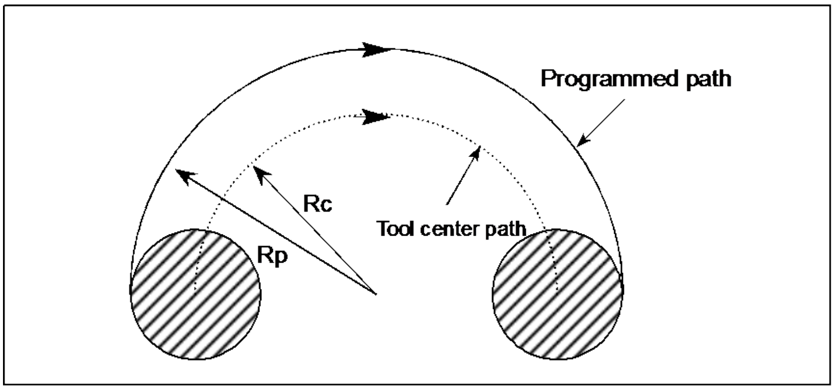
Set a minimum deceleration ratio (MDR) for an inner circular cutting feedrate change by automatic corner override.

In the case of circular cutting offset inward, the actual feedrate is determined by a specified feedrate (F) as follows:

$$F \times \frac{Rc}{Rp}$$

Rc: Radius of tool center path
Rp: Programmed radius

Thus, the feedrate along the programmed path satisfies the specified value of F.



However, if Rc is too small when compared with Rp, Rc/Rp ≒ 0 results to stop the tool. So, a minimum deceleration ratio (MDR) is set, and the feedrate of the tool is set to F×(MDR) when Rc/Rp ≤ MDR.
When this parameter is 0, the minimum deceleration ratio (MDR) is 100%.

1711	Inner determination angle (θp) for inner corner override

[Input type] Parameter input
[Data type] Real path
[Unit of data] deg
[Min. unit of data] Depend on the increment system of the reference axis
[Valid data range] 2 to 178

Set an inner determination angle for inner corner override in automatic corner overriding.

1712	Override value for inner corner override

[Input type] Parameter input
[Data type] Byte path
[Unit of data] %
[Valid data range] 1 to 100

Set an inner corner override value in automatic corner overriding.

1713	Start distance (Le) for inner corner override

[Input type] Setting input
[Data type] Real path
[Unit of data] mm, inch (input unit)
[Min. unit of data] Depend on the increment system of the reference axis
[Valid data range] 9 digit of minimum unit of data (refer to standard parameter setting table (A))
(When the increment system is IS-B, -999999.999 to +999999.999)

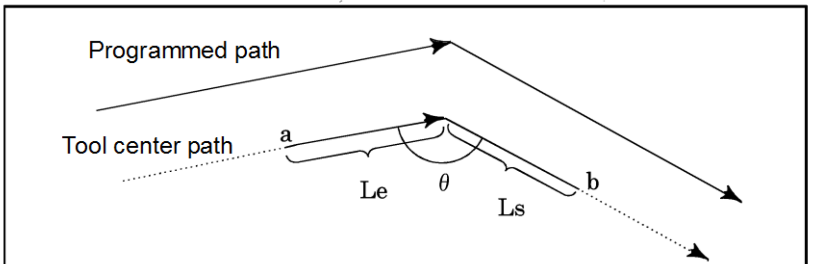
Set a start distance for inner corner override in automatic corner overriding.

1714	End distance (Ls) for inner corner override

[Input type] Setting input
[Data type] Real path
[Unit of data] mm, inch (input unit)
[Min. unit of data] Depend on the increment system of the reference axis
[Valid data range] 9 digit of minimum unit of data (refer to standard parameter setting table (A))
(When the increment system is IS-B, -999999.999 to +999999.999)

Set an end distance for inner corner override in automatic corner overriding.

When $\theta \leq \theta p$, an inner corner is assumed. (Parameter No. 1711 is used to set θp.)
When a corner is determined to be an inner corner, an override is applied to the feedrate in the range of Le in the previous block from the intersection of the corner and in the range of Ls in the next block from the intersection of the corner.
Distances Le and Ls represent linear distances from the intersection of a corner to points on the tool center path.
Le and Ls are set in parameters Nos. 1713 and 1714.



An override is applied to the range from point a to point b.

7.1.9 External Deceleration

Overview

The control axis is externally decelerated. The feedrate is decelerated by the external deceleration signals from the machine. The deceleration rate is set by the parameters.
The external deceleration signal are provided for each axis and direction.
As five types of deceleration condition settings can be dynamically selected by the signals.
External deceleration can be applied to rapid traverse rate, cutting feedrate, and manual handle feedrate.
For manual handle federate, external deceleration can be applied under the following conditions.

- Rapid traverse and cutting feed

Five types of deceleration conditions can be set by the parameters.
When deceleration conditions specified by multiple external signals input during machining are conflicted, the condition with the lowest external deceleration rate is applied.
External deceleration settings 2, 3. 4, and 5 can be switched between enabled and disabled by the parameters.

- Manual handle feed

Five types of deceleration conditions can be set by the parameters. For handle feed, the maximum feedrate is switched when the external deceleration signal in the positive or negative direction for the handle axis is set to 0. When multiple conditions are conflicted, the condition with the lowest maximum feedrate is applied.

- *Setting the parameters*

Valid / invalid of the external deceleration signals in the cutting feed and the external deceleration rate for linear interpolation type positioning is set by the following parameters.

No.1005#4 In cutting feed, an external deceleration signal in the + direction for each axis is disable(0) / enable(1)

No.1005#5 In cutting feed, an external deceleration signal in the - direction for each axis is disable(0) / enable(1)

No.1405#5 As the external deceleration rate for linear interpolation type positioning, the external deceleration rate for cutting feed is used(0) / the external deceleration rate in rapid traverse for the 1st axis in the entire system is used(1)

External deceleration settings 1～5 are set by the following parameters.

External deceleration / Meaning	Setting 1	Setting 2	Setting 3	Setting 4	Setting 5
Valid / invalid of the external deceleration setting	-	No.1406#0	No.1406#1	No.12750#0	No.12750#1
External deceleration rate of cutting feed	No.1426	No.1440	No.1443	No.12751	No.12754
External deceleration rate of rapid traverse for each axis	No.1427	No.1441	No.1444	No.12752	No.12755
Maximum manual handle feedrate for each axis	No.1434	No.1442	No.1445	No.12753	No.12756

- Manual continuous feed

When the manual handle feed is enabled (bit 0 (HPG) of parameter No.8131) is 1), and the parameter No.7100#0 is set to 1, the external deceleration is enabled as same condition for the manual handle feed. Besides, the external deceleration is enabled as same condition for the rapid feed.

Signal

External deceleration signals 1
*+ED1 to *+ED8<Gn118>,*-ED1 to *-ED8<Gn120>
External deceleration signals 2
*+ED21 to *+ED28<Gn101>,*-ED21 to *-ED28<Gn103>
External deceleration signals 3
*+ED31 to *+ED38<Gn107>,*-ED31 to *-ED38<Gn109>
External deceleration signals 4
*+ED41 to *+ED48<Gn341>,*-ED41 to *-ED48<Gn342>
External deceleration signals 5
*+ED51 to *+ED58<Gn343>,*-ED51 to *-ED58<Gn344>

[Classification] Input signal

[Function] These signals specifies whether to apply external deceleration to each direction for each control axis. The sign + or - preceding ED indicates the direction of feed which is decelerated. The number following ED indicates the number of external deceleration setting. The last number indicates the number of a control axis.

* xEDyz

z : 1 ….. The 1st axis is decelerated.
2 ….. The 2nd axis is decelerated.
3 ….. The 3rd axis is decelerated.
:

y : None.. External deceleration setting 1 is selected.
2 ….. External deceleration setting 2 is selected.
3 ….. External deceleration setting 3 is selected.
4 ….. External deceleration setting 4 is selected.
5 ….. External deceleration setting 5 is selected.

x : + : The feed is decelerated in the plus (+) direction.
- : The feed is decelerated in the minus (-) direction.

[Operation] When a signal becomes 0, the corresponding axis decelerates in the specified direction.
If a specified feedrate is lower than the external deceleration rate, the specified feedrate is selected.

Manual handle feed maximum feedrate change signal HNDLF<Gn023.3>

[Classification] Input signal

[Function] This signal switches for the maximum handle feedrate.

[Operation] When this signal is 0, clamping is performed by the manual rapid traverse rate (parameter No. 1424) or parameter No. 1420. The external deceleration function is disabled for handle feed.
When this signal is 1, clamping is performed by the maximum handle feedrate (parameter No. 1434). The external deceleration function is enabled for handle feed.

[Valid data range] Refer to the standard parameter setting table (C)
(When the increment system is IS-B, 0.0 to +999000.0)
Set external deceleration rate 5 for each axis in rapid traverse.

12756	Maximum manual handle feedrate setting 5 for each axis

[Input type] Parameter input
[Data type] Real axis
[Unit of data] mm/min, inch/min, deg/min (machine unit)
[Min. unit of data] Depend on the increment system of the applied axis
[Valid data range] Refer to the standard parameter setting table (C)
(When the increment system is IS-B, 0.0 to +999000.0)
Set a maximum manual handle feedrate 5 for each axis.

7.1.9.1 Deceleration area setting

When the axis is moved to outside specified area, the feedrate can be automatically decelerated.
In area that the movement condition is severe (the end point of stroke ,etc), the feedrate can be decreased.
Therefore, the feedrate ban be increased in other areas.
This function is activated when bit 0 (ADE) of parameter No.12780 is set to 1.

NOTE
1 For this function, enable "External Deceleration"(bit 2(EDC) of parameter No.8131 is 1).
2 This function is also invalid for functions in which external deceleration is invalid.

Explanation

Set to the deceleration area by the parameter No.12781 and No.12782.
If the axis is outside this area, the feedrate is automatically reduced so that the feedrate after applying the override is less than the speed set by parameter No. 12783(rapid traverse) or No.12784(cutting feed).

	Parameter	
	Rapid traverse	Cutting feed
Deceleration rate	12783	12784

3-dimensional coordinate conversion / Tilted working plane command

When this function is used in 3-dimensional coordinate conversion / tilted working plane indexing, set the linear interpolation positioning (parameter LRP (No.1401#1)=1).

- Use with other functions

This function is disabled when the following functions are used together.
- Manual operation
- PMC control function
- Real time custom macro

- Manual handle interrupt

This function cannot be used with the following functions.
- Synchronous / Composite control
- Superimposed control

Parameter

	#7	#6	#5	#4	#3	#2	#1	#0
12780								ADE

[Input type] Parameter input
[Data type] Bit path

#0 ADE Deceleration area setting function is :
0: Disabled.
1: Enabled.

12781	Coordinate value of deceleration area (+ direction)

[Input type] Parameter input
[Data type] Real axis
[Unit of data] mm, inch, deg (machine unit)
[Min. unit of data] Depend on the increment system of the applied axis
[Valid data range] 9 digit of minimum unit of data (refer to standard parameter setting table (A))
(When the increment system is IS-B, -999999.999 to +999999.999)
Set the coordinate values of the plus direction in deceleration area boundary.
When the axis moves in the plus direction from this parameter setting value, deceleration is automatically performed so that the speed set to the following parameters is achieved.

	Parameter	
	Rapid traverse	Cutting feed
Deceleration rate	12783	12784

When the multiple axes are moving in deceleration area, the deceleration ratio is calculated for each axis, and the highest deceleration ratio is applied.

12782	Coordinate value of deceleration area (- direction)

[Input type] Parameter input
[Data type] Real axis
[Unit of data] mm, inch, deg (machine unit)
[Min. unit of data] Depend on the increment system of the applied axis
[Valid data range] 9 digit of minimum unit of data (refer to standard parameter setting table (A))
(When the increment system is IS-B, -999999.999 to +999999.999)
Set the coordinate values of the minus direction in deceleration area boundary.
When the axis moves in the minus direction from this parameter setting value, deceleration is automatically performed so that the speed set to the following parameters is achieved.

	Parameter	
	Rapid traverse	Cutting feed
Deceleration rate	12783	12784

When the multiple axes are moving in deceleration area, the deceleration ratio is calculated for each axis, and the highest deceleration ratio is applied.

12783	Deceleration rate of in deceleration area (for rapid traverse)

[Input type] Parameter input
[Data type] Real axis
[Unit of data] mm/min, inch/min, deg/min (machine unit)
[Min. unit of data] Depend on the increment system of the applied axis
[Valid data range] Refer to the standard parameter setting table (C)
(When the increment system is IS-B, 0.0 to +999000.0)
Set the rapid traverse rate of each axis in the deceleration area.
When this parameter is set to 0, this axis is not decelerated by this function during rapid traverse.

12784	Deceleration rate of in deceleration area (for cutting feed)

[Input type] Parameter input
[Data type] Real axis
[Unit of data] mm/min, inch/min, deg/min (machine unit)
[Min. unit of data] Depend on the increment system of the applied axis
[Valid data range] Refer to the standard parameter setting table (C)
(When the increment system is IS-B, 0.0 to +999000.0)
Set the cutting feed rate of each axis in the deceleration area.
When this parameter is set to 0, this axis is not decelerated by this function during cutting feed.

7.1.10 Positioning by Optimum Accelerations

Overview

When rapid traverse is specified during automatic operation, the rapid traverse rate, time constant, and loop gain can be switched according to the travel distance of the block by the function for positioning by optimum accelerations. So, the time required for positioning and in-position check operations can be reduced, resulting in cycle time reduction.
When rapid traverse (G00) is specified during automatic operation, the rapid traverse rate, time constant, and loop gain are switched to one of seven levels according to the travel distance of the block. Parameters are used to specify the rapid traverse rates, time constants, and loop gains corresponding to travel distances.

- Valid command

This function is enabled by the G00 command. In addition, this function is enabled for rapid traverse in a canned cycle, automatic reference position return, and machine coordinate system selection. However, this function is disabled in the cases indicated below, and the feedrate, time constant, and loop gain set in parameters Nos. 1420, 1620, and 1825 respectively are applied.

(1) When automatic reference position return (G28) is specified before reference position establishment
(2) During the Cs contour control mode
(3) During the rigid tapping mode
(4) During the 3-dimensional coordinate system conversion mode

> ⚠ **CAUTION**
> This function is disabled for positioning in a canned cycle.

- Cutting feed

This function is disabled for cutting feed.

- Manual operation
This function is disabled during manual operation.

- Manual intervention
If a manual operation is inserted during automatic operation by halting rapid traverse with feed hold or mode switching, the value of the loop gain is changed to the value set in parameter No. 1825. If the program is restarted, the feedrate, time constant, and loop gain corresponding to the remaining travel distance are used for the rest of the block.

- PMC axis control
This function is disabled for PMC axis control.

- Rapid traverse overlap
When this function is enabled, rapid traverse overlap (bit 4 (RTO) of parameter No. 1601 = 1) is enabled if the same axis is not specified in successive blocks.

```
Example)
    Rapid traverse overlap is performed with the following commands:
    N01 G00 X10.0 ;
    N02 Z-10.0 ;
    Rapid traverse overlap is not performed with the following commands:
    N11 G00 X10.0 Z-10.0 ;
    N12 Z-20.0 ;
```

- Rapid traverse bell-shaped acceleration/deceleration
When rapid traverse bell-shaped acceleration/deceleration is used, T1, T2, and the rapid traverse rate in the Fig. 7.1.10 are switched.

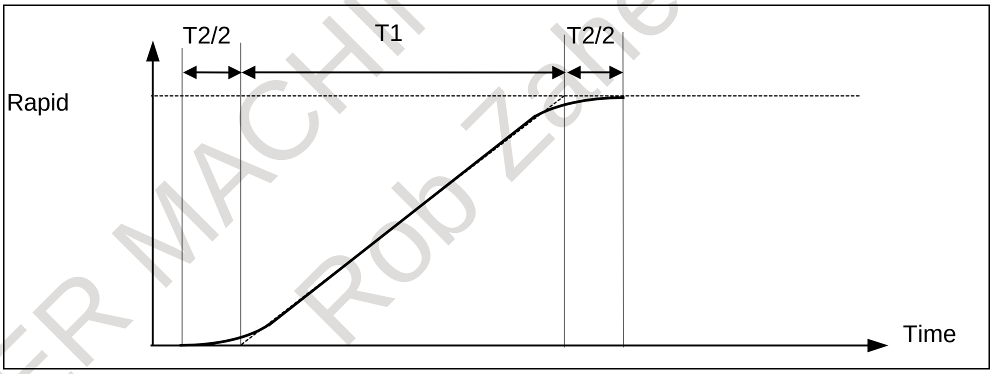

Fig. 7.1.10

- Angular axis control
This function is disabled for an axis to which angular axis control is applied.

- Coordinate system rotation
During the coordinate system rotation mode, switching is performed for the travel distance after coordinate system rotation.

- Scaling (M series)
During the scaling mode, switching is performed for the travel distance after coordinate system rotation. This also applies during the scaling mode.

- Tool radius/Tool nose radius compensation
During the cutter compensation mode or tool-nose radius compensation mode, switching is performed for the travel distance after compensation.

- Linear interpolation type rapid traverse

When linear interpolation type rapid traverse is used (bit 1 (LRP) of parameter No. 1401 = 1), this function is disabled.

- AI contour control

During the AI contour control mode, this function is disabled if look-ahead acceleration/deceleration before interpolation or optimum torque acceleration/deceleration is used for rapid traverse.

- Axis synchronous control

When using this function together with axis synchronous control, enable this function for both of the master axis and slave axis (bit 0 (OAD) of parameter No. 6131 = 1) and set the same feedrate, time constant, and loop gain values for the master axis and slave axis.

Parameter

	#7	#6	#5	#4	#3	#2	#1	#0
6131								OAD

[Input type] Parameter input
[Data type] Bit axis

> **NOTE**
> When this parameter is set, the power must be turned off before operation is continued.

#0 OAD The function for positioning by optimum acceleration (seven step switching function of rapid traverse rate by positioning distance and time constant, loop gain at rapid traverse rate in automatic operation) is
0: Disabled.
1: Enabled.

	#7	#6	#5	#4	#3	#2	#1	#0
6132								ILG

[Input type] Parameter input
[Data type] Bit path

#0 ILG In the function for positioning by optimum acceleration, the switch of the loop gain is
0: Enabled. (Parameters Nos. 6181 to 6187 is used.)
1: Disabled. (Parameter No. 1825 is used.)

6136	Distance D1 for level 1 of positioning by optimum acceleration for each axis
6137	Distance D2 for level 2 of positioning by optimum acceleration for each axis
6138	Distance D3 for level 3 of positioning by optimum acceleration for each axis
11230	Distance D4 for level 4 of positioning by optimum acceleration for each axis
11231	Distance D5 for level 5 of positioning by optimum acceleration for each axis
11232	Distance D6 for level 6 of positioning by optimum acceleration for each axis

[Input type] Parameter input
[Data type] Real axis
[Unit of data] mm, inch, deg (machine unit)

[Valid data range] Refer to the standard parameter setting table (B)

When using the function for switching the rapid traverse rate, time constant, and loop gain according to the positioning distance, this parameter sets the positioning distance for each axis.

> **NOTE**
> 1 To use this parameter, set bit 0 (OADx) of parameter No. 6131 to 1.
> 2 If 0 is set in all of parameters Nos. 6136 to 6138 and 11230 to 11232, this function is disabled.
> 3 The settings must satisfy the following: D1<D2<D3<D4<D5<D6.
> 4 Switching in up to seven steps is possible. When up to four steps are used, for example, set parameters so that expression D1<D2<D3 is satisfied, and set a maximum value (such as +999999.999 mm) for D4, D5, and D6.
> 5 For axes with diameter specification, set a diameter value. If 10.000 mm is set for an axis with diameter specification, for example, switching is made when a movement takes place over a distance of 10.000 mm in diameter.
> 6 In parameters Nos. 6136 to 6138 and 11230 to 11232, set a distance for each axis. Block lengths must not be specified in these parameters.

6161	**Level 1 rapid traverse rate**
6162	**Level 2 rapid traverse rate**
6163	**Level 3 rapid traverse rate**
6164	**Level 4 rapid traverse rate**
6165	**Level 5 rapid traverse rate**
6166	**Level 6 rapid traverse rate**
6167	**Level 7 rapid traverse rate**

[Input type] Parameter input
[Data type] Real axis
[Unit of data] mm/min, inch/min, deg/min (machine unit)
[Valid data range] Refer to the standard parameter setting table(C)

The rapid traverse rate for each axis is set.

6171	**Level 1 rapid traverse time constant**
6172	**Level 2 rapid traverse time constant**
6173	**Level 3 rapid traverse time constant**
6174	**Level 4 rapid traverse time constant**
6175	**Level 5 rapid traverse time constant**
6176	**Level 6 rapid traverse time constant**
6177	**Level 7 rapid traverse time constant**

[Input type] Parameter input
[Data type] Word axis
[Unit of data] msec
[Valid data range] 0 to 4000

The rapid traverse time constant for each axis is set.

6181	Level 1 servo loop gain
6182	Level 2 servo loop gain
6183	Level 3 servo loop gain
6184	Level 4 servo loop gain
6185	Level 5 servo loop gain
6186	Level 6 servo loop gain
6187	Level 7 servo loop gain

[Input type] Parameter input
[Data type] Word axis
[Unit of data] 0.01/sec
[Valid data range] 1 to 9999

The servo loop gain for each axis is set.
If 0 is set, parameter No. 1825 is used.

6191	Time constant T2 of level 1 bell-shaped acceleration/deceleration in rapid traverse
6192	Time constant T2 of level 2 bell-shaped acceleration/deceleration in rapid traverse
6193	Time constant T2 of level 3 bell-shaped acceleration/deceleration in rapid traverse
6194	Time constant T2 of level 4 bell-shaped acceleration/deceleration in rapid traverse
6195	Time constant T2 of level 5bell-shaped acceleration/deceleration in rapid traverse
6196	Time constant T2 of level 6 bell-shaped acceleration/deceleration in rapid traverse
6197	Time constant T2 of level 7 bell-shaped acceleration/deceleration in rapid traverse

[Input type] Parameter input
[Data type] Word axis
[Unit of data] msec
[Valid data range] 0 to 512

Time constant T2 of bell-shaped acceleration/deceleration in rapid traverse for each axis is set.

- Table for correspondence between positioning distances and parameter numbers

The correspondence is indicated in the Table 7.1.10.

Table 7.1.10

Level	Positioning distance d	Rapid traverse rate	Rapid traverse time constant T1	Rapid traverse time constant T2	Servo loop gain

7.1.11 AI Contour Control I and AI Contour Control II

Overview

The AI contour control I and AI contour control II functions are provided for high-speed, high-precision machining. This function enables suppression of acceleration/deceleration delays and servo delays that become larger with increases in the feedrate and reduction of machining profile errors.
There are two types of AI contour control; these two types are referred to temporarily as AI contour control I and AI contour control II. AI contour control I is designed mainly for part machining, and AI contour control II is for machining of successive minute straight lines such as mold machining and so on.
AI contour control represents both AI contour control I and AI contour control II in the rest of this manual.

The functions listed below are valid in the AI contour control mode.

Table 7.1.11 (a) Valid functions

Function	AI contour control I	AI contour control II
Number of blocks read ahead	40 *1 (When G8 is specified: 1)	200 *2 (When G8 is specified: 1)
Look-ahead acceleration/deceleration before interpolation	Linear or bell-shaped acceleration/deceleration	Linear or bell-shaped acceleration/deceleration
Speed control with feedrate difference on each axis	Enabled	Enabled
Speed control with acceleration in circular interpolation	Enabled	Enabled
Speed control with acceleration on each axis	Enabled (When G8 is specified: Not enabled)	Enabled (When G8 is specified: Not enabled)
Smooth speed control	Not enabled	Enabled (When G8 is specified: Not enabled)
Speed control with cutting load	Not enabled	Enabled
Disregard of feedrate command	Not enabled	Enabled

*1 In the system of which maximum controllable paths are more than 2, the number of blocks is 30.
*2 The number of blocks can be expanded to 400 blocks by Look-ahead blocks expansion of AI contour control II.

Format

G05.1 Q1 [R_] ; **AI contour control mode on**
:
G05.1 Q0 ; **AI contour control mode off**
R : Machining condition selecting level (1 to 10)

The AI contour control mode can be controlled also with the formats that have been used for the conventional advanced preview control, high-precision contour control, and AI high-precision contour control functions.

G08 P1 [R_] ;	**AI contour control mode on**
:	
G08 P0 ;	**AI contour control mode off**
R : Machining condition selecting level (1 to 10)	
G05 P10000 [R_] ;	**AI contour control mode on**
:	
G05 P0 ;	**AI contour control mode off**
R : Machining condition selecting level (1 to 10)	

NOTE

1 Always specify G05.1, G08, and G05 in an independent block.
(Do not specify other G codes at the same time.)
2 G05 can be specified only for AI contour control II.
3 The AI contour control mode can also be turned off at a reset.
4 The AI contour control mode can be turned on at the start of automatic operation by setting bit 0 (SHP) of parameter No. 1604.
5 G05.1, G08, and the G05 commands are separate commands respectively. Please turn off the AI contour control mode by the command that turns on the AI contour control mode. AI contour control cannot be turned off by a different command.
6 There are the following conditions when each AI contour control mode on / off is commanded in the multiple.

(1) The AI contour control mode commands are G05, G05.1, and G08 in the order of a high-ranking command (G05 > G05.1 > G08). It is necessary to turn on the AI contour control mode from the subordinate position command sequentially when the multiple commands are executed.

(2) When the AI contour control mode is turned on by the G05P10000 command, even if the AI contour control mode ON/OFF command is executed by G05.1Q1/Q0 command in the mode, the command is ignored.

Example)

G05P10000 AI contour control mode on by G05
G05.1Q1 This command is ignored.
G05.1Q0 This command is ignored.
G05P0 AI contour control mode off by G05

(3) After the AI contour control mode is turned on by the G05P10000 or the G05.1Q1, if the G08 command is executed in the mode, alarm PS5110 “IMPROPER G-CODE (AICC MODE)” occurs.

Example)

G05P10000(G05.1Q1) AI contour control mode on by G05(G05.1)
G08P1(P0) Alarm PS5110 occurs

(4) When the multiple commands are executed, each command that turns on/off the AI contour control mode must be nested.

Example)

G08P1 AI contour control mode on by G08
:
G05.1Q1 AI contour control mode on by G05.1
:
G05P10000 AI contour control mode on by G05
:
G05P0 AI contour control mode off by G05
:
G05.1Q0 AI contour control mode off by G05.1
:
G08P0 AI contour control mode off by G08

⚠ **CAUTION**

Set bit 6 (AP5) of parameter No.11549 to 1 if AI contour control is executed simultaneously by more than 5 paths. If AI contour control is executed simultaneously by more than 5 paths without setting this parameter to 1, sufficient performance might not be obtained.

Explanation

- Look-ahead acceleration/deceleration before interpolation

There are two types of look-ahead acceleration/deceleration before interpolation, the linear acceleration/deceleration type and the bell-shaped acceleration/deceleration type.
Look-ahead bell-shaped acceleration/deceleration before interpolation produces smoother acceleration/deceleration.

- Setting an acceleration

A permissible acceleration for the linear acceleration/deceleration of each axis is set in parameter No. 1660. For bell-shaped acceleration/deceleration, acceleration change time (B) (period of transition from constant speed state (A) to constant acceleration/ deceleration state (C)) is set in parameter No. 1772. In the constant acceleration/deceleration state (C), acceleration/deceleration is performed with the maximum tangential acceleration not exceeding the permissible acceleration of each axis specified in parameter No. 1660.
The acceleration change time specified in parameter No. 1772 is held constant, regardless of the tangential acceleration.

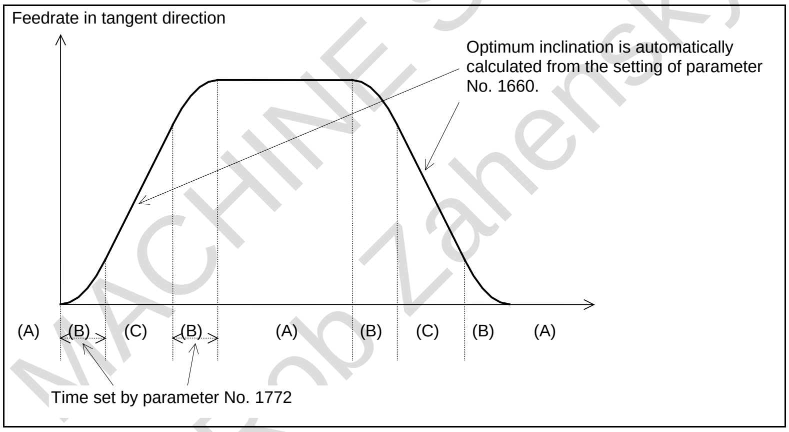

Fig. 7.1.11 (a)

- Method of determining the tangent acceleration

Acceleration/deceleration is performed with the largest tangent acceleration/deceleration that does not exceed the permissible acceleration set for each axis.

(Example)
X-axis permissible acceleration: 1000 mm/sec^2
Y-axis permissible acceleration: 1200 mm/sec^2
Acceleration change time: 20 msec

Program:

```
N1 G01 G91 X20.0 F6000     Move on the X-axis.
G04 X0.01
N2 Y20.0                   Move on the Y-axis.
G04 X0.01
N3 X20.0 Y20.0             Move in the XY direction (at 45 degrees).
```

Since N3 performs interpolation for the X and Y axes in the 45-degree direction, the acceleration of the Y axis is controlled according to the X axis to become 1000 mm/s^2. Therefore, the combined acceleration is 1414 mm/s^2.

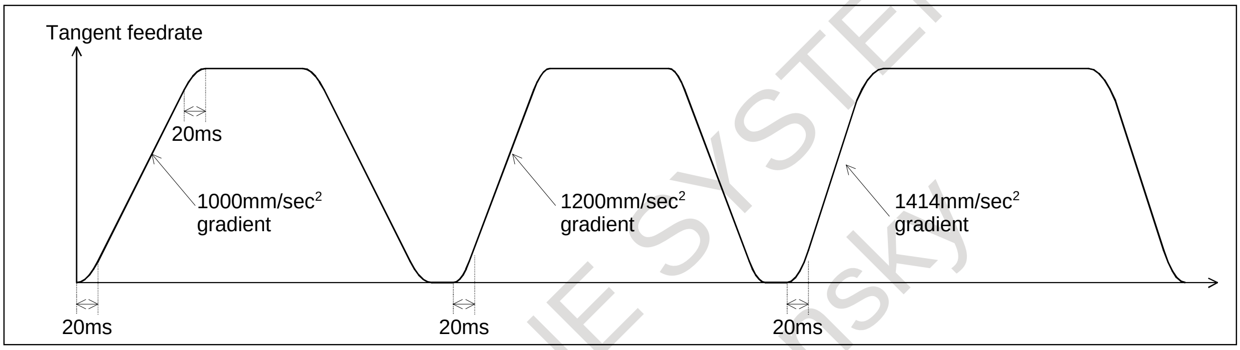

Fig. 7.1.11 (b)

- Acceleration

Acceleration is performed so that the feedrate programmed for a block is attained at the beginning of the block.
When look-ahead acceleration/deceleration before interpolation is valid for multiple blocks, acceleration can be performed across more than one block.

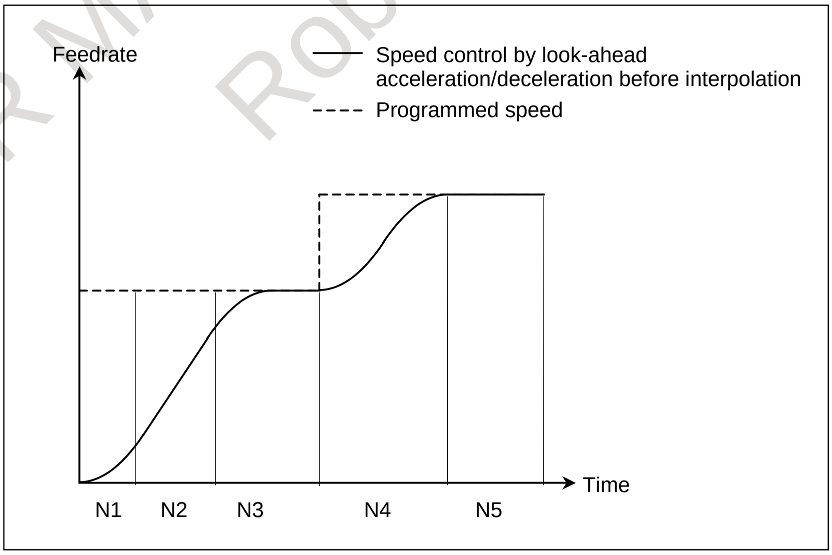

Fig. 7.1.11 (c)

- Deceleration

Deceleration starts in advance so that the feedrate programmed for a block is attained at the beginning of the block.
When look-ahead acceleration/deceleration before interpolation is valid for multiple blocks, deceleration can be performed across more than one block.

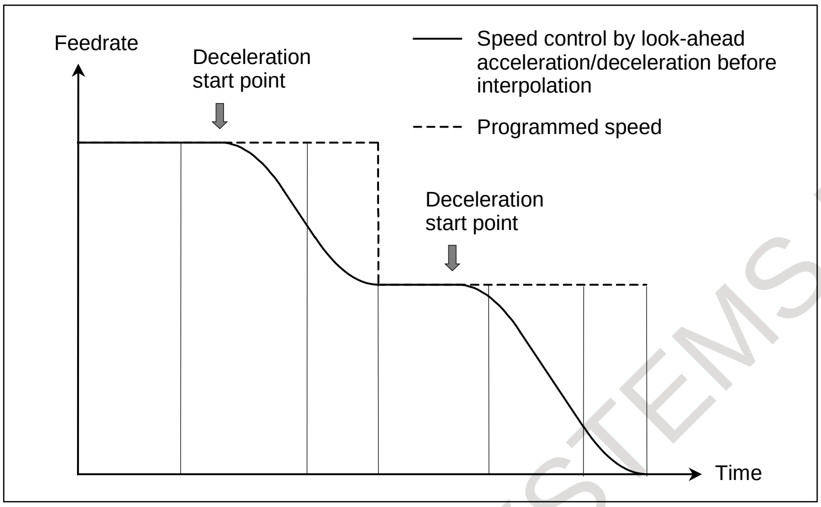

Fig. 7.1.11 (d)

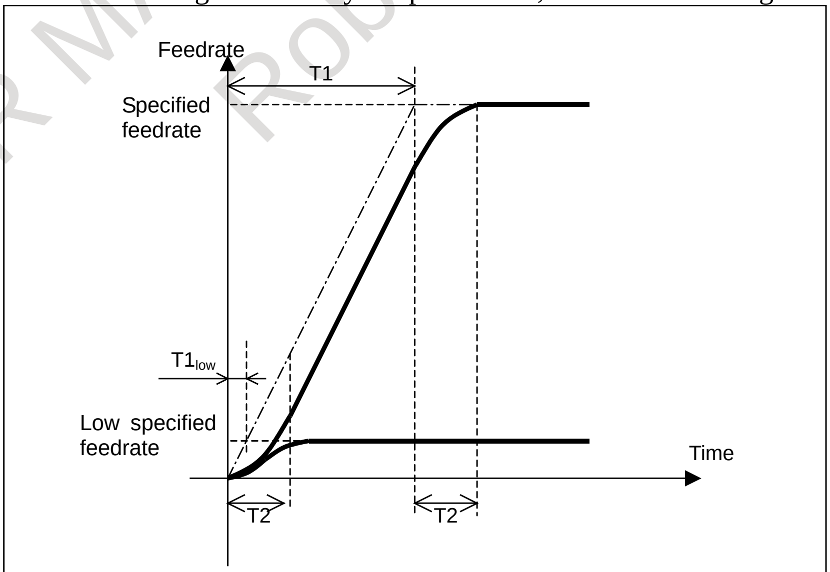
- Deceleration based on a distance

If the total distance of the blocks read ahead becomes shorter than or equal to the deceleration distance obtained from the current feedrate, deceleration starts.
If the total distance of the blocks read ahead during deceleration increases, acceleration is performed.
If the blocks of a small amount of travel are successively specified, deceleration and acceleration may be performed alternately, making the feedrate inconsistent.
To avoid this, decrease the programmed feedrate.

- Function for changing time constant of bell-shaped acceleration/deceleration

Look-ahead bell-shaped acceleration/deceleration before interpolation is performed according to the acceleration and acceleration change time set by the parameters, as shown in the figure below.



T1 : Time obtained from specified feedrate and specified acceleration (specified feedrate/acceleration (parameter No. 1660))
T2 : Acceleration change time (parameter No. 1772)

Fig. 7.1.11 (e)

Here, the acceleration change time (T2) remains constant regardless of the specified feedrate, while the acceleration time for the linear section (T1), which is determined by acceleration, varies with the specified feedrate. If T1 becomes shorter than T2 when the specified feedrate is low, linear acceleration/deceleration not achieving the specified acceleration results, as shown in the figure below.

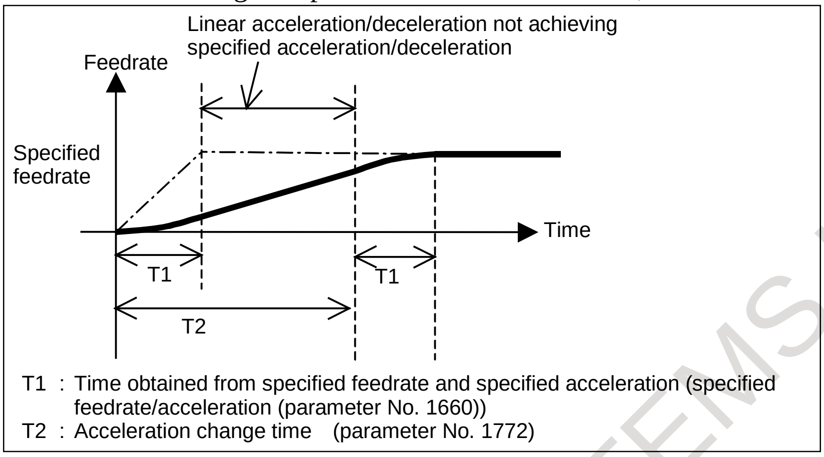


Fig. 7.1.12 (f)

In such a case, set bit 3 (BCG) of parameter No. 7055 to 1. Then, the internal acceleration and vector time constant of look-ahead acceleration/ deceleration before interpolation are changed to make the acceleration/deceleration pattern as close as possible to the optimum look-ahead bell-shaped acceleration/deceleration before interpolation based on a specified acceleration/deceleration reference speed, and so acceleration/deceleration time is reduced.

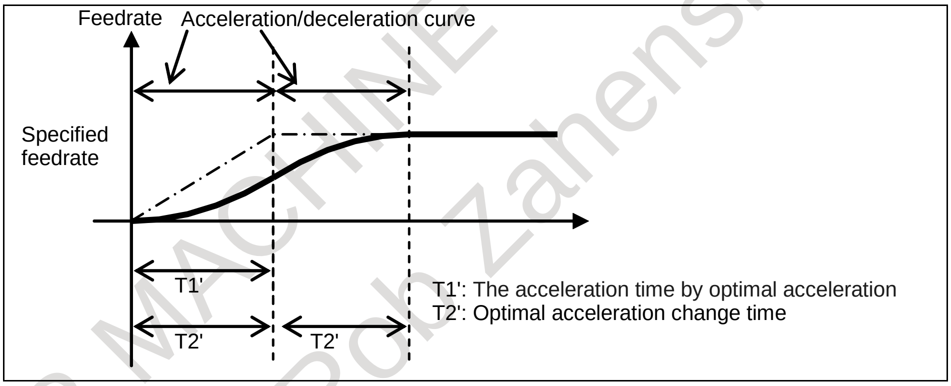

Fig. 7.1.11 (g)

There are three methods for specifying the acceleration/deceleration reference speed.

(1) Specifying the speed using an F in a G05.1 Q1 block
(2) Setting the speed on parameter No. 7066
(3) Setting the speed specified with the F command issued at the start of cutting as the reference speed

When F is specified in a G05.1Q1 block, the specified feedrate is assumed to be the acceleration/deceleration reference speed. This command can be used only in the feed per minute mode.
If no F command is specified in a G05.1Q1 block, the feedrate specified in parameter No. 7066 is assumed to be the acceleration/deceleration reference speed. If 0 is set in parameter No. 7066, the F command specified in the cutting start block is assumed to be the acceleration/deceleration reference speed.

> **NOTE**
> When function for changing time constant of look-ahead bell-shaped acceleration/deceleration before interpolation is enabled (bit 3 (BCG) of parameter No. 7055 is set to 1), be sure to specify acceleration rate of the reference axis.
> If acceleration rate of the reference axis is not specified, optimum acceleration rate is not obtained.

- Acceleration/deceleration after cutting feed interpolation in AI contour control mode

For cutting feed in AI contour control mode, in addition to look-ahead acceleration/deceleration before interpolation, acceleration/deceleration after interpolation can be enabled.
The time constant of acceleration/deceleration after interpolation is set to the parameter (No.1769).
Type of acceleration/deceleration after interpolation is selected by bit 6 (LS2) and bit 3 (BS2) of parameters No. 1602.
Using exponential acceleration/deceleration: LS2 is set to 0 and BS2 is set to 0.
Using linear acceleration/deceleration: LS2 is set to 1 and BS2 is set to 0.
Using bell-shaped acceleration/deceleration: BS2 is set to 1.
If shape of acceleration/deceleration after interpolation is exponential acceleration/deceleration, FL feedrate for each axis is set to parameter No. 1763.

Feedrate control function

In AI contour control mode, the feedrate is automatically controlled by the look-ahead of blocks.
The feedrate is determined using the following conditions. If the specified feedrate exceeds the determined feedrate, look-ahead acceleration/ deceleration before interpolation is performed to achieve the determined feedrate.
(1) Feedrate changes on each axis at a corner and the permissible feedrate change that has been set
(2) Expected acceleration on each axis and the permissible acceleration that has been set
(3) Cutting load that is expected from the travel direction on the Z-axis

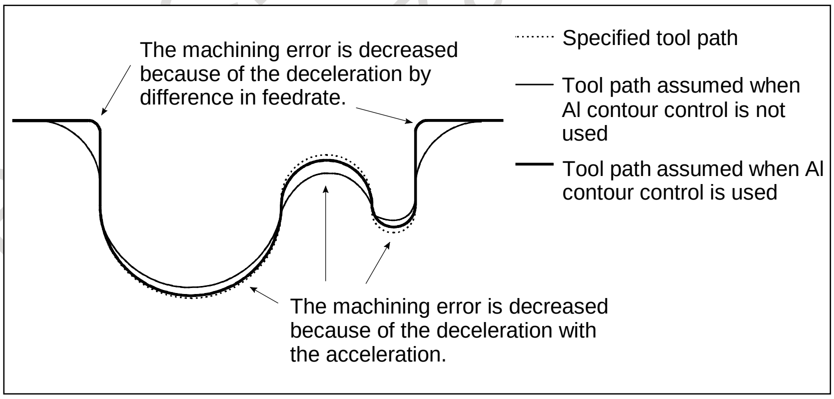

Fig. 7.1.11 (h)

For details, see the explanation of each function.

- Speed control based on the feedrate difference on each axis at a corner

By using the speed control based on the feedrate difference on each axis at a corner, if a feedrate change occurs on an axis on each axis at a corner, the feedrate is determined so that any feedrate difference exceeding the permissible feedrate difference on that axis that has been set for parameter No. 1783 does not occur, and deceleration is automatically performed.

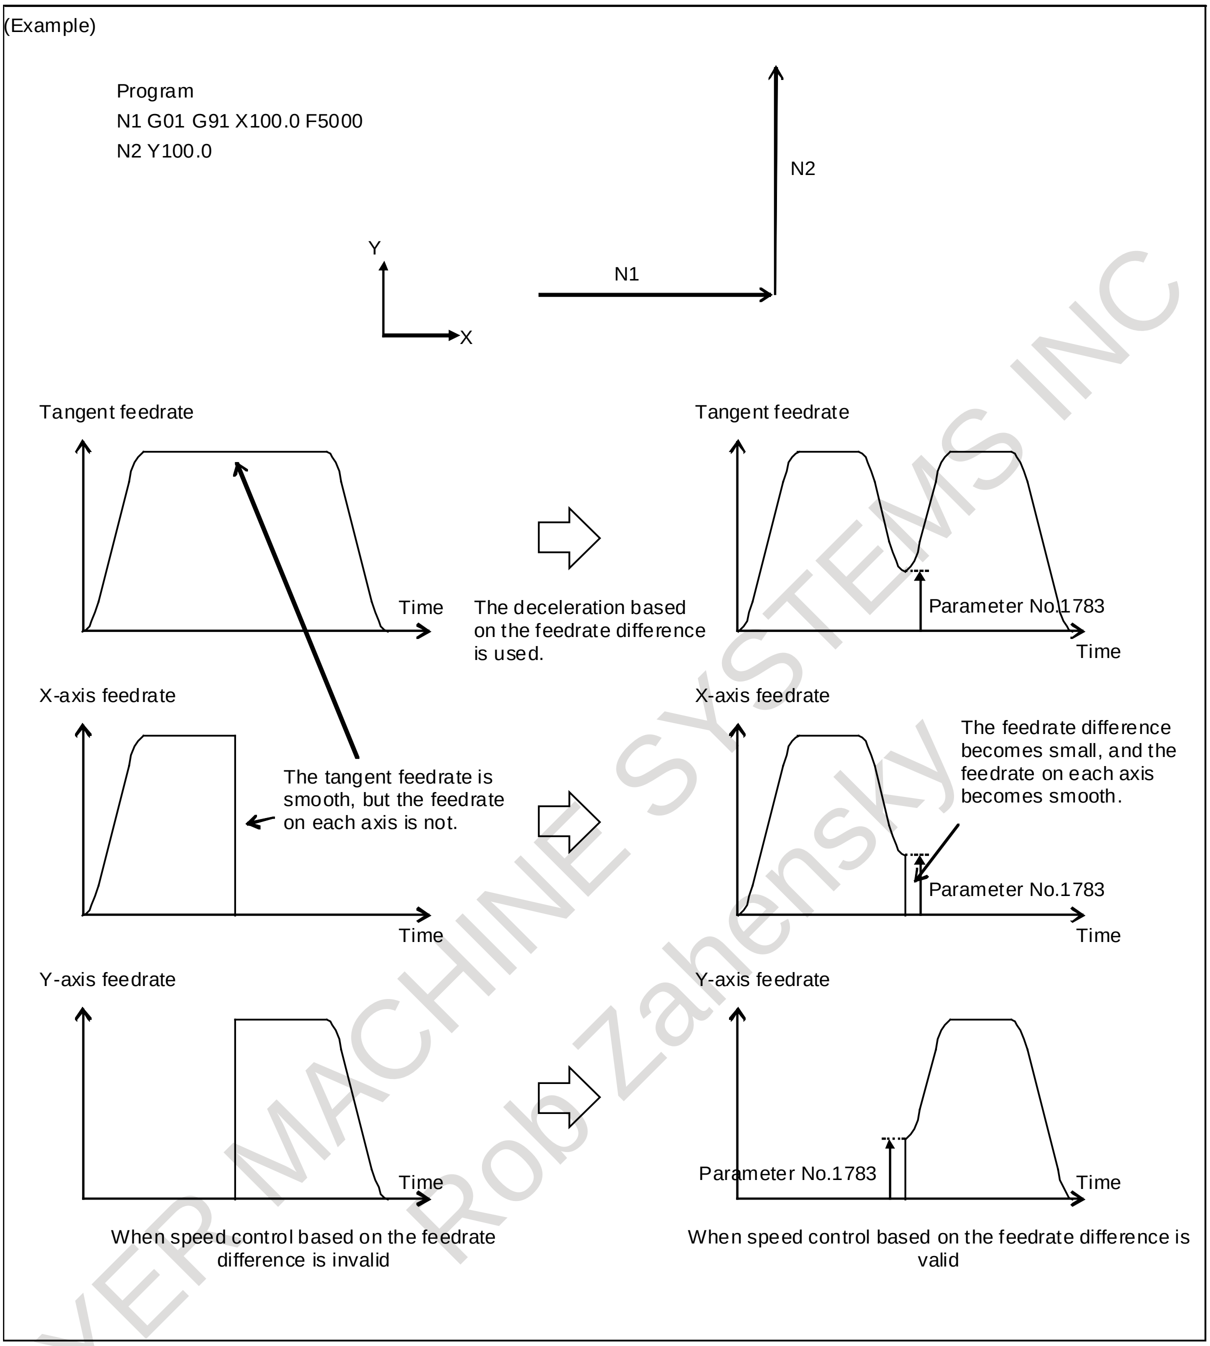

Fig. 7.1.11 (i)

The method of deceleration based on the feedrate difference differs depending on the setting made for parameter FNW (bit 6 of No. 19500).
If parameter FNW is set to 0, the largest feedrate that does not exceed the permissible feedrate difference set for parameter No. 1783 is assumed to be the deceleration feedrate.
In this case, the deceleration feedrate differs if the travel direction differs, even if the shape is the same.

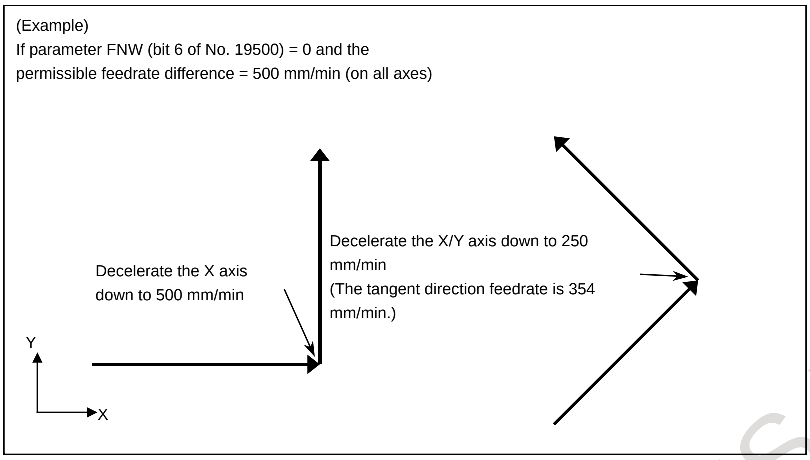

Fig. 7.1.11 (j)

In the left-side example in the figure above, the X axis is inverted at the corner from the position direction to the negative direction, and deceleration is performed so that the feedrate difference becomes 500 mm/min. In other words, the feedrate is 250 mm/min both when the axis moves in the position direction and when it moves in the negative direction. As a result, the tangent direction feedrate becomes 354 mm/min.

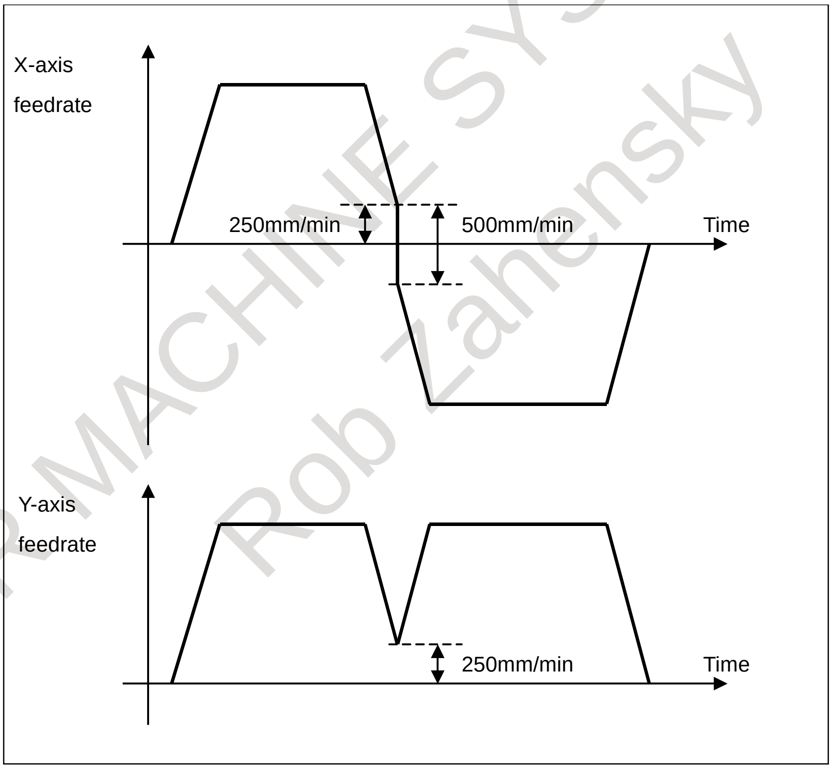

Fig. 7.1.11 (k)

If parameter FNW is set to 1, the feedrate is determined not only with the condition that
the permissible feedrate difference and permissible acceleration on each axis are not exceeded, but also that the deceleration feedrate is constant regardless of the travel direction if the shape is the same.
If this parameter is set to 1, the deceleration feedrate determined with the feedrate difference may be up to 30% lower than that determined if this parameter is set to 0.

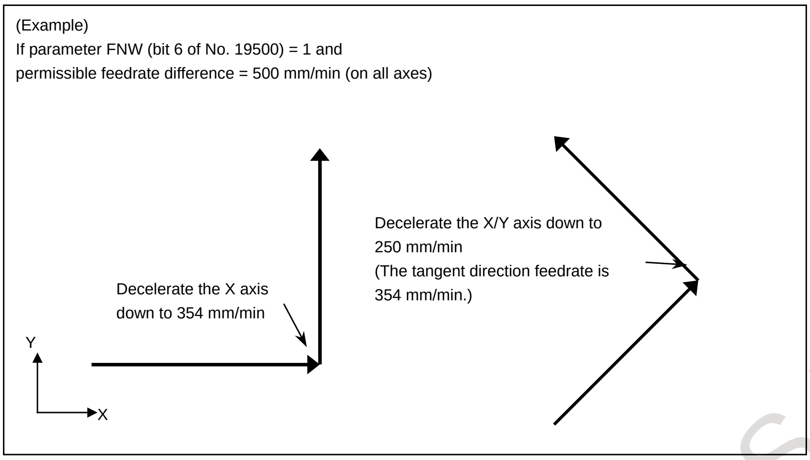

Fig. 7.1.11 (l)

- Speed control with acceleration in circular interpolation

When high-speed cutting is performed in circular interpolation, helical interpolation, or spiral interpolation, the actual tool path has an error with respect to the programmed path. In circular interpolation, this error can be approximated from the equation given below.

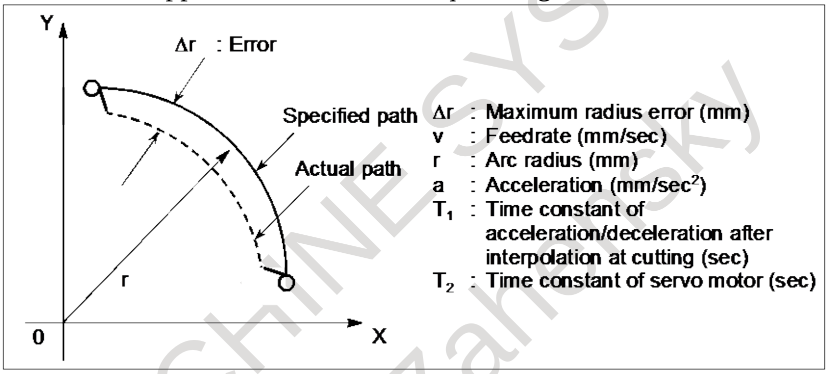

Fig. 7.1.11 (m)

$$\Delta r = \frac{1}{2}(T_1^2 + T_2^2)\frac{v^2}{r} = \frac{1}{2}(T_1^2 + T_2^2)\cdot a \quad \text{.......... (Equation 1)}$$

In actual machining, permissible error Δr is given, so the maximum permissible acceleration a (mm/sec^2) in equation 1 is determined.

Expression 1 is an expression when type of acceleration/deceleration after interpolation is exponential acceleration/deceleration. The radius error in the case of linear acceleration/deceleration after interpolation is smaller than in case of exponential acceleration/deceleration by a factor of 12, excluding any error caused by a servo motor time constant. The radius error in the case of bell-shaped acceleration/deceleration after interpolation is a half of linear acceleration/deceleration after interpolation.

When a specified feedrate causes the radial error from an arc having a programmed radius to exceed the permissible error, speed control with acceleration in circular interpolation automatically clamps the arc-cutting feedrate by using parameter settings.

Let the permissible acceleration calculated from the permissible acceleration set for each axis be A. Then, maximum permissible feedrate v with programmed radius r is expressed as follows:

$$v = \sqrt{A \cdot r} \quad \text{.......... (Equation 2)}$$

If a specified feedrate exceeds feedrate v obtained from equation 2, the feedrate is clamped at feedrate v automatically.

The permissible acceleration is specified in parameter No. 1735. If there is a difference in permissible acceleration between two axes for circular interpolation, the lower acceleration is regarded as the permissible acceleration.

If the radius of an arc is small, too small value can be calculated as deceleration v. In such a case, the lower feedrate limit can be set in parameter No. 1732 to prevent the feedrate from being decreased too much.

- Speed control with the acceleration on each axis

When consecutive small lines are used to form a curve, as in the example shown in the Fig. 7.1.11 (n), the feedrate differences on each axis at the individual corners are not very large. Thus, deceleration with the feedrate differences is not effective. Consecutive small feedrate differences, however, cause a large acceleration on each axis, as a whole.
In such a case, deceleration can be performed to reduce the impact on the machine and the machining error caused by too large an acceleration. The deceleration feedrate is determined to be the feedrate that does not cause the acceleration on each axis to exceed the permissible acceleration set for parameter No. 1737.
The deceleration feedrate is determined for each corner. The actual feedrate is the smaller of the deceleration feedrate determined at the start point of the block and that determined at the end point.
Depending on the specified figure, a very low deceleration feedrate may be calculated. In such a case, the lower feedrate limit can be set in parameter No. 1738 to prevent the feedrate from being decreased too much.

In the following example, the acceleration (gradient of the broken line in the feedrate graph) at too large at corners N2 to N4 and N6 to N8 and, therefore, deceleration is performed.

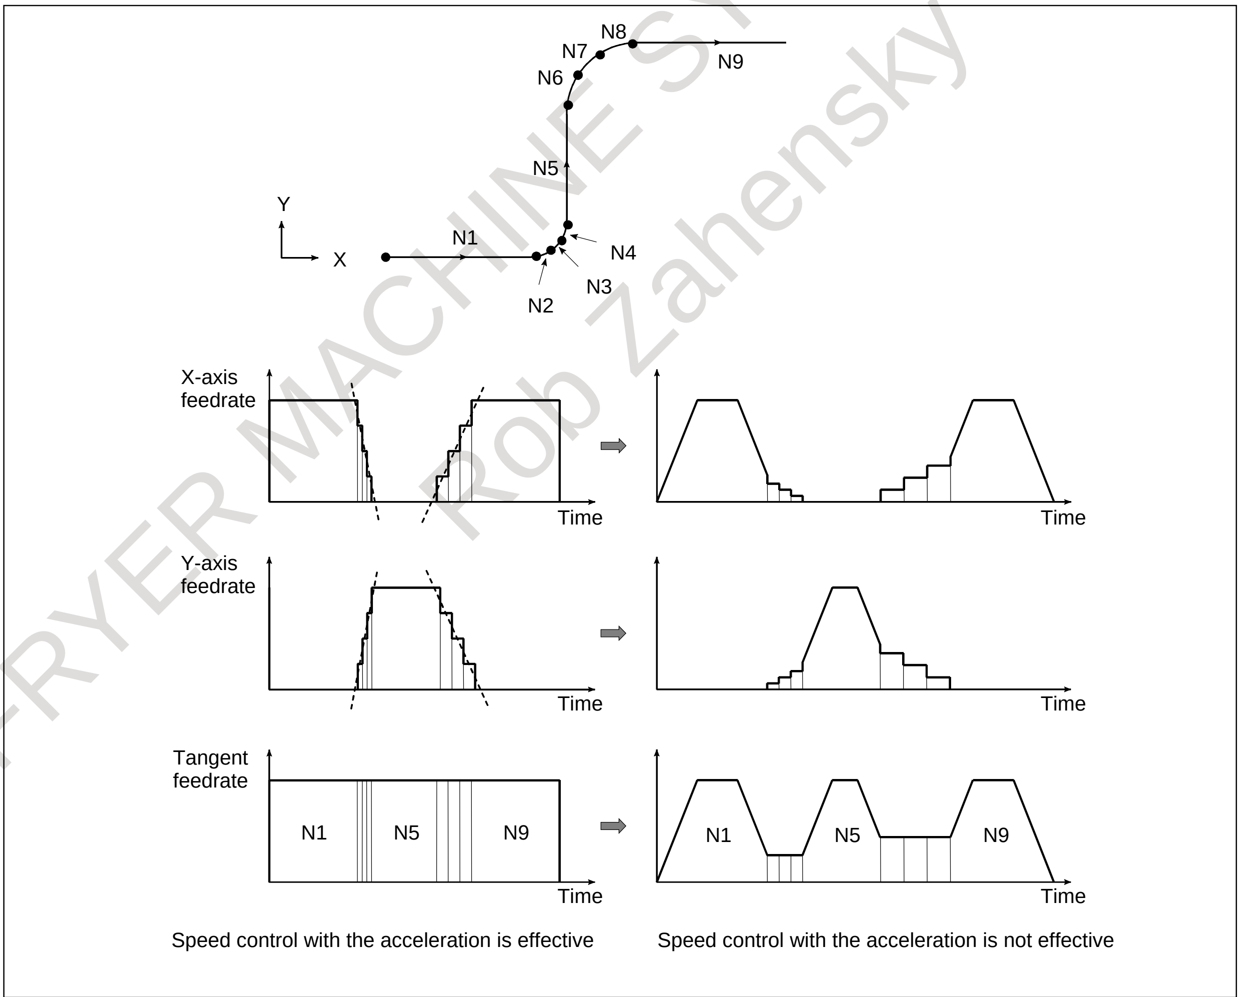

Fig. 7.1.11 (n)

The method of determining the feedrate with the acceleration differs depending on the setting of parameter FNW (bit 6 of No. 19500).

If parameter FNW is set to 0, the highest feedrate that does not cause the permissible acceleration set for parameter No. 1737 to be exceeded is assumed to be the deceleration feedrate. In this case, the deceleration feedrate differs depending on the travel direction even if the shape is the same, as shown in the figure below.

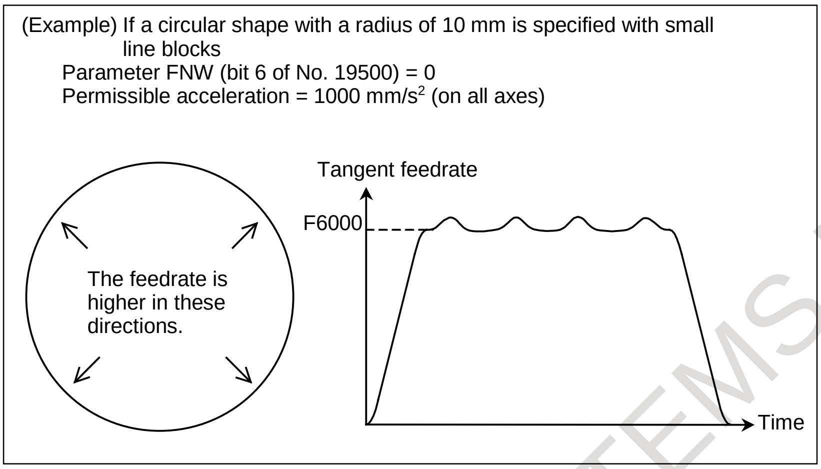

Fig. 7.1.11 (o)

If parameter FNW is set to 1, the feedrate is determined with not only the condition that the permissible acceleration on each axis is not exceeded but also the condition that the deceleration feedrate is constant regardless of the travel direction if the shape is the same.
If this parameter is set to 1, the deceleration feedrate determined with the feedrate difference or acceleration may be up to 30% lower than that determined if this parameter is set to 0.

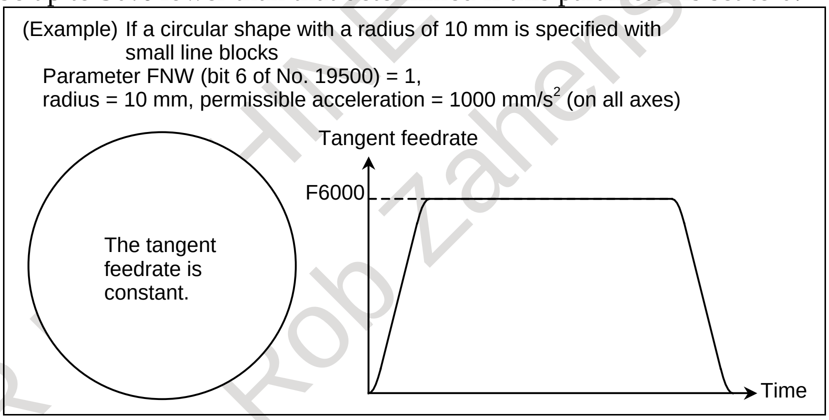

Fig. 7.1.11 (p)

> **NOTE**
> In circular interpolation, the tangent feedrate is constant regardless of the setting of the parameter.

When this function is effective, the feedrate might be clamped as well as the travel distance in the block is small even if the travel distance in the block is long. Speed control with the acceleration is invalidated in the block longer than the block length set to parameter No. 19518 if bit 1 (HNG) of parameter No. 19517 is set to 1.

- Smooth speed control

In speed control with acceleration, the smooth speed control function recognizes the entire figure from preceding and following blocks including blocks read ahead to make a smooth feedrate determination.
When a curve is specified with successive minute straight lines, programmed values are rounded to the least input increment before issued, so the machining profile is approximated with a broken line.

When the feedrate is determined with acceleration in an ordinary manner, an optimum feedrate is automatically calculated exactly for a programmed figure, so a large acceleration may result depending on the command, which can lead to deceleration.
In such a case, the use of smooth speed control enables speed control by recognizing the entire figure, which provides smooth speed control while suppressing local deceleration, therefore increasing the feedrate.

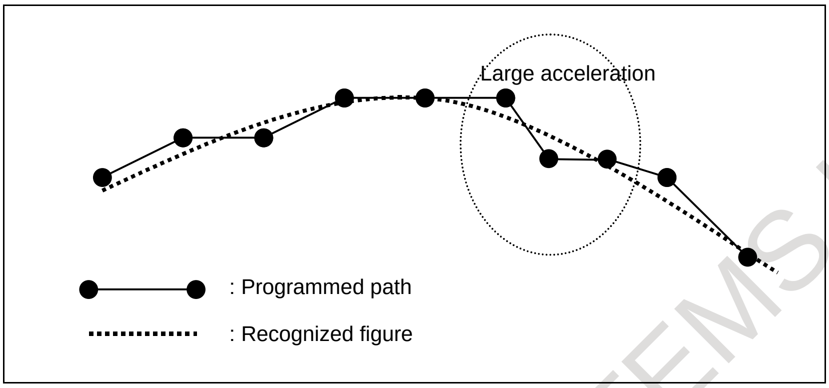

Fig. 7.1.11 (q)

Also for a part of a programmed figure in which a large acceleration would be required, the acceleration is obtained based on the figure recognized from multiple blocks, and the feedrate is determined so that the acceleration is within the permissible acceleration set in parameter No. 1737.

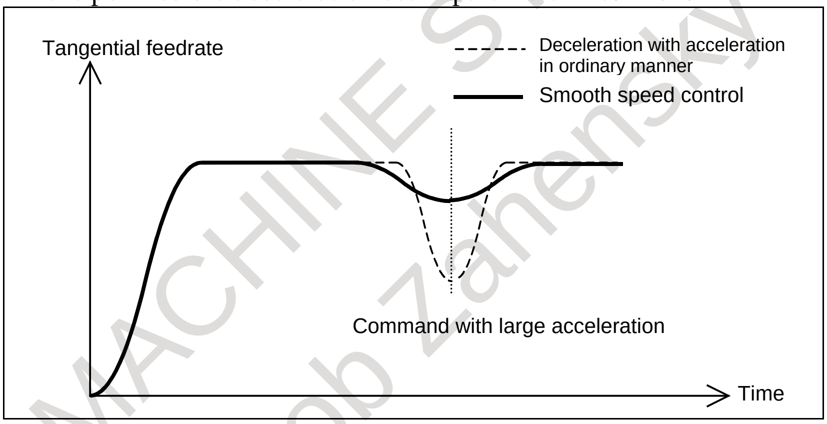

Fig. 7.1.11 (r)

Smooth speed control obtains the acceleration by using the figure recognized from the preceding and following blocks including blocks read ahead, so smooth speed control is enabled even in parts in which the acceleration increases.
Smooth speed control is enabled under the following conditions:
(1) Speed control with acceleration is enabled in the AI contour control II mode.
(2) Successive linear interpolation commands are specified.
(3) Bit 0 (HPF) of parameter No. 19503 is set to 1.

> ⚠ **CAUTION**
> When smooth speed control is used, the feedrate in a certain figure such as a corner may become larger than the feedrate obtained by ordinary speed control with acceleration. For corners, set parameter No. 1783, which is the permissible feedrate difference parameter for speed control with the feedrate difference at corners, to perform appropriate deceleration by speed control with the corner feedrate difference.

When this function is effective, the feedrate might be clamped as well as the travel distance in the block is small even if the travel distance in the block is long. Smooth speed control is invalidated in the block longer than the travel distance set to parameter No. 19518 if bit 1 (HNG) of parameter No. 19517 is set to 1.

- Deceleration with the cutting load

Usually, the cutting resistance produced when machining is performed with the bottom of the cutter as the tool lowers along the Z-axis is greater than the cutting resistance produced when machining is performed with the side of the cutter as the tool rises along the Z-axis. Therefore, deceleration is required.
In AI contour control II, the tool travel direction on the Z-axis is used as a condition for calculating the machining feedrate.
This function is enabled when parameter ZAG (bit 4 of No. 8451) is set to 1.

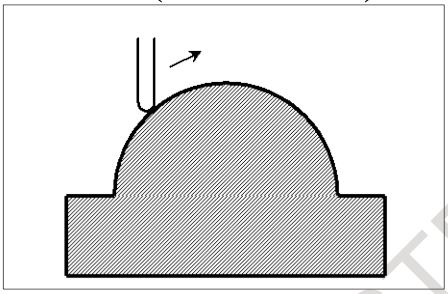

Fig. 7.1.11 (s) During ascent on the Z-axis

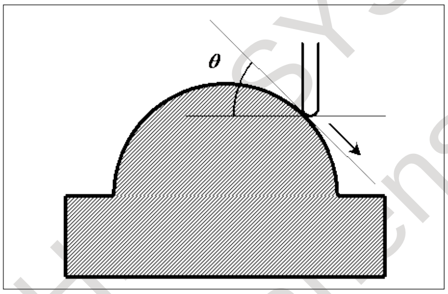

Fig. 7.1.11 (t) During descent on the Z-axis

The descent angle θ during descent on the Z-axis (angle formed by the XY plane and the tool center path) is as shown in the Fig. 7.1.11 (s). The descent angle is classified into four areas, and the override values for the individual areas are set for the following parameters:

Parameter No. 8456 for area 2
Parameter No. 8457 for area 3
Parameter No. 8458 for area 4

For area 1, however, no parameter is available, and an override of 100% is used at all times. The feedrate obtained according to other feedrate control is multiplied by the override value of the area to which descent angle θ belongs.

Area1 $0° \le \theta < 30°$
Area2 $30° \le \theta < 45°$
Area3 $45° \le \theta < 60°$
Area4 $60° \le \theta < 90°$

The feedrate can be overridden with an inclination by setting bit 1 (ZG2) of parameter No. 19515 to 1. In this case, specify the override value for area 1 in parameter No. 19516.

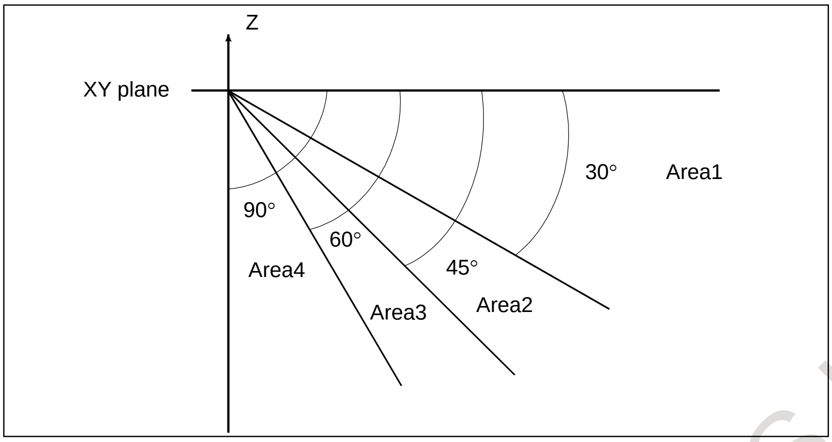

Fig.7.1.11 (u)

> ⚠ **CAUTION**
> 1 The speed control with the cutting feed is effective only when the tool is parallel with the Z-axis. Thus, it may not be possible to apply this function, depending on the structure of the machine used.
> 2 In the speed control with the cutting feed, the travel direction on the Z-axis is determined with the appropriate NC command. If, therefore, manual intervention is performed on the Z-axis with manual absolute on, or if a mirror image is applied on the Z-axis, the direction on the Z-axis cannot be determined. When using the speed control with the cutting load, do not use these functions.
> 3 When performing 3-dimensional coordinate system conversion, determine the descent angle on the Z-axis using the converted coordinate system.
> 4 Speed control with the cutting load is enabled for all interpolations in the AI contour control II mode. This function, however, can be made valid only for linear interpolations by setting bit 4 (ZOL) of parameter No. 19503 to 1.

- Ignoring feedrate commands

In a block in which AI contour control II is enabled, all feedrate commands (F commands) can be ignored by setting parameter NOF (bit 7 of No. 8451).
The term feedrate commands, as used here, refer to the following commands:

(1) Modal F commands before the block in which AI contour control II is enabled
(2) F commands and modal F commands in the block in which AI contour control II is enabled

When the feedrate commands are ignored, it is assumed that the upper feedrate limit specified for parameter No. 8465 is specified.
When a rotation axis is singly specified, it is assumed that the upper feedrate limit specified for parameter No. 8466 is specified.
Note, however, that any issued F commands and modal F commands are stored within the CNC.
Thus, in a block in which AI contour control II changes from the enabled state to the disabled state, the modal values of the F commands described in (1) and (2) described above are used as modal F commands, instead of the modal values of the F commands calculated by AI contour control II.

- Another example of determining the feedrate

If a specified feedrate exceeds the upper feedrate limit of AI contour control (in parameter No. 8465, or parameter No. 8466 (when a rotation axis is singly specified))), the feedrate is clamped at the upper feedrate. The upper feedrate limit is clamped at the maximum cutting feedrate (parameter No. 1432) for acceleration/deceleration before interpolation

Status display

Depending on the control mode, one of the status indications shown below blinks at the lower right of the screen.

Table7.1.11 (b)

	AI contour control I	AI contour control II
Status display	AICC 1	AICC 2

- In the case of AI contour control I, the character string to be displayed can be changed using parameter Nos. 3241 to 3247.
- In the case of AI contour control II, the character string to be displayed can be changed using parameter Nos. 3251 to 3257..

The advanced preview feed forward function when the AI contour control mode is off

The advanced preview feed forward function is enabled when bit 1 (FEED) of parameter No. 2005 for enabling the advanced preview feed forward function is set to 1 and a value is set in parameter No. 2092, regardless of whether AI contour control is turned on or off.
By setting bit 2 (AOFF) of parameter No. 1611 to 1, the advanced preview feed forward function is disable when command for turning on AI contour control is not specified yet.

Example of the advanced preview feed forward function turned on/off

(1) Bit 0 (SHP) of parameter No. 1604 is set to 0
When bit 0 (SHP) of parameter No. 1604 is set to 0, the AI contour control mode is not turned on if the command for AI contour control ON is not specified. Program operation in this state is explained below.

```
O0001;
N01 G90 G01 X50.0 Y50.0 F1000. ;
N02 G05.1 Q1 ;
N03 X100.0 Y100.0 ;
N04 G05.1 Q0 ;
N05 X150.0 Y150.0 ;
N06 M02 ;
```

(a) When bit 2 (AOFF) of parameter No. 1611 is set to 0
The advanced preview feed forward function is enabled in the N01, N03, and N05 blocks.
(b) When bit 2 (AOFF) of parameter No. 1611 is set to 1
The advanced preview feed forward function is enabled in the N03 block.
The advanced preview feed forward function is disabled in the N01 and N05 blocks.

(2) Bit 0 (SHP) of parameter No. 1604 is set to 1
When bit 0 (SHP) of parameter No. 1604 is set to 1, the program operates in the same way as when G05.1Q1 is specified at automatic operation start time (from the reset state). Program operation from the reset state is explained below.

```
O0001;
N01 G90 G01 X50.0 Y50.0 F1000. ;
N02 G05.1 Q1 ;
N03 X100.0 Y100.0 ;
N04 G05.1 Q0 ;
N05 X150.0 Y150.0 ;
N06 M99;
```

(a) When bit 2 (AOFF) of parameter No. 1611 is set to 0
The advanced preview feed forward function is enabled in all movement blocks of N01, N03, and N05.

(b) When bit 2 (AOFF) of parameter No. 1611 is set to 1
Immediately after automatic operation is started, the advanced preview feed forward function is enabled in the N01 and N03 blocks and the advanced preview feed forward function is disabled in the N05 block.
If N06 specifies M99 to return to the start of the program, the advanced preview feed forward function is disabled in the N01 block because N04 turns off the AI contour control mode.

(3) When none of the AI contour control is specified
G05.1Q1 cannot be specified. This state is equivalent to the state where G05.1Q0 is specified, that is, AI contour control is off at all times. Program operation in this state is described below.

```
O0002;
N01 G90 G01 X50.0 Y50.0 F1000. ;
N02 X100.0 Y100.0 ;
N03 X150.0 Y150.0 ;
N04 M02 ;
```

(a) When bit 2 (AOFF) of parameter No. 1611 is set to 0
The advanced preview feed forward function is enabled in the N01, N02, and N03 blocks.
(b) When bit 2 (AOFF) of parameter No. 1611 is set to 1
The advanced preview feed forward function is disabled in the N01, N02, and N03 blocks.

Limitation

- Conditions for temporarily canceling the AI contour control mode

If one of the commands listed below is issued in the AI contour control mode, the AI contour control mode is canceled temporarily.
If the system becomes ready for AI contour control after it is canceled, the AI contour control mode is restored automatically.

- Positioning (rapid traverse)
- Single-direction positioning
- Spindle positioning
- Rigid tapping
- Threading cycle (threading and multiple repetitive threading)
- Electronic gear box
- Superimposed control
- When no move command is specified
- One-shot G code other than the following:
  Tool offset
  Cutter compensation vector retention
  Cutter compensation corner rounding
  Exact stop

Example

```
O0010
…
G5.1 Q1;
G01
…
X1.0Y2.0Z3.0;   } AI contour control mode
M220;           Start superimposed control     } AI contour control mode is
…                                              } temporarily canceled.
M221;           Cancel superimposed control
X2.0Y2.0Z4.0;   } Automatically return the system to AI contour control mode
…               } AI contour control mode
X4.0Y1.0Z2.0;
G5.1 Q0;
…
M30;
```

(Note The way to specify synchronous, composite, and superimposed controls differ from one machine tool builder to another. For details, refer to the manual issued by the machine tool builder.)

- Functions that cannot be specified in the AI contour control mode

In the AI contour control mode, the functions listed below cannot be specified. Alarm PS5110 "IMPROPER G-CODE (AICC MODE)" occurs. Before specifying these functions, turn off the AI contour control mode; after the command ends, turn on the mode again.

- Threading
- Circular threading
- Variable lead threading

To specify threading, circular threading, and variable lead threading in the AI contour control mode, set THA (bit 1 of parameter No. 1611). However, the AI contour control mode is automatically cancelled.

- Modal G codes usable when AI contour control is specified

In a modal G code state listed below, AI contour control can be specified.
Do not specify AI contour control in modal states other than these.

G13.1	: Polar coordinate interpolation mode cancel
G15	: Polar coordinate command cancel
G40	: Tool radius compensation cancel
G40.1	: Normal direction control cancel
G50	: Scaling cancel
G50.1	: Programmable mirror image cancel
G50.2	: Polygon turning cancel
G64	: Cutting mode
G67	: Macro modal call cancel
G69	: Coordinate system rotation/3-dimensional coordinate system conversion cancel
G80	: Canned cycle cancel
G97	: Constant surface speed control cancel

- Retrace

When the reverse execution is started in AI contour control mode, a reverse execution ends immediately depending on a program then the backward movement is not possible.

During reverse execution and forward reexecution, the feedrate clamp function by acceleration under AI contour control is disabled.

- Manual handle interrupt

Manual handle interrupt is available in AI contour control mode.

- DNC operation

AI contour control is available during DNC operation.

Signal

AI contour control mode signal AICC <Fn062.0>

[Classification] Output signal

[Function] This signal indicates that the system is in AI contour control mode.

[Output cond.] This signal is set to 1 when the cutting command or other conditions for AI contour control is met in AI contour control mode.
This signal is set to "0" in the following cases.

(1) In the automatic operation suspend state
(2) In the automatic operation stop state
(3) When rapid traverse or other conditions under which AI contour control is automatically cancelled are met
(4) When AI contour mode is cancelled

> **NOTE**
> Even if the conditions for automatically canceling AI contour control, such as rapid traverse, are satisfied, the signal is output if bit 1 (AIR) of parameter No. 1612 is 1 (status display in AI contour control mode and the AI contour control mode signal are enabled).

Signal address

	#7	#6	#5	#4	#3	#2	#1	#0
F062								AICC

Parameter

1432	Maximum cutting feedrate for all axes in the acceleration/deceleration before interpolation

[Input type] Parameter input
[Data type] Real axis
[Unit of data] mm/min, inch/min, deg/min (machine unit)
[Min. unit of data] Depend on the increment system of the applied axis
[Valid data range] Refer to the standard parameter setting table (C)
(When the increment system is IS-B, 0.0 to +999000.0)

Set a maximum cutting feedrate for each axis in the look-ahead acceleration/deceleration before interpolation mode such as AI contour control. When this parameter is set to 0 or the look-ahead acceleration/deceleration before interpolation mode is not set, the maximum cutting feedrate set in parameter No. 1430 is used.

	#7	#6	#5	#4	#3	#2	#1	#0
1602		LS2			BS2			

[Input type] Parameter input
[Data type] Bit path

#3 BS2 Acceleration/deceleration after interpolation for cutting feed in a mode of look-ahead acceleration/deceleration before interpolation such as the AI contour control mode:

0: Exponential acceleration/deceleration or linear acceleration/ deceleration is used. (The setting of bit 6 (LS2) of parameter No. 1602 is followed.)

1: Bell-shaped acceleration/deceleration is used.

#6 LS2 Acceleration/deceleration after interpolation for cutting feed in a mode of look-ahead acceleration/deceleration before interpolation such as the AI contour control mode:
0: Exponential acceleration/deceleration is used.
1: Linear acceleration/deceleration is used.

	#7	#6	#5	#4	#3	#2	#1	#0
1604								**SHP**

[Input type] Parameter input
[Data type] Bit path

#0 SHP When automatic operation is started, the state equivalent to the specification of G5.1Q1 for AI contour control is:
0: Not set
1: Set

> **NOTE**
> It is necessary to reset CNC once after this parameter is changed.

	#7	#6	#5	#4	#3	#2	#1	#0
1611						**AOF**		

[Input type] Parameter input
[Data type] Bit path

#2 AOF When AI contour control mode is off and the parameter of the advanced-preview feed forward function is valid, the advanced-preview feed forward function is:
0: Enabled.
1: Disabled.

	#7	#6	#5	#4	#3	#2	#1	#0
1612							**AIR**	

[Input type] Parameter input
[Data type] Bit path

#1 AIR The status display and mode signal in AI contour control mode is:
0: Enabled only when the conditions for executing AI contour control are satisfied.
1: Enabled always in AI contour control mode.
If this parameter is set to 1, in-mode blinking display and the AI contour control mode signal AICC <Fn062.0> remain enabled in the AI contour control mode.

> **NOTE**
> The parameter is invalid during a stop on feed hold or a single-block stop.

1660	**Maximum allowable acceleration rate in acceleration/deceleration before interpolation for each axis**

[Input type] Parameter input
[Data type] Real axis
[Unit of data] mm/sec^2, inch/sec^2, deg/sec^2 (machine unit)
[Min. unit of data] Depend on the increment system of the applied axis

[Valid data range] Refer to the standard parameter setting table (D)
(When the machine system is metric system, 0.0 to +100000.0. When the machine system is inch system, machine, 0.0 to +10000.0.)
Set a maximum allowable acceleration rate in look-ahead acceleration/ deceleration before interpolation for each axis.
If a value greater than 100000.0 is set, the value is clamped to 100000.0.
If 0 is set, the specification of 100000.0 is assumed. If 0 is set for all axes, however, look-ahead acceleration/deceleration before interpolation is not performed.
If a maximum allowable acceleration rate set for one axis is greater than a maximum allowable acceleration rate set for another axis by a factor of 2 or more, the feedrate at a corner where the direction of travel abruptly changes can decrease temporarily.

1732	Minimum allowable feedrate for the deceleration function based on acceleration in circular interpolation

[Input type] Parameter input
[Data type] Real path
[Unit of data] mm/min, inch/min, deg/min (machine unit)
[Min. unit of data] Depend on the increment system of the reference axis
[Valid data range] Refer to the standard parameter setting table (C)
(When the increment system is IS-B, 0.0 to +999000.0)
With the deceleration function based on acceleration in circular interpolation, an optimum feedrate is automatically calculated so that acceleration produced by changing the move direction in circular interpolation does not exceed the maximum allowable acceleration rate specified in parameter No. 1735.
If the radius of an arc is very small, a calculated feedrate may become too low.
In such a case, the feedrate is prevented from decreasing below the value specified in this parameter.

1735	Maximum allowable acceleration rate for the deceleration function based on acceleration in circular interpolation for each axis

[Input type] Parameter input
[Data type] Real axis
[Unit of data] mm/sec^2, inch/sec^2, deg/sec^2 (machine unit)
[Min. unit of data] Depend on the increment system of the applied axis
[Valid data range] Refer to the standard parameter setting table (D)
(When the machine system is metric system, 0.0 to +100000.0. When the machine system is inch system, machine, 0.0 to +10000.0.)
Set a maximum allowable acceleration rate for the deceleration function based on acceleration in circular interpolation.
Feedrate is controlled so that acceleration produced by changing the move direction in circular interpolation does not exceed the value specified in this parameter.
For an axis with 0 set in this parameter, the deceleration function based on acceleration is disabled.
If a different value is set in this parameter for each axis, a feedrate is determined from the smaller of the acceleration rates specified for the two circular axes.

1737	Maximum allowable acceleration rate for the deceleration function based on acceleration in AI contour control for each axis

[Input type] Parameter input
[Data type] Real axis
[Unit of data] mm/sec^2, inch/sec^2, deg/sec^2 (machine unit)
[Min. unit of data] Depend on the increment system of the applied axis

[Valid data range] Refer to the standard parameter setting table (D)
(When the machine system is metric system, 0.0 to +100000.0. When the machine system is inch system, machine, 0.0 to +10000.0.)
Set a maximum allowable acceleration rate produced by changing the tool move direction.
For an axis with 0 set in this parameter, the deceleration function based on acceleration is disabled. If 0 is set for all axes, the deceleration function based on acceleration is not performed.
In circular interpolation, however, the deceleration function based on feedrate control using acceleration in circular interpolation (parameter No. 1735) is enabled.

1738	Minimum allowable feedrate for the deceleration function based on acceleration in AI contour control

[Input type] Parameter input
[Data type] Real path
[Unit of data] mm/min, inch/min, deg/min (machine unit)
[Min. unit of data] Depend on the increment system of the reference axis
[Valid data range] Refer to the standard parameter setting table (C)
(When the increment system is IS-B, 0.0 to +999000.0)
With the deceleration function based on acceleration in AI contour control, a feedrate most suitable for a desired figure is automatically calculated.
Depending on the figure, however, the calculated feedrate may become too low.
In such a case, the feedrate is prevented from decreasing below the value specified in this parameter.
If overriding using the deceleration function based on cutting load is enabled, a feedrate lower than the minimum allowable feedrate may be used.

1763	FL rate for acceleration/deceleration after cutting feed interpolation for each axis in the acceleration/deceleration before interpolation mode

[Input type] Parameter input
[Data type] Real axis
[Unit of data] mm/min, inch/min, deg/min (machine unit)
[Min. unit of data] Depend on the increment system of the applied axis
[Valid data range] Refer to the standard parameter setting table (C)
(When the increment system is IS-B, 0.0 to +999000.0)
Set a minimum allowable feedrate (FL rate) for acceleration/ deceleration after cutting feed interpolation in look-ahead acceleration/deceleration before interpolation as in AI contour control.

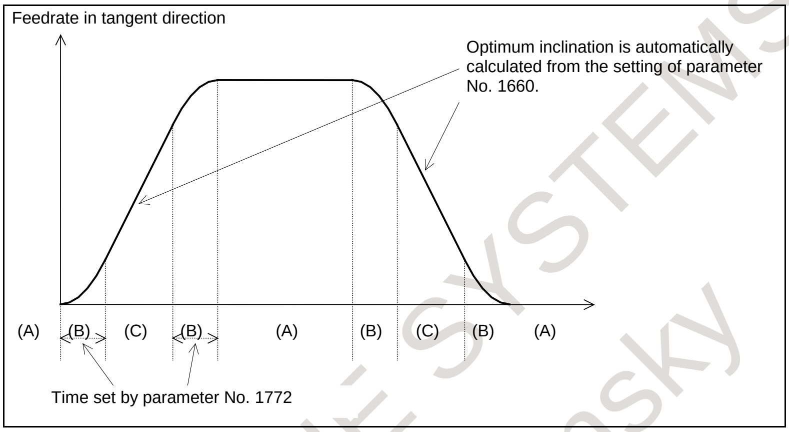
1769	Time constant for acceleration/deceleration after cutting feed interpolation in the acceleration/deceleration before interpolation mode

[Input type] Parameter input
[Data type] Word axis
[Unit of data] msec
[Valid data range] 0 to 4000
In the look-ahead acceleration/deceleration before interpolation mode as in AI contour control, not the ordinary time constant (parameter No. 1622) but the value of this parameter is used.
Be sure to specify the same time constant value for all axes except for a special application. If different values are set, correct linear and circular figures cannot be obtained.

1772	Acceleration change time of bell-shaped acceleration/deceleration before interpolation

[Input type] Parameter input
[Data type] 2-word path
[Unit of data] msec
[Valid data range] 0 to 200

Set an acceleration change time of look-ahead bell-shaped acceleration/ deceleration before interpolation (time for changing from the state of constant feedrate (A) to the state of constant acceleration/deceleration (C) at the acceleration rate calculated from the acceleration rate set in parameter No. 1660: time of (B) in the figure).
If the setting is negative or 0, bell-shaped acceleration/deceleration before interpolation is invalid. If the setting is 200 or more, the setting is clamped by 200.



1783	Maximum allowable feedrate difference for feedrate determination based on corner feedrate difference

[Input type] Parameter input
[Data type] Real axis
[Unit of data] mm/min, inch/min, deg/min (machine unit)
[Min. unit of data] Depend on the increment system of the applied axis
[Valid data range] Refer to the standard parameter setting table (C)
(When the increment system is IS-B, 0.0 to +999000.0)

If a feedrate component change for each axis exceeding the value set in this parameter occurs at the joint of blocks, the feedrate determination function based on corner feedrate difference finds a feedrate not exceeding the set value and performs deceleration by using look-ahead acceleration/deceleration before interpolation. Thus, a shock to the machine and machining error at a corner can be reduced.
Feedrate determination function based on corner feedrate difference disabled for an axis this parameter is zero.

3241	Character blinking in the AI contour control I mode (first character)
to	to
3247	Character blinking in the AI contour control I mode (seventh character)

[Input type] Parameter input
[Data type] Word path
[Valid data range] 0 to 95

Set the first to seventh blinking characters in the AI contour control I mode by using ASCII codes represented as decimal numbers.
When 0 is set in all of these parameters, "AICC 1" blinks.
Code numbers 032 to 095 in the "CHARACTER CODE LIST" can be set.

3251	**Character blinking in the AI contour control II mode (first character)**
to	**to**
3257	**Character blinking in the AI contour control II mode (seventh character)**

[Input type] Parameter input
[Data type] Word path
[Valid data range] 0 to 95

Set the first to seventh blinking characters in the AI contour control II mode by using ASCII codes represented as decimal numbers.
When 0 is set in all of these parameters, "AICC 2" blinks.
Code numbers 032 to 095 in the "CHARACTER CODE LIST" can be set.

CHARACTER CODE LIST

Character	Code	Comment	Character	Code	Comment	Character	Code	Comment
	032	Space	6	054		L	076

	#7	#6	#5	#4	#3	#2	#1	#0
7055					**BCG**			

[Input type] Parameter input
[Data type] Bit path

#3 BCG The pre-interpolation bell-shaped acceleration/deceleration time constant change function is:
0: Disabled.
1: Enabled.

NOTE
When function for changing time constant of look-ahead bell-shaped acceleration/deceleration before interpolation is enabled (bit 3 (BCG) of parameter No. 7055 is set to 1), be sure to specify acceleration rate of the reference axis (parameter No. 1660).
If acceleration rate of the reference axis is not specified, optimum acceleration rate is not obtained.

7066	Acceleration/deceleration reference speed for the time constant change function of bell-shaped acceleration/deceleration before interpolation

[Input type] Setting input
[Data type] Real path
[Unit of data] mm/min, inch/min, deg/min (input unit)
[Min. unit of data] Depend on the increment system of the reference axis
[Valid data range] Refer to the standard parameter setting table (C)
(When the increment system is IS-B, 0.0 to +999000.0)
This parameter is used when the time constant change function of look-ahead bell-shaped acceleration/deceleration before interpolation is used.
If the setting is 0, bell-shaped acceleration/deceleration before interpolation is invalid.

	#7	#6	#5	#4	#3	#2	#1	#0
8451	NOF			ZAG				

[Input type] Setting input
[Data type] Bit path

#4 ZAG The deceleration function based on cutting load in AI contour control II (deceleration based on Z-axis fall angle) is:
0: Not performed.
1: Performed.
When this parameter is set to 1, be sure to set parameters Nos. 8456, 8457, and 8458.

#7 NOF In AI contour control II, an F command is:
0: Not ignored.
1: Ignored.
When this parameter is set to 1, the specification of the maximum allowable feedrate set in parameter No. 8465 is assumed.

8456	Override for area 2 that is applied during deceleration according to the cutting load in AI contour control II
8457	Override for area 3 that is applied during deceleration according to the cutting load in AI contour control II
8458	Override for area 4 that is applied during deceleration according to the cutting load in AI contour control II

[Input type] Setting input
[Data type] Word path
[Unit of data] %
[Valid data range] 1 to 100

For the function of decelerating according to the cutting load in AI contour control II, the override set in a parameter can be applied according to the angle at which the tool moves downward along the Z-axis. The feedrate obtained according to other conditions is multiplied by the override for the area containing angle θ at which the tool moves downward.
However, when bit 1 (ZG2) of parameter No. 19515 is set to 0, no parameter is available to area 1, and 100% is applied at all times. When bit 1 (ZG2) of parameter No. 19515 is set to 1, set an override value for area 1 in parameter No. 19516.

Area 1 $0° \leq \theta < 30°$
Area 2 $30° \leq \theta < 45°$
Area 3 $45° \leq \theta < 60°$
Area 4 $60° \leq \theta \leq 90°$

	#7	#6	#5	#4	#3	#2	#1	#0
8459					OVRB			

[Input type] Parameter input
[Data type] Bit path

#3 OVRB For deceleration based on a feedrate difference or acceleration rate in AI contour control, override is:
0: Disabled.
1: Enabled.
Usually, override is enabled for a specified feedrate, and AI contour control is applied to the specified feedrate. When this parameter is set to 1, override is applied to a feedrate placed under AI contour control.

8465	Maximum allowable feedrate for AI contour control

[Input type] Setting input
[Data type] Real path
[Unit of data] mm/min, inch/min, deg/min (input unit)
[Min. unit of data] Depend on the increment system of the reference axis
[Valid data range] Refer to the standard parameter setting table (C)
(When the increment system is IS-B, 0.0 to +999000.0)
This parameter sets the maximum allowable feedrate for contour control.
If a feedrate higher than the setting of this parameter is specified in the AI contour control mode, the feedrate is clamped to that set in this parameter.
If this parameter is set to 0, no clamping is performed.
When bit 7 (NOF) of parameter No. 8451 is set to 1, the tool moves, assuming that the feedrate set in this parameter is specified. If 0 is set in this parameter at this time, a movement is made at the specified feedrate.

8466	Maximum allowable feedrate for AI contour control (when a rotation axis is singly specified)

[Input type] Setting input
[Data type] Real path
[Unit of data] mm/min, inch/min, deg/min (machine unit)
[Min. unit of data] Depend on the increment system of the reference axis
[Valid data range] Refer to the standard parameter setting table (C)
(When the increment system is IS-B, 0.0 to +999000.0)
This parameter sets the maximum allowable feedrate for AI contour control when a rotation axis is singly specified.

If a feedrate higher than the setting of this parameter is specified in the AI contour control mode, the feedrate is clamped to that set in this parameter.
If this parameter is set to 0, the feedrate is clamped to that set in parameter No. 8465.
When bit 7 (NOF) of parameter No. 8451 is set to 1 and a rotation axis is singly specified, the tool moves, assuming that the feedrate set in this parameter is specified. If 0 is set in this parameter at this time, the tool moves at the feedrate specified in parameter No. 8465.

	#7	#6	#5	#4	#3	#2	#1	#0
11223				CML				

[Input type] Parameter input
[Data type] Bit path

#4 CML When AI contour control is effective and machine lock is applied:
0: Operates in accordance with conventional specifications.
1: Operates at almost the same speed and cycle time as machine lock is invalid.

	#7	#6	#5	#4	#3	#2	#1	#0
11240							AMP	

[Input type] Parameter input
[Data type] Bit path

#1 AMP Movement with G53 command, and movement from middle point to reference position with G28 or G30 command are done with:
0: Acceleration/deceleration after interpolation.
1: Acceleration/deceleration before interpolation.

NOTE
This parameter is enabled when the following conditions.
- In AI contour control mode
- Bit 4(ZRL) of parameter No.1015 is set to 1.
- Bit 1(LRP) of parameter No.1401 is set to 1
- Parameter No.1671 of at least one of axes is set to value except 0.
- Bit 5(FRP) of parameter No.19501 is set to 1.

	#7	#6	#5	#4	#3	#2	#1	#0
11549		AP5						

[Input type] Parameter input
[Data type] Bit

#6 AP5 In multi-path system, AI contour control is:
0: Not executed simultaneously by more than 5 paths. (Set to 0 necessarily if AI contour control is not executed simultaneously by more than 5 paths.)
1: Executed simultaneously by more than 5 paths. (Set to 1 necessarily if AI contour control is executed simultaneously by more than 5 paths.)

NOTE
1 When this parameter is set, the power must be turned off before operation is continued.
2 If AI contour control is executed simultaneously by more than 5 paths without setting this parameter to 1, sufficient performance might not be obtained.

	#7	#6	#5	#4	#3	#2	#1	#0
19500	FCC	FNW						

[Input type] Parameter input
[Data type] Bit path

#6 FNW When the feedrate is determined according to the feedrate difference and acceleration in AI contour control:
0: The maximum feedrate at which the allowable feedrate difference and acceleration for each axis are not exceeded is used.
1: A feedrate is determined to ensure that a constant deceleration rate is applied to the same figure regardless of the direction of movement.

#7 FCC When there is an axis that requires one or more seconds for acceleration in look-ahead acceleration/deceleration before interpolation:
0: Emphasis is placed on precision, so that the specified feedrate may not be reached.
1: Emphasis is placed on speed, so that the specified feedrate is produced.
When this parameter is set to 1, the precision of curved interpolation such as circular interpolation may decrease.

	#7	#6	#5	#4	#3	#2	#1	#0
19503				ZOL				HPF

[Input type] Parameter input
[Data type] Bit path

#0 HPF When a feedrate is determined based on acceleration in AI contour control II, smooth feedrate control is:
0: Not used.
1: Used.

#4 ZOL The deceleration function based on cutting load in AI contour control II (deceleration based on Z-axis fall angle) is:
0: Enabled for all commands.
1: Enabled for linear interpolation commands only.

	#7	#6	#5	#4	#3	#2	#1	#0
19515							ZG2	

[Input type] Parameter input
[Data type] Bit path

#1 ZG2 When the deceleration function based on cutting load in AI contour control II (deceleration based on Z-axis fall angle) is used:
0: Stepwise override values are applied.
1: Inclined override values are applied.
This parameter is valid only when bit 4 (ZAG) of parameter No. 8451 is set to 1.

When this parameter is set to 1, be sure to set parameters Nos. 19516, 8456, 8457, and 8458.

19516	Override for area 1 in deceleration based on cutting load in AI contour control II

[Input type] Parameter input
[Data type] Word path
[Unit of data] %
[Valid data range] 1 to 100

This parameter sets an override value for area 1 when the deceleration function based on cutting load in AI contour control II is used.
This parameter is valid only when bit 1 (ZG2) of parameter No. 19515 is set to 1.

	#7	#6	#5	#4	#3	#2	#1	#0
19517							HNG	SNG

[Input type] Parameter input
[Data type] Bit path

#0 SNG When smooth speed control is effective, by block length of the linear interpolation, smooth speed control and speed control with change of acceleration on each axis;
0: Are not invalidated.
1: Are invalidated.
When smooth speed control is effective, smooth speed control and speed control with change of acceleration on each axis are invalidated in the block longer than the block length set to parameter No. 19518 if this parameter is set to 1.

#1 HNG By block length of the linear interpolation, speed control with acceleration on each axis and speed control with change of acceleration on each axis;
0: Are not invalidated.
1: Are invalidated.
Speed control with acceleration on each axis and speed control with change of acceleration on each axis are invalidated in the block longer than the block length set to parameter No. 19518 if this parameter is set to 1.

19518	Block length in speed control with acceleration or smooth speed control and speed control with change of acceleration are invalidated

[Input type] Parameter input
[Data type] Real path
[Unit of data] mm, inch (input unit)
[Min. unit of data] Depend on the increment system of the reference axis
[Valid data range] 0 or positive 9 digit of minimum unit of data (refer to the standard parameter setting table (B))
(When the increment system is IS-B, 0.0 to +999999.999)

This parameter sets the block length to invalidate speed control with acceleration on each axis or smooth speed control and speed control with change of acceleration on each axis by block length of the linear interpolation.
This parameter is effective when bit 1 (HNG) of parameter No. 19517 is set to 1 or bit 0 (SNG) of parameter No. 19517 is set to 1 if smooth speed control is effective.
Speed control with acceleration on each axis of smooth speed control and speed control with change of acceleration on each axis are invalidated in the block longer than the block length set to this parameter.
If 0.0 is set, the specification of 10.0 is assumed.

Alarm and message

Number	Message	Description
PS5009	PARAMETER ZERO (DRY RUN)	The dry run rate parameter No. 1410 or the parameter for the maximum cutting feedrate for each axis is 0. The parameter for the maximum cutting feedrate for each axis is No. 1432 if look-ahead acceleration/deceleration before interpolation is enabled and No. 1430 otherwise. Functions that cause look-ahead acceleration/deceleration before interpolation include AI contour control.
PS5011	PARAMETER ZERO (CUT MAX)	The setting of the parameter for the maximum cutting feedrate is 0. The parameter is No. 1432 if look-ahead acceleration/deceleration before interpolation is enabled and No. 1430 otherwise. Functions that cause look-ahead acceleration/deceleration before interpolation include AI contour control.
PS5110	IMPROPER G-CODE (AICC MODE)	An unspecifiable G code was specified in the AI contour control mode.

Notes

- About processing macro statements

In AI contour control mode, the NC statements of multiple blocks are read ahead. Macro statements such as arithmetic expressions and conditional branches are processed as soon as they are buffered (i.e. read into the buffer). Therefore, the timing of the macro statement execution is not always the specified order.
In case that you need to execute the macro statement after completing the NC block just before the macro statement, specify M code or G code that is not buffered just before the macro statement. Specially, in case of reading/writing the system variables to control signals, coordinates, compensation value, etc., it may be different system variable data by the timing of the NC statement execution. To avoid this phenomenon, specify such M codes or G codes before the macro statement, if necessary.

- Setting of acceleration/deceleration, and feedrate

In the mode of look-ahead acceleration/deceleration before interpolation, when a time required for acceleration or deceleration is over one second, the feedrate could not reach the specified data.
When bit 7 (FCC) of parameter No.19500 is set to 1, the feedrate can reach the specified data.
In this case, however, the interpolation precision may be lower in curve interpolation such as circular interpolation.

7.1.12 Speed Command Extension in Least Input Increments C

Overview

When the least input increment C (IS-C) is selected, the limitations indicated in Table 7.1.12 (a) and Table 7.1.13 (b) have conventionally been applied to the speed and acceleration parameters.
For example, when the unit of data is mm, and the increment system is IS-C, the maximum rapid traverse rate and maximum cutting speed have been unable to exceed 100000 mm/min due to the limitations on the valid data range.

- Conventional speed and angular velocity parameters

Table 7.1.12 (a)

Unit of data	Increment system	Minimum data unit	Valid data range
mm/min deg/min	IS-C	0.0001	0.0000 to +99999.9999
inch/min	IS-C	0.00001	0.00000 to +4000.00000

- Conventional acceleration and angular acceleration parameters

Table 7.1.12 (v)

Unit of data	Increment system	Minimum data unit	Valid data range
mm/sec^2 deg/sec^2	IS-C	0.0001	0.0000 to +99999.9999
inch/sec^2	IS-C	0.00001	0.00000 to +9999.99999

With an axis for which bit 7 (IESP) of parameter No. 1013 is set to 1 and IS-C is specified as the increment system, this function extends the parameter input limitations to those indicated in Table 7.1.13 (c) and Table 7.1.13 (d).
With this function, values greater than the conventionally allowed values can be set in the speed and acceleration parameters.
For example, the upper limit of the maximum rapid traverse rate and maximum cutting speed after this function is applied is:
- About 1000000 mm/min when the unit of data is mm, and IS-C is used

- Speed and angular velocity parameters when this function is used

Table 7.1.13 (c)

Unit of data	Increment system	Minimum data unit	Valid data range
mm/min deg/min	IS-C	0.001	0.000 to +999000.000
inch/min	IS-C	0.0001	0.0000 to +9600.0000

- Acceleration and angular acceleration parameters when this function is used

Table 7.1.13 (d)

Unit of data	Increment system	Minimum data unit	Valid data range
mm/sec^2 deg/sec^2	IS-C	0.001	0.000 to +999999.999
inch/sec^2	IS-C	0.0001	0.0000 to +99999.9999

> **NOTE**
> Note that the least input increment and valid data range of set data vary from the conventional ones.

- Feed forward

In case that the speed command is extended, when the feed forward function is enabled (bit 1 (FEED) of parameter No.2005 = 1), please set to 1 bit 3 (ISE64) of parameter No.2282.

Limitation

- Time constant parameters for linear acceleration/deceleration after interpolation and bell-shaped acceleration/deceleration after interpolation

If linear acceleration/deceleration after interpolation or bell-shaped acceleration/deceleration after interpolation is used in an operation such as rapid traverse, cutting feed, or manual feed, the maximum allowable time constant value is a half of the conventional maximum allowable value.
The table below indicates the pertinent time constant parameters:

Parameter number	Meaning
1620	Time constant T or T1 used for linear acceleration/deceleration or bell-shaped acceleration/deceleration in rapid traverse for each axis
1621	Time constant T2 used for bell-shaped acceleration/deceleration in rapid traverse for each axis
1622	Time constant of acceleration/deceleration in cutting feed for each axis
1624	Time constant of acceleration/deceleration in jog feed for each axis
1626	Acceleration/deceleration time constant in threading cycles for each axis

Parameter number	Meaning
1769	Time constant for acceleration/deceleration after cutting feed interpolation in the look-ahead acceleration/deceleration before interpolation mode
5271-5274	Time constant for acceleration/deceleration in rigid tapping extraction (first-stage to fourth-stage gear)
5365-5368	Bell-shaped acceleration/deceleration time constant in rigid tapping (first-stage to fourth-stage gear)

- VCMD waveform display function

As the speed increases, the amount of data that can be obtained for VCMD waveform display increases. So, the maximum treatable amount of data may be exceeded, resulting in incorrect waveform display.

- Positional deviation amount display on the servo setting screen

If the positional deviation amount exceeds -9999999 when a fast movement is made in the negative direction, the displayed number of digits decreases by one digit due to a limitation on display space.
To reference a correct positional deviation amount, check diagnosis data No. 300, "Servo positional deviation".

Parameter

	#7	#6	#5	#4	#3	#2	#1	#0
1013	IESPx							

[Input type] Parameter input
[Data type] Bit axis

> **NOTE**
> When this parameter is set, the power must be turned off before operation is continued.

#7 IESPx When the least input increment is C (IS-C), the function to allow to set the larger value to the parameter of the speed and the acceleration:
0: Not used.
1: Used.

As for the axis which set this parameter when the least input increment is C (IS-C), the larger value can be set to the parameter of the speed and the acceleration.
The valid data ranges for the speed and acceleration parameters are indicated in Table 7.1.13 (c) and Table 7.1.13 (d) provided in "Overview".
When this function is made effective, the digit number below the decimal point of the parameter on input screen is changed. The digit number below the decimal point decreases by one digit in case of the least input increment C (IS-C).

	#7	#6	#5	#4	#3	#2	#1	#0
2282					ISE64			

[Input type] Parameter input
[Data type] Bit axis

#3 ISE64 The speed limitation on the feed forward function (bit 1 (FEED) of parameter No. 2005 = 1) is:
0: Remains unchanged from the conventional value.
1: Extended.
When the feed forward function is enabled, the speed limitation on an axis for which this parameter is set is extended as indicated below if the increment system is IS-C.

	IS-C	
	Conventional	Extended
Speed [Unit: mm/min]	100000	999000

Notes

NOTE
1 To use this function, the corresponding servo software is required.
2 This function cannot be set for an axis under PMC axis control.

7.2 ACCELERATION/DECELERATION CONTROL

7.2.1 Automatic Acceleration/Deceleration

7.2.1.1 Automatic acceleration/deceleration

Overview

To prevent a mechanical shock, acceleration/deceleration is automatically applied when the tool starts and ends its movement (Fig. 7.2.1.1 (a)).

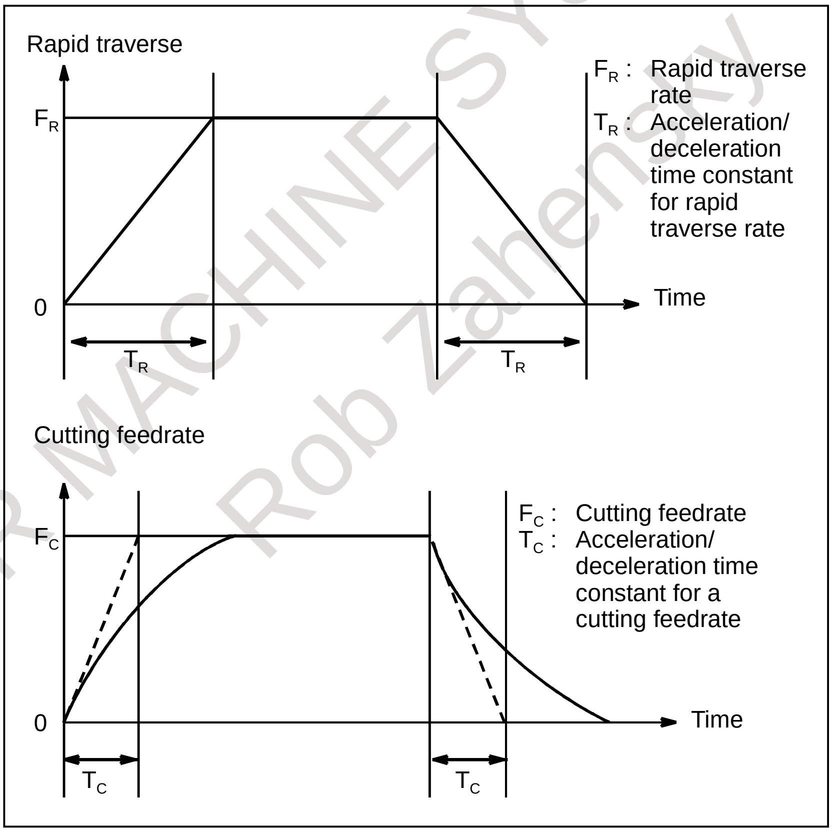

Fig. 7.2.1.1 (a)

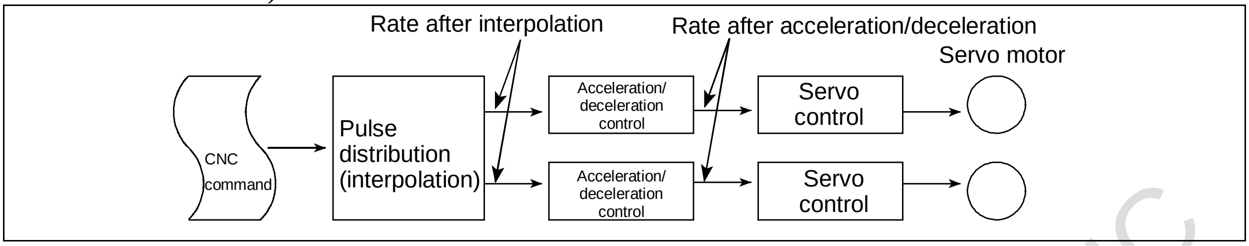
Acceleration and deceleration is performed when starting and ending movement, resulting in smooth start and stop.
Automatic acceleration/deceleration is also performed when feedrate changes, so the change in speed is also smooth.
It is not necessary to take acceleration/deceleration into consideration when programming.
Rapid traverse : Linear acceleration/deceleration (time constant per axis is set by parameter No. 1620)
Cutting feed : Exponential acceleration/deceleration (time constant per axis is set by parameter 1622)

Jog feed : Exponential acceleration/deceleration (time constant per axis is set by parameter No. 1624)



Parameter

	#7	#6	#5	#4	#3	#2	#1	#0
1610			**THLx**	**JGLx**			**CTBx**	**CTLx**

[Input type] Parameter input
[Data type] Bit axis

#0 CTLx Acceleration/deceleration in cutting feed or dry run during cutting feed
0: Exponential acceleration/deceleration is applied.
1: Linear acceleration/deceleration after interpolation is applied.

> **NOTE**
> This parameter is initial setting parameter. For details, refer to the appendix "Automatic setting / Initial setting parameter" in this manual.

#1 CTBx Acceleration/deceleration in cutting feed or dry run during cutting feed
0: Exponential acceleration/deceleration or linear acceleration/ deceleration is applied. (depending on the setting in bit 0 (CTLx) of parameter No. 1610)
1: Bell-shaped acceleration/deceleration is applied.

> **NOTE**
> This parameter is initial setting parameter. For details, refer to the appendix "Automatic setting / Initial setting parameter" in this manual.

#4 JGLx Acceleration/deceleration in jog feed
0: Exponential acceleration/deceleration is applied.
1: The same acceleration/deceleration as for cutting feedrate is applied. (Depending on the settings of bits 1 (CTBx) and 0 (CTLx) of parameter No. 1610)

> **NOTE**
> This parameter is initial setting parameter. For details, refer to the appendix "Automatic setting / Initial setting parameter" in this manual.

#5 THLx Acceleration/deceleration in threading cycles
0: Exponential acceleration/deceleration is applied.
1: The same acceleration/deceleration as for cutting feedrate is applied. (Depending on the settings of bits 1 (CTBx) and 0 (CTLx) of parameter No. 1610) As the time constant and FL rate, however, the settings of parameters Nos. 1626 and 1627 for threading cycles are used.

1620	Time constant T or T1 used for linear acceleration/deceleration or bell-shaped acceleration/deceleration in rapid traverse for each axis

[Input type] Parameter input
[Data type] Word axis
[Unit of data] msec
[Valid data range] 0 to 4000

Specify a time constant used for acceleration/deceleration in rapid traverse.

[Example]

For linear acceleration/deceleration

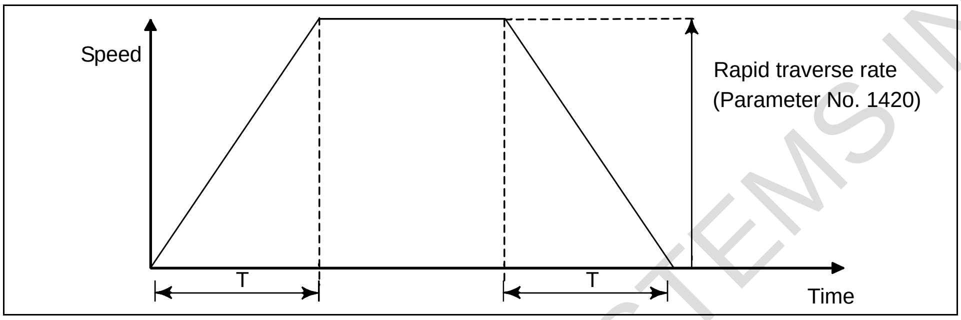


Fig. 7.2.1.1 (b)

T : Setting of parameter No. 1620

For bell-shaped acceleration/deceleration

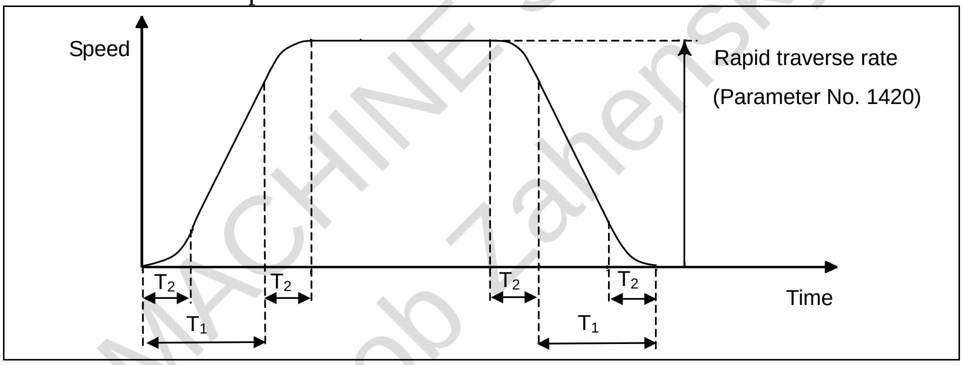

Fig. 7.2.1.1 (c)

T_1 : Setting of parameter No. 1620
T_2 : Setting of parameter No. 1621
(However, $T_1 \geq T_2$ must be satisfied.)
Total acceleration (deceleration) time : $T_1 + T_2$
Time for linear portion : $T_1 - T_2$
Time for curve portion : $T_2 \times 2$

1621	Time constant T_2 used for bell-shaped acceleration/deceleration in rapid traverse for each axis

[Input type] Parameter input
[Data type] Word axis
[Unit of data] msec
[Valid data range] 0 to 512

Specify time constant T_2 used for bell-shaped acceleration/ deceleration in rapid traverse for each axis.

1622	Time constant of acceleration/deceleration in cutting feed for each axis

[Input type] Parameter input
[Data type] Word axis
[Unit of data] msec
[Valid data range] 0 to 4000

Set the time constant used for exponential acceleration/deceleration in cutting feed, bell-shaped acceleration/deceleration after interpolation or linear acceleration/ deceleration after interpolation in cutting feed for each axis. Which type to use is selected with bits 1 (CTBx) and 0 (CTLx) of parameter No. 1610. Except for special applications, the same time constant must be set for all axes in this parameter. If the time constants set for the axes differ from each other, proper straight lines and arcs cannot be obtained.

1623	FL rate of exponential acceleration/deceleration in cutting feed for each axis

[Input type] Parameter input
[Data type] Real axis
[Unit of data] mm/min, inch/min, deg/min (machine unit)
[Min. unit of data] Depend on the increment system of the applied axis
[Valid data range] Refer to the standard parameter setting table (C)
(When the increment system is IS-B, 0.0 to +999000.0)

Set the lower limit (FL rate) of exponential acceleration/deceleration in cutting feed for each axis.

1624	Time constant of acceleration/deceleration in jog feed for each axis.

[Input type] Parameter input
[Data type] Word axis
[Unit of data] msec
[Valid data range] 0 to 4000

Set the time constant used for acceleration/deceleration in jog feed for each axis.

1625	FL rate of exponential acceleration/deceleration in jog feed for each axis

[Input type] Parameter input
[Data type] Real axis
[Unit of data] mm/min, inch/min, deg/min (machine unit)
[Min. unit of data] Depend on the increment system of the applied axis
[Valid data range] Refer to the standard parameter setting table (C)
(When the increment system is IS-B, 0.0 to +999000.0)

Set the FL rate of exponential acceleration/deceleration in jog feed for each axis.
This parameter allows only the exponential type.

1626	Acceleration/deceleration time constant in threading cycles for each axis

[Input type] Parameter input
[Data type] Word axis
[Unit of data] msec
[Valid data range] 0 to 4000

Set a time constant for acceleration/deceleration after interpolation in the threading cycles G92 (T series), G76 (T series), and G76.7 (M series) for each axis.

1627	FL rate for acceleration/deceleration in threading cycles for each axis

[Input type] Parameter input

[Data type] Real axis
[Unit of data] mm/min, inch/min, deg/min (machine unit)
[Min. unit of data] Depend on the increment system of the applied axis
[Valid data range] Refer to the standard parameter setting table (C)
(When the increment system is IS-B, 0.0 to +999000.0)
Set an FL rate for acceleration/deceleration after interpolation in the threading cycles G92 (T series), G76 (T series), and G76.7 (M series) for each axis. Set 0 at all times except in a special case.

7.2.1.2 Rapid traverse block overlap

Overview

If rapid traverse blocks continue or the block next to a rapid traverse block does not move, the next block can be executed when the feedrate of each axis of a rapid traverse block is decreased to the reduction ratio set by the parameter.

Explanation

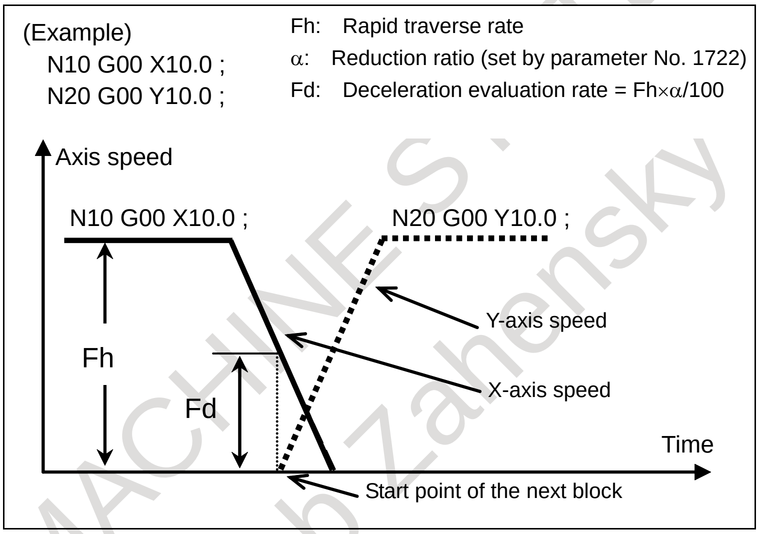

Fig. 7.2.1.2

> **NOTE**
> Whether the speed is reduced to the reduction ratio is determined based on parameter No. 1420 (rapid traverse rate for each axis).

Limitation

Rapid traverse block overlap is disabled when:

- Pre-interpolation acceleration/deceleration is used for rapid traverse.
- The rapid traverse block overlap disable signal ROVLP <Gn053.5> is "1".
- In the rapid traverse command, dry run is enabled (bit 6 (RDR) of parameter No. 1401 = 1) and dry run signal DRN <Gn046.7> is "1". (This function is not disabled, however, if manual rapid traverse selection signal RT <Gn019.7> is set to "1".)
- Rapid traverse is of linear interpolation type (bit 1 (LRP) of parameter No. 1401 = 1) and the acceleration/deceleration is constant over time (bit 4 (PRT) of parameter No. 1603 = 1).

Signal

Rapid traverse block overlap disable signal ROVLP<Gn053.5>

[Classification] Input signal
[Function] This signal disables rapid traverse block overlap.

Signal address

	#7	#6	#5	#4	#3	#2	#1	#0
Gn053			ROVLP					

Parameter

	#7	#6	#5	#4	#3	#2	#1	#0
1601				RTO				

[Input type] Parameter input
[Data type] Bit path

#4 RTO Block overlap in rapid traverse
0: Blocks are not overlapped in rapid traverse.
1: Blocks are overlapped in rapid traverse.

1722	Rapid traverse feedrate reduction ratio for overlapping rapid traverse blocks

[Input type] Parameter input
[Data type] Byte axis
[Unit of data] %
[Valid data range] 0 to 100

This parameter is used when rapid traverse blocks are arranged successively, or when a rapid traverse block is followed by a block that does not cause movement. When the feedrate for each axis of a block is reduced to the ratio set in this parameter, the execution of the next block is started.

NOTE
The parameter No. 1722 is effective when bit 4 (RTO) of parameter No. 1601 is set to 1.

7.2.1.3 Programmable rapid traverse overlap

Overview

The programmable rapid traverse overlap supports:
- Changing the feedrate reduction ratio for rapid traverse overlap from the macro program becomes possible.
- Shortening the cycle time becomes possible by doing rapid traverse overlap between threading cycle blocks.

- Programmable rapid traverse overlap

If the bit 0 (PRO) of parameter No. 1612=0, the feedrate reduction ratio for rapid traverse overlap is specified by the parameter No. 1722. If the parameter PRO=1, the ratio is specified by the system variables. Even if the parameter PRO=1, and the system variables other than 1 to 100 is specified, the ratio is specified by the parameter No. 1722.

#100851 Feedrate reduction ratio for rapid traverse overlap (1st axis)
#100852 Feedrate reduction ratio for rapid traverse overlap (2nd axis)
:
#100874 Feedrate reduction ratio for rapid traverse overlap (24th axis)

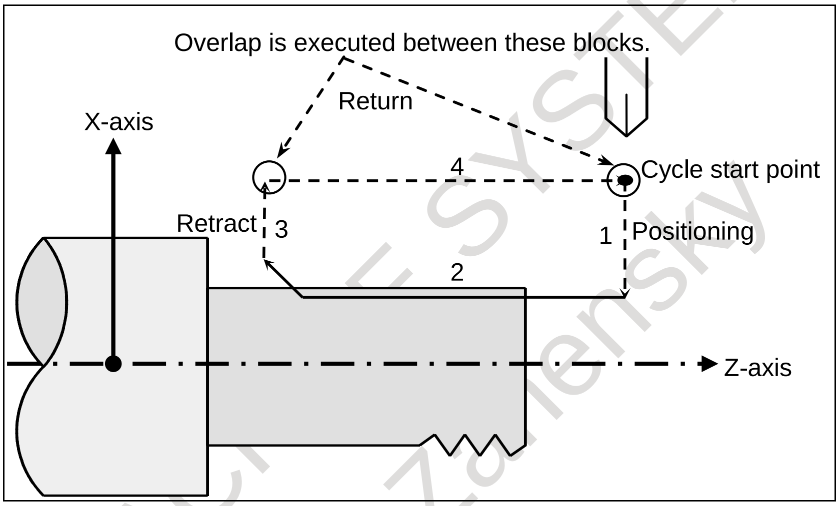
> **NOTE**
> 1 Available up to the number of controlled axes.
> 2 After the value is set, it is available until the system is reset.

To use this function, set the following signals and parameters.

- ROVLP<Gn053.5> is "0"
  Rapid traverse block overlap disable signal
- Bit 4 (RTO) of parameter No. 1601=1
  Blocks are overlapped in rapid traverse.
- Bit 0 (PRO) of parameter No. 1612=1
  The feedrate reduction ratio for rapid traverse overlap is specified by the system variables.

- Rapid traverse overlap between threading cycle blocks

Rapid traverse overlap is executed between "retract(3)" and "return(4)" and between "return(4)" and "next-threading cycle positioning(1)".



To use this function, set the following parameters.

- Bit 0 (CFR) of parameter No. 1611=1 :
  For retraction after threading, the type of acceleration /deceleration after interpolation for rapid traverse is used.
- Bit 4 (PRT) of parameter No. 1603=0 :
  For positioning, acceleration/deceleration of acceleration fixed type is used.

The thread cutting cycle retract function is disabled.

Explanation

- Programmable rapid traverse overlap

How to specify the feedrate reduction ratio for rapid traverse overlap by the system variables.

Example)

O0001;
N10 #100851=50;　　Write to system variable (ratio is 50%)
N20 G00 X10.00;
N30 G00 Z10.00;　　} Execute overlap (ratio is 50%)
;
N50 #100851=100;　　Rewrite to system variable (ratio is 100%)
N60 G00 X30.00;
N70 G00 Z50.00;　　} Execute overlap (ratio is 100%)
N80 M02;

> **NOTE**
> 1 To specify the feedrate reduction ratio for rapid traverse overlap by the system variables is executed as macro program.
> 2 Whether the feedrate has been reduced as specified by the reduction ratio is compare with the parameter No. 1420 (Rapid traverse rate for each axis).

- Rapid traverse overlap between threading cycle blocks

To use rapid traverse overlap between threading cycle blocks, set the bit 3 (TCO) of parameter No. 1611 = 1.

Rapid traverse overlap between threading cycle blocks is executed as shown Fig. 7.2.1.3.

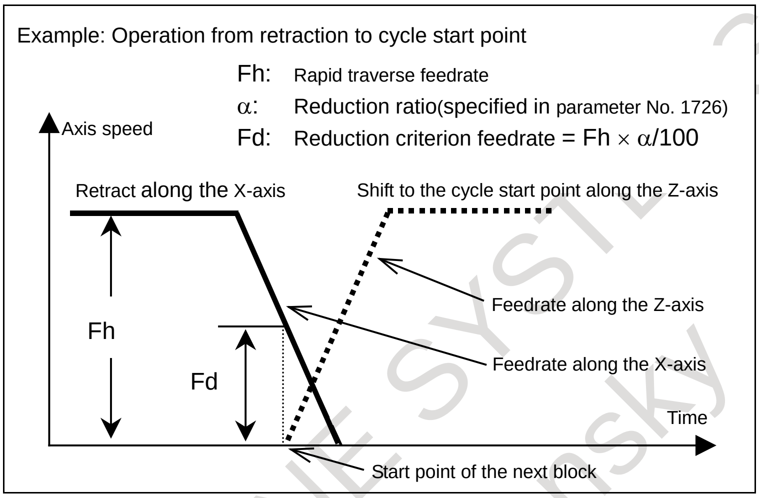


Fig. 7.2.1.3

> **NOTE**
> Whether the feedrate has been reduced as specified by the reduction ratio is compare with the parameter No. 1420 (Rapid traverse rate for each axis).

Restrictions

In following conditions, both rapid traverse block overlap and rapid traverse overlap between threading cycle blocks are disabled.

- Look-ahead acceleration/deceleration before interpolation is used in rapid traverse
- The bit 6 (RDR) of parameter No. 1401 = 1 (dry run for rapid traverse is enabled), and the dry run signal DRN<Gn046.7> is "1" and the manual rapid traverse selection signal RT <Gn019.7> is set to "0".
- The bit 1 (LRP) of parameter No. 1401 = 1 (positioning is performed with linear interpolation) and bit 4 (PRT) of parameter No. 1603=1 (acceleration/deceleration of time fixed type is used).

・Restrictions about programmable rapid traverse overlap

- Rapid traverse block overlap is disabled if the rapid traverse block overlap disable signal ROVLP<Gn053.5> is "1".

・Restrictions about rapid traverse overlap between threading cycle blocks

- If this function is enabled, thread cycle retract function is disabled.
- The threading cycle command must be commanded in G40 mode (Cutter/tool nose radius compensation cancel mode).
- Rapid traverse block overlap disable signal ROVLP<Gn053.5> is invalid.

Signal

Rapid traverse block overlap disable signal ROVLP<Gn053.5>

[Classification] Input signal

[Function] This signal disables rapid traverse block overlap.

Signal address

	#7	#6	#5	#4	#3	#2	#1	#0
Gn053			ROVLP					

Parameter

	#7	#6	#5	#4	#3	#2	#1	#0
1601				RTO				

[Input type] Parameter input

[Data type] Bit path

#4 RTO Block overlap in rapid traverse
0: Blocks are not overlapped in rapid traverse.
1: Blocks are overlapped in rapid traverse.

	#7	#6	#5	#4	#3	#2	#1	#0
1611					TCO			

[Input type] Parameter input

[Data type] Bit path

#3 TCO Blocks in a threading cycle are:
0: Not overlapped in rapid traverse.
1: Overlapped in rapid traverse.

In a threading cycle that is a canned cycle, the rapid traverse overlap function can perform rapid traverse overlap between a retract operation and return operation and between a return operation and a positioning operation for the next threading cycle.
The rapid traverse deceleration ratio in an overlap between blocks is set in parameter No. 1726.

> **NOTE**
> When this function is used, threading cycle retraction is disabled.

	#7	#6	#5	#4	#3	#2	#1	#0
1612								PRO

[Input type] Parameter input

[Data type] Bit path

#0 PRO The feedrate reduction ratio for rapid traverse overlap is specified by :
0: The parameter No. 1722
1: The system variables #100851[#_ROVLP[1]]-#100874[#_ROVLP[24]]

This function is available in following conditions.
Rapid traverse block overlap disable signal ROVLP<Gn053.5>="0" and bit 4 (RTO) of parameter No. 1601=1(Blocks are overlapped in rapid traverse).

1722	Rapid traverse feedrate reduction ratio for overlapping rapid traverse blocks

[Input type] Parameter input
[Data type] Byte axis
[Unit of data] %
[Valid data range] 0 to 100

This parameter is used when rapid traverse blocks are arranged successively, or when a rapid traverse block is followed by a block that does not cause movement. When the feedrate for each axis of a block is reduced to the ratio set in this parameter, the execution of the next block is started.

> **NOTE**
> The parameter No. 1722 is effective when bit 4 (RTO) of parameter No. 1601 is set to 1.

1726	Rapid traverse rate reduction ratio for overlapping threading cycle blocks

[Input type] Parameter input
[Data type] Byte axis
[Unit of data] %
[Valid data range] 0 to 100

In a threading cycle that is a canned cycle, when the feedrate for each axis is reduced to the deceleration ratio set in this parameter between a retraction and a return to the cycle start point or between a return to the cycle start point and a movement to the threading start point, the execution of the next block is started.

> **NOTE**
> The parameter No. 1726 is valid when bit 3 (TCO) of parameter No. 1611 is set to 1.

7.2.1.4 Smart overlap

Outline

Cycle time can be reduced by Smart overlap that can overlap at rapid traverse to cutting feed, cutting feed to rapid traverse, and rapid traverse to rapid traverse.

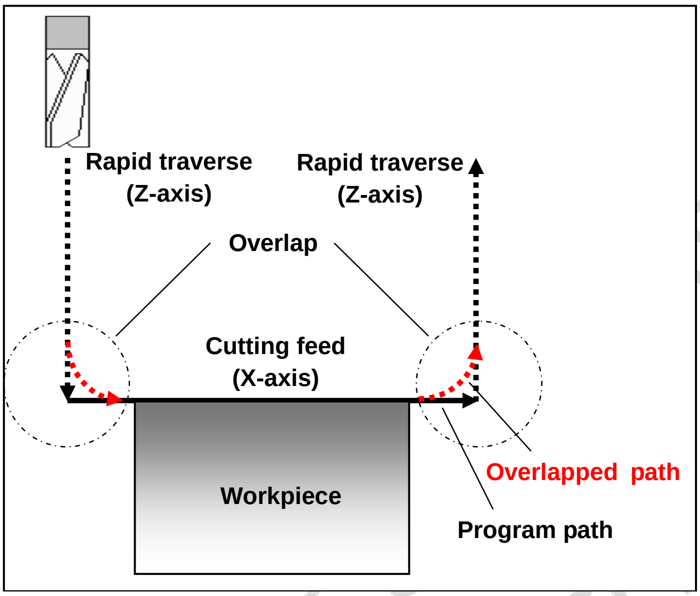

Fig. 7.2.1.4 (a) Overlapped path

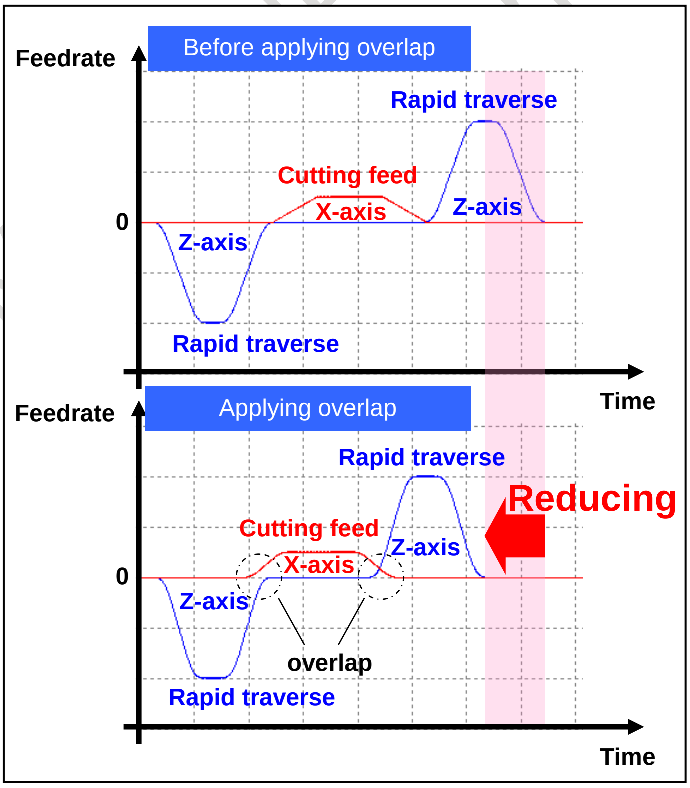

Fig. 7.2.1.4 (b) Effect of overlap

Explanation

When bit 1 (SOVx) of parameter (No.11236) is set to 1, Smart overlap is effective.
Overlap time can be set by parameter (Nos.11248 and 11249). The commands between blocks can be overlapped at the amount of the set overlap time. If the commands to which overlap is effective is consecutive, it overlaps between not only two blocks but two or more blocks.

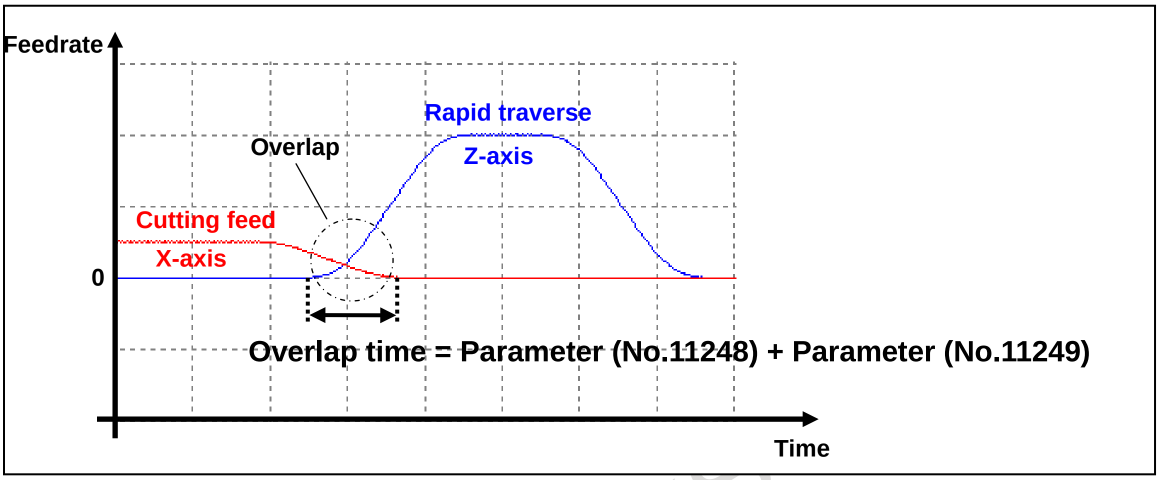

Fig.7.2.1.4 (c) Overlap time

･ Method for parameter setting

Set the parameters as follows to use Smart overlap is used.

1. For the axis for which Smart overlap is to be enabled, set bit 1 (SOVx) of parameter (No. 11236) to 1.

2. Set overlap time to parameter (No.11248).
   - Parameter (No.11248) is used as a common time constant for acceleration/deceleration after interpolation in rapid traverse and cutting feed. (This is called as acceleration/deceleration by Smart overlap.)
   - Usually set below the value of parameter (No.1622) (Time constant of acceleration/deceleration in cutting feed for each axis).
     In addition, set below the value of parameter (No.1769) (Time constant for acceleration/deceleration after cutting feed interpolation in the acceleration/deceleration before interpolation mode) when AICC (AI Contour Control) is used.
   - Set the same value to all axes to enable Smart overlap.
   - Usually set 0 to parameter (No.11249).

3. Set the following value to parameter (No.1621) (Time constant T2 used for acceleration/deceleration in rapid traverse for each axis).
   - Parameter (No.1621) = Parameter (No.1621) - Parameter (No.11248)
   - If the value in the above expression is minus, set 0 to parameter (No.1621).
   - If vibration is generated by the rapid traverse command, adjust the parameter (No.1621) of axes to which the vibration is generated by setting a bigger value.

4. Set the following value to parameter (No.1622) (Time constant of acceleration/deceleration in cutting feed for each axis).
   - Parameter (No.1622) = Parameter (No.1622) - Parameter (No.11248)
   - If the value in the above expression is minus, set 0 to parameter (No.1622).

5. When AICC (AI Contour Control) is used, set the following value parameter (No.176) (Time constant for acceleration/deceleration after cutting feed interpolation in the acceleration/deceleration before interpolation mode).
   - Parameter (No.1769) = Parameter (No.1769) - Parameter (No.11248)

- If the value in the above expression is minus, set 0 to parameter (No.1769).

6. When rapid traverse acceleration/deceleration before interpolation is used, set the following value parameter (No.11242) (Time constant of acceleration/deceleration after interpolation of acceleration/deceleration before interpolation in rapid traverse).
   - Parameter (No.11242) = Parameter (No.11242) - Parameter (No.11248)
   - If the value in the above expression is minus, set 0 to parameter (No.11242).

   If parameter (No.11242) is 0, set the following value to parameter (No.1672) (Acceleration change time of bell-shaped acceleration/deceleration before interpolation for linear rapid traverse) because the adjustment by time constant for acceleration/deceleration after interpolation is unavailable.
   - Parameter (No.1672) = Parameter (No.1672) - Parameter (No.11248)
   - If the value in the above expression is minus, set 0 to parameter (No.1672).

7. When the each function of Table 7.2.1.4 (a), adjust time constants for acceleration/deceleration after interpolation of the each function.
   - The value of parameter (No.11248) is subtracted from the time constants of the each function.
   - When the bell-shaped acceleration/deceleration is “constant acceleration/deceleration type” + “constant acceleration/deceleration time type”, the value of parameter (No.11248) is subtracted from the time constant of “constant acceleration/deceleration time type”.
   - If the problem (vibrate is generated, and etc.) occurs on each function, adjust the time constants of the each function by setting a bigger value.

Table 7.2.1.4 (a) Time constants for acceleration/deceleration after interpolation of the each function

Function	Parameter
TIME CONSTANT FOR ACC/DEC IN JOG	No.1624
T CONSTANT AFTER IPL(THREAD CYCLE)	No.1626
TIME CNST2 AFTER IP(RAPID)	No.1674
TIME CNST2(BELL) AFTER IP(RAPID)	No.1675
TIME CNST3 AFTER IP(RAPID)	No.1676
TIME CNST3(BELL) AFTER IP(RAPID)	No.1677
TIME CNST2 AFTER IP(CUT)	No.1678
TIME CNST3 AFTER IP(CUT)	No.1679
TIME CONSTANT FOR ACC/DEC (GEAR 1 TO 4)	Nos.5261 to 5264
TIME CNST IN EXTRACTION (GEAR 1 TO 4)	Nos.5271 to 5274
TIME CNST FOR BELL (GEAR 1 TO 4)	Nos.5365 to 5368
LEVEL 1 TO 7 RAPID TRAVERSE TIME CONSTANT (Positioning by optimum accelerations)	Nos.6171 to 6177
TIME CNST T2 FOR LEVEL 1 TO 7 RAPID BELL (Positioning by optimum accelerations)	Nos.6191 to 6197
T CONSTANT AFTER IPL(SKIP FUNCTION)	No.6280
T CONSTANT AFTER RAPID (MH RETRACE)	No.6495
T CONST BELL AFTER RAPID(MH RETRACE)	No.6496
T CONST AFTER CUT (M-HANDLE RETRACE)	No.6497
T CONSTANT FOR LINEAR (RETRACT)	No.7745
T CONST FOR LINEAR IN RAPID(S-IMPOS)	No.8192
T CONST FOR BELL IN RAPID (S-IMPOSE)	No.8195
T CONST IN CUT (2 AXES SUPERIMPOSED)	No.8196
T CONST FOR LINEAR IN RAPID(3 S-IMP)	No.8197
T CONST FOR BELL IN RAPID (S-IMPOSE)	No.8198
T CONST IN CUT (3 AXES SUPERIMPOSED)	No.8199
TIME CONSTANT AFTER IPL(SP WITH SV)	No.11016
T CONST AFTER CUT IPL IN BEFOR IPL	No.11052
TIME CONST FOR RIGID TAPPING (G1 TO G4)	Nos.11060 to 11063
TIME CONST IN EXTRACT FOR R-TAP(G1 TO G4)	Nos.11065 to 11068
T-CON AIPL IN BIPL(RAPID)(msec)	No.11242

Function	Parameter
T CONST IN RAPID (TCP OR WSC MODE)	No.11263

> ⚠CAUTION
> If the overlap time is set bigger value than the original setting time constant for acceleration/deceleration after cutting feed interpolation, the machining accuracy of the workpiece might deteriorate.

[Example of parameter setting]

The example of parameter setting in case of setting overlap time as 16msec is shown below.

Table 7.2.1.4 (b) Example of parameter setting

Move command	Axis	Before applying Smart overlap				
		Parameter				Total (*1)
Rapid traverse		**No.1620**	**No.1621**	**-**	**No.11248**	-

	X	4000		0		16
	Y	4000	24	0		16
	Z	4000		0		16

(*1) Total of time constant for acceleration/deceleration after interpolation (Parameter No.1660, No.1772, No.1671 and No.1672 are excluded for acceleration/deceleration before interpolation)

Parameter No.1620: Time constant T1 used for acceleration/deceleration after interpolation in rapid traverse
Parameter No.1660: Maximum allowable acceleration rate in acceleration/deceleration before interpolation (AICC)
Parameter No.1772: Acceleration change time of bell-shaped acceleration/deceleration before interpolation (AICC)
Parameter No.1671: Maximum allowable acceleration rate in acceleration/deceleration before interpolation for linear rapid traverse
Parameter No.1672: Acceleration change time of bell-shaped acceleration/deceleration before interpolation for linear rapid traverse

[Example]
This example is the case of automatic operation on parameter setting of Table 7.2.1.4 (b) without AICC.

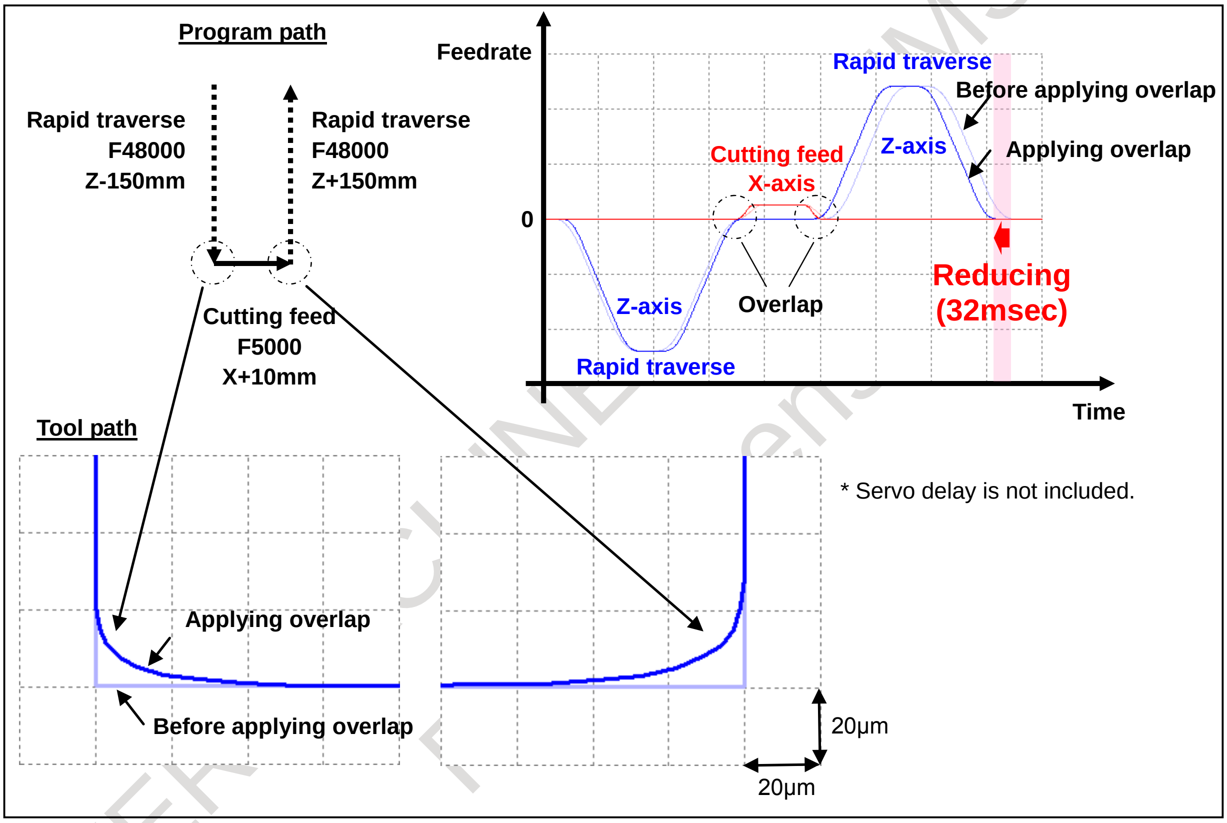

Fig. 7.2.1.4 (d) Example

- Clamp of overlap value

As the feedrate increases, overlap value becomes larger. To suppress it, by setting parameter (Nos.10740 to 10742), the overlap value can be clamped depending on program command.
(During Smart overlap, normal in-position check is not executed.)

Table 7.2.1.4 (c) Maximum overlap value

Program command		Maximum overlap value (Parameter Number)
Current block	Next block	
Rapid traverse	Rapid traverse	No.10740
Rapid traverse	Cutting feed	No.10741
Cutting feed	Rapid traverse	No.10742

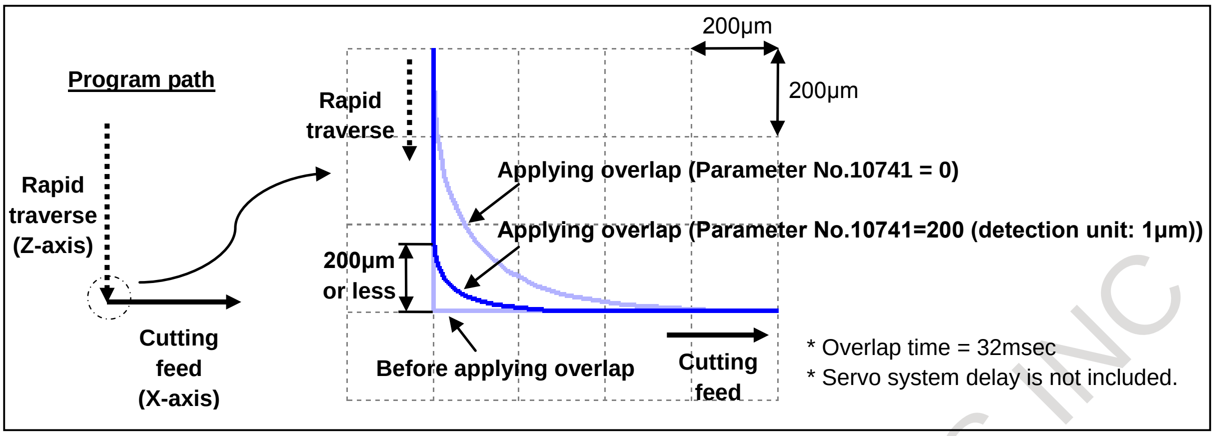

Fig. 7.2.1.4 (e) Clamp of overlap value

> **NOTE**
> 1 When parameter (Nos.10740 to 10742) is set to 0, the overlap value does not be clamped.
> 2 When you clamp overlap value, set the value of in-position width or more to parameter Nos.10740 to 10742.

- Disabling overlap

By setting 1 to bits 0 to 7 of parameter (No.11247), overlap can be disabled depending on program command.

Table 7.2.1.4 (d) Disabling overlap

Program command		Parameter		overlap
Current block	Next block	Number	value	
Rapid traverse	Rapid traverse	SRR(No.11247#0)	0	Enabled
			1	Disabled
	Cutting feed	SRC(No.11247#1)	0	Enabled
			1	Disabled
	No movement	SRN(No.11247#2)	0	Enabled
			1	Disabled
Cutting feed	Rapid traverse	SCR(No.11247#3)	0	Enabled
			1	Disabled
	Cutting feed	None	-	Enabled
	No movement	SCN(No.11247#4)	0	Disabled
			1	Enabled
No movement	Rapid traverse	SNR(No.11247#5)	0	Disabled
			1	Enabled
	Cutting feed	SNC(No.11247#6)	0	Enabled
			1	Disabled
	No movement	SNN(No.11247#7)	0	Enabled
			1	Disabled

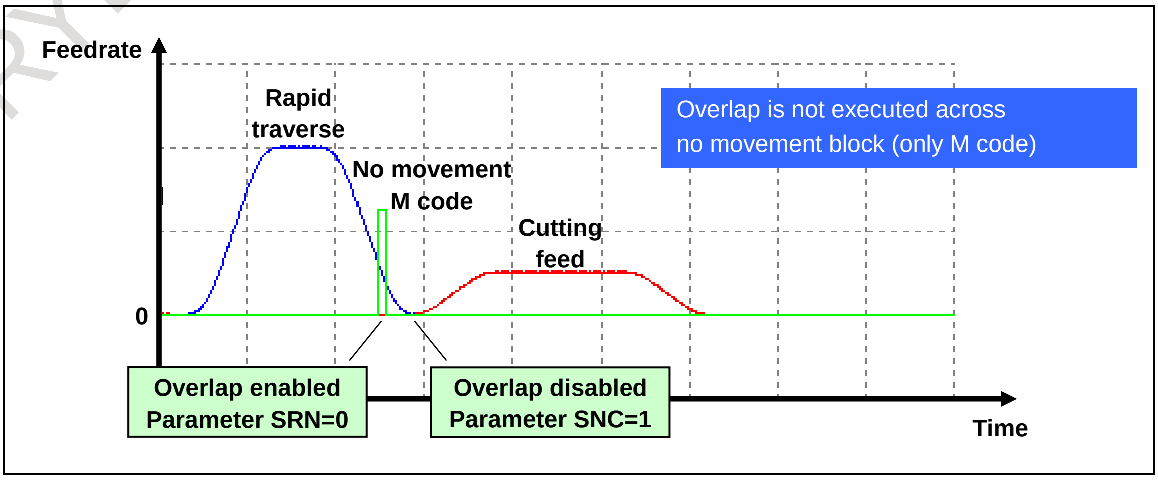

Fig. 7.2.1.4 (k) Example 6 of overlap

- Relation to each function

The relation to each function is as follows.

- Rapid traverse block overlap
  Rapid traverse block overlap can be used concurrently with Smart overlap. When rapid traverse block overlap and Smart overlap are used at the same time, overlap is performed from the bigger of the overlap value specified for the two functions.

- Optimum acceleration/deceleration for rigid tapping
  The function for acceleration/deceleration by Smart overlap is ineffective in Optimum acceleration/deceleration for rigid tapping block. Moreover, the overlap is not performed before and after the block.

- High precision oscillation function
  The function for acceleration/deceleration by Smart overlap is ineffective while High precision oscillation function is executing. Moreover, the overlap is not performed before and after the block.

- Axis synchronous control
  The function for acceleration/deceleration by Smart overlap is ineffective while Synchronization establishment function is executing. Moreover, the overlap is not performed before and after the block.

- PMC Axis Control
  Automatic acceleration/deceleration is ineffective while the skip command (03h) of PMC axis control is executing. The acceleration/deceleration by Smart overlap is ineffective too, and the overlap is not performed before and after the block.
  For the other commands of PMC axis control, the acceleration/deceleration by Smart overlap is effective, but the overlap is not performed before and after the block.

- Function of deceleration stop in case of power failure
  The function for acceleration/deceleration by Smart overlap is ineffective while the deceleration stop in case of power failure is executing. Moreover, the overlap is not performed before and after the block.

- Arbitrary speed threading
  The function for acceleration/deceleration by Smart overlap is ineffective while arbitrary speed threading is executing. Moreover, the overlap is not performed before and after the block.

- Non-buffering block
  The acceleration/deceleration by Smart overlap is effective in the non-buffering block. However, the overlap is ineffective before and after the block. In the following examples, the overlap is not performed between N1-N2 and between N2-N3.
  Example)
  N1 Gxx ;
  N2 Mxx ;···Non-buffering M code
  N3 Gxx ;

- Automatic reference position return (G28, G30)
  The acceleration/deceleration by Smart overlap is effective in the automatic reference position return command. However, the overlap is ineffective between the movement to the reference point and the next block. The overlap is effective between before the reference point return command block and the movement to the middle point.

- In-position check disable reference position return (G28.2,G30.2)
  This command is similar to automatic reference point return (G28,G30).

- High-speed G53 function (G53P1)
High-speed G53 function is non-buffering G code. But, the acceleration/deceleration by Smart overlap is effective, and the overlap is also effective before and after the block.

- Threading
The acceleration/deceleration by Smart overlap is effective in the start block of threading (Block that waits for one-rotation signal). However, the overlap is ineffective between previous block.

- Threading cycle
Smart overlap is performed between "retract" and "return" and between "return" and "positioning" in the threading cycle.

- Rigid tapping
The acceleration/deceleration by Smart overlap is effective in the following blocks. However, the overlap is not performed before and after the block.
  - Movement block from I point (Initial point) to R point and movement block from R point to Z point (hole bottom)
  - Movement block from R point to Z point (hole bottom) and movement block from Z point (hole bottom) to R point.
  - Movement block from Z point (hole bottom) to R point and movement block from R point to I point (Initial point)

- Exact Stop (G09)/Exact Stop mode (G61)
The function for acceleration/deceleration by Smart overlap is effective in the exact stop block. However, the overlap is not performed between the next block.

- Synchronous/Composite control, Superimposed control
If Smart overlap is effective even one axis, an operation equivalent to that of following setting is performed.
- Bit 5 (NCS) of parameter No.8160 is 1, bit 7 (NRS) of parameter No.8160 is 1, bit 1 (MSO) of parameter No.8168 is 1

- In-position check
If Smart overlap is effective even one axis, an operation equivalent to that of following setting is performed.
- Bit 4 of parameter No.11503 is 1

- In-position check signal
In Smart overlap between cutting feed blocks, the in-position check signal can be switched enabled and disabled by the parameter SIE(No.10735#4) .

- Manual operation
Smart overlap is also effective in manual operation.

- Dwell command
Between dwell command and the previous block, overlap can be switched between enabled and disabled by the parameter SOD(No.10735#7).

Disabling Smart overlap of rigid tap

When Smart overlap is applied to rigid tap, the sum of the time constant of acceleration/deceleration after interpolation(parameters No.5261 to 5264, etc) in rigid tap and the time constant of acceleration/deceleration after interpolation(parameters Nos.11248 and 11249) in Smart overlap is the total time. Therefore, it is necessary to subtract the time constant of acceleration/deceleration after interpolation in Smart overlap from the time constant of acceleration/deceleration after interpolation in rigid tap and adjust so that the total time constant of acceleration/deceleration after interpolation does not change. However, if the time constant of acceleration/deceleration after interpolation in rigid tap is less than the time constant of acceleration/deceleration after interpolation in Smart overlap, all the time constant of acceleration/deceleration after interpolation in Smart overlap cannot be subtracted from the time constant of acceleration/deceleration after interpolation in rigid tap. As a result, the total time constant of acceleration/deceleration after interpolation may be increased and the cycle time may be extended.

Table 7.2.1.4 (e) Adjustment example of time constant of acceleration/deceleration after interpolation

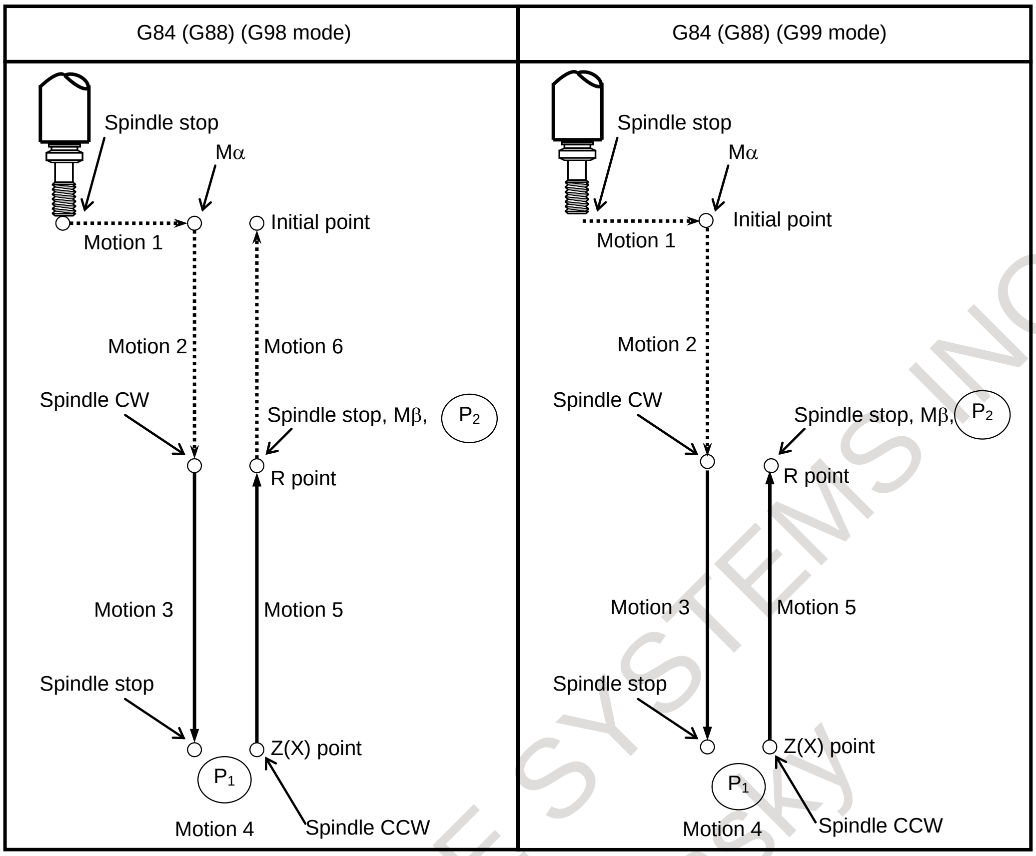
	Time constant of acceleration/deceleration after interpolation		Total time constant of acceleration/deceleration after interpolation
	rigid tap	Smart overlap	
Before Smart overlap applying	No.5261=16 No.5365=4	No.11248=0 No.11249=0	20
After Smart overlap application (Subtract can be done)	No.5261=0 No.5365=0	No.11248=16 No.11249=4	20
After Smart overlap application (Subtract cannot be done)	No.5261=0 No.5365=0	No.11248=24 No.11249=8	32

By setting bit 5 (SRI) or bit 6 (RIS) of parameter No. 10735 to 1, Smart overlap can be invalidated at the cutting and extraction in rigid tap. Therefore, the cycle time can be prevented being postponed in rigid tap.
For each rigid tap, the parameters of time constant of acceleration/deceleration after interpolation that is valid and the parameters to invalidate the Smart overlap are shown in the table below.

Table 7.2.1.4 (f) Parameters effective for each rigid tap

Type of rigid tap	Time constant of acceleration/deceleration after interpolation	Smart overlap invalid
Rigid tap	No.5261 to No.5264, No.5271 to No.5274, No.5365 to No.5368	Parameter SRI
Retraction for rigid tapping		
3-dimensional rigid tapping		
Retraction for 3-dimensional rigid tapping		
Rigid tapping by manual handle		
Rigid tapping of spindle control with servo motor	No.11060 to No.11063, No.11065 to No.11068, No.11052	Parameter RIS
Rigid tapping of spindle control with Cs contour control		
FSSB High-speed rigid tapping	Compliant with the base rigid tap	-

> **NOTE**
> - In synchronous control slave axis, setting of the path of the synchronous master axis is effective for the parameters SRI and RIS.
> - In composite control axes of composite control, setting of the path of the composite target axis is effective for the parameters SRI and RIS.



Rapid traverse
Cutting feed

P1 Dwell specified by address P in the program

P2 Dwell set by parameter No. 5111 (not performed in the FANUC Series 15 program format)

Mα Output of an M code for C-axis clamping

Mβ Output of an M code for C-axis unclamping (β=α+1) (not performed in the FANUC Series 15 program format)

Supplement: P1, Mα, Mβ, and P2, when not specified, are not executed and output.

When the parameter SIE or RIS is set to 0

In motion 3 and 5, the parameters (Nos.11248 and 11249) are added to the time constant of acceleration/deceleration after interpolation in rigid tap.

When the parameter SIE or RIS is set to 1

In motion 3 and 5, the parameters (Nos.11248 and 11249) are not added to the time constant of acceleration/deceleration after interpolation in rigid tap.

NOTE

Even when parameters SRI and RIS are set to 1, there is no change in motion 1, 2, 4, 6.

NOTE

NOTE

1. Smart overlap is effective for the rigid tapping and threading, etc. Therefore, please confirm the screw precision.
2. Smart overlap is effective for the skip command. Therefore, the skip coordinates value is influenced. So, when the accumulated pulses by acceleration/deceleration of Smart overlap is considered and compensated, set bit 1 (SEB) of parameter (No. 6201) to 1.
3. When the overlap is executed at the block where the direction of the movement reverses, the direction of the movement reverses before the tool reaches the programmed position. In the drilling, the tool doesn't reach the programmed bottom of a hole.

Parameter

	#7	#6	#5	#4	#3	#2	#1	#0
10735	SOD	RIS	SRI	SIE				ARF

[Input type] Parameter input
[Data type] Bit path

#0 ARF In Smart overlap, between movement block of reference position return to the middle point and previous block overlap is :
0: Enabled.
1: Disabled.

#4 SIE In the axis that Smart overlap is effective, the in-position check signal is:
0: Disabled.
1: Enabled.

NOTE

Smart overlap is effective between the following blocks, but the in-position check signal is not effective.
- Rapid traverse - Rapid traverse
- Rapid traverse - Cutting feed
- Rapid traverse - No movement
- Cutting feed - Rapid traverse
- Cutting feed - No movement
- No movement - Rapid traverse
- No movement - Cutting feed
- No movement - No movement

#5 SRI In cutting and extraction in the rigid tap, Smart overlap is:
0: Depending on the setting in bit 1 (SOVx) of parameter No.11236
1: Disabled.

NOTE

This parameter is effective for the next rigid tap.

- Rigid tap
- Rigid tapping by manual handle
- 3-dimensional rigid tapping
- Retraction for rigid tapping
- Retraction for 3-dimensional rigid tapping

#6 RIS In cutting and extraction in the rigid tapping of spindle control with servo motor Smart overlap is:

0: Depend on the bit 1 (SOVx) of parameter No.11236 setting.
1: Disabled.

#7 SOD In Smart overlap, between dwell block and previous block overlap is :

0: Enabled.
1: Disabled.

10740	Maximum overlap value of Smart overlap for each axis（Rapid traverse - Rapid traverse)

[Input type] Parameter input
[Data type] 2-word axis
[Unit of data] Detection unit
[Valid data range] 0 to 99999999

The maximum clamp value of Smart overlap between the rapid traverse block and the rapid traverse block is set.
The overlap value is clamped by the value set to this parameter. So, the inner deviation in the corner can be suppressed.

NOTE

When a value less than 0 are set, the specification of 0 is assumed.
In this case, the overlap by Smart overlap is not clamped.
When you clamp overlap value, set the value of in-position width or more.

10741	Maximum overlap value of Smart overlap for each axis（Rapid traverse – Cutting feed)

[Input type] Parameter input
[Data type] 2-word axis
[Unit of data] Detection unit
[Valid data range] 0 to 99999999

The maximum clamp value of Smart overlap between the rapid traverse block and the cutting feed block is set.
The overlap value is clamped by the value set to this parameter. So, the inner deviation in the corner can be suppressed.

NOTE

When a value less than 0 are set, the specification of 0 is assumed.
In this case, the overlap by Smart overlap is not clamped.
When you clamp overlap value, set the value of in-position width or more.

10742	Maximum overlap value of Smart overlap for each axis (Cutting feed - Rapid traverse)

[Input type] Parameter input
[Data type] 2-word axis
[Unit of data] Detection unit
[Valid data range] 0 to 99999999

The maximum clamp value of Smart overlap between the cutting feed block and the rapid traverse block is set.
The overlap value is clamped by the value set to this parameter. So, the inner deviation in the corner can be suppressed.

NOTE
When a value less than 0 are set, the specification of 0 is assumed.
In this case, the overlap by Smart overlap is not clamped.
When you clamp overlap value, set the value of in-position width or more.

	#7	#6	#5	#4	#3	#2	#1	#0
11236							SOVx	

[Input type] Parameter input
[Data type] Bit axis

NOTE
When this parameter is set, the power must be turned off before operation is continued.

#1 SOVx Smart overlap is
0: Disabled.
1: Enabled.

	#7	#6	#5	#4	#3	#2	#1	#0
11247	SNN	SNC	SNR	SCN	SCR	SRN	SRC	SRR

[Input type] Parameter input
[Data type] Bit path

#0 SRR In Smart overlap, between rapid traverse block and rapid traverse block overlap is :
0: Enabled.
1: Disabled.

#1 SRC In Smart overlap, between rapid traverse block and cutting feed block overlap is :
0: Enabled.
1: Disabled.

#2 SRN In Smart overlap, between rapid traverse block and non-movement block overlap is :
0: Enabled.
1: Disabled.

#3 SCR In Smart overlap, between cutting feed block and rapid traverse block overlap is :
0: Enabled.
1: Disabled.

#4 SCN In Smart overlap, between cutting feed block and non-movement block overlap is :
0: Enabled.
1: Disabled.

#5 SNR In Smart overlap, between non-movement block and rapid traverse block overlap is :
0: Enabled.
1: Disabled.

#6 SNC In Smart overlap, between non-movement block and cutting feed block overlap is :
0: Enabled.
1: Disabled.

#7 SNN In Smart overlap, between non-movement block and non-movement overlap is :
0: Enabled.
1: Disabled.

11248	Time constant 1 of acceleration/deceleration after interpolation in Smart overlap for each axis

[Input type] Parameter input
[Data type] Word axis
[Unit of data] msec
[Valid data range] 0 to 64

Set the time constant 1 of acceleration/deceleration after interpolation in Smart overlap for each axis.

11249	Time constant 2 of acceleration/deceleration after interpolation in Smart overlap for each axis

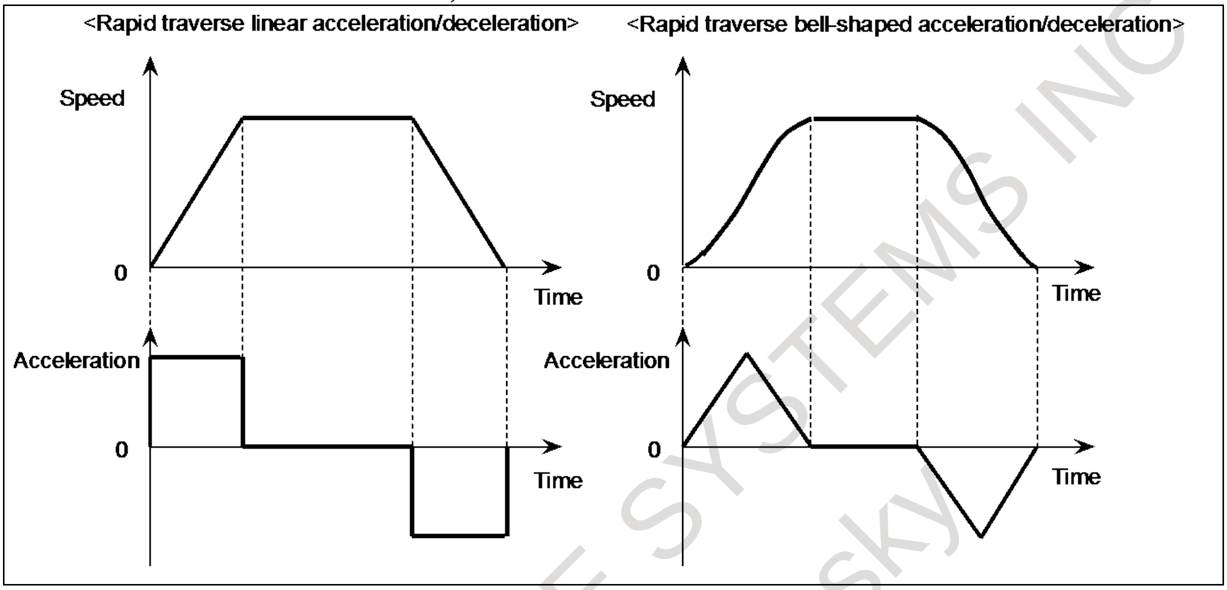
[Input type] Parameter input
[Data type] Word axis
[Unit of data] msec
[Valid data range] 0 to 64

Set the time constant 2 of acceleration/deceleration after interpolation in Smart overlap for each axis for each axis.

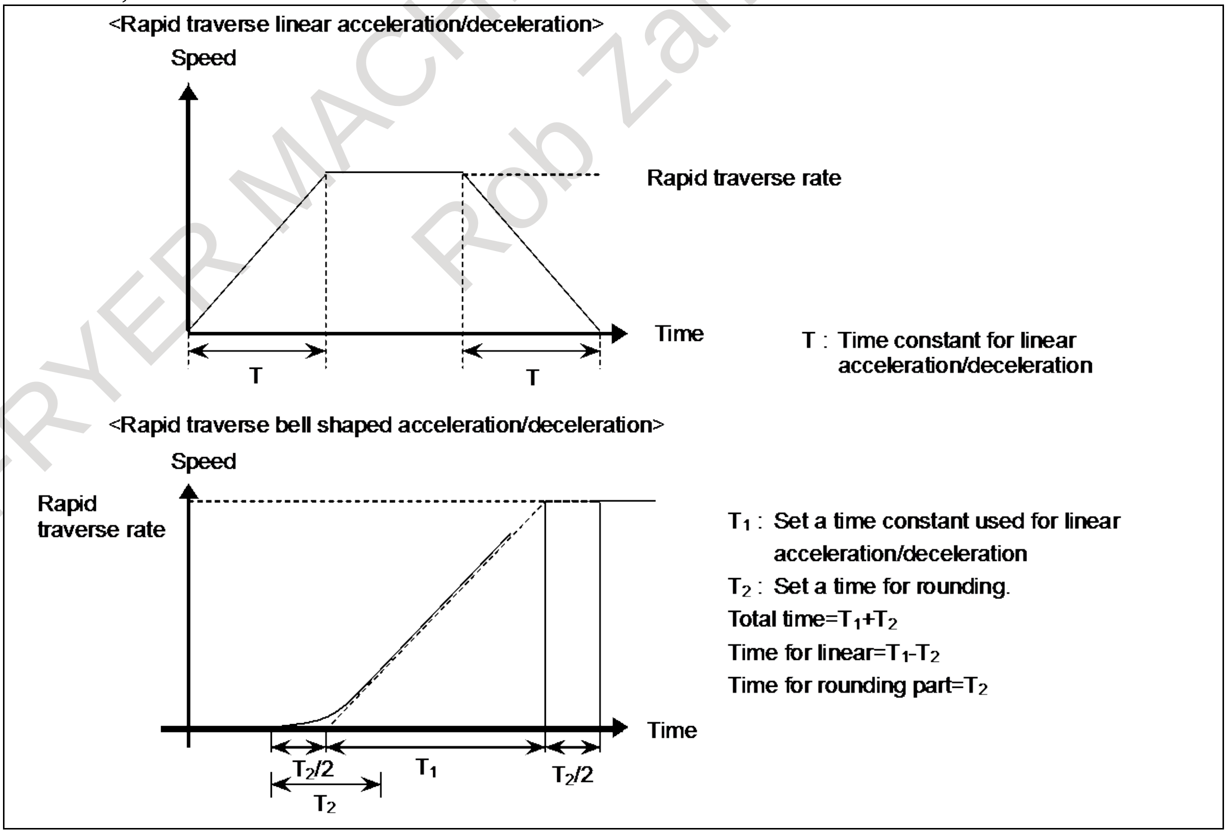
7.2.2 Rapid Traverse Bell-shaped Acceleration/Deceleration

Overview

Rapid traverse bell-shaped acceleration/deceleration smoothly increases or decreases the rapid traverse rate, reducing the stress and strain imposed on the machine due to the variation in the acceleration with changes in the feedrate. As the time constant for bell-shaped acceleration/deceleration can be smaller than that for linear acceleration/deceleration, the time needed for acceleration/ deceleration can be reduced.



This function is enabled when the time constants for rapid traverse bell-shaped acceleration/deceleration T_1 and T_2 are specified in parameters Nos. 1620 and 1621, respectively.
In this case, the time needed for acceleration/deceleration is as follows.



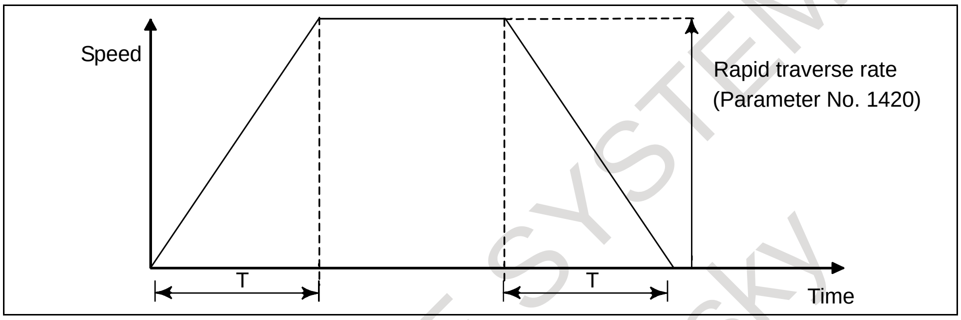
Set a time when rapid traverse override is 100%. When it is less than 100%, the total time is reduced (constant acceleration method).
Value of T_1 is determined from motor torque. Set a value of T_2 to 24 msec or 32 msec.

Parameter

1620	Time constant T or T1 used for linear acceleration/deceleration or bell-shaped acceleration/deceleration in rapid traverse for each axis

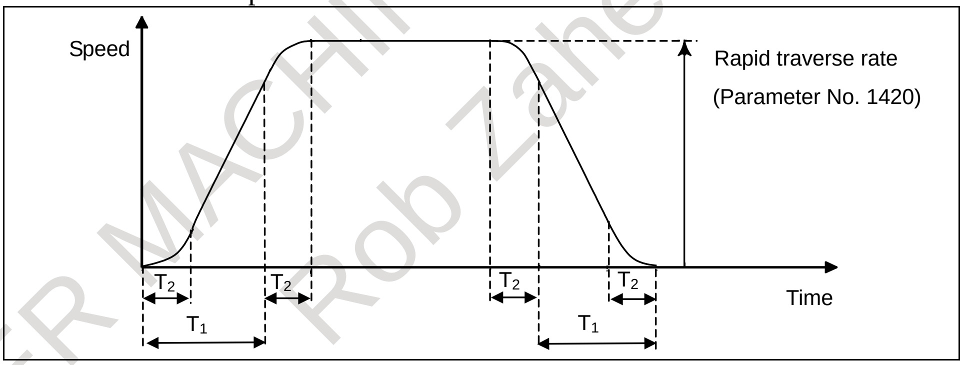
[Input type] Parameter input
[Data type] Word axis
[Unit of data] msec
[Valid data range] 0 to 4000

Specify a time constant used for acceleration/deceleration in rapid traverse.
[Example]
For linear acceleration/deceleration



T : Setting of parameter No. 1620

For bell-shaped acceleration/deceleration



T_1 : Setting of parameter No. 1620
T_2 : Setting of parameter No. 1621
(However, $T_1 \geq T_2$ must be satisfied.)
Total acceleration (deceleration) time : $T_1 + T_2$
Time for linear portion : $T_1 - T_2$
Time for curve portion : $T_2 \times 2$

1621	Time constant T_2 used for bell-shaped acceleration/deceleration in rapid traverse for each axis

[Input type] Parameter input
[Data type] Word axis
[Unit of data] msec
[Valid data range] 0 to 512

Specify time constant T_2 used for bell-shaped acceleration/ deceleration in rapid traverse for each axis.

Manual name	Item name
CONNECTION MANUAL (FUNCTION) (This manual)	Automatic acceleration/deceleration

7.2.3 Linear Acceleration/Deceleration after Cutting Feed Interpolation

Overview

If linear Acceleration/Deceleration after Cutting Feed Interpolation is enabled (if bit 0 (CTL) of parameter No. 1610 is set to 1), acceleration/ deceleration is performed as follows:

Cutting feed:

Linear acceleration/deceleration (constant acceleration time)

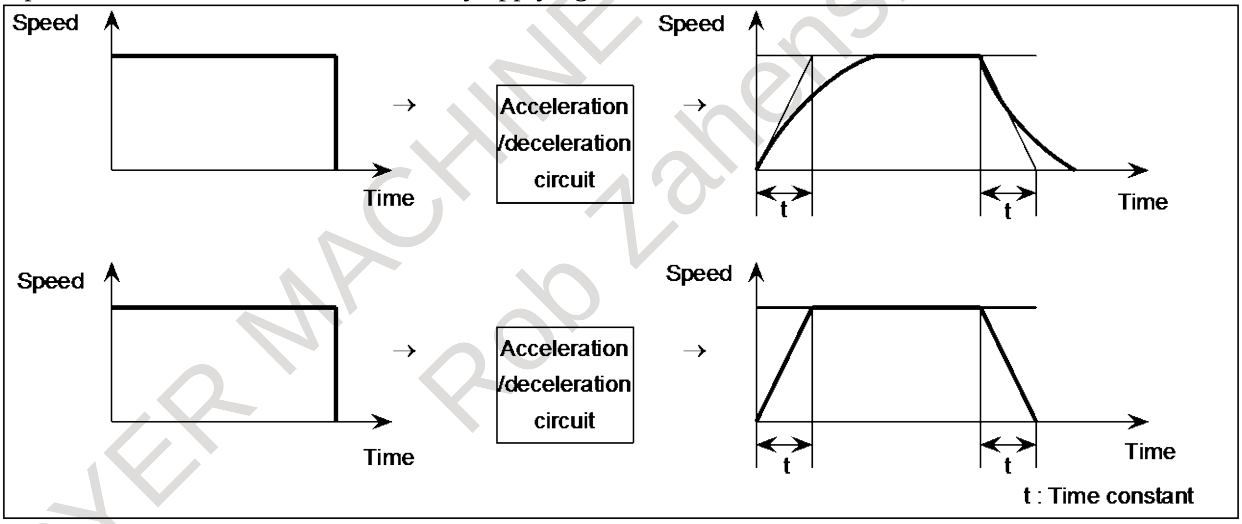
Specify the acceleration/deceleration time constant for each axis in parameter No. 1622.

Jog feed:

Exponential or linear acceleration/deceleration (constant acceleration time)

Specify the acceleration/deceleration time constant for each axis in parameter No. 1624.

If the time constant for linear acceleration/deceleration is the same as that for exponential acceleration/deceleration, the delay of linear acceleration/deceleration in relation to a command is 1/2 of the delay of exponential acceleration/deceleration, so that the time required for acceleration and deceleration can be reduced. If circular interpolation is performed, especially when high-speed cutting is being performed, the actual tool path created after acceleration/deceleration will deviate from the programmed arc in the radial direction. This deviation can also be reduced, in comparison with exponential acceleration/deceleration, by applying linear acceleration/deceleration.



This function is enabled when bit 0 (CTL) of parameter No. 1610 is set to 1. If bell-shaped Acceleration/Deceleration after Cutting Feed Interpolation is also enabled, bell-shaped acceleration/deceleration is executed. The time constants for cutting feed and jog feed for each axis are specified in parameters Nos. 1622 and 1624 respectively, in the same way as for exponential acceleration/deceleration. The values specified for the FL feedrate for cutting feed (parameter No. 1623) and the FL feedrate for jog feed (parameter No. 1625) are ignored (always assumed to be 0).

Parameter

	#7	#6	#5	#4	#3	#2	#1	#0
1610				JGLx				CTLx

[Input type] Parameter input
[Data type] Bit axis

#0 CTLx Acceleration/deceleration in cutting feed or dry run during cutting feed
0: Exponential acceleration/deceleration is applied.
1: Linear acceleration/deceleration after interpolation is applied.

> **NOTE**
> This parameter is initial setting parameter. For details, refer to the appendix "Automatic setting / Initial setting parameter" in this manual.

#4 JGLx Acceleration/deceleration in jog feed
0: Exponential acceleration/deceleration is applied.
1: The same acceleration/deceleration as for cutting feedrate is applied.
(Depending on the settings of bits 1 (CTBx) and 0 (CTLx) of parameter No. 1610)

> **NOTE**
> This parameter is initial setting parameter. For details, refer to the appendix "Automatic setting / Initial setting parameter" in this manual.

1622	Time constant of acceleration/deceleration in cutting feed for each axis

[Input type] Parameter input
[Data type] Word axis
[Unit of data] msec
[Valid data range] 0 to 4000

Set the time constant used for exponential acceleration/deceleration in cutting feed, bell-shaped acceleration/deceleration after interpolation or linear acceleration/deceleration after interpolation in cutting feed for each axis. Which type to use is selected with bits 1 (CTBx) and 0 (CTLx) of parameter No. 1610. Except for special applications, the same time constant must be set for all axes in this parameter. If the time constants set for the axes differ from each other, proper straight lines and arcs cannot be obtained.

1624	Time constant of acceleration/deceleration in jog feed for each axis.

[Input type] Parameter input
[Data type] Word axis
[Unit of data] msec
[Valid data range] 0 to 4000

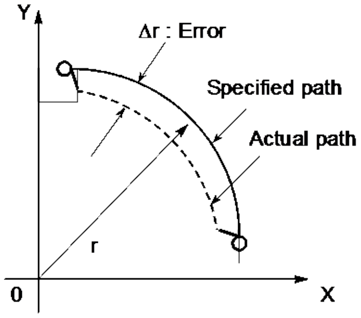
Set the time constant used for acceleration/deceleration in jog feed for each axis.

Note

NOTE

1 If linear Acceleration/Deceleration after Cutting Feed Interpolation is enabled, linear acceleration/deceleration is executed during cutting feed and during a dry run. Linear acceleration/deceleration can also be executed during jog feed if the bit 4 (JGL) of parameter No. 1610 is specified accordingly.

2 In circular interpolation especially when circular cutting is executed at high speed, the actual path of the accelerated or decelerated tool deviates from the specified arc in the direction of the radius.



Δr : Maximum radius error (mm)
v : Feedrate (mm/s)
r : Radius of arc (mm)
T_1 : Acceleration/deceleration after interpolation time constant cutting (sec)
T_2 : Time constant of servo motor (sec) (Inverse of position loop gain)

The maximum error in the radial direction (Δr) can be approximated by the following expressions:

$$\Delta r = \left(\frac{1}{2}T_1^2 + \frac{1}{2}T_2^2\right)\frac{V^2}{r}$$ …Exponential acceleration/deceleration

$$\Delta r = \left(\frac{1}{24}T_1^2 + \frac{1}{2}T_2^2\right)\frac{V^2}{r}$$ …Linear acceleration/deceleration after interpolation

$$\Delta r = \left(\frac{1}{48}T_1^2 + \frac{1}{2}T_2^2\right)\frac{V^2}{r}$$ …Bell-shaped acceleration /deceleration after interpolation

If the error caused by the time constant of the servo motor is excluded, the error cause by linear acceleration/deceleration after interpolation is 1/12 of that caused by exponential acceleration/deceleration. The radius error in the case of bell-shaped acceleration/deceleration after interpolation is a half of linear acceleration/deceleration after interpolation.

3 Linear acceleration/deceleration can be executed both for cutting feed and for jog feed along a PMC axis. Acceleration/deceleration for cutting feed is executed even if acceleration/deceleration for jog feed is selected. In jog feed along the PMC axis, the time constant for cutting feed is used instead of that for jog feed.

7.2.4 Bell-Shaped Acceleration/Deceleration after Cutting Feed Interpolation

Overview

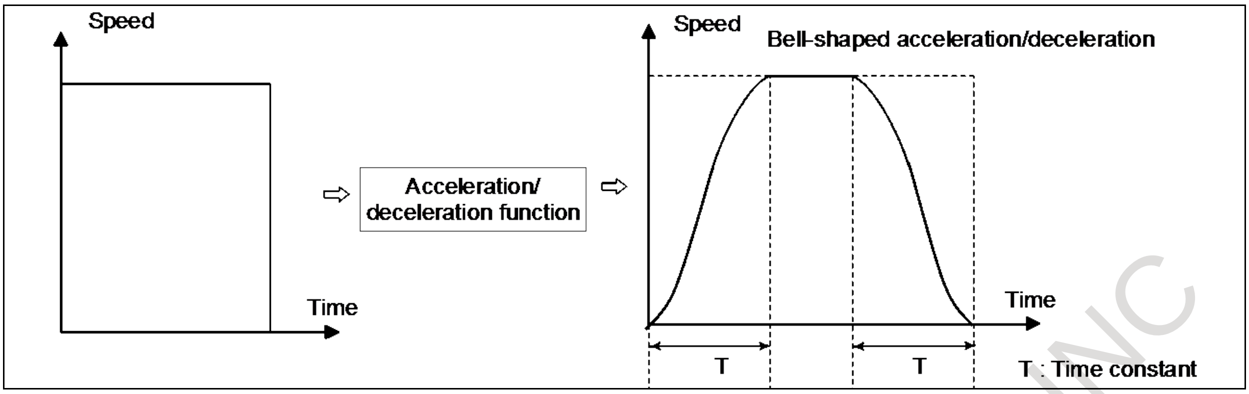
The bell-shaped acceleration/deceleration after cutting feed interpolation provides smooth acceleration and deceleration to reduce stress and strain on the machine. If this function is enabled (if bit 1 (CTB) of parameter No. 1610 is set to 1), acceleration/deceleration is performed as follows:

Cutting feed:

Bell-shaped acceleration/deceleration (constant acceleration time)
Specify the acceleration/deceleration time constant for each axis in parameter No. 1622.

Jog feed:

Exponential or bell-shaped acceleration/deceleration (constant acceleration time)
Specify the acceleration/deceleration time constant for each axis in parameter No. 1624.



Bell-shaped acceleration/deceleration after cutting feed interpolation is enabled when bit 1 (CTB) of parameter No.1610 is specified. The time constants for cutting feed and for jog feed for each axis are specified in parameters Nos. 1622 and 1624 respectively, in the same way as exponential acceleration/deceleration. The values specified for the FL feedrate for cutting feed (parameter No. 1623) and the FL feedrate for jog feed (parameter No. 1625) are ignored (always assumed to be 0).

Parameter

	#7	#6	#5	#4	#3	#2	#1	#0
1610				JGLx			CTBx	CTLx

[Input type] Parameter input
[Data type] Bit axis

#0 CTLx Acceleration/deceleration in cutting feed or dry run during cutting feed
0: Exponential acceleration/deceleration is applied.
1: Linear acceleration/deceleration after interpolation is applied.

> **NOTE**
> This parameter is initial setting parameter. For details, refer to the appendix "Automatic setting / Initial setting parameter" in this manual.

#1 CTBx Acceleration/deceleration in cutting feed or dry run during cutting feed
0: Exponential acceleration/deceleration or linear acceleration/ deceleration is applied. (depending on the setting in bit 0 (CTLx) of parameter No. 1610)
1: Bell-shaped acceleration/deceleration is applied.

> **NOTE**
> This parameter is initial setting parameter. For details, refer to the appendix "Automatic setting / Initial setting parameter" in this manual.

#4 JGLx Acceleration/deceleration in jog feed
0: Exponential acceleration/deceleration is applied.
1: The same acceleration/deceleration as for cutting feedrate is applied. (Depending on the settings of bits 1 (CTBx) and 0 (CTLx) of parameter No. 1610)

> **NOTE**
> This parameter is initial setting parameter. For details, refer to the appendix "Automatic setting / Initial setting parameter" in this manual.

1622	Time constant of acceleration/deceleration in cutting feed for each axis

[Input type] Parameter input
[Data type] Word axis
[Unit of data] msec
[Valid data range] 0 to 4000

Set the time constant used for exponential acceleration/deceleration in cutting feed, bell-shaped acceleration/deceleration after interpolation or linear acceleration/deceleration after interpolation in cutting feed for each axis. Which type to use is selected with bits 1 (CTBx) and 0 (CTLx) of parameter No. 1610. Except for special applications, the same time constant must be set for all axes in this parameter. If the time constants set for the axes differ from each other, proper straight lines and arcs cannot be obtained.

1624	Time constant of acceleration/deceleration in jog feed for each axis.

[Input type] Parameter input
[Data type] Word axis
[Unit of data] msec
[Valid data range] 0 to 4000

Set the time constant used for acceleration/deceleration in jog feed for each axis.

Note

> **NOTE**
> 1 If bell-shaped acceleration/deceleration after interpolation during cutting feed is enabled, bell-shaped acceleration/deceleration is executed during cutting feed and during a dry run. Bell-shaped acceleration/deceleration can also be executed during jog feed if the bit 4 (JGL) of parameter No. 1610 is specified accordingly.
> 2 In circular interpolation, the actual tool path after acceleration/deceleration deviates from the programmed arc in the radial direction. To overcome this radial deviation, see the note on linear Acceleration/Deceleration after Cutting Feed Interpolation.
> 3 Bell-shaped acceleration/deceleration can be executed both for cutting feed and for jog feed along a PMC axis. The time constant for acceleration/deceleration for jog feed is the same as that for cutting feed. In jog feed along the PMC axis, the time constant for cutting feed is used instead of that for jog feed.

7.2.5 Optimum Torque Acceleration/Deceleration

Overview

This function enables acceleration/deceleration in accordance with the torque characteristics of the motor and the characteristics of the machines due to its friction and gravity.
Usually, because of the friction of the machine, gravity, the torque characteristics of the motor, and other factors, the acceleration/ deceleration performance (torque for acceleration/deceleration) is different with direction of movement, acceleration or deceleration. In this function, acceleration pattern of rapid traverse for the following situations, plus movement and acceleration, plus movement and deceleration, minus movement and acceleration, minus movement and deceleration can be set into parameters according to the torque for acceleration/deceleration of each situation. Acceleration/deceleration can be performed according to these parameter setting, so that the most of the capability of the motor can be used and positioning time can be reduced.

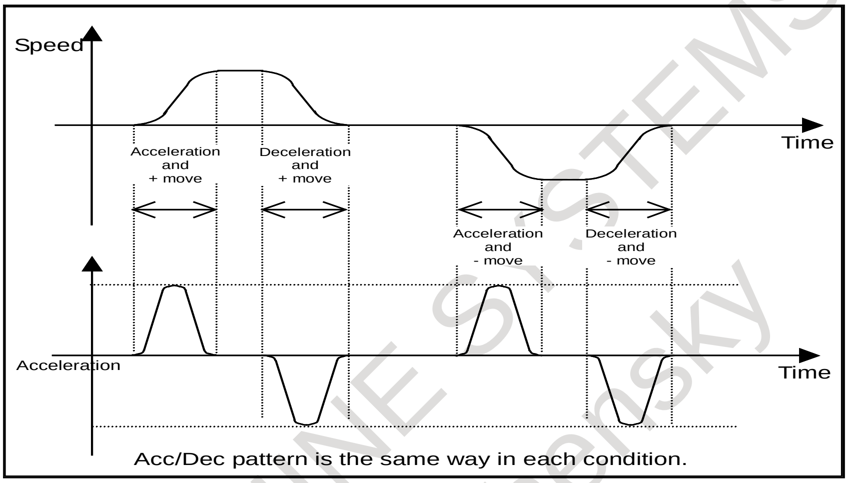


Fig. 7.2.5 (a) Conventional acceleration/deceleration

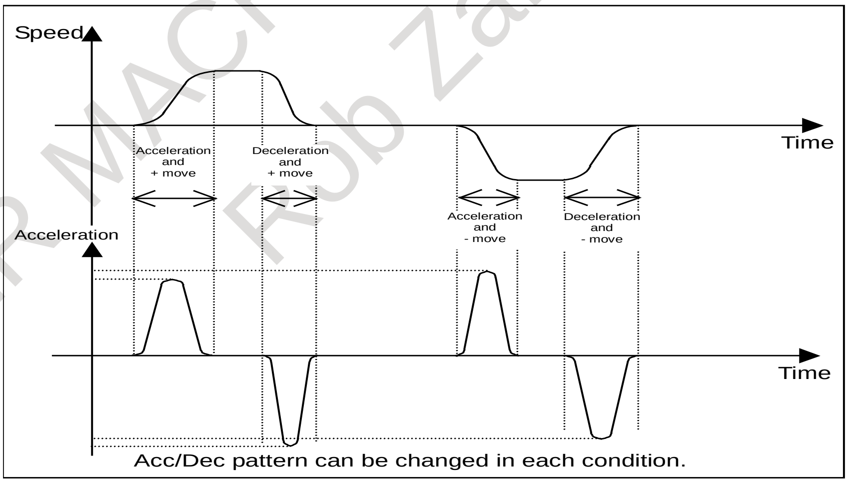

Fig. 7.2.5 (b) Acceleration/deceleration with this function

Explanation

Optimum torque acceleration/deceleration selects the acceleration pattern set with parameters on the basis of the axial movement direction and the acceleration/deceleration state, determines the acceleration for each axis from the current speed, and controls the tangential acceleration/deceleration for rapid traverse.

- Setting optimum torque acceleration/deceleration

When bit 0 (FAP) of parameter No. 19540 and bit 1 (LRP) of parameter No. 1401 are set to 1, and a value other than 0 is set for any one of the axes as the reference acceleration in parameter No. 1671 as shown in the Fig. 7.2.5 (a), rapid traverse is accelerated/decelerated by optimum torque acceleration/deceleration.

Table 7.2.5 (a) Optimum torque acceleration/deceleration

Bit 0 (FAP) of parameter No. 19540 (Optimum torque acc/dec)	Bit 1 (LRP) of parameter No. 1401 (Linear type positioning)	Reference acceleration	Bell-shaped acceleration change time	Acceleration pattern
1	1	No.1671	No.1672	See "Setting an acceleration pattern".

To enable bell-shaped acceleration/deceleration in addition to optimum torque acceleration/deceleration, set the bell-shaped acceleration change time with parameter No. 1672.

NOTE
To use optimum torque acceleration/deceleration, set bit 5 (FRP) of parameter No. 19501 to 1.

- Required conditions in addition to parameter setting

If the conditions for performing AI contour control and for look-ahead acceleration/deceleration before interpolation are satisfied, optimum torque acceleration/deceleration is performed for accelerating and decelerating rapid traverse. However, when bit 0 (FAE) of parameter No. 11240 is set to 1, optimum torque acceleration/deceleration is enabled even if AI contour control is disabled. If rapid traverse is subject to optimum torque acceleration/deceleration, after-interpolation acceleration/deceleration does not apply to rapid traverse.

- Cases in which optimum torque acceleration/ deceleration is disabled

If optimum torque acceleration/deceleration is disabled by parameter settings, or the required conditions other than parameter settings are not satisfied, acceleration/deceleration after interpolation is used to accelerate and decelerate rapid traverse.

- Setting acceleration pattern data

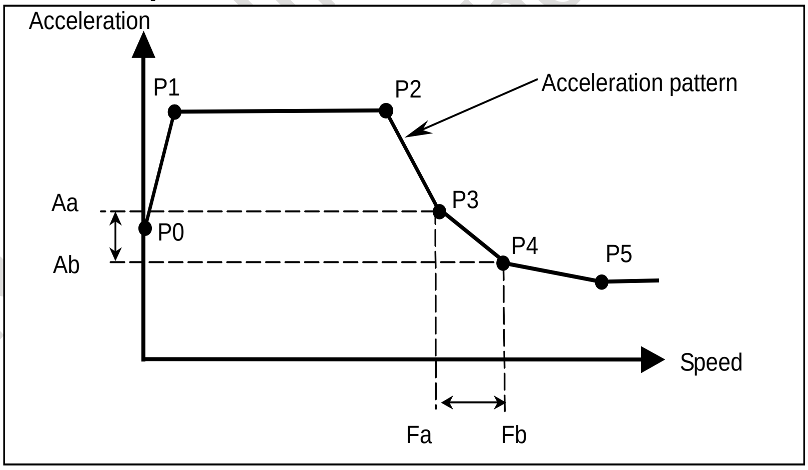

Fig. 7.2.5 (c) Setting acceleration pattern

Set the speed and the acceleration at each of the acceleration setting points P0 to P5 for each condition, plus movement and acceleration, plus movement and deceleration, minus movement and acceleration, minus movement and deceleration, and for each axis.
The line joining the acceleration setting points is regarded a acceleration pattern.
For example, while the speed is between Fa and Fb in the Fig. 7.2.5 (c), the acceleration is calculated with Aa and Ab. Tangential acceleration is controlled not to exceed the calculated acceleration for each axis.

> **NOTE**
> It is not desirable to set an acceleration pattern in which a large acceleration is set right at a speed of 0, because this will shock the machine. So, **be sure to set an acceleration pattern so that a relatively low acceleration rate is applied at speed 0** as shown Fig. 7.2.5 (c).

Table 7.2.5 (b) Parameters for acceleration pattern

Acceleration setting point	Speed parameter	Acceleration parameter			
		During acceleration		During deceleration	
		During movement in plus direction	During movement in minus direction	During movement in plus direction	During movement in minus direction
P0	(Speed 0)	No.19545	No.19551	No.19557	No.19563
P1	No.19541	No.19546	No.19552	No.19558	No.19564
P2	No.19542	No.19547	No.19553	No.19559	No.19565
P3	No.19543	No.19548	No.19554	No.19560	No.19566
P4	No.19544	No.19549	No.19555	No.19561	No.19567
P5	No.1420	No.19550	No.19556	No.19562	No.19568

The speed at P0 is 0, and the speed at P5 is the rapid traverse rate specified with parameter No. 1420. The speeds at P1 to P4 are to be set into speed parameters Nos. 19541 to 19544 as ratio to the rapid traverse speed (parameter No. 1420).
Any acceleration setting point for which the speed parameter (one of Nos. 19541 to 19544) is set to 0 will be skipped, and the next point whose speed parameter is set to a non-zero value will be joined together connected with line. The polygonal line is regarded as acceleration pattern.
The accelerations at P0 to P5 are to be set into acceleration parameters Nos. 19545 to 19568 as ratio to the reference acceleration. If any of the acceleration parameters Nos. 19545 to 19568 is set to 0, the acceleration is assumed 100% (Reference acceleration). Acceleration parameters should be set to 0 at the acceleration setting point whose speed parameter is set to 0.
If this function is enabled and parameter No. 1671 for an axis are set to 0, the following values are assumed as the reference acceleration for that axis:
1000.0mm/sec^2, 100.0inch/sec^2, 100.0 degree/sec^2

- Example of setting acceleration pattern data

In this example, the machine is equipped with the α*i*S 30/4000.
Motor speed at rapid traverse is 3000 (min^{-1}).

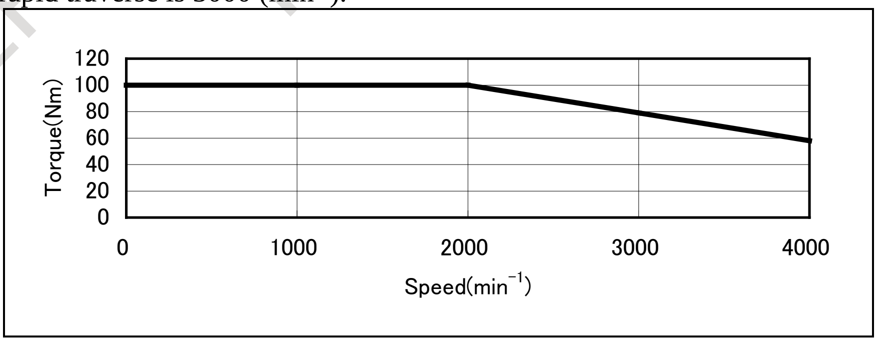

Fig. 7.2.5 (d) Speed-torque characteristics of model α*i*S 30/4000

Specifications of the motor model α*i*S 30/4000

Rotor inertia	:0.0099(Kgm^2)	
Maximum torque	:100(Nm)	Speed 0 to 2000(min^{-1})
Torque at rapid traverse	:79(Nm)	Speed 3000(min^{-1})
Minimum torque	:58(Nm)	Speed 4000(min^{-1})

It assumes that 10 (Nm) is needed for the friction torque, so that the torque for acceleration/deceleration is shown as the following figure.
Because the friction torque is different on each machine, it is necessary to observe the actual torque output on the machine for deciding acceleration pattern.

Maximum torque	:90(=100-10)(Nm)	Speed 0 to 2000(min^{-1})
Torque at rapid traverse	:69(=79-10)(Nm)	Speed 3000(min^{-1})
Minimum torque	:48(=58-10)(Nm)	Speed 4000(min^{-1})

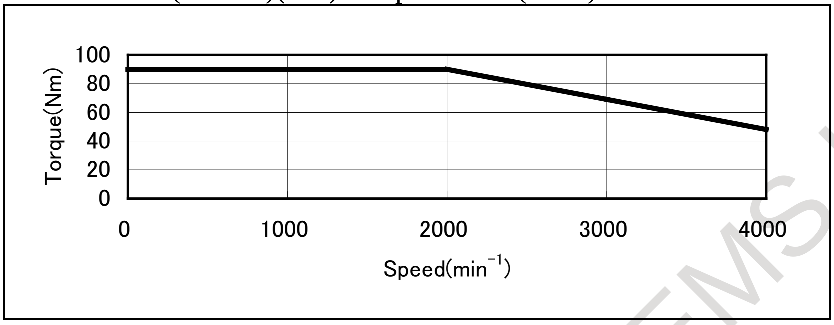

Fig. 7.2.5 (e) Torque for Acc/Dec with consideration of friction

Let the torque be x (Nm), the inertia be y(Kgm^2), and the ball screw pitch p(mm), then the acceleration A is calculated as follows:

$$A=\frac{x[N\cdot m]}{y[kg\cdot m^2]}\times\frac{p}{2\pi}[mm]=\frac{x([kg\cdot m/\sec^2][m])}{y[kg\cdot m^2]}\times\frac{p}{2\pi}[mm]$$

$$=\frac{x\times p}{2\pi\times y}[mm/\sec^2]$$

Machine specification is assumed as follows,

Ball screw pitch : 16 (mm)
Inertia : The machine inertia is to be 2.0 times higher than that of the rotor.
(Rotor inertia: 0.0099 (Kgm^2))

Assumption magnification as inertia of rotor and machine : 3.0 times
According to the above equation of torque and acceleration, the acceleration at maximum torque is,

$$\frac{90\times 16}{2\pi\times 3.0\times 0.0099}=7717[mm/\sec^2]$$

The acceleration when torque 69 (Nm) at rapid traverse rate (3000 min^{-1}) is,

$$\frac{69\times 16}{2\pi\times 3.0\times 0.0099}=5916[mm/\sec^2]$$

From the above data, the parameters related to acceleration pattern is given in the Table 7.2.5 (c).
The example assumes that the torque for acceleration/deceleration is the same regardless of whether acceleration or deceleration is in progress or whether the movement is in the plus or minus direction.

- When setting the speed at P1, use the following value as a rough guide:
  If a bell-shaped acceleration change time (parameter No. 1672) is set, use as a rough guide the ratio of the following speed to the rapid traverse rate:
  Reference acceleration × T2/4
  where T2 is the bell-shaped acceleration change time (msec).
  For example, assume T2 to be 40 msec, then the speed at P1 should be approximately
  4124 [mm/sec^2]×40 [msec]/4
  =4124 [mm/sec^2]×602×40 [msec]/60000/4
  =2474 [mm/min]
- If no bell-shaped acceleration change time (parameter No. 1672) is set, use about 5% of the rapid traverse rate as a rough guide.

Table 7.2.5 (c) Example of setting parameters related to acceleration pattern

	Parameter number	Setting	Unit	Remarks
Rapid traverse rate	1420	48000.	mm/min	The ball screw pitch is assumed 16 mm, so that the rapid traverse rate is 48000 mm/min at the maximum speed 3000 (min^{-1}).
Reference acceleration	1671	4124.	msec	Reference acceleration is 4124mm/sec^2.
Speed at P1	19541	515	0.01%	- Assuming that parameter No. 1672 (bell-shaped acceleration change time) is set to 40 (msec), the speed at P1 will be 2474 mm/min from the calculation described on the previous page. Set its ratio to the rapid traverse rate, or 5.15%. 0.0515=2474/48000 - If parameter No. 1672 (bell-shaped acceleration change time) is not set, set about 5.00%.
Speed at P2	19542	6666	0.01%	Since the torque characteristic is constant (90 Nm) in speeds reaching 2000 min^{-1}, set P2 to the ratio of the speed (32000 mm/min) at 2000 min^{-1} to the rapid traverse rate (48000 mm/min). 0.6666=32000 / 48000
Speeds at P3 to P4	19543 to 19544	0	0.01%	P3 to P4 are skipped because the torque drops almost linearly from the speed 2000 (min^{-1}) to 3000 (min^{-1}).
Acceleration at P0	19545,19551, 19557,19563	9356	0.01%	Set half the acceleration at P1, or 9356.
Acceleration at P1	19546,19552, 19558,19564	18712	0.01%	At P1, 90(Nm) can be used for the acceleration/deceleration, so set the ratio of the acceleration at 90 (Nm) to the reference acceleration. (1.8712 = 7717/4124)
Acceleration at P2	19547,19553 19559,19565	18712	0.01%	At P2, set the same speed as that at P1.
Acceleration at P3 to P4	19548 to 19549, 19554 to 19555, 19560 to 19561 19566 to 19567	0	0.01%	0 is set because P3 to P4 are skipped.
Acceleration at P5	19550,19556 19562,19568	14345	0.01%	At P5, 69(Nm) can be used for the acceleration/deceleration, so set the ratio of the acceleration at 69 (Nm) to the reference acceleration. (1.4345 = 5916 / 4124)

With the above parameter settings, the acceleration pattern will be shown as the Fig. 7.2.5 (f). From speeds from 0 mm/min to 2474 mm/min, the acceleration as calculated in accordance with the acceleration pattern is applied; from speeds from 2474 mm/min to 32000 mm/min, an acceleration of 7716 mm/sec^2; and from speeds from 32000 mm/min to 48000 mm/min, the acceleration as calculated in accordance with the acceleration pattern.

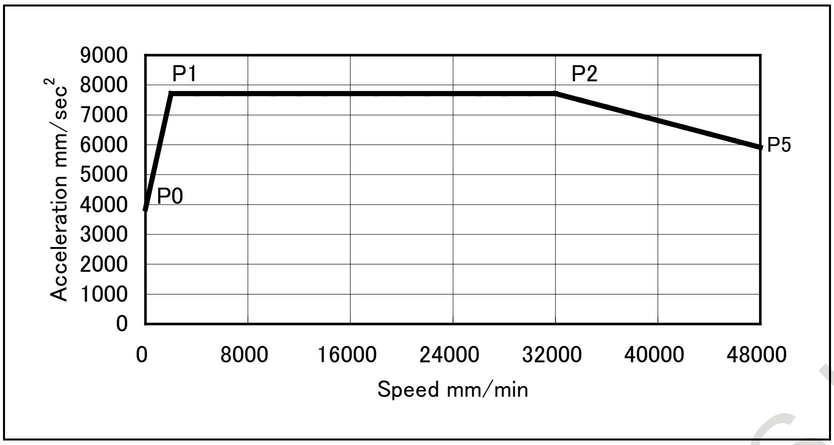

Fig. 7.2.5 (f) Acceleration pattern with consideration of friction

> **NOTE**
> The values in the model αiS 30/4000 speed-torque characteristic diagram are just typical ones. The values will change depending on the digital servo software, parameters, input voltage, and other factors.
> The optimum acceleration will, therefore, change due to the characteristics of the machine.

- Examples of setting if the torque of acceleration/deceleration differs depending on whether acceleration or deceleration is in progress and whether the movement is in the plus or minus direction

From the effect of gravity and friction, torque for acceleration/deceleration is different on each condition, such as acceleration, deceleration or plus move (up), minus move (down).
The following example is for the vertical axis and gravity and friction torque are assumed as follows.
Torque of gravity : 20 (Nm)
Torque of friction : 10 (Nm)
Because these value are different on each machine, it is necessary to observe the output torque on the actual machine for deciding acceleration pattern.
The conditions are the same as the previous example.
(Condition)

Motor speed at rapid traverse	: 3000(min^{-1})
Ball screw pitch	: 16(mm)
Inertia	: The machine inertia is to be 2.0 times higher than that of the rotor.
Rotor inertia	: 0.0099(Kgm^2)
Maximum motor torque	: 100(Nm) Speed 0 to 2000(min^{-1})
Motor torque at rapid traverse	: 79(Nm) Speed 3000(min^{-1})
Minimum motor torque	: 58(Nm) Speed 4000(min^{-1})

(1) In case of plus move (up) and acceleration
Because torque of Gravity and friction work against the output torque of motor, the torque for acceleration/deceleration is as follows.

Maximum torque	: 70(=100-20-10) (Nm)	Speed 0 to 2000(min^{-1})
Torque at rapid traverse	: 49(=79-20-10) (Nm)	Speed 3000(min^{-1})
Minimum torque	: 28(=58-20-10) (Nm)	Speed 4000(min^{-1})

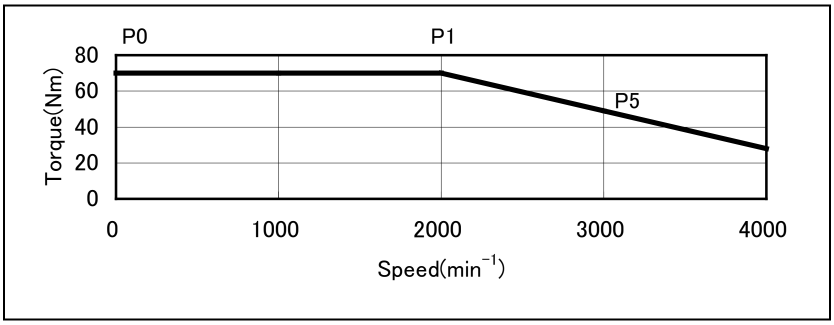

Fig. 7.2.5 (g) Torque for Acc/Dec in case of + move and acceleration with consideration of gravity and friction.

Parameter setting is as follows,

Fig.7.2.5 (d)

	Parameter number	Setting	Unit	Remarks
Acceleration at P0	19545	7277	0.01%	Set half the acceleration at P1, or 7277.
Acceleration at P1-P2	19546,19547	14554	0.01%	At P1 and P2, 70(Nm) can be used for the acceleration/ deceleration, so set the ratio of the acceleration at 70 (Nm) to the reference acceleration. (1.4554 = 6002 / 4124)
Acceleration at P3-P4	19548 to 19549	0	0.01%	0 is set because P3 to P4 are skipped.
Acceleration at P5	19550	10187	0.01%	At P5, 49(Nm) can be used for the acceleration/deceleration, so set the ratio of the acceleration at 49 (Nm) to the reference acceleration. (1.0187 = 4201 / 4124)

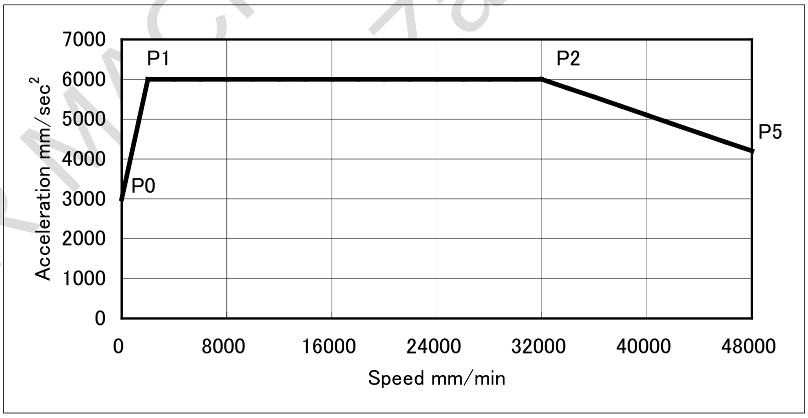

Fig. 7.2.5 (h) Acceleration pattern in case of + move and acceleration with consideration of gravity and friction.

(2) In case of plus move (up) and deceleration
Because torque of Gravity and friction work forward to the output torque of motor, the torque for acceleration/deceleration is as follows.

Maximum torque	:	130(=100+20+10) (Nm)	Speed 0 to 2000(min^{-1})
Torque at rapid traverse	:	109(=79+20+10) (Nm)	Speed 3000(min^{-1})
Minimum torque	:	88(=58+20+10) (Nm)	Speed 4000(min^{-1})

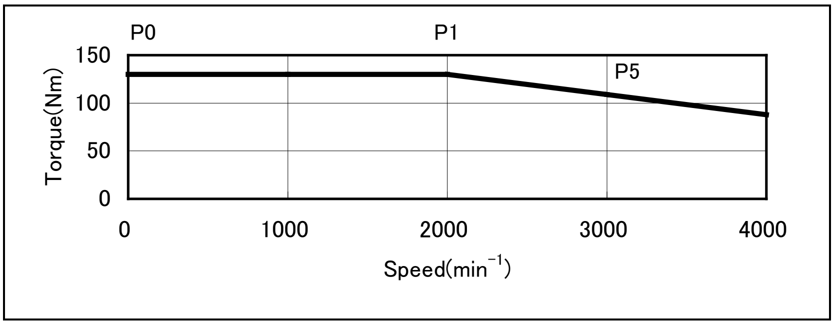

Fig. 7.2.5 (i) Torque for Acc/Dec in case of + move and deceleration with consideration of gravity and friction.

Parameter setting is as follows,

Fig.7.2.5 (e)

	Parameter number	Setting	Unit	Remarks
Acceleration at P0	19557	13514	0.01%	Set half the acceleration at P1, or 13514.
Acceleration at P1-P2	19558, 19559	27027	0.01%	At P1 and P2, 130(Nm) can be used for the acceleration/ deceleration, so set the ratio of the acceleration at 130 (Nm) to the reference acceleration. (2.7027 = 11146 / 4124)
Acceleration at P3-P4	19560 to 19561	0	0.01%	0 is set because P3 to P4 are skipped.
Acceleration at P5	19562	22662	0.01%	At P5, 109(Nm) can be used for the acceleration/deceleration, so set the ratio of the acceleration at 109 (Nm) to the reference acceleration. (2.2662 = 9346 / 4124)

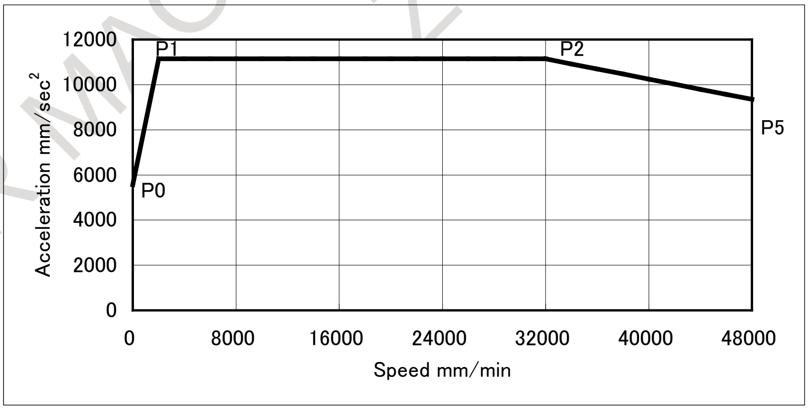

Fig. 7.2.5 (j) Acceleration pattern in case of + move and deceleration with consideration of gravity and friction.

(3) In case of minus move (down) and acceleration

Because torque of Gravity works forward to the output torque of motor and torque of friction works against the output torque of motor, torque for acceleration/deceleration is as follows.

Maximum torque	:	110(=100+20-10) (Nm)	Speed 0 to 2000(min^{-1})
Torque at rapid traverse	:	89(=79+20-10) (Nm)	Speed 3000(min^{-1})
Minimum torque	:	68(=58+20-10) (Nm)	Speed 4000(min^{-1})

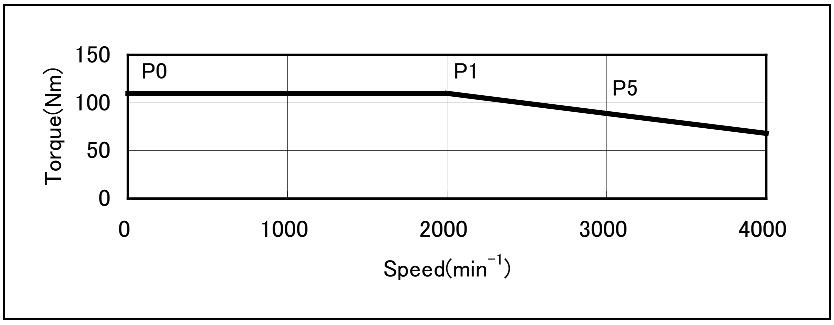

Fig. 7.2.5 (k) Torque for Acc/Dec in case of - move and acceleration with consideration of gravity and friction.

Parameter setting is as follows,

Fig.7.2.5 (f)

	Parameter number	Setting	Unit	Remarks
Acceleration at P0	19551	11435	0.01%	Set half the acceleration at P1, or 11435.
Acceleration at P1-P2	19552,19553	22869	0.01%	At P1 and P2, 110(Nm) can be used for the acceleration/ deceleration, so set the ratio of the acceleration at 110 (Nm) to the reference acceleration. (2.2869 = 9431 / 4124)
Acceleration at P3-P4	19554 to 19555	0	0.01%	0 is set because P3 to P4 are skipped.
Acceleration at P5	19556	18504	0.01%	At P5, 89(Nm) can be used for the acceleration/deceleration, so set the ratio of the acceleration at 89 (Nm) to the reference acceleration. (1.8504 = 7631 / 4124)

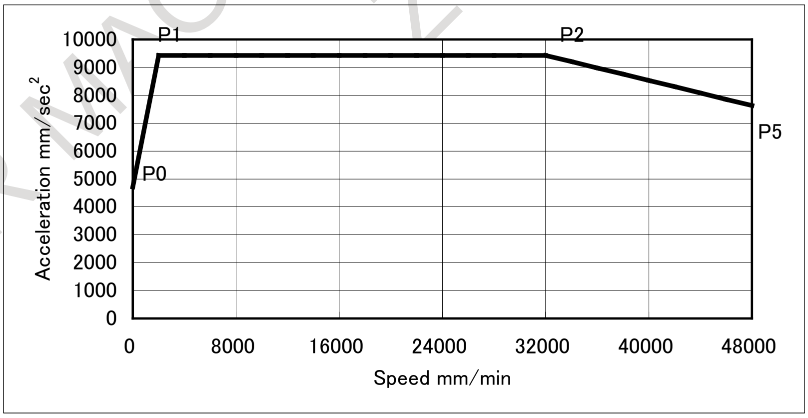

Fig. 7.2.5 (l) Acceleration pattern in case of - move and acceleration with consideration of gravity and friction.

(4) In case of minus move (down) and deceleration
Because torque of Gravity works against the output torque of motor and torque of friction works forward to the output torque of motor, torque for acceleration/deceleration is as follows.

Maximum torque	:	90(=100-20+10) (Nm)	Speed 0 to 2000(min^{-1})
Torque at rapid traverse	:	69(=79-20+10) (Nm)	Speed 3000(min^{-1})
Minimum torque	:	48(=58-20+10) (Nm)	Speed 4000(min^{-1})

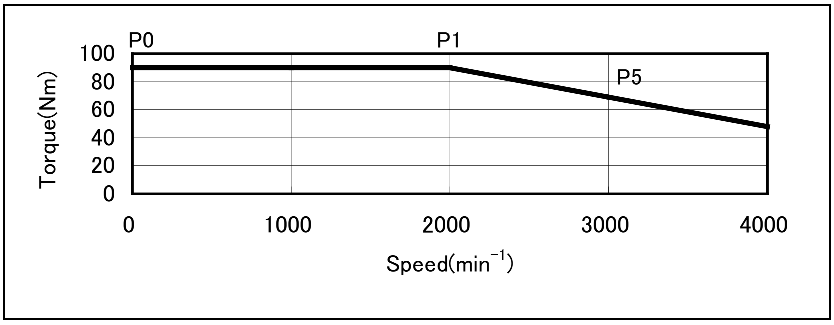

Fig. 7.2.5 (m) Torque for Acc/Dec in case of - move and deceleration with consideration of gravity and friction.

Parameter setting is as follows,

Fig.7.2.5 (g)

	Parameter number	Setting	Unit	Remarks
Acceleration at P0	19563	9356	0.01%	Set half the acceleration at P1, or 9356.
Acceleration at P1-P2	19564,19565	18712	0.01%	At P1 and P2, 90(Nm) can be used for the acceleration/ deceleration, so set the ratio of the acceleration at 90 (Nm) to the reference acceleration. (1.8712 = 7717 / 4124)
Acceleration at P3-P4	19566 to 19567,	0	0.01%	0 is set because P3 to P4 are skipped.
Acceleration at P5	19568	14345	0.01%	At P5, 69(Nm) can be used for the acceleration/deceleration, so set the ratio of the acceleration at 69 (Nm) to the reference acceleration. (1.4345 = 5916 / 4124)

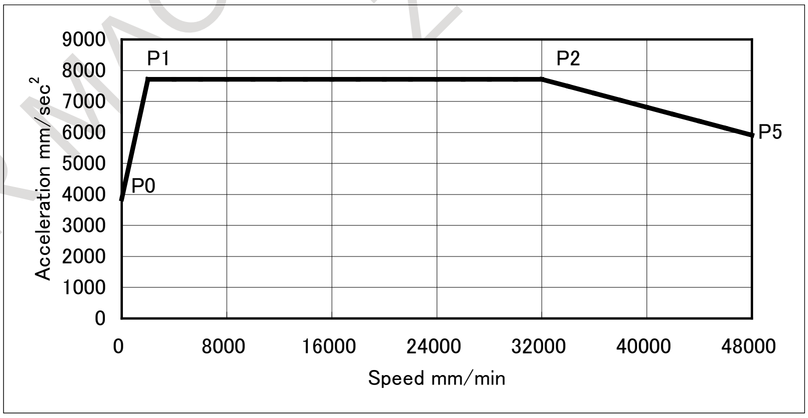

Fig. 7.2.5 (n) Acceleration pattern in case of - move and deceleration with consideration of gravity and friction.

Limitation

- Linear interpolation positioning

Optimum torque acceleration/deceleration is not enabled unless linear interpolation positioning is set (bit 1 (LRP) of parameter No. 1401 is set to 1).

- Valid modes and conditions

Optimum torque acceleration/deceleration is enabled when look-ahead acceleration/deceleration before interpolation (AI contour control mode) is active and the conditions under which look-ahead accel-

eration/deceleration before interpolation is performed are satisfied (bit 1 (LRP) of parameter No. 1401 is set to 1, and bit 5 (FRP) of parameter No. 19501 is set to 1, and parameter No.1671 is set to non-zero value).
However, when bit 0 (FAE) of parameter No. 11240 is set to 1, optimum torque acceleration/deceleration is enabled even if AI contour control is disabled.

- Target axes

Optimum torque acceleration/deceleration cannot be performed for a specific axis only. All axes operated by programmed commands are targeted for optimum torque acceleration/deceleration. This means that the PMC axes are excluded.

- Acceleration pattern

In the same direction move, it is necessary that the acceleration during deceleration is set 1/3 of one during acceleration at least.

Also, the acceleration pattern data must be set so that the time required for the deceleration from the rapid traverse rate to a speed of 0 does not exceed 4000 (msec). This does not include the acceleration change time of bell-shaped acceleration/deceleration.

If the deceleration acceleration ratio or the time required for the deceleration to a speed of 0 exceeds the above range, alarm DS1710, "ILLEGAL ACC. PARAMETER (OPTIMUM TORQUE ACC/DEC)" will be issued at the time rapid traverse is executed.

A slight error will occur between the specified acceleration and the actual acceleration.

Parameter

1671	Maximum allowable acceleration rate in acceleration/deceleration before interpolation for linear rapid traverse for each axis, or allowable reference acceleration rate in optimum torque acceleration/deceleration

[Input type] Parameter input
[Data type] Real axis
[Unit of data] mm/sec^2, inch/sec^2, deg/sec^2 (machine unit)
[Min. unit of data] Depend on the increment system of the applied axis
[Valid data range] Refer to the standard parameter setting table (D)
(When the machine system is metric system, 0.0 to +100000.0. When the machine system is inch system, machine, 0.0 to +10000.0.)

(1) Set a maximum allowable acceleration rate in look-ahead acceleration/ deceleration before interpolation for linear rapid traverse.
If a value greater than 100000.0, the value is clamped to 100000.0.
If 0 is set, the specification of the following is assumed:
1000.0 mm/sec^2
100.0 inch/sec^2
100.0 degrees/sec^2
If 0 is specified for all axes, however, look-ahead acceleration/deceleration before interpolation is not performed.

(2) Allowable reference acceleration rate in optimum torque acceleration/deceleration

1672	Acceleration change time of bell-shaped acceleration/deceleration before interpolation for linear rapid traverse, or acceleration change time of bell-shaped acceleration/deceleration in optimum torque acceleration/deceleration

[Input type] Parameter input
[Data type] 2-word path
[Unit of data] msec
[Valid data range] 0 to 200

(1) Set an acceleration change time of bell-shaped acceleration/ deceleration for linear rapid traverse (time for changing from the state of constant feedrate (A) to the state of constant acceleration/deceleration (C) at the acceleration rate calculated from the acceleration rate set in parameter No. 1671: time of (B) in the figure below).

(2) Set an acceleration change time of bell-shaped acceleration/ deceleration in optimum torque acceleration/deceleration (time for changing from the state of constant feedrate (A) to the state of acceleration/deceleration (C) at the acceleration rate calculated from optimum torque acceleration/deceleration: time of (B) in the figure).

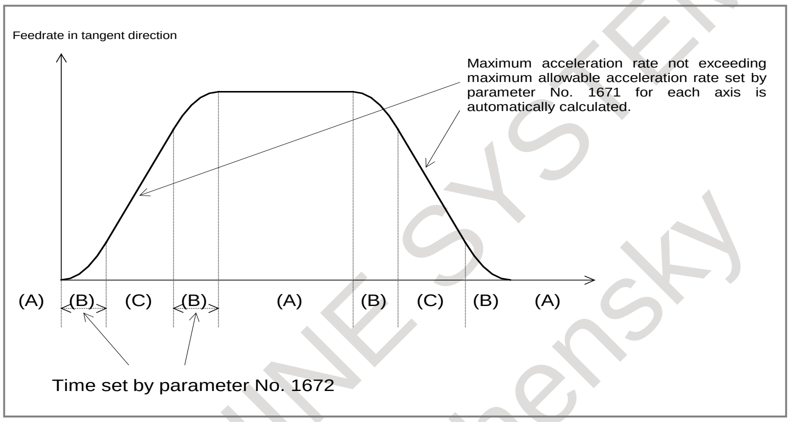

Fig. 7.2.5 (o)

	#7	#6	#5	#4	#3	#2	#1	#0
11240								FAE

[Input type] Parameter input
[Data type] Bit path

#0 FAE During positioning when the AI contour control mode is canceled, the optimum torque acceleration/deceleration is:
0: Disabled.
1: Enabled.

	#7	#6	#5	#4	#3	#2	#1	#0
19501			FRP					

[Input type] Parameter input
[Data type] Bit path

#5 FRP Linear rapid traverse is:
0: Acceleration/deceleration after interpolation
1: Look-ahead acceleration/deceleration before interpolation

Set a maximum allowable acceleration rate for each axis in parameter No. 1671.
When using look-ahead bell-shaped acceleration/deceleration before interpolation, set an acceleration rate change time in parameter No. 1672.

When this parameter is set to 1, look-ahead acceleration/deceleration before interpolation is also applied to rapid traverse if all conditions below are satisfied. At this time, acceleration/deceleration after interpolation is not applied.

- Bit 1 (LRP) of parameter No. 1401 is set to 1: Linear interpolation type positioning
- A value other than 0 is set in parameter No. 1671 for an axis.
- The AI contour control mode is set.

If all of these conditions are not satisfied, acceleration/deceleration after interpolation is applied.

	#7	#6	#5	#4	#3	#2	#1	#0
19540								FAP

[Input type] Parameter input
[Data type] Bit path

#0 FAP Optimal torque acceleration/deceleration is:
0: Disabled.
1: Enabled.

When the linear positioning parameters, namely bit 1 (LRP) of parameter No. 1401 and bit 0 (FAP) of parameter No. 19540, are set to 1, and a value other than 0 is set in reference acceleration parameter No. 1671 for an axis, the acceleration/deceleration for rapid traverse becomes optimal torque acceleration/deceleration in the mode for look-ahead acceleration/deceleration before interpolation (or the AI contour control mode). Optimal torque acceleration/ deceleration is controlled according to parameter-set restricted acceleration curve data.

Setting an acceleration pattern

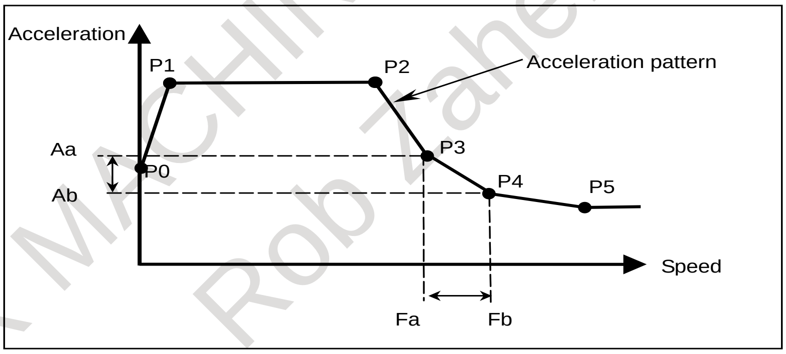

Fig. 7.2.5 (p)

Set the speed at each of the acceleration setting points (P0 to P5) in a corresponding parameter, then in parameters for each axis, set acceleration rates applicable in the following four cases at these speeds: when a movement in the positive direction is accelerated, when a movement in the positive direction is decelerated, when a movement in the negative direction is accelerated, and when a movement in the negative direction is decelerated.
The line connecting the acceleration setting points is the acceleration pattern.
The acceleration rate for each axis is calculated. For example, between speeds Fa to Fb in the above figure, the acceleration rates corresponding to these speeds, Aa to Ab, are used for calculation.
The tangent acceleration is controlled so that it does not exceed the calculated acceleration rate for each axis.

> ⚠ **CAUTION**
> When an acceleration pattern is set, setting a high acceleration rate immediately after a speed of 0 can cause an impact on the machine, so it is not desirable. Therefore, **be sure to apply a relatively low acceleration rate at a speed of 0** as shown in the above figure.

19541	**Optimal torque acceleration/deceleration (speed at P1)**
to	**to**
19544	**Optimal torque acceleration/deceleration (speed at P4)**

[Input type] Parameter input
[Data type] Word axis
[Unit of data] 0.01%
[Valid data range] 0 to 10000

The speeds at acceleration setting points P1 to P4 are to be set with speed parameters Nos. 19541 to 19544 as ratios to the rapid traverse speed (parameter No. 1420). The speed at P0 is 0, and the speed at P5 is the rapid traverse rate specified with parameter No. 1420. Any acceleration setting point for which the speed parameter (one of Nos. 19541 to 19544) is set to 0 will be skipped.

19545	**Optimal torque acceleration/deceleration (acceleration at P0 during movement in + direction and acceleration)**
to	**to**
19550	**Optimal torque acceleration/deceleration (acceleration at P5 during movement in + direction and acceleration)**
19551	**Optimal torque acceleration/deceleration (acceleration at P0 during movement in - direction and acceleration)**
to	**to**
19556	**Optimal torque acceleration/deceleration (acceleration at P5 during movement in - direction and acceleration)**
19557	**Optimal torque acceleration/deceleration (acceleration at P0 during movement in + direction and deceleration)**
to	**to**
19562	**Optimal torque acceleration/deceleration (acceleration at P5 during movement in + direction and deceleration)**
19563	**Optimal torque acceleration/deceleration (acceleration at P0 during movement in - direction and deceleration)**
to	**to**
19568	**Optimal torque acceleration/deceleration (acceleration at P5 during movement in - direction and deceleration)**

[Input type] Parameter input
[Data type] Word axis
[Unit of data] 0.01%
[Valid data range] 0 to 32767

For each travel direction and each acceleration/deceleration operation, set the allowable acceleration rate at each of the acceleration setting points (P0 to P5). As an allowable acceleration rate, set a ratio to the value set in the reference acceleration parameter No. 1671. When 0 is set, the specification of 100% is assumed.

Alarm and message

Number	Message	Description
DS1710	ILLEGAL ACC. PARAMETER (OPTIMUM TORQUE ACC/DEC)	There are errors in the parameters of permissible acceleration for Optimum Torque Acceleration/Deceleration. One of the following is the cause. 1) The ratio of the acceleration for deceleration to the acceleration for the acceleration is lower than the limited value. 2) The time to decelerate to 0 is larger than the maximum.

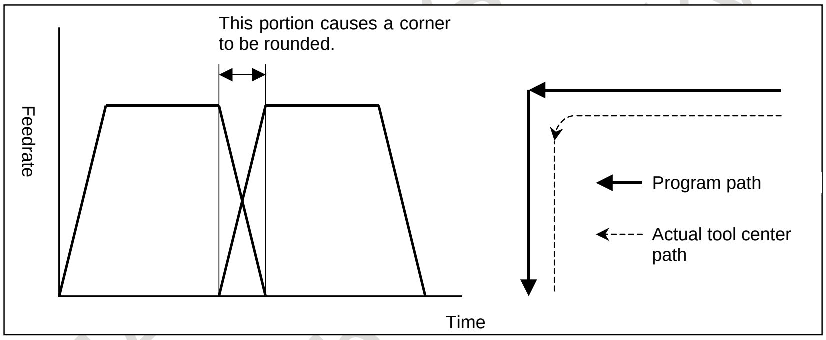
OPERATOR'S MANUAL (B-64694EN)	Optimum torque acceleration/deceleration

7.2.6 Corner Control

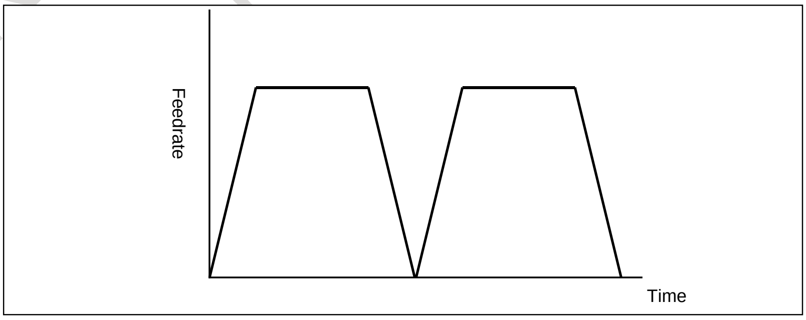
7.2.6.1 In-position check signal

Overview

On general CNCs, the feedrate during cutting feed never becomes 0 between two successive blocks. So, a corner may be rounded.



By using the in-position check signal, control can be exercised so that machining can proceed to the next block after checking that the acceleration/deceleration processing of the previous block is completed and the effective area has been entered.



Signal

In-position check signal SMZ<Gn053.6>

[Classification] Input signal

[Function] This signal selects whether to make an in-position check between successive cutting feed blocks during automatic operation.
In general, slight rounding occurs between successive cutting feed blocks because of an acceleration/deceleration delay or servo delay.
By making an in-position check (to proceed to the next block after waiting until acceleration/deceleration and servo delays disappear), this rounding can be eliminated.

[Operation] When this signal is set to "0", machining proceeds to the next block without making an in-position check between successive cutting feed blocks during automatic operation.
When this signal is set to "1", machining proceeds to the next block after making an in-position check between successive cutting feed blocks during automatic operation.

NOTE
Before and after a block for positioning, an in-position check is made, regardless of the setting of this signal.
(However, the setting of bit 5 (NCI) of parameter No. 1601 is followed.)

Signal address

	#7	#6	#5	#4	#3	#2	#1	#0
Gn053		SMZ						

7.2.6.2 In-position check

Overview

Whether the position of the servo motor is within a specified range is checked.
If the in-position check function is enabled, the CNC checks the position during deceleration. If the position is found to exceed the specified range, the CNC does not execute the next block.

NOTE
1 The purpose of in-position check is to check that the servo motor has reached within a specified range (specified with parameter No. 1826).
2 In-position check is executed for all axes in the path. Therefore, the axis which is not commanded is also the target of in-position check.

Signal

In-position signals INP1 to INP8<Fn104>

[Classification] Output signal

[Function] These signals indicate that the control axes are set to the in-position condition.
They are provided for each control axis, and the end number in the signal name corresponds to the control axis number.

INPx

x : 1 ..... The 1st axis is set to the in-position condition.
2 ..... The 2nd axis is set to the in-position condition.
3 ..... The 3rd axis is set to the in-position condition.
: :

[Output cond.] These signals turn to "1" in the following case :

- The move command of the corresponding control axis is not specified and the servo error of the corresponding control axis is within the specified allowance.

> **NOTE**
> Even if the servo error of the corresponding control axis is within the specified allowance (in-position width), the signal is not set to "1" when the axis is moving or there is acceleration/deceleration delay.

These signals turn to "0" in the following cases :

- The move command of the corresponding control axis is specified.
- The servo error of the corresponding control axis exceeds the specified allowance.

Signal address

	#7	#6	#5	#4	#3	#2	#1	#0
Fn104	INP8	INP7	INP6	INP5	INP4	INP3	INP2	INP1

Parameter

	#7	#6	#5	#4	#3	#2	#1	#0
1601			NCI					

[Input type] Parameter input
[Data type] Bit path

#5 NCI An in-position check:

0: Confirms that the specified feedrate becomes 0 (the acceleration/deceleration delay becomes 0) at deceleration time and that the machine position has reached a specified position (the servo positional deviation is within the in-position width set by parameter No. 1826).

1: Confirms only that the specified feedrate becomes 0 (the acceleration/deceleration delay becomes 0) at deceleration time.

1826	In-position width for each axis

[Input type] Parameter input
[Data type] 2-word axis
[Unit of data] Detection unit
[Valid data range] 0 to 99999999

The in-position width is set for each axis.
When the deviation of the machine position from the specified position (the absolute value of the positioning deviation) is smaller than the in-position width, the machine is assumed to have reached the specified position. (The machine is in the in-position state.)

Note

> **NOTE**
> 1 The in-position signals INP1 to INP8 <Fn104> may turn to "1" even during the movement if the axis is fed at very low speed.
> 2 The in-position check function is enabled at the interface between two cutting blocks, when the exact stop command (G09) or exact stop mode command (G61) is specified

7.2.6.3 In-position check disable signal

Overview

In-position check disable signal NOINPS <Gn023.5> can be used to specify whether an in-position check is executed.

Explanation

In-position check disable signal NOINPS <Gn023.5> can be used to disable a in-position check between blocks. When an in-position check is disabled, the CNC does not perform an in-position check during deceleration. That is, the CNC starts the next block before entering the in-position. This reduces the cycle time.

NOTE

1. When an in-position check is disabled, the CNC starts the next block before entering the in-position. Note that this may cause a difference between the program command and the actual tool path.
2. In-position check disable signal NOINPS <Gn023.5> can disable an in-position check between blocks, but cannot disable an in-position check by the following G codes.
   - Reference position return (G28)
   - 2nd/3rd/4th reference position return (G30)
   - Machine coordinate system selection (G53)
   - Single direction positioning (G60)

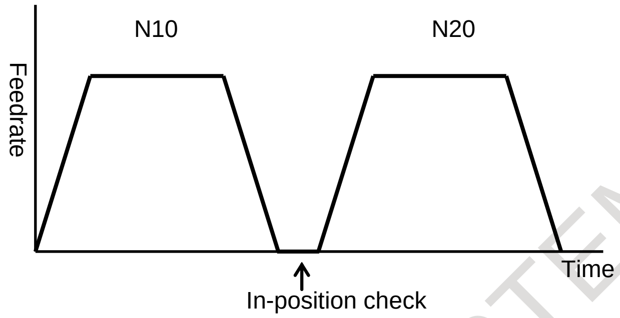
   However, this signal can disable an in-position check at the midpoint of G28 and G30, or at the motion end point of G60.
   To disable an in-position check in the reference position in G28 and G30, specify reference position return (G28.2, G30.2).

Example

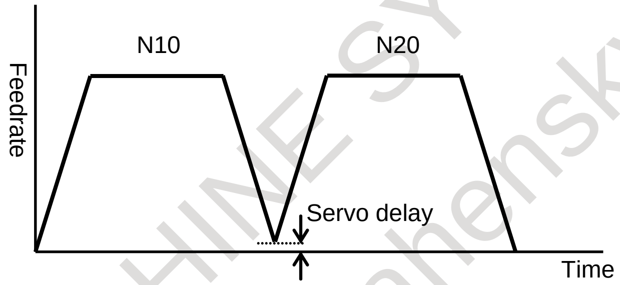
```
O0001;
N10 G00 X50.0;
N20 G00 X100.0;
N30 M30;
```

Note) The program starts at the position in which X-coordinate is 0.0.

<1> When NOINPS <Gn023.5> is "0"
(An in-position check is performed.)



<2> When NOINPS <Gn023.5> is "1"
(An in-position check is not performed.)



Signal

In-position check disable signal NOINPS <Gn023.5>

[Classification] Input signal

[Function] Specifies whether an in-position check is performed.

[Operation] When this signal is set to "1", the controller operates as follows.

An in-position check is not performed regardless of the setting of bit 5 (NCI) of parameter No. 1601. That is, the next block is executed before the in-position is entered.

The operation when an in-position check is not performed is the same as that in the case where bit 5 (NCI) of parameter No. 1601 is 1.

When this signal is set to "0", the controller operates as follows.

An in-position check follows the setting of bit 5 (NCI) of parameter No. 1601.

Signal address

	#7	#6	#5	#4	#3	#2	#1	#0
Gn023			NOINPS					

Parameter

	#7	#6	#5	#4	#3	#2	#1	#0
1601			NCI					

[Input type] Parameter input
[Data type] Bit path

#5 NCI An in-position check:
0: Confirms that the specified feedrate becomes 0 (the acceleration/deceleration delay becomes 0) at deceleration time and that the machine position has reached a specified position (the servo positional deviation is within the in-position width set by parameter No. 1826).
1: Confirms only that the specified feedrate becomes 0 (the acceleration/deceleration delay becomes 0) at deceleration time.

7.2.6.4 In-position check independently of feed/rapid traverse

Overview

If separate in-position check for cutting feed and rapid traverse is executed, a small in-position check range can be specified between those cutting feed blocks that require a high degree of precision. A large in-position check range can be specified between those rapid traverse blocks that require quick positioning.

Signal

See Item “In-position check.”.

Parameter

	#7	#6	#5	#4	#3	#2	#1	#0
1601			NCI					

[Input type] Parameter input
[Data type] Bit path

#5 NCI An in-position check:
0: Confirms that the specified feedrate becomes 0 (the acceleration/deceleration delay becomes 0) at deceleration time and that the machine position has reached a specified position (the servo positional deviation is within the in-position width set by parameter No. 1826).
1: Confirms only that the specified feedrate becomes 0 (the acceleration/deceleration delay becomes 0) at deceleration time.

	#7	#6	#5	#4	#3	#2	#1	#0
1801			CIN	CCI				

[Input type] Parameter input
[Data type] Bit path

#4 CCI As the in-position width for cutting feed:
0: The parameter No. 1826 applicable to rapid traverse as well is used.
1: The parameter No. 1827 dedicated to cutting feed is used.
This parameter enables the in-position width for cutting feed (parameter No. 1827) to be set instead of the in-position width for rapid traverse (parameter No. 1826).

By setting bit 4 (CCI) of parameter No. 1801, choose whether to use this function or the conventional in-position check function.
This function, when specified, is enabled for all axes. So, for an axis that does not require this function, set the same data in parameters Nos. 1826 and 1827.

#5 CIN When CCI is set to 1, the dedicated parameter for specifying an in-position width for cutting feed is used:
0: Only when the next block specifies cutting feed.
1: Regardless of the next block.
The table indicates the relationships between the parameters for cutting feed and rapid traverse.

		Bit 5 (CIN) of parameter No. 1801			
		0		**1**	
Bit 4 (CCI) of parameter No. 1801	**0**	Rapid traverse → Rapid traverse	No. 1826	Rapid traverse → Rapid traverse	No. 1826
		Rapid traverse → Cutting feed	No. 1826	Rapid traverse → Cutting feed	No. 1826
		Cutting feed → Cutting feed	No. 1826	Cutting feed → Cutting feed	No. 1826
		Cutting feed → Rapid traverse	No. 1826	Cutting feed → Rapid traverse	No. 1826
	1	Rapid traverse → Rapid traverse	No. 1826	Rapid traverse → Rapid traverse	No. 1826
		Rapid traverse → Cutting feed	No. 1826	Rapid traverse → Cutting feed	No. 1826
		Cutting feed → Cutting feed	No. 1827	Cutting feed → Cutting feed	No. 1827
		Cutting feed → Rapid traverse	No. 1826	Cutting feed → Rapid traverse	No. 1827

The parameters CCI and CIN can also be applied to a Cs axis.

1826	In-position width for each axis

[Input type] Parameter input
[Data type] 2-word axis
[Unit of data] Detection unit
[Valid data range] 0 to 99999999

The in-position width is set for each axis.
When the deviation of the machine position from the specified position (the absolute value of the positioning deviation) is smaller than the in-position width, the machine is assumed to have reached the specified position. (The machine is in the in-position state.)

1827	In-position width in cutting feed for each axis

[Input type] Parameter input
[Data type] 2-word axis
[Unit of data] Detection unit
[Valid data range] 0 to 99999999

Set an in-position width for each axis in cutting feed. This parameter is used when bit 4 (CCI) of parameter No. 1801=1.

Note

> **NOTE**
> If the bit 5 (NCI) of parameter No. 1601 is set to 1, so that position check is not performed during deceleration, this function is invalid. The system starts execution of the next block as soon as deceleration has been completed, without checking whether the servo position error is within the specified range.

7.2.7 Feed Forward in Rapid Traverse

Overview

Feed-forward control can be available even during rapid traverse. In this case, the servo position deviation is reduced, thus it reduces the time required for positioning to within the specified range.

Parameter

	#7	#6	#5	#4	#3	#2	#1	#0
1800					FFR			

[Input type] Parameter input
[Data type] Bit path

#3 FFR Feed-forward control in rapid traverse is:
0: Disabled
1: Enabled
Feed-forward is enabled only in normal cutting feed. When this parameter is set to 1, feed-forward is enabled in rapid traverse as well. This capability reduces the servo positional deviation, thus reducing the time required to enter the in-position width at the time of positioning.

> **NOTE**
> The parameter setting becomes valid after reference position return is completed.

Reference item

For details of this function, refer to the "FANUC SERVO MOTOR α*i* series Maintenance Manual (B-65285EN)."

7.2.8 Optimum Acceleration/Deceleration for Rigid Tapping

Overview

This function can be used to flexibly set the acceleration/deceleration during cutting in rigid tapping according to the torque characteristics of a spindle motor and the mechanical characteristics such as machine friction. Depending on the torque characteristics of a spindle motor and the mechanical characteristics, the acceleration/deceleration performance (referred to below as the maximum acceleration curve) that can be output is not symmetrical in the low-speed and high-speed parts. The conventional acceleration/deceleration (linear-shaped/bell-shaped) is symmetrical, so it was impossible to make the most of the motor performance.
This function can be used to perform acceleration/deceleration so that the actual speed curve can follow the maximum acceleration curve as close as possible. This can make the most of the motor performance and reduce the cutting time. When rigid tapping is used in an area where the acceleration of the spindle motor is constant, however, reduction in the cutting time cannot be expected.

If the acceleration pattern is set for the parameter for each gear, rigid tapping by acceleration following the maximum acceleration curve.

In acceleration/deceleration during withdrawal, the acceleration/deceleration pattern during cutting is used.

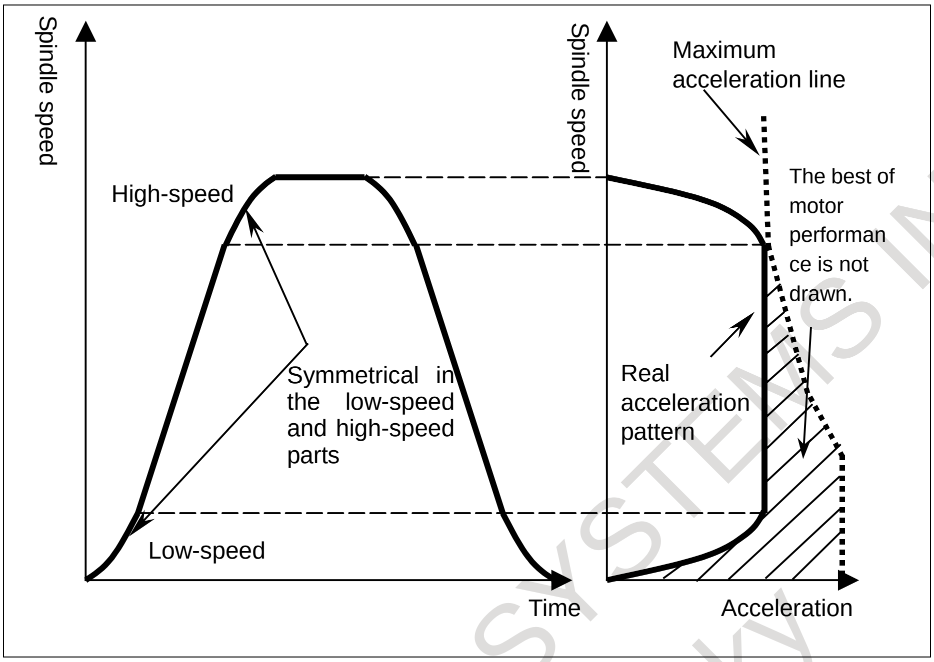


Fig. 7.2.8 (a) Conventional acceleration/deceleration (bell-shaped)

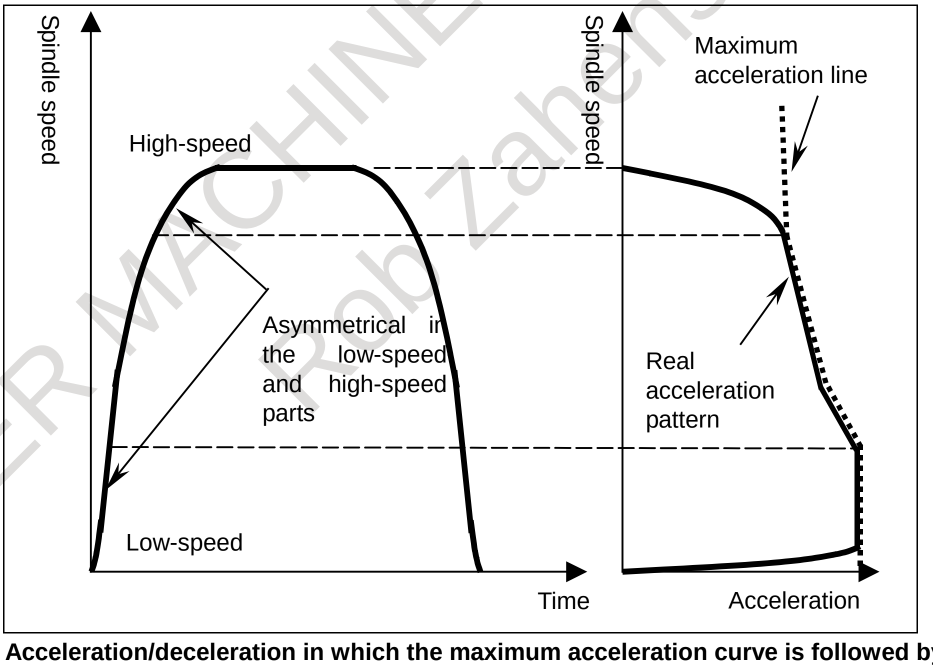

Fig. 7.2.8 (b) Acceleration/deceleration in which the maximum acceleration curve is followed by the actual acceleration curve by this function

Explanation

This function selects an acceleration pattern set in the parameter based on the acceleration/deceleration state of the spindle and the selected gears (between the spindle and the spindle motor), calculates the allowable acceleration of the spindle from the current spindle acceleration, and performs rigid tapping by controlling acceleration/deceleration so that the allowable acceleration of the spindle is not exceeded.

NOTE

In the text in this section, up to four stages of gears between the spindle and the spindle motor in rigid tapping are described. Up to four stages of gears are used in lathe systems, but up to three stages of gears are used in machining centers.

- Setting optimum acceleration/deceleration

Set bit 0 (RAU) of parameter No. 11420 to 1 to enable this function.

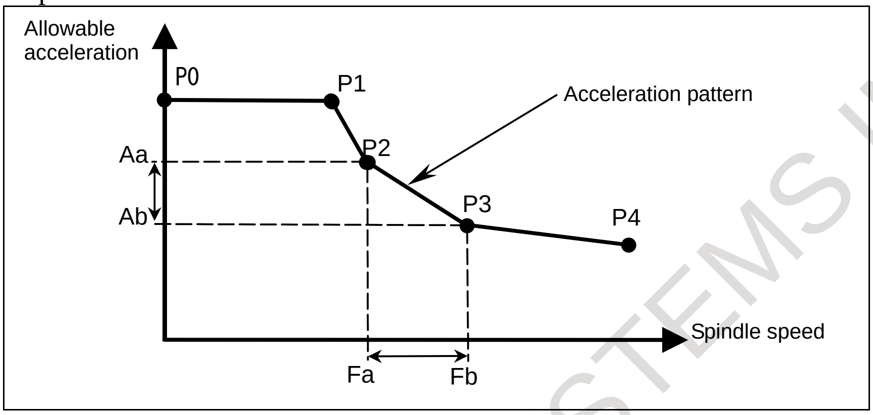

Fig. 7.2.8 (c) Acceleration setting point

For the parameter for each gear, set the rotation speed and allowable acceleration in the acceleration setting points (P0 to P4) for each spindle acceleration/deceleration. The kinked line connecting the acceleration setting points is the acceleration pattern.
In changes in the allowable acceleration, when, for example, speed Fa shifts to speed Fb in Fig. 7.2.8 (c), the allowable accelerations Aa and Ab corresponding to these speeds are used.

Table 7.2.8 (a) Parameters for acceleration patterns for each gear

Gear	Parameter number for maximum acceleration	Parameter number for maximum spindle speed	Acceleration setting points	Parameter number for spindle speed	Allowable acceleration parameter number Forward/Reverse	
					Acceleration	Deceleration
Gear 1	11421	5241	P0	None (0%)	11441	11461
			P1	11429	11442	11462
			P2	11430	11443	11463
			P3	11431	11444	11464
			P4	None (100%)	11445	11465
Gear 2	11422	5242	P0	None (0%)	11446	11466
			P1	11432	11447	11467
			P2	11433	11448	11468
			P3	11434	11449	11469
			P4	None (100%)	11450	11470
Gear 3	11423	5243	P0	None (0%)	11451	11471
			P1	11435	11452	11472
			P2	11436	11453	11473
			P3	11437	11454	11474
			P4	None (100%)	11455	11475
Gear 4	11424	5244	P0	None (0%)	11456	11476
			P1	11438	11457	11477
			P2	11439	11458	11478
			P3	11440	11459	11479
			P4	None (100%)	11460	11480

- Set the parameter of the gear to be used.
- Set parameters Nos. 11421 to 11424 to the maximum acceleration (rev/sec^2).
  If these parameters are set to 0, a DS alarm DS1711, "ILLEGAL ACC. PARAMETER (RIGID TAPPING OPTIMUM ACC/DEC)" is issued during execution.
- Since the spindle speed for P0 does not need to be set because it is 0%.
- Since the spindle speed for P4 does not need to be set because it is 100%.
- Set parameters Nos. 11429 to 11440 to the spindle speed for P1 to P3 as the ratio relative to the maximum spindle speed (parameters Nos. 5241 to 5244) in rigid tapping.
- Set parameters Nos. 11441 to 11480 to the allowable acceleration for P0 to P4 as the ratio relative to the maximum acceleration (parameters Nos. 11421 to 11424).
- Skip the acceleration setting point in which parameters Nos. 11429 to 11440 for spindle speed are set to 0 and treat a line connecting to the next acceleration setting point in which a nonzero value is set.
- When parameters Nos. 11441 to 11480 for allowable acceleration are set to 0, a value of 100% is assumed.

- Expression indicating the relationship between torque and acceleration

When the torque is $T(N \cdot m)$ and the inertia is $J\left(kg \cdot m^2\right)$, acceleration $A\left(rev/\sec^2\right)$ is calculated by the following expression.

$$\begin{aligned} A &= T(N \cdot m) / J\left(kg \cdot m^2\right)/(2\pi) \\ &= T\left(\left(kg \cdot m/\sec^2\right)(m)\right)/J\left(kg \cdot m^2\right)/(2\pi) \\ &= T/\left((2\pi) \cdot J\right) \end{aligned}$$

- Example of setting an acceleration pattern

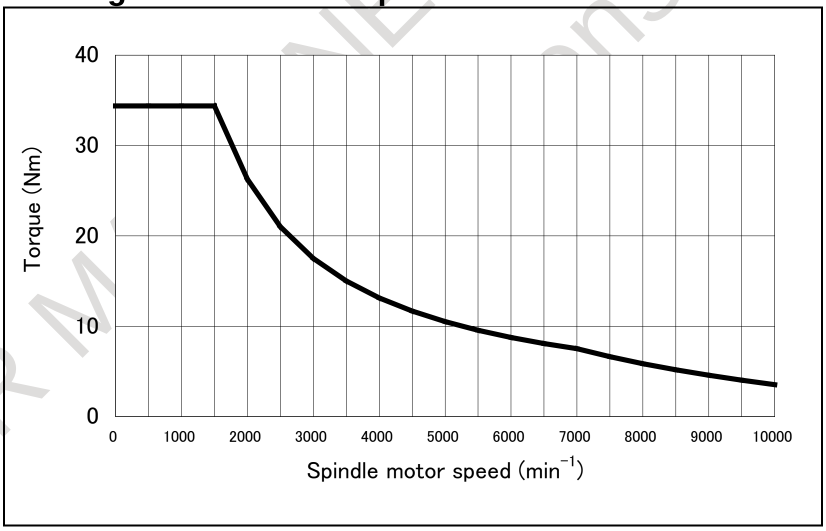

Fig. 7.2.8 (d) Speed vs. torque characteristics of model αiI3/10000-B in the operational area of 30 minutes and S3 60%

Structure
- The spindle and spindle motor are mutually connected directly.
- The spindle inertia is almost the same as the rotor inertia.
- The total inertial is double the rotor inertia.
- Model αiI3/10000-B motor

Specification of the model αiI3/10000-B motor

Rotor inertia	0.0148 $\left(kg \cdot m^2\right)$
Maximum torque	34.3 $(N \cdot m)$: Speed 0 to 1500 $\left(\min^{-1}\right)$
Spindle inertia	0.0148 $\left(kg \cdot m^2\right)$

The acceleration $A(rev/\sec^2)$ at the maximum torque of $34.3(N \cdot m)$ is calculated from the above expression, which indicates the relationship between torque vs. acceleration.

$$A = 34.3/((2\pi) \cdot 2.0 \cdot 0.0148)(rev/\sec^2)$$
$$= 184.426(rev/\sec^2)$$

An example of setting the parameters for acceleration patterns is shown in Table 7.2.8 (b).
Setting conditions

- The acceleration is constant for both acceleration and deceleration.
- The spindle and spindle motor is mutually connected directly (1:1).
- The maximum spindle speed is 6000 min^{-1}.

Table 7.2.8 (b) Example of setting the parameters for acceleration patterns

	Parameter No.	Setting value (unit)	Remarks
Maximum speed of spindle	5241	6000 (min^{-1})	
Maximum acceleration	11421	184 (rev/sec^2)	Sets the maximum acceleration A.
Spindle speed (P1)	11429	25 (%)	Since the rotation speed for a torque of 34.3 (Nm) is up to 1500 (min^{-1}), set P1 to 25% (1500 min^{-1}).
Spindle speed (P2)	11430	33 (%)	Since the torque drops linearly from 1500 (min^{-1}) to 2000 (min^{-1}), set P2 to 33% (1980 min^{-1}).
Spindle speed (P3)	11431	50 (%)	Since the torque drops linearly from 2000 (min^{-1}) to 3000 (min^{-1}), set P3 to 50% (3000 min^{-1}).
Acceleration (P0)	11441 11461	100 (%)	Set the acceleration at a rotation speed of 0 to 100% (torque 34.3 (Nm)).
Acceleration (P1)	11442 11462	100 (%)	Set the acceleration at the rotation speed of P1 to 100% (torque 34.3 (Nm)).
Acceleration (P2)	11443 11463	72 (%)	Set the acceleration at the rotation speed of P2 to 72% (torque 25 (Nm)).
Acceleration (P3)	11444 11464	43 (%)	Set the acceleration at the rotation speed of P3 to 43% (torque 15 (Nm)).
Acceleration (P4)	11445 11465	23 (%)	Set the acceleration at the rotation speed of P4 to 23% (torque 8 (Nm)).

If the parameters are set as described in Table 7.2.8 (c), the acceleration pattern is assumed as shown in Fig. 7.2.8 (e).

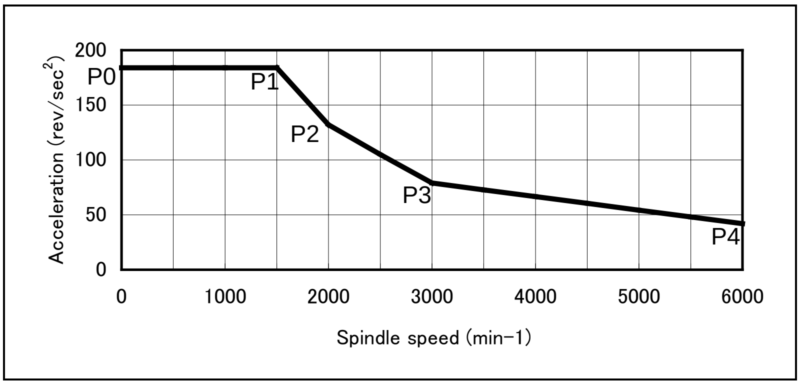

Fig. 7.2.8 (e)

At P0, the rotation speed is 0 min^{-1} and the acceleration is 184 rev/sec^2.
At P1, the rotation speed is 1500 min^{-1} and the acceleration is 184 rev/sec^2.

At P2, the rotation speed is 1980 min^{-1} and the acceleration is 132 rev/sec^2.
At P3, the rotation speed is 3000 min^{-1} and the acceleration is 79 rev/sec^2.
At P4, the rotation speed is 6000 min^{-1} and the acceleration is 42 rev/sec^2.

NOTE

1. The acceleration pattern needs to be set according to the specification of a spindle motor and the characteristics of a machine.
2. Maximum spindle speed parameters Nos. 5241 to 5244 and spindle speed parameters Nos. 11429 to 11440 may not match the speed of the spindle motor. The acceleration pattern needs to be set by taking the actual speed of the spindle motor into account.
   For example, when half the spindle speed is the speed of the spindle motor, the acceleration at the spindle speed of 6000 min^{-1} needs to be determined on the basis of the torque at the motor speed of 3000 min^{-1}.
3. The acceleration pattern needs to be changed when optimum acceleration/deceleration for rigid tapping is not operating in any path.

- Bell-shaped acceleration/deceleration

When using bell-shaped acceleration/deceleration, set parameters Nos. 11425 to 11428 to the bell-shaped acceleration change time.
When not using bell-shaped acceleration/deceleration, set these parameters to 0.

- Acceleration/deceleration after interpolation

When optimum acceleration/deceleration for rigid tapping is enabled, acceleration/deceleration after compensation is not applied.

- Override

Various types of override are disabled, but the following override can be enabled.
- Extraction override
- Override signal

See the Section 11.12, “Rigid Tapping” for details.

- Retraction for rigid tapping

Even in retraction for rigid tapping, optimum acceleration/deceleration for rigid tapping is enabled.

- Functions that can be used simultaneously

Optimum acceleration/deceleration for rigid tapping can be used concurrently with the following functions.
- 3-dimensional coordinate system conversion (3-dimensional rigid tapping)
- Tilted working plane indexing
- Axis synchronous control
- Composite control
- Tandem control
- Multi-spindle control
- Spindle command synchronous control

Restrictions

- Rigid tapping types

Optimum acceleration/deceleration for rigid tapping cannot be used in the following rigid tapping functions.
- Rigid tapping with analog spindle
- Rigid tapping by manual handle
- Rigid tapping with Cs contour control

- Rigid tapping with servo motor

- Functions that cannot be used simultaneously

Optimum acceleration/deceleration for rigid tapping cannot be used concurrently with the following functions.

- General purpose retract
  Retract signal RTRCT <Gn066.4> is ignored while the optimum acceleration/deceleration for rigid tapping is executed.

- Acceleration line pattern

- An acceleration pattern can be set for both acceleration and deceleration, but the ratio of deceleration to acceleration must be one-third or greater. For example, when the acceleration of a certain acceleration setting point (Pn) is set to 90%, the deceleration of corresponding to the point must be 30% or greater.
- The acceleration pattern of deceleration needs to be set so that the time required for deceleration from the maximum spindle speed to a rotation speed of 0 is 4000 msec or less. However, this time does not include acceleration change time for bell-shaped acceleration/deceleration.
- If the ratio of deceleration to acceleration or the time required for deceleration to a rotation speed of 0 falls outside the range, an alarm DS1711, “ILLEGAL ACC. PARAMETER (RIGID TAPPING OPTIMUM ACC/DEC)” is issued during execution.
- There is slight calculation error between the set acceleration and the actual acceleration.

Example of the adjustment (Tuning assist by SERVO GUIDE)

“Tuning assist of rigid tapping acc./dec.” in SERVO GUIDE is used for tuning.
“Tuning assist of rigid tapping acc./dec.” is supported in SERVO GUIDE edition 9.40 or later.

(1)Measurement of spindle speed waveform

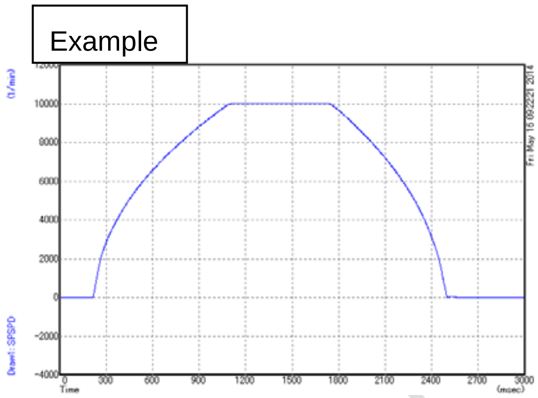
Measure Acc./Dec. waveform of spindle speed (SPSPD) to maximum spindle speed on velocity control mode.
Be careful about the following points then so that you can get the similar characteristic in the rigid tapping mode. (But, when a synchronous spindle motor is used, these items are not to be cared.)

When flux control is applied (bit 2 of parameter No.4002 = 1), set bit 2 of parameter No.4007 to 1 before measurement as the temporary setting only for the measurement. Reset bit 2 of parameter No.4007 to 0 after the measurement.
Change the motor voltage of velocity control mode (No.4083 etc.) to 100 temporarily.
After motor excitation command is input, start the measurement after waiting for a while (0.5~2.0 seconds or so) before excitation rising.

> **NOTE**
> If the parameter table for each motor model has setting “bit 2 of parameter No.4007 = 1”, it isn’t necessary to reset bit 2 of parameter No.4007 to 0 after the measurement. Please refer to FANUC AC SPINDLE MOTOR α*i*/β*i* series BUILT-IN SPINDLE MOTOR B*i* series parameter manual (B-65280EN) about the detail of the parameter table for each motor model.

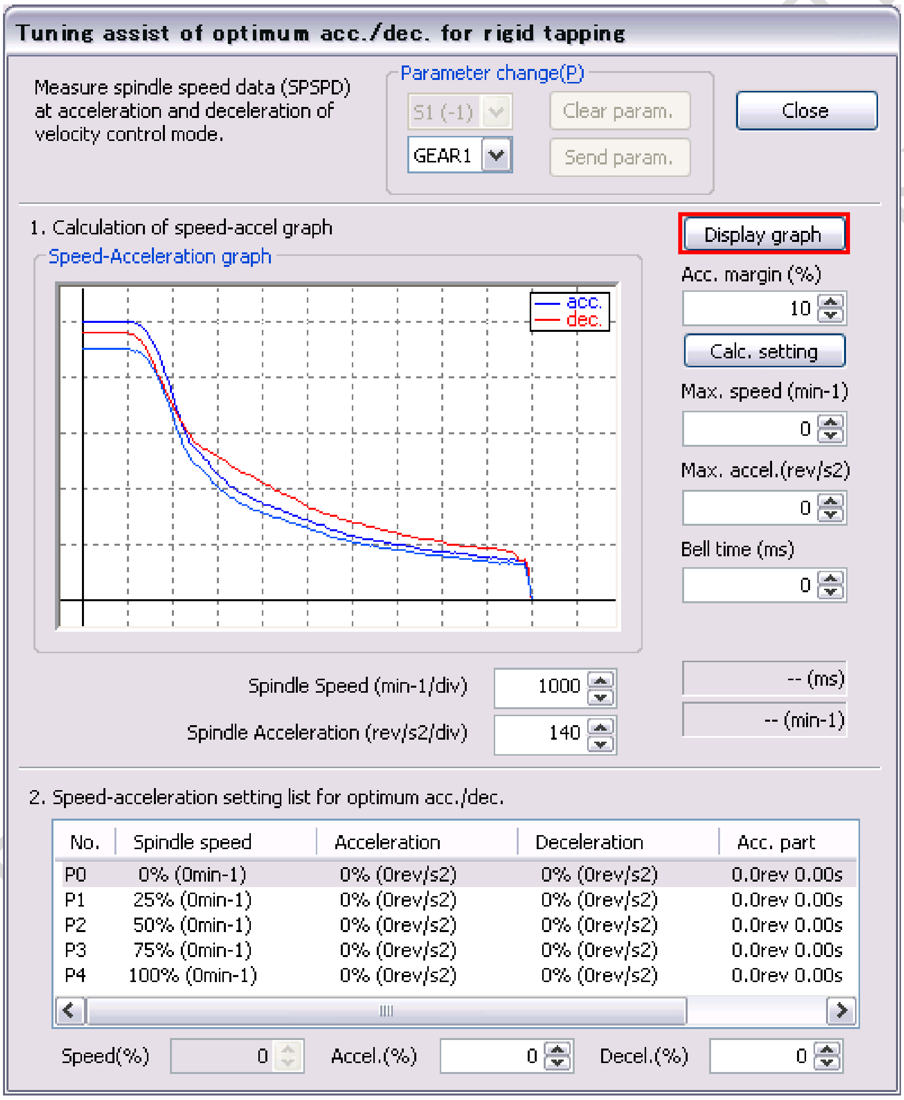
An example measurement program (maximum spindle speed is $10000min^{-1}$)

M03 S0;	Input of motor excitation command
G04 X2.0;	Time for excitation rising
S10000;	Acceleration command until $10000min^{-1}$
G04 X1.5;	Time for acceleration
S0;	Deceleration command until $0min^{-1}$
G04 X1.5;	Time for deceleration
M05;	Stop of motor excitation command
M30;	Program end



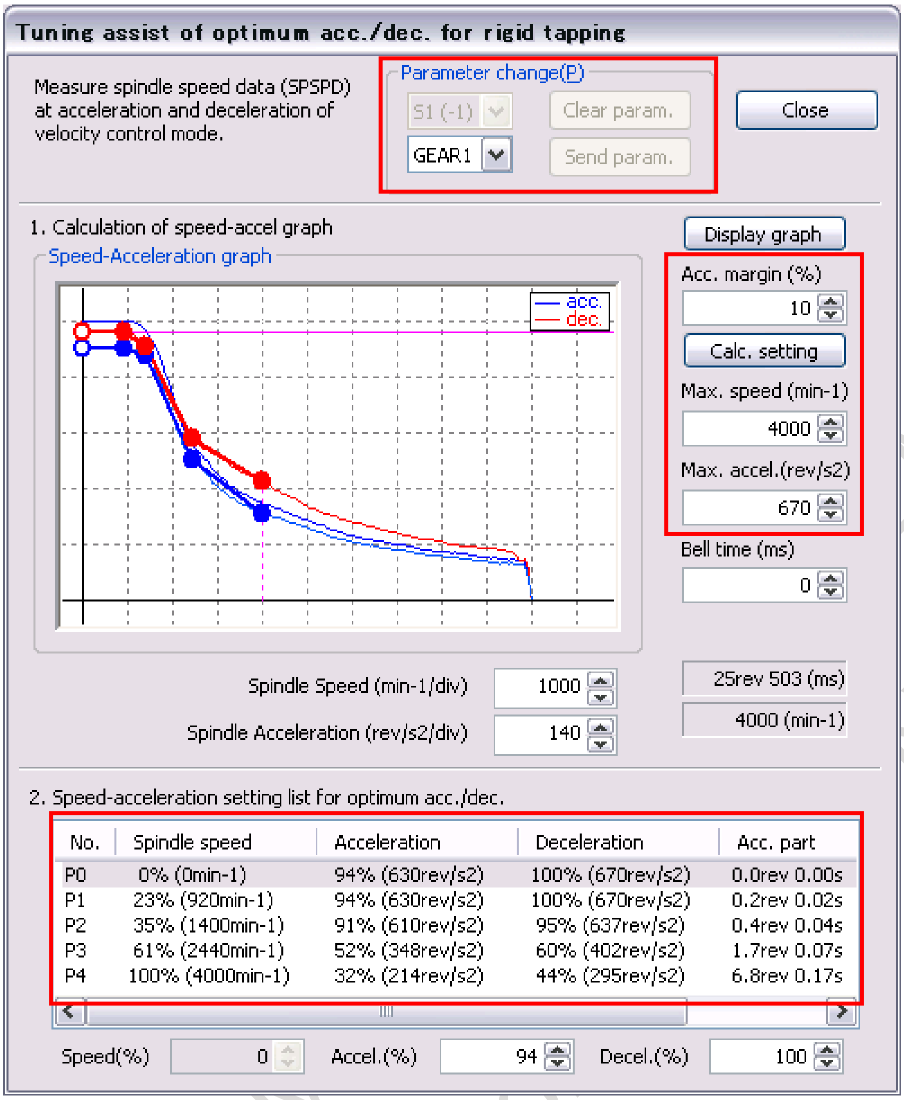
(2)Setup of “Tuning assist of rigid tapping acc./dec.”

Select “Rigid tapping tuning” from “Tool” menu of measurement spindle speed waveform, and select “Optimum acc./dec. for rigid tapping”.



Push “Display graph” button on tuning assist window, then speed-acceleration characteristics calculated by measured spindle waveform are displayed.

(3)Parameter setting of optimum acc./dec. for rigid tapping

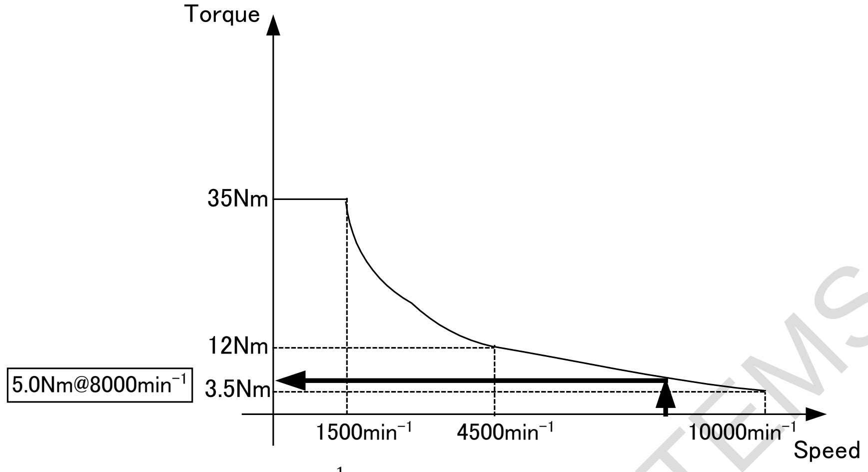


Set “Acc. margin” in consideration of the load of rigid tapping. (Standard setting: 5 to 10%)
When “Calc. setting” button is pushed after the value is input to “Max. speed”, the setting values are calculated according to speed-acceleration curve.
After the initial values are calculated, select the used gear setting in group box of “Parameter change”. Then, “function bit” and “Max. acc.” and “allowable acc.” and “allowable dec.” are input to target parameters of CNC by pushing “Send param.” button.

After the above-mentioned setting is over, check the operation of rigid tapping.

Example of the adjustment (Manual tuning)

Assuming that we use the spindle motor, which has following character, at 8000min^{-1} for rigid tapping.



This motor has small torque at 8000min^{-1}. When the acceleration is constant value in all speed, the torque in low speed area is not utilized enough, because the tolerable acceleration is limited by the torque in high speed area.

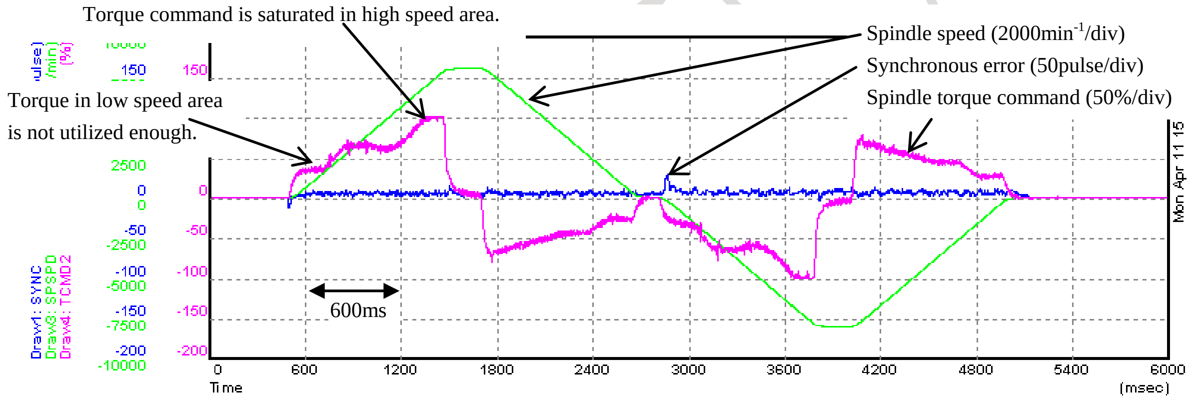


Fig. 7.2.8 (f) Example of measurement result without optimum acc./dec. for rigid tapping

The adjustment of optimum acc./dec. for rigid tapping is performed by following processes.

(1) The initial setting of the acceleration/deceleration pattern

(2) Tune the parameters so that the spindle torque command reaches near 100% in all speed area.

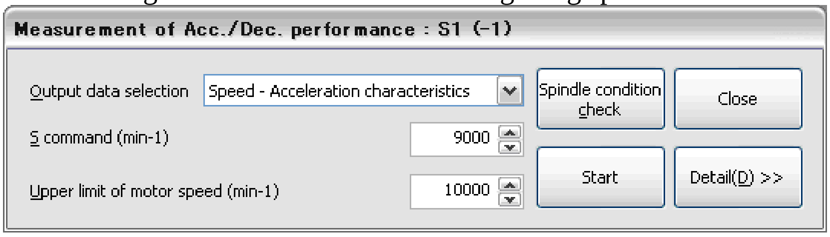
The detail of these processes is explained below.

> **NOTE**
> 1 Perform the adjustment of optimum acc./dec. for rigid tapping after the adjustment of position gain and velocity loop gain. (Refer to the “Adjustment Procedure” of "Rigid Tapping" in “FANUC AC SPINDLE PARAMETER MANUAL (B-65280EN)“ for the details of the adjustment of the gain.)
> 2 In this document, the example treats gear 1. The same procedure can be performed for other gear number.

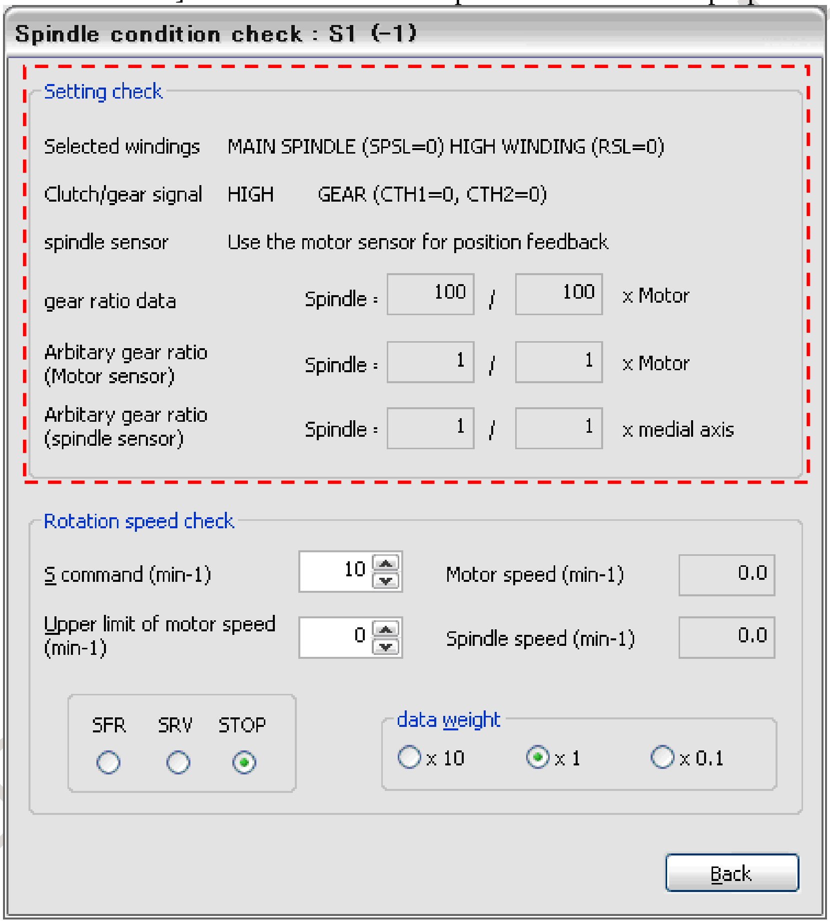
(1)The initial setting of the acceleration/deceleration pattern

Please use “Acc./Dec performance measurement” for spindle tuning in SERVO GUIDE to determine the initial settings for optimum acc./dec. for rigid tapping.

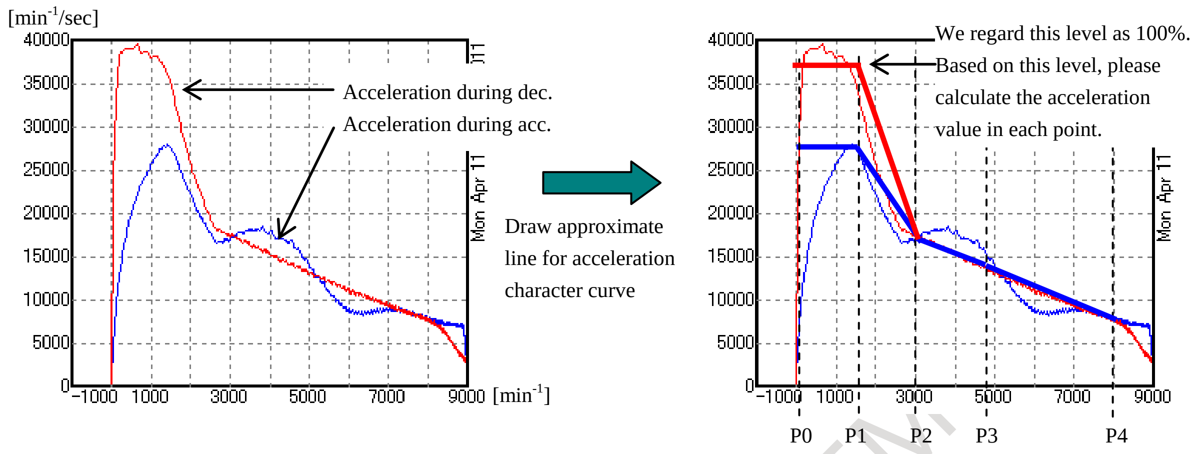
Please open Graph Window and select [Tool] -> [Spindle Tuning] -> [Acc./Dec performance measurement]. The following window will be shown after getting spindle information.



Click [Spindle condition check] and confirm whether spindle conditions are proper or not.



Go back to the measurement window and after setting S command and upper limit of motor speed, click "Start". Please set higher value than the maximum rigid tapping speed in S command box, if you can.



Please estimate the initial setting values from the measurement result. Please draw approximate line through each setting point (P0-P4) to determine the acceleration character during acc./dec.. The above data shows the character in acc./dec. with maximum torque. So available torque in rigid tapping will be less than this character. Please set the initial value for optimum acc./dec. for rigid tapping as 70% or so of approximate line.

Example)The maximum acceleration (parameter No.11421) can be seen at 0-1500min^{-1} in deceleration. It's value is

$$37800(0 \sim 1500\,\mathrm{min}^{-1})[\mathrm{min}^{-1}/\mathrm{sec}] \div 60[\mathrm{sec}] \times 0.7 = 441[rev/\mathrm{sec}^2]$$

The rest of acceleration settings should be set as the proportion of this value.

Example)Parameter No.11441 is calculated from acceleration value (27600min^{-1}/sec) at 0-1500min^{-1} in acceleration as follows:

$$27600[\mathrm{min}^{-1}/\mathrm{sec}]/37800[\mathrm{min}^{-1}/\mathrm{sec}] \times 100 = 73[\%]$$

Table 7.2.8 (c) Initial settings for optimum acc./dec. for rigid tapping

Gear	Maximum acceleration [rev/sec^2]	Maximum spindle speed [min^{-1}]	Acc. setting point	Spindle speed (Ratio to max. speed [%])	Acc. setting (Ration to max. acc. [%]) Forward / Reverse	
					During acc.	During dec.
Gear 1	No.11421=441	No.5241=8000	P0	None(0%)	No.11441=73	No.11461=100
			P1	No.11429=19	No.11442=73	No.11462=100
			P2	No.11430=38	No.11443=46	No.11463=46
			P3	No.11431=60	No.11444=36	No.11464=36
			P4	None(100%)	No.11445=20	No.11465=20

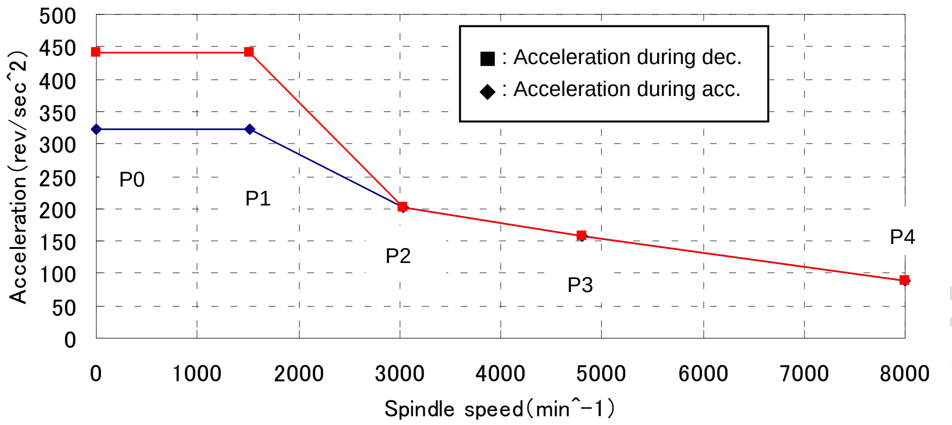


Fig. 7.2.8 (g) Initial settings for optimum acc./dec. for rigid tapping

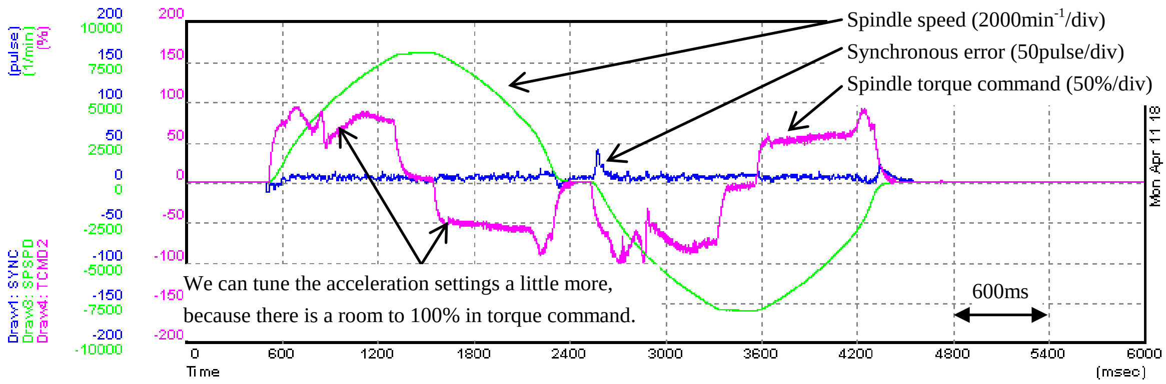

Fig. 7.2.8 (h) Example of measurement result after initial setting of optimum acc./dec. for rigid tapping

(2) Tune the parameters so that the spindle torque command reaches near 100% in all speed area

Capture the data during the rigid tapping under initial setting of optimum acc./dec. for rigid tapping by using SERVO GUIDE. The data of spindle speed (SPSPD) and torque command (TCMD2(NOTE)) should be captured. After confirming the measurement result with initial setting, please tune the acceleration parameters so that the spindle torque command reaches near 100% in all speed area. When you tune them, please use the test program, which has the assumed maximum rigid tapping speed, and start tuning from the high speed point (P4) first, and continue tuning the low speed points in order.

NOTE

TCMD2 shows the torque command rate, in which the maximum torque, considering torque limit value at each speed, is 100%.
To capture this data, following SERVO GUIDE and spindle software is required.
SERVO GUIDE: Ver.8.10 or later
Spindle soft: 9DA0 series 14 edition or later
If you can't use TCMD2, please use TCMD. However, TCMD does not consider torque limit value. Thus, TCMD might be saturated at a value which is lower than 100%. You can see whether torque command is saturated or not by watching the data of bit12 of "SFLG1". Please watch them together, if you use TCMD.

Table 7.2.8 (d) After tuning settings for optimum acc./dec. for rigid tapping

Gear	Maximum acceleration [rev/sec^2]	Maximum spindle speed [min^{-1}]	Acc. setting point	Spindle speed (Ratio to max. speed [%])	Acc. setting (Ration to max. acc. [%]) Forward / Reverse	
					During acc.	During dec.
Gear 1	No.11421=441	No.5241=8000	P0	None(0%)	No.11442=73	No.11462=100
			P1	No.11429=19	No.11442=73	No.11462=100
			P2	No.11430=38	No.11443=52	No.11463=60
			P3	No.11431=60	No.11444=47	No.11464=55
			P4	None(100%)	No.11445=20	No.11465=40

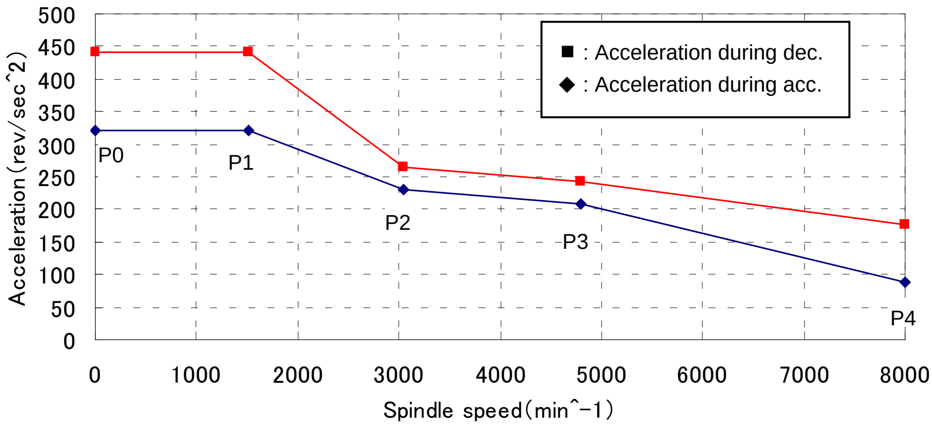

Fig. 7.2.8 (i) After tuning settings for optimum acc./dec. for rigid tapping

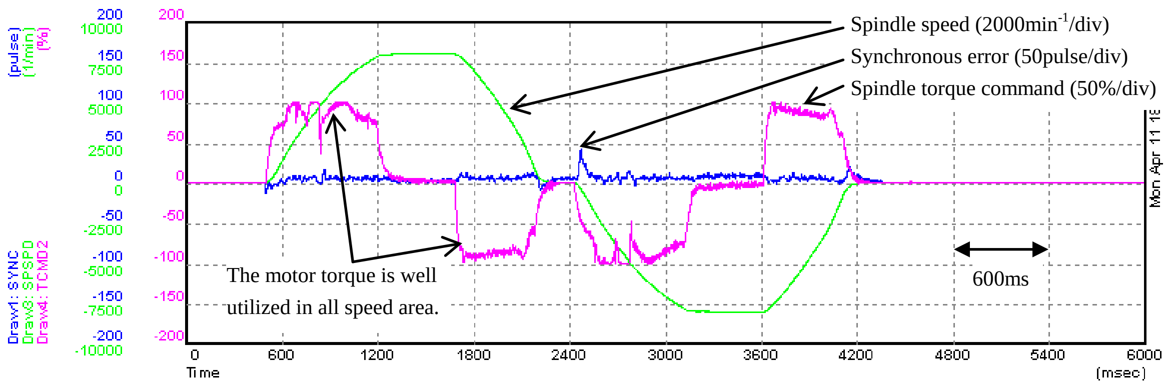

Fig. 7.2.8 (j) Example of measurement result after tuning of optimum acc./dec. for rigid tapping

In the above example, the acceleration time and deceleration time are reduced as follows by applying optimum acc./dec. for rigid tapping.

	Function OFF	Function ON
Acceleration time	976 ms	720 ms
Deceleration time	976 ms	588 ms

Parameter

	#7	#6	#5	#4	#3	#2	#1	#0
11420								RAU

7.2.9 Rapid Traverse Acceleration/deceleration before Interpolation

Overview

In linear type rapid traverse, the positioning path is linear. If look-ahead acceleration/deceleration before interpolation is enabled, however, acceleration/deceleration can be performed with the linear path kept.

When the following conditions are met, look-ahead acceleration/deceleration before interpolation is enabled for rapid traverse.

- When rapid traverse is of linear interpolation type (Bit 1 (LRP) of parameter No. 1401 is set to 1)
- When look-ahead acceleration/deceleration before interpolation is enabled for rapid traverse (Bit 5 (FRP) of parameter No. 19501 is set to 1)
- A value other than 0 is set in parameter No. 1671 for an axis.
- The AI contour control mode is set.

Deceleration and stop is always performed between blocks for which look-ahead acceleration/deceleration before interpolation is enabled.
Rapid traverse block overwrapping is disabled.

- Bell-shaped acceleration/deceleration before interpolation for rapid traverse

If parameter No. 1672 is set to bell-shaped change time when look-ahead acceleration/deceleration before interpolation is enabled for rapid traverse, acceleration/deceleration becomes bell-shaped.

- Enabling acceleration/deceleration after interpolation for acceleration/deceleration before interpolation

If parameter No. 11242 is set for each axis to the time constant of acceleration/deceleration after interpolation for rapid traverse look-ahead acceleration/deceleration before interpolation, it is possible to enable acceleration/deceleration after interpolation is for look-ahead acceleration/deceleration before interpolation.

> **NOTE**
> When enabling acceleration/deceleration after interpolation for rapid traverse acceleration/deceleration before interpolation, be sure to set the same time constant for all axes except a special purpose. Otherwise, the correct line cannot be obtained.

- Acceleration/deceleration before interpolation for rapid traverse in AICC mode off

If all of the following conditions are satisfied, look-ahead acceleration/deceleration before interpolation for rapid traverse is enabled in AICC mode off.

- AICC I or AICC II+ options is valid.
- The parameters for which look-ahead acceleration/deceleration before interpolation for rapid traverse is enabled are set.
- The setting of look-ahead acceleration/deceleration before interpolation for rapid traverse in the AICC mode off is enabled (Bit 4 (ARB) of parameter No.11240 is set to 1.)

> **NOTE**
> In the function which look-ahead acceleration/deceleration before interpolation is invalid, this function is also disabled.

- Acceleration/deceleration before interpolation for rapid traverse in rigid tapping.

When look-ahead acceleration/deceleration before interpolation for rapid traverse is valid, if the setting of look-ahead acceleration/deceleration before interpolation for rapid traverse in rigid tapping is enabled (Bit 5 (RRB) of parameter No.11240 is set to 1), look-ahead acceleration/deceleration before interpolation for rapid traverse in rigid tapping is valid. (Rapid traverse in rigid tapping is the motion of dotted line in Fig.7.2.9 .)

However, the specification of acceleration/deceleration in the following functions follows the specification of each function.

- Optimum Acceleration/Deceleration for Rigid Tapping
- Rigid Tapping with Servo Motor

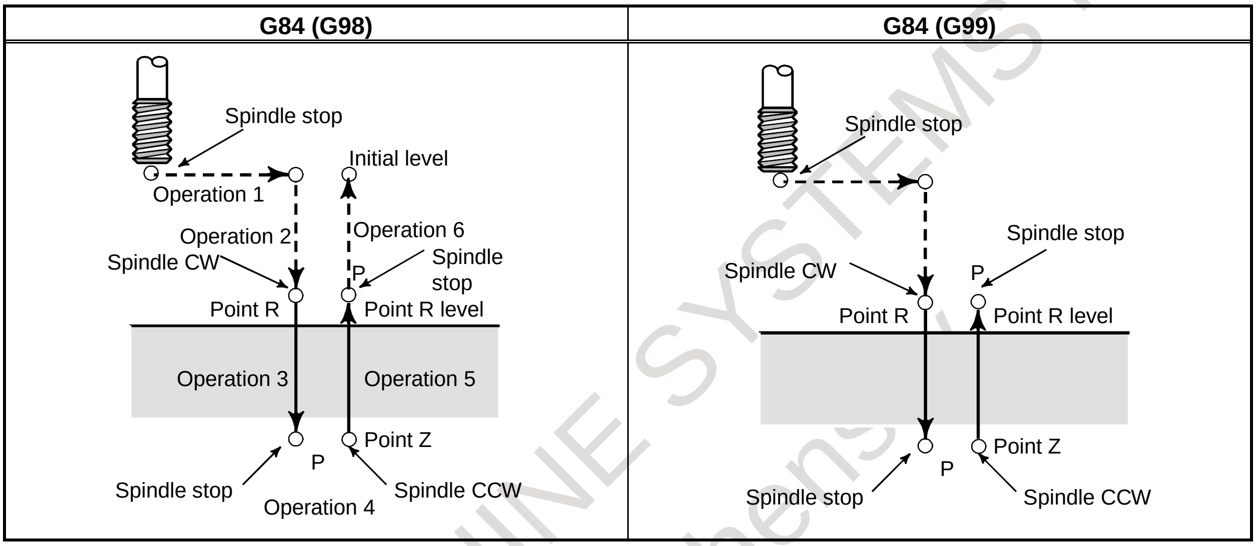

Fig.7.2.9 Rigid tapping command

Parameter

	#7	#6	#5	#4	#3	#2	#1	#0
1401							LRP	

[Input type] Parameter input
[Data type] Bit path

#1 LRP Positioning (G00)
0: Positioning is performed with non-linear type positioning so that the tool moves along each axis independently at rapid traverse.
1: Positioning is performed with linear interpolation so that the tool moves in a straight line.
When using 3-dimensional coordinate system conversion, set this parameter to 1.

1671	Maximum allowable acceleration rate in acceleration/deceleration before interpolation for linear rapid traverse for each axis, or maximum allowable reference acceleration rate in optimum torque acceleration/deceleration

[Input type] Parameter input
[Data type] Real axis
[Unit of data] mm/sec^2, inch/sec^2, deg/sec^2 (machine unit)
[Min. unit of data] Depend on the increment system of the applied axis
[Valid data range] Refer to the standard parameter setting table (D)
(When the machine system is metric system, 0.0 to +100000.0. When the machine system is inch system, machine, 0.0 to +10000.0.)

(1) Set a maximum allowable acceleration rate in look-ahead acceleration/ deceleration before interpolation for linear rapid traverse.
If a value greater than 100000.0, the value is clamped to 100000.0.
If 0 is set, the specification of the following is assumed:
1000.0 mm/sec^2
100.0 inch/sec^2
100.0 degrees/sec^2
If 0 is specified for all axes, however, look-ahead acceleration/deceleration before interpolation is not performed.
(2) Maximum allowable reference acceleration rate in optimum torque acceleration/deceleration

1672	Acceleration change time of bell-shaped acceleration/deceleration before interpolation for linear rapid traverse, or acceleration change time of bell-shaped acceleration/deceleration in optimum torque acceleration/deceleration

[Input type] Parameter input
[Data type] 2-word path
[Unit of data] msec
[Valid data range] 0 to 200

(1) Set an acceleration change time of bell-shaped acceleration/ deceleration for linear rapid traverse (time for changing from the state of constant feedrate (A) to the state of constant acceleration/deceleration (C) at the acceleration rate calculated from the acceleration rate set in parameter No. 1671: time of (B) in the figure below).
(2) Set an acceleration change time of bell-shaped acceleration/ deceleration in optimum torque acceleration/deceleration (time for changing from the state of constant feedrate (A) to the state of acceleration/deceleration (C) at the acceleration rate calculated from optimum torque acceleration/deceleration: time of (B) in the figure).

	#7	#6	#5	#4	#3	#2	#1	#0
11240			RRB	ARB				

[Input type] Parameter input
[Data type] Bit path

#4 ARB Look-ahead acceleration/deceleration before interpolation for rapid traverse in AICC mode off is:
0: Disabled.
1: Enabled.

NOTE
This parameter is enabled when the parameters for which look-ahead acceleration/deceleration before interpolation for rapid traverse is enabled are set. (Refer to bit 5 (FRP) of parameter No.19501.)

#5 RRB Look-ahead acceleration/deceleration before interpolation for rapid traverse in rigid tapping is:
0: Disabled.
1: Enabled.

NOTE
This parameter is enabled when look-ahead acceleration/deceleration before interpolation for rapid traverse is valid. (Refer to bit 5 (FRP) of parameter No.19501.)

11242	Time constant of acceleration/deceleration after interpolation of acceleration/deceleration before interpolation in rapid traverse

[Input type] Parameter input
[Data type] Word axis
[Unit of data] msec
[Valid data range] 0 to 4000

This parameter is used for the time constant of look-ahead acceleration/deceleration before interpolation in rapid traverse.
Be sure to specify the same time constant value for all axes except for a special application. If different time constants are set, a correct linear line cannot be obtained.

	#7	#6	#5	#4	#3	#2	#1	#0
19501			FRP					

[Input type] Parameter input
[Data type] Bit path

#5 FRP Linear rapid traverse is:
0: Acceleration/deceleration after interpolation
1: Look-ahead acceleration/deceleration before interpolation

Set a maximum allowable acceleration rate for each axis in parameter No. 1671.
When using look-ahead bell-shaped acceleration/deceleration before interpolation, set an acceleration rate change time in parameter No. 1672.

When this parameter is set to 1, look-ahead acceleration/deceleration before interpolation is also applied to rapid traverse if all conditions below are satisfied. At this time, acceleration/deceleration after interpolation is not applied.
- Bit 1 (LRP) of parameter No. 1401 is set to 1: Linear interpolation type positioning
- A value other than 0 is set in parameter No. 1671 for an axis.
- The AI contour control mode is set.

If all of these conditions are not satisfied, acceleration/deceleration after interpolation is applied.

7.2.10 Time constant of acceleration / deceleration after interpolation switching function by signal

Overview

Time constant of acceleration / deceleration after interpolation can be switched by input signal of PMC.

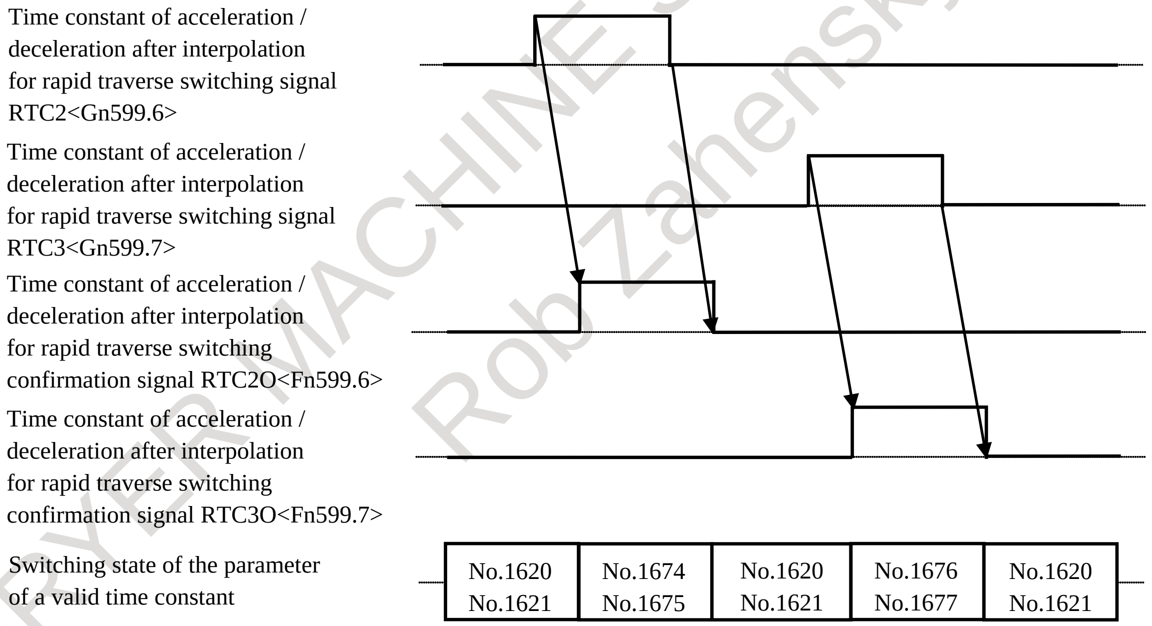
Explanation

In this function, time constant of acceleration / deceleration after interpolation for rapid traverse and cutting feed can be switched by input signal of PMC.

- Time constant of acceleration / deceleration after interpolation for rapid traverse switching

A time constant of acceleration / deceleration after interpolation for rapid traverse can be switched to either of the three following kinds by time constant of acceleration / deceleration after interpolation for rapid traverse switching signals RTC2, RTC3<Gn599.6, Gn599.7>.
- The usual time constant for rapid traverse (Parameter Nos. 1620 and 1621)
- The second time constant for rapid traverse (Parameter Nos. 1674 and 1675)
- The third time constant for rapid traverse (Parameter Nos. 1676 and 1677)

Example of time chart for time constant of acceleration / deceleration after interpolation for rapid traverse switching

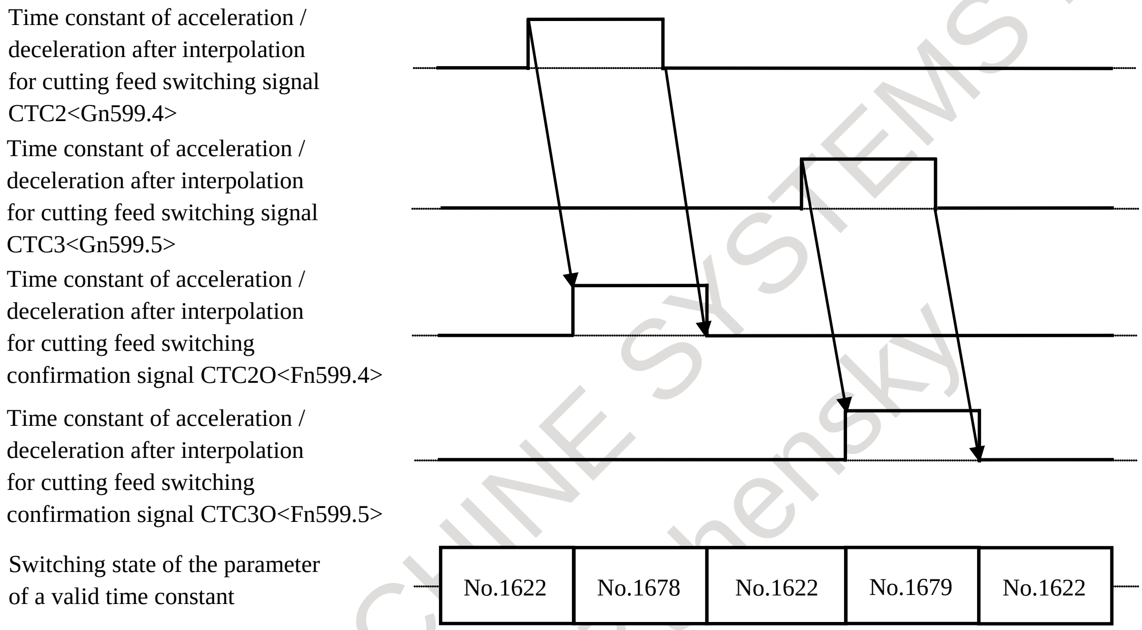


Confirm an effective parameter by time constant of acceleration / deceleration after interpolation for rapid traverse switching confirmation signal RTC2O, RTC3O.

- Time constant of acceleration / deceleration after interpolation for cutting feed switching

A time constant of acceleration / deceleration after interpolation for cutting feed can be switched to either of the three following kinds by time constant of acceleration / deceleration after interpolation for cutting feed switching signals CTC2, CTC3<Gn599.4, Gn599.5>.
- The usual time constant for cutting feed (Parameter No. 1622)
- The second time constant for cutting feed (Parameter No. 1678)
- The third time constant for cutting feed (Parameter No. 1679)

Example of time chart for time constant of acceleration / deceleration after interpolation for cutting feed switching



Confirm an effective parameter by time constant of acceleration / deceleration after interpolation for cutting feed switching confirmation signal CTC2O, CTC3O.

NOTE

1) If -1 is set to parameters Nos. 1674 or 1676 or a value not within the valid data range is specified in these parameters, the second or the third time constant of acceleration / deceleration after interpolation for rapid traverse is invalid in its axis.
2) If -1 is set to parameters Nos. 1678 or 1679 or a value not within the valid data range is specified in these parameters, the second or the third time constant of acceleration / deceleration after interpolation for cutting feed is invalid in its axis.
3) To switch a time constant of acceleration / deceleration after interpolation, all the valid axes should stop. When the axis has not stopped, the time constant is switched at the next program block after stopping all the valid axes.
4) When an axis has been moved to other path by flexible path axis assignment function, a time constant of acceleration / deceleration after interpolation is switched by RTC2, RTC3, CTC2 and CTC3 of the path after moving.
5) A slave axis of synchronous control is used the same kind of acceleration / deceleration after interpolation as a master axis. However, as for the time constant, each one is used. When the master axis is a valid axis for this function, and the slave axis is an invalid axis, as for the time constant of the slave axis, the usual time constant is used.

6) A movement axis of composite control is used the same kind of acceleration / deceleration after interpolation as a specified axis. However, as for the time constant, each one is used. When the specified axis is a valid axis for this function, and the movement axis is an invalid axis, as for the time constant of the movement axis, the usual time constant is used.

7) In the following cases, a time constant for this function is invalid.
   - A time constant of acceleration / deceleration after interpolation for manual handle retrace is valid

8) In the following cases, a time constant for rapid traverse for this function is invalid.
   - As for the axes (a master axis and a slave axis) in superimposed control (with speed control)
   - A time constant of acceleration / deceleration after interpolation for positioning by optimum accelerations is valid
   - Acceleration / deceleration before interpolation for rapid traverse of AI contour control is valid

9) In the following cases, a time constant for cutting feed for this function is invalid.
   - A time constant of acceleration / deceleration after interpolation for the skip is valid
   - A time constant of acceleration / deceleration after interpolation for rigid tapping is valid
   - A time constant of acceleration / deceleration after interpolation for spindle control with servo motor is valid
   - A time constant of exponential acceleration / deceleration after interpolation in cutting feed for PMC axis control is valid
   - Acceleration / deceleration before interpolation of AI contour control is valid

7.2.10.1 Time constant of acceleration/deceleration after interpolation in the mode of acceleration/deceleration before interpolation switching function by PMC signal

Outline

A time constant of acceleration/deceleration after interpolation in the mode of acceleration/deceleration before interpolation can be switched by PMC signal.

Explanation

In this function, the following time constant can be switched by PMC signal.

- Time constant of acceleration/deceleration after interpolation of acceleration/deceleration before interpolation in rapid traverse
- Time constant of acceleration/deceleration after cutting feed interpolation in the acceleration/deceleration before interpolation mode

- Time constant of acceleration/deceleration after interpolation of acceleration/deceleration before interpolation in rapid traverse switching

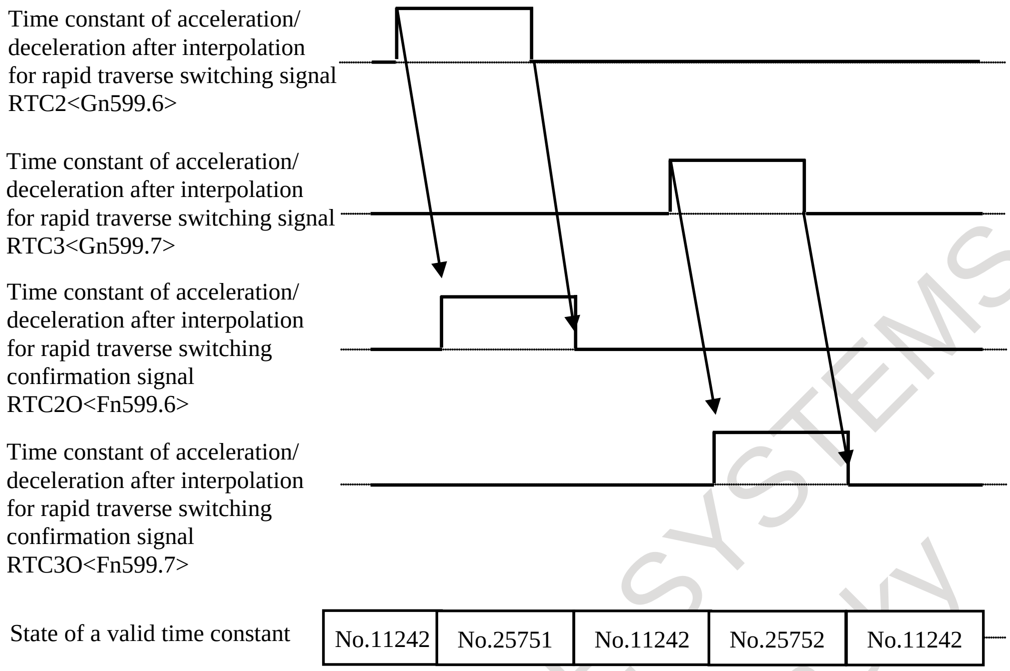
When parameter BRT(No.25750#0) is set to 1, a time constant of acceleration/deceleration after interpolation of acceleration/deceleration before interpolation in rapid traverse can be switched to either of the following three parameters by time constant of acceleration/deceleration after interpolation for rapid traverse switching signals RTC2, RTC3<Gn599.6, Gn599.7>.

Set parameter No. 11242 to a value from 1 to 4000, when executing “Time constant of acceleration/deceleration after interpolation of acceleration/deceleration before interpolation in rapid traverse switching”.

- The time constant of acceleration/deceleration after interpolation of acceleration/deceleration before interpolation in rapid traverse
(Parameter No. 11242)
- The second time constant of acceleration/deceleration after interpolation of acceleration/deceleration before interpolation in rapid traverse
(Parameter No. 25751)

- The third time constant of acceleration/deceleration after interpolation of acceleration/deceleration before interpolation in rapid traverse
(Parameter No. 25752)

Example)

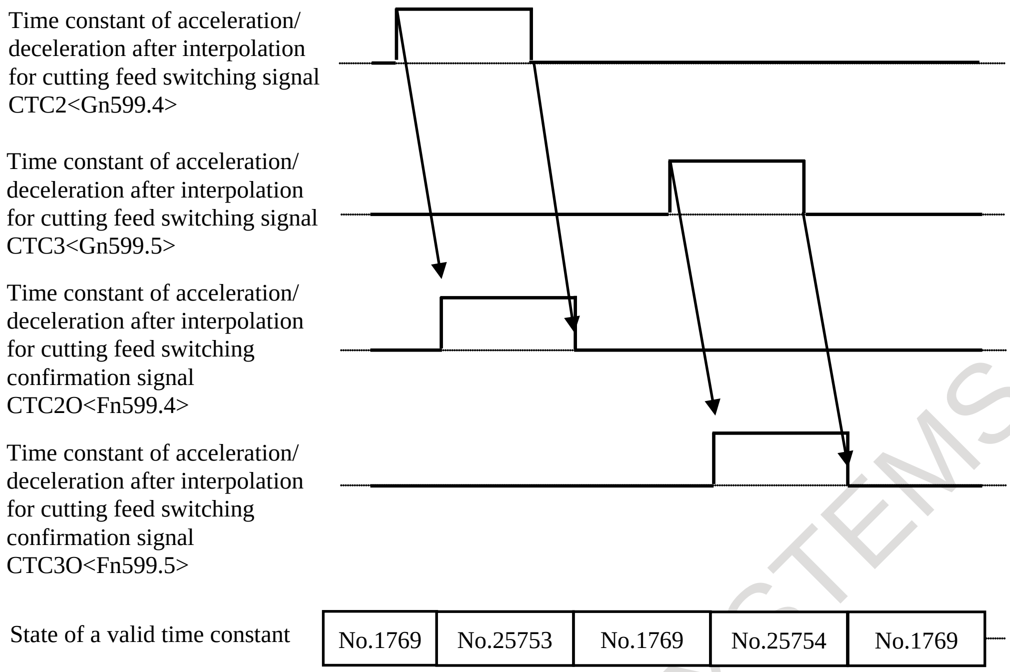


- Time constant of acceleration/deceleration after cutting feed interpolation in the acceleration/deceleration before interpolation mode switching

When parameter BCT(No.25750#1) is set to 1, a time constant of acceleration/deceleration after cutting feed interpolation in the acceleration/deceleration before interpolation mode can be switched to either of the following three parameters by time constant of acceleration/deceleration after interpolation for cutting feed switching signals CTC2, CTC3<Gn599.4, Gn599.5>.

- The time constant of acceleration/deceleration after cutting feed interpolation in the acceleration/deceleration before interpolation mode
(Parameter No. 1769)
- The second time constant of acceleration/deceleration after cutting feed interpolation in the acceleration/deceleration before interpolation mode
(Parameter No. 25753)
- The third time constant of acceleration/deceleration after cutting feed interpolation in the acceleration/deceleration before interpolation mode
(Parameter No. 25754)

Example)



NOTE

1) In a function of not supporting time constant of acceleration/deceleration after interpolation of acceleration/deceleration before interpolation, this function is disabled.
2) When the parameter No.25751 or 25752 is set to -1, the second or third time constant of acceleration/deceleration after interpolation of acceleration/deceleration before interpolation in rapid traverse is disabled.
3) When the parameter No.25753 or 25754 is set to -1, the second or third time constant of acceleration/deceleration after cutting feed interpolation in the acceleration/deceleration before interpolation mode is disabled.
4) To switch a time constant of acceleration/deceleration after interpolation, all the valid axes must be stopped. When the axis has not stopped, the time constant is switched at the next program block after stopping all the valid axes.
5) When the parameters Nos.25751 to 25754 are changed during switching to a time constant of acceleration/deceleration after interpolation for this function, the time constant is also changed.
6) When an axis has been moved to other path by flexible path axis assignment function, a time constant of acceleration/deceleration after interpolation is switched by RTC2, RTC3, CTC2 and CTC3 of the path after moving.
7) A slave axis of the synchronous control is used the same kind of acceleration/deceleration after interpolation as a master axis. However, as for the time constant, each one is used. When the master axis is a valid axis for this function, and the slave axis is an invalid axis, as for the time constant of the slave axis, the usual time constant is used.
8) A movement axis of the composite control is used the same kind of acceleration/deceleration after interpolation as a specified axis. However, as for the time constant, each one is used. When the specified axis is a valid axis for this function, and the movement axis is an invalid axis, as for the time constant of the movement axis, the usual time constant is used.
9) In the following case, a time constant for this function is valid.
   - A time constant of acceleration/deceleration after interpolation in the acceleration/deceleration before interpolation mode for the canned cycle for drilling is valid
   - A time constant of acceleration/deceleration after interpolation in the acceleration/deceleration before interpolation mode for the automatic corner speed control is valid

10) In the following case, a time constant for this function is invalid.
   - A time constant of acceleration/deceleration after interpolation for the manual handle retrace is valid
11) In the following cases, a time constant for rapid traverse for this function is invalid.
   - As for the axes (a master axis and a slave axis) in the superimposed control (with speed control)
12) In the following cases, a time constant for cutting feed for this function is invalid.
   - A time constant of acceleration/deceleration after interpolation for the skip function is valid
   - A time constant of acceleration/deceleration after interpolation for the rigid tapping is valid

Signal

Time constant of acceleration / deceleration after interpolation for rapid traverse switching signals RTC2, RTC3 <Gn599.6, Gn599.7>

[Classification] Input signal

[Function] It changes to selected the kind of a time constant of acceleration / deceleration after interpolation for rapid traverse.

[Operation] The time constant of acceleration/deceleration after interpolation for rapid traverse is switched as the following table.

Table 7.2.10 (e) Switching the time constant of acc/dec after interpolation for rapid traverse

RTC2 <Gn599.6>	RTC3 <Gn599.7>	BRT (No.25750#0)	time constant of acc/dec after interpolation for rapid traverse	time constant of acc/dec after interpolation of acc/dec before interpolation in rapid traverse

1	1	1	No.1678	No.25753

Time constant of acceleration / deceleration after interpolation for rapid traverse switching confirmation signals RTC2O, RTC3O <Fn599.6, Fn599.7>

[Classification] Output signal

[Function] These signals indicate that the change to a time constant of acceleration / deceleration after interpolation for rapid traverse for this function is valid.

[Operation] These signals are set to “1” when time constant for rapid traverse switching is valid.
These signals are set to “0” when time constant for rapid traverse switching is invalid.
RTC2O and RTC3O support as follows.
RTC2O: The second time constant for rapid traverse (Parameter Nos. 1674 and 1675)
RTC3O: The third time constant for rapid traverse (Parameter Nos. 1676 and 1677)

NOTE
When the usual time constant of acceleration / deceleration after interpolation for rapid traverse is not used even if these signals are “1”, a time constant for rapid traverse for this function is invalid.

Time constant of acceleration / deceleration after interpolation for cutting feed switching confirmation signals CTC2O, CTC3O <Fn599.4, Fn599.5>

[Classification] Output signal

[Function] These signals indicate that the change to a time constant of acceleration / deceleration after interpolation for cutting feed for this function is valid.

[Operation] These signals are set to “1” when time constant for cutting feed switching is valid.
These signals are set to “0” when time constant for cutting feed switching is invalid.
CTC2O and CTC3O support as follows.
CTC2O: The second time constant for cutting feed (Parameter No. 1678)
CTC3O: The third time constant for cutting feed (Parameter No. 1679)

NOTE
When the usual time constant of acceleration / deceleration after interpolation for cutting feed is not used even if these signals are “1”, a time constant for cutting feed for this function is invalid.

Signal address

	#7	#6	#5	#4	#3	#2	#1	#0
Gn599	RTC3	RTC2	CTC3	CTC2				
Fn599	RTC3O	RTC2O	CTC3O	CTC2O				

Parameter

The parameter used by this function is shown as follows.

1674	The second time constant T or T1 of linear acceleration / deceleration or bell-shaped acceleration / deceleration for rapid traverse for each axis

1676	The third time constant T or T1 of linear acceleration / deceleration or bell-shaped acceleration / deceleration for rapid traverse for each axis

[Input type] Parameter input
[Data type] Word axis
[Data unit] msec
[Data range] -1 to 4000

Specify the second or the third time constant of acceleration / deceleration after interpolation for rapid traverse for each axis. As for the axis for which this parameter is set values of -1 or beyond the range, the second or the third time constant for rapid traverse is invalid.

> **NOTE**
> If bit 6 (CTC) of parameter No. 11502 is 1, this parameter is written during moving axes.

1675	The second time constant T_2 of bell-shaped acceleration / deceleration for rapid traverse for each axis

1677	The third time constant T_2 of bell-shaped acceleration / deceleration in rapid traverse for each axis

[Input type] Parameter input
[Data type] Word axis
[Data unit] msec
[Data range] 0 to 512

Specify the second or the third time constant T2 used for bell-shaped of acceleration / deceleration after interpolation for rapid traverse for each axis. When these parameters are set values beyond the range, the specification of 0 is assumed.

1678	The second time constant of acceleration / deceleration for cutting feed for each axis

1679	The third time constant of acceleration / deceleration for cutting feed for each axis

[Input type] Parameter input
[Data type] Word axis
[Data unit] msec
[Data range] -1 to 4000

Specify the second or the third time constant of acceleration / deceleration after interpolation for cutting feed for each axis. As for the axis for which these parameters are set values -1 or beyond the range, the second or the third time constant for cutting feed is invalid.

	#7	#6	#5	#4	#3	#2	#1	#0
25750							BCT	BRT

[Input type] Parameter input
[Data type] Bit path

#0 BRT By time constant of acceleration/deceleration after interpolation for rapid traverse switching signals RTC2, RTC3 <Gn599.6, Gn599.7>, time constant of acceleration/deceleration after interpolation of acceleration/deceleration before interpolation in rapid traverse is:
0: not switched.
1: switched.

#1 BCT By time constant of acceleration/deceleration after interpolation for cutting feed switching signals CTC2, CTC3 <Gn599.4, Gn599.5>, time constant of acceleration/deceleration after cutting feed interpolation in the acceleration/deceleration before interpolation mode is:
0: not switched.
1: switched.

25751	the second time constant of acceleration/deceleration after interpolation of acceleration/deceleration before interpolation in rapid traverse for each axis
25752	the third time constant of acceleration/deceleration after interpolation of acceleration/deceleration before interpolation in rapid traverse for each axis

[Input type] Parameter input
[Data type] Word axis
[Data unit] msec
[Data range] -1 to 4000

Set the second or third time constant of acceleration/deceleration after interpolation of acceleration/deceleration before interpolation in rapid traverse for each axis.
When the parameter is set to -1, the second or third time constant of acceleration/deceleration after interpolation of acceleration/deceleration before interpolation in rapid traverse is disabled.

25753	the second time constant of acceleration/deceleration after cutting feed interpolation in the acceleration/deceleration before interpolation mode for each axis
25754	the third time constant of acceleration/deceleration after cutting feed interpolation in the acceleration/deceleration before interpolation mode for each axis

[Input type] Parameter input
[Data type] Word axis
[Data unit] msec
[Data range] -1 to 4000

Set the second or third time constant of acceleration/deceleration after cutting feed interpolation in the acceleration/deceleration before interpolation mode for each axis.
When the parameter is set to -1, the second or third time constant of acceleration/deceleration after cutting feed interpolation in the acceleration/deceleration before interpolation mode is disabled.

7.2.11 Servo loop gain / in-position width switching function by signal

Overview

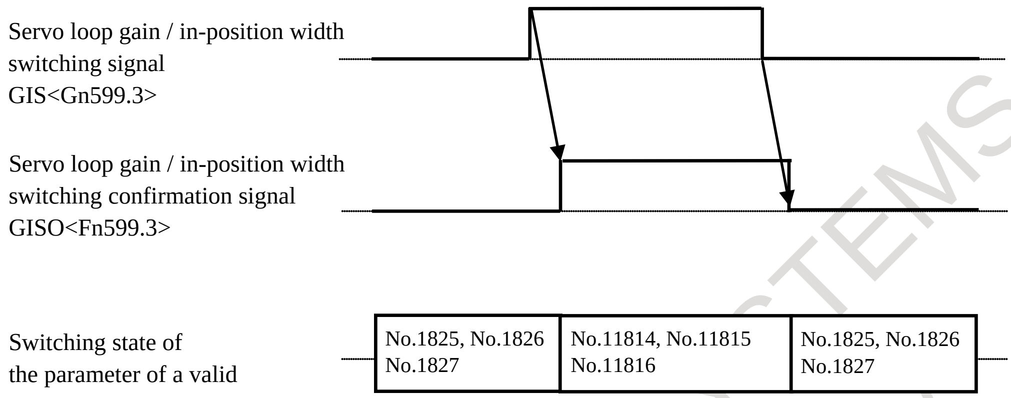
Servo loop gain / in-position width can be switched by input signal of PMC.

Explanation

In this function, servo loop gain and in-position width can be switched to either of the two following kinds by servo loop gain/in-position width switching signal GIS <Gn599.3>.

- The usual servo loop gain (Parameter No. 1825), the usual in-position width (Parameter Nos. 1826 and 1827)
- The second servo loop gain (Parameter No. 11814), the second in-position width (Parameter Nos. 11815 and 11816)

Example of time chart for servo loop gain / in-position width switching



Confirm an effective parameter by servo loop gain / in-position width switching confirmation signal GISO.

Note

1) If -1 is set to parameters No. 11814 or a value not within the valid data range is specified in this parameter, the switching of servo loop gain is invalid in its axis.
2) If -1 is set to parameters No. 11815 or a value not within the valid data range is specified in this parameter, the switching of in-position width is invalid in its axis.
3) If -1 is set to parameters No. 11816 or a value not within the valid data range is specified in this parameter, the switching of in-position width for cutting is invalid in its axis.
4) To switch servo loop gain and in-position width, all the valid axes should stop. When the axis has not stopped, servo loop gain and in-position width are switched after stopping all the valid axes.
5) The following tables show using with other functions.

Table 7.2.11 (a) Using with other functions

Function name	Description
Spindle speed function	Because servo loop gain is not used as for spindle motor, this function becomes invalid.
Positioning by optimum accelerations	When this function is valid, positioning by optimum accelerations is invalid. When this function is switched when positioning by optimum accelerations is valid, this function is valid after stopping all the valid axes.
Cs contour control	In Cs contour control, this function is invalid.
Setting axes for interpolation with a Cs contour control axis	When this function is valid, setting axes for interpolation with a Cs contour control axis is invalid. When this function is switched when servo loop gain is switched by setting axes for interpolation with a Cs contour control axis, servo loop gain of this function is valid after stopping all the valid axes.
Spindle positioning	In spindle positioning, this function is invalid.
Rigid tapping	In the spindle of rigid tapping, this function is invalid. In the drilling axis of rigid tapping, this function is invalid.
Index table indexing	As for the control axis set to parameter No.5510 as index table indexing, this function is invalid.
Electronic gear box (EGB)	In electronic gear box, this function is invalid.

The use example is shown as follows. Only servo loop gain is described in the use example, and when servo loop gain of this function is valid, in-position width of this function is valid, too.

- Positioning by optimum accelerations

In X axis, Y axis, and Z axis, positioning by optimum accelerations is valid axes.

Program	Description
O0001 ;	Optimum accelerations is valid
G00X50.0 ;	
Y50.0 ;	
Z50.0 ;	
Mxx ;	Servo loop gain / in-position width switching signal GIS<Gn599.3>="1"
X100.0 ;	This function is valid, Optimum accelerations is invalid
Y100.0 ;	
Z100.0 ;	
Myy ;	Servo loop gain / in-position width switching signal GIS<Gn599.3>="0"
X150.0 ;	Optimum accelerations is valid
Y150.0 ;	
Z150.0 ;	
M30 ;	

- Cs contour control axis, setting axes for interpolation with a Cs contour control axis

C axis is Cs contour control axis、A axis is setting axes for interpolation with a Cs contour control axis (C axis).

Program	Description
O0002 ;	Usual servo loop gain is valid in A axis
G00A50.0 ;	
A100.0 ;	
Maa ;	Cs contour control mode of C axis turns on
A50.0 C50.0 ;	Setting axes for interpolation with a Cs contour control axis is valid in A axis
A0.0 C100.0 ;	
Mxx ;	Servo loop gain / in-position width switching signal GIS<Gn599.3>="1"
A50.0 ;	In A axis, this function is valid, setting axes for interpolation with a Cs contour control axis is invalid
C50.0 ;	
Myy ;	Servo loop gain / in-position width switching signal GIS<Gn599.3>="0"
A100.0 C0.0 ;	Setting axes for interpolation with a Cs contour control axis is valid in A axis
A50.0 C50.0 ;	
Mbb ;	Cs contour control mode of C axis turns off
A0.0 ;	Usual servo loop gain is valid in A axis
M30 ;	

* As for C axis, this function always is invalid because of the spindle motor.

6) It is not changed to the servo loop gain of this function when there is a control axis by which this function is invalid by the other functions, and there is a possibility not to be able to interpolate correctly.

Signal

Servo loop gain / in-position width switching signal GIS<Gn599.3>

[Classification] Input signal

[Function] It switches servo loop gain and in-position width.

[Operation] - When GIS is "0", it switches to the usual servo loop gain (Parameter No.1825), the usual in-position width (Parameter Nos.1826 and 1827).

- When GIS is "1", it switches to the second servo loop gain (Parameter No.11814), the second in-position width (Parameter Nos.11815 and 11816).

Servo loop gain / in-position width switching confirmation signal GISO<Fn599.3>

[Classification] Output signal

[Function] This signal indicates that the change to servo loop gain / in-position width for this function is valid.

[Output condition] This signal is set to “1” when servo loop gain / in-position width switching function by signal is valid. This signal is set to “0” when servo loop gain / in-position width switching function by signal is invalid.

> **NOTE**
> When the usual servo loop gain / in-position width is not used even if this signal is “1”, servo loop gain / in-position width for this function is invalid.

Signal address

	#7	#6	#5	#4	#3	#2	#1	#0
Gn599					GIS			

	#7	#6	#5	#4	#3	#2	#1	#0
Fn599					GISO			

Parameter

The parameter used by this function is shown as follows.

11814	The second servo loop gain for each axis

[Input type] Parameter input
[Data type] Word axis
[Data unit] 0.01/sec
[Data range] -1, 1 to 9999

Specify the second servo loop gain for each axis.
As for the axis for which this parameter is set values of -1 or beyond the range, the second servo loop gain is invalid.

11815	The second in-position width for each axis

[Input type] Parameter input
[Data type] 2-word axis
[Data unit] Detection unit
[Data range] -1 to 99999999

Specify the second in-position width for each axis.
As for the axis for which this parameter is set values of -1 or beyond the range, the second in-position width is invalid.

11816	The second in-position width in cutting for each axis

[Input type] Parameter input
[Data type] 2-word axis
[Data unit] Detection unit
[Data range] -1 to 99999999

Specify the second in-position width in cutting for each axis.
As for the axis for which this parameter is set values of -1 or beyond the range, the second in-position width in cutting is invalid.

7.2.12 IN-ACCELERATION/DECELERATION SIGNAL

M

Overview

During deceleration in a block for cutting feed, the in-acceleration/deceleration signal ACDEC<Fn520.3> is output to the machine.

Explanation

If deceleration is performed in a block for cutting feed (G01, G02, G03), the in-acceleration/deceleration signal ACDEC<Fn520.3> is output to the machine during deceleration. For the time set in parameter No. 1650 after the execution of the next block (or the remaining movement of the current block) is started upon completion of deceleration, the ACDEC signal continues to be output. The ACDEC signal is turned off when the set time has elapsed.
In this case, deceleration means any of the cases indicated below.
That is, during execution of a block for cutting feed (G01, G02, G03), deceleration is specified to decrease the speed to 0 by any of the following:

(1) Interlock
(2) Override 0%
(3) Single-block stop
(4) Automatic operation stop by feed hold
(5) Exact stop check
(6) The next block neither specifies cutting feed nor movement.

During deceleration in such a case, the ACDEC is output.

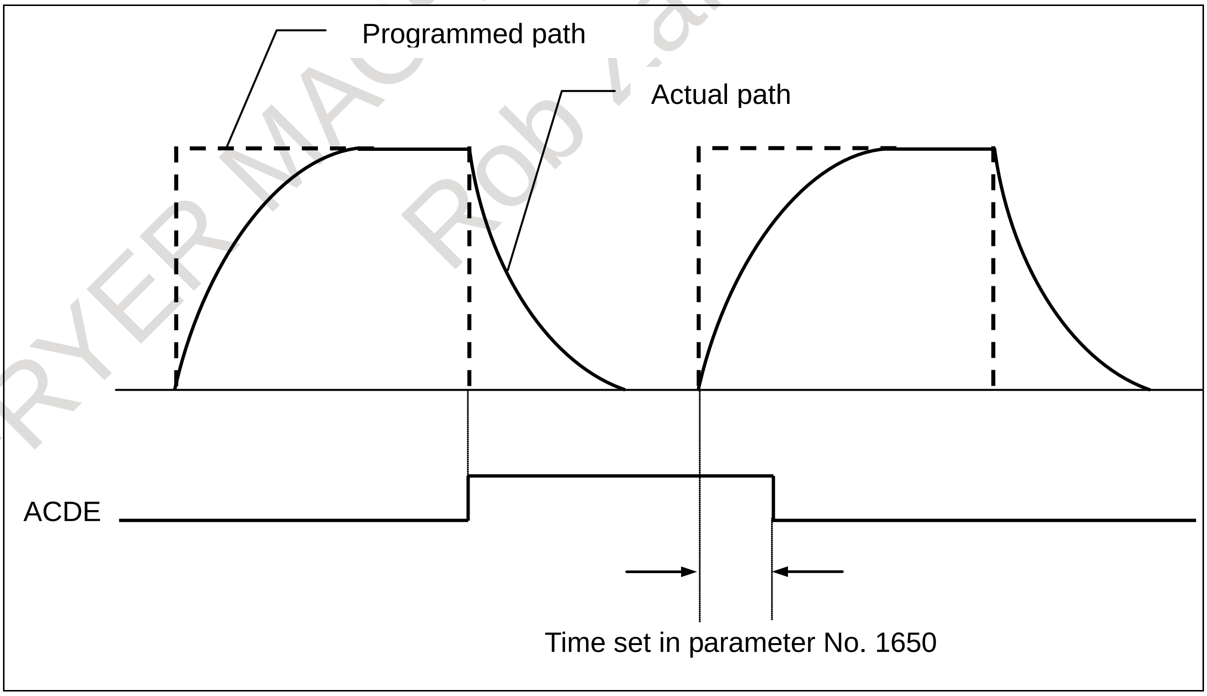


Fig.7.2.12 (a) In-acceleration/deceleration signal

For example, if interlock is applied during cutting feed, the ACDEC signal is output. The ACDEC signal is turned off when the time set in parameter No. 1650 has elapsed after interlock is canceled. If the block after the output of the ACDEC signal is a block not specifying cutting feed, such as a block specifying positioning (G00) or specifying an M function alone, the ACDEC signal continues to be output. In this case, the ACDEC signal is turned off when the time set in parameter No. 1650 has elapsed after execution of the next block for cutting feed is started.

NOTE
The ACDEC signal is turned off by a reset.

Signal

In-acceleration/deceleration signal ACDEC<Fn520.3>

[Classification] Output signal
[Function] Posted to the PMC during deceleration in a block for cutting feed (G01, G02, G03).
[Operation] If deceleration is performed in a block for cutting feed (G01, G02, G03), this signal is set to 1 during deceleration. This signal continues to be set to 1 for the time set in parameter No. 1650 after execution of the next block is started upon completion of deceleration. This signal is set to 0 when the time set in parameter No. 1650 has elapsed.
This signal is also set to 0 by a reset.

Signal address

	#7	#6	#5	#4	#3	#2	#1	#0
Fn520					ACDEC			

Parameter

1650	Timer for the acceleration/deceleration signal

[Input type] Parameter input
[Data type] Word path
[Unit of data] msec
[Valid data range] 0 to 32767
Set the output duration of the acceleration/deceleration signal.

Note

NOTE
This function is disabled for look-ahead acceleration/deceleration before interpolation.

7.3 JERK CONTROL

M

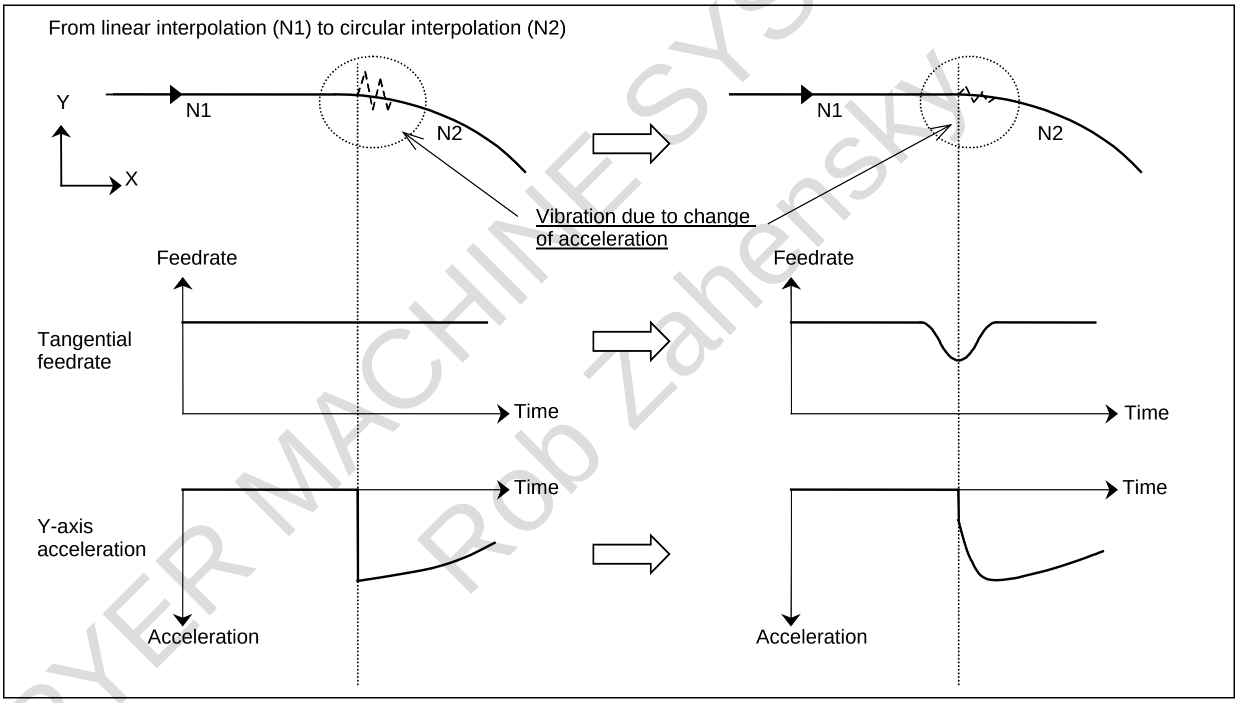
7.3.1 Speed Control with Change of Acceleration on Each Axis

Overview

In portions in which acceleration changes largely, such as a portion where a programmed figure changes from a straight line to curve, vibration or shock on the machine may occur. Speed control with change of acceleration on each axis is a function to suppress machining errors due to vibration and machine shock generated by change of acceleration. This function obtains a feedrate so that change of acceleration is within the parameter-set permissible acceleration change amount for each axis, and performs deceleration by using look-ahead acceleration/deceleration before interpolation.

Explanation

In the following example, the Y-axis acceleration changes largely at the contact point between a linear interpolation and circular interpolation, so deceleration is performed.



- Setting the permissible acceleration change amount

The permissible acceleration change amount for each axis is set in parameter No. 1788. When 0 is set in this parameter for a certain axis, speed control with change of acceleration is not performed for that axis.

- Parameter setting example

Suppose a figure shown Fig. 7.3.5 in which a straight line is followed by an arc. Let the specified feedrate and the arc radius be 6000 mm/min and 10 mm, respectively. Then, the Y-axis acceleration change amount at the contact point of the linear and arc portions is obtained as follows:

$$\frac{v^2}{r} = 1000mm/s^2$$

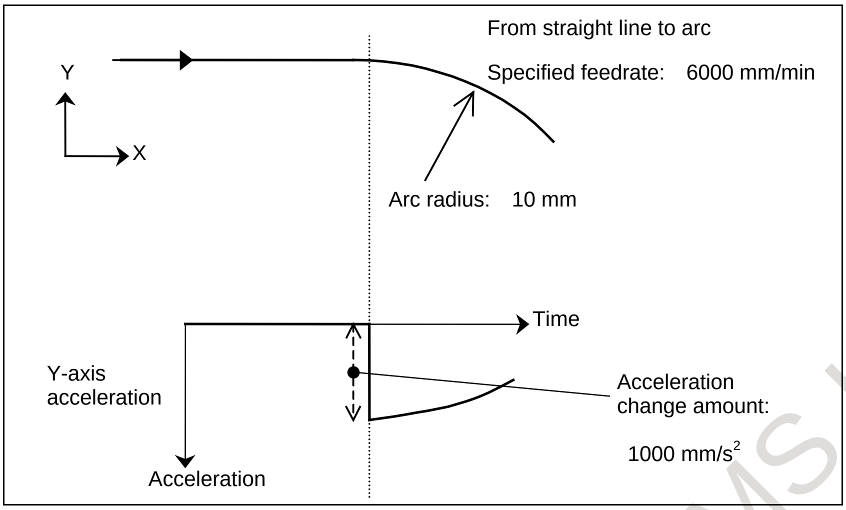


Fig. 7.3.1

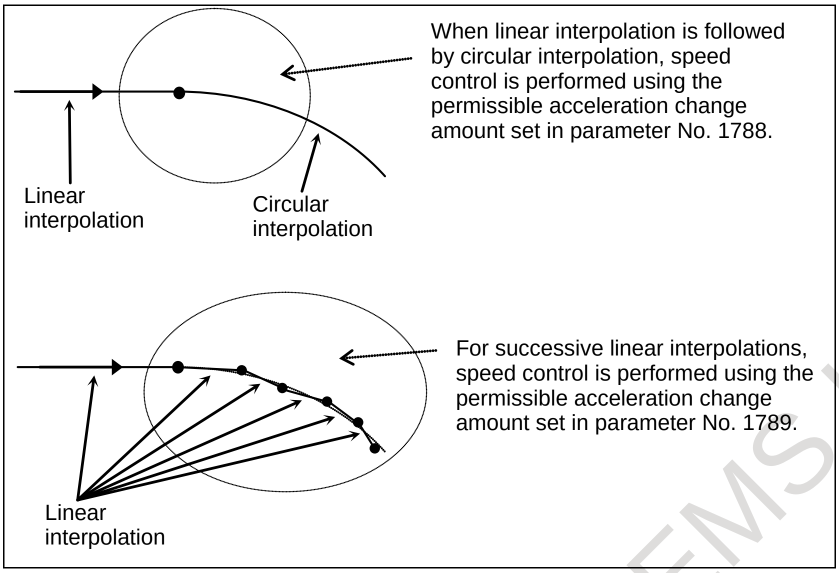
To suppress the change of acceleration to 300 mm/sec^2, set 300 mm/sec^2 for the Y-axis in parameter No. 1788.
Note that the change of acceleration is determined from the interpolation data of the CNC, so it may differ from the theoretical value.
The actual machine is affected by acceleration/deceleration and other factors, so the value to be set in the parameter should be determined after adjustments are made.

- For successive linear interpolations

When there are successive linear interpolations, speed control with change of acceleration obtains the deceleration feedrate from the change in acceleration between the start point and end point of a specified block.
When a curve is specified using successive minute straight lines, programmed values are rounded to the least input increment before issued, so the machining profile is approximated with a broken line. The error due to rounding may increase change of acceleration, and especially when the line segments specified by blocks are short, deceleration is performed frequently. As a result, the machining speed cannot increase enough. In such a case, a relatively large value should be set in parameter No. 1789 as the permissible acceleration change amount for each axis in successive linear interpolations to improve the machining speed.
When a value other than 0 is set in parameter No. 1789 for an axis for which deceleration with change of acceleration is enabled, this setting is regarded as the permissible acceleration change amount at corners in which linear interpolations meet. (For portions where a linear interpolation and circular interpolation meet and where circular interpolations meet, the setting in parameter No. 1788 is used.)
When 0 is set in parameter No. 1789 for an axis, the setting in parameter No. 1788 specifying the ordinary permissible acceleration change amount is used even at a corner in which linear interpolations meet.
When smooth speed control is used in speed control with permissible acceleration in AI contour control II, the deceleration feedrate is obtained from the change of acceleration calculated by smooth speed control.
Therefore, the deceleration feedrate may be higher than the ordinary deceleration feedrate.



Parameter

1788	Maximum allowable acceleration change rate in feedrate determination based on acceleration change for each axis

[Input type] Parameter input
[Data type] Real axis
[Unit of data] mm/sec^2, inch/sec^2, deg/sec^2 (machine unit)
[Min. unit of data] Depend on the increment system of the applied axis
[Valid data range] Refer to the standard parameter setting table (D)
(When the machine system is metric system, 0.0 to +100000.0. When the machine system is inch system, machine, 0.0 to +10000.0.)
Set a maximum allowable acceleration change rate for each axis in feedrate control based on acceleration change under control on the rate of change of acceleration.
For an axis with 0 set in this parameter, feedrate control based on acceleration change is disabled.
If 0 is set for all axes, feedrate control based on acceleration change is not exercised.

1789	Maximum allowable acceleration change rate in feedrate determination based on acceleration change for each axis (linear interpolation)

[Input type] Parameter input
[Data type] Real axis
[Unit of data] mm/sec^2, inch/sec^2, deg/sec^2 (machine unit)
[Min. unit of data] Depend on the increment system of the applied axis
[Valid data range] Refer to the standard parameter setting table (D)
(When the machine system is metric system, 0.0 to +100000.0. When the machine system is inch system, machine, 0.0 to +10000.0.)
Set a maximum allowable acceleration change rate for each axis in feedrate control based on acceleration change under control on the rate of change of acceleration in successive linear interpolation operations.
In feedrate control based on acceleration change at a corner between linear interpolation operations, the maximum allowable acceleration change rate not set in parameter No. 1788 but set in this parameter is valid.
For an axis with 0 set in this parameter, the maximum allowable acceleration change rate set in parameter No. 1788 is valid.
Feedrate control based on acceleration change is disabled for an axis with 0 set in parameter No. 1788, so that the setting of this parameter for such an axis is ignored.

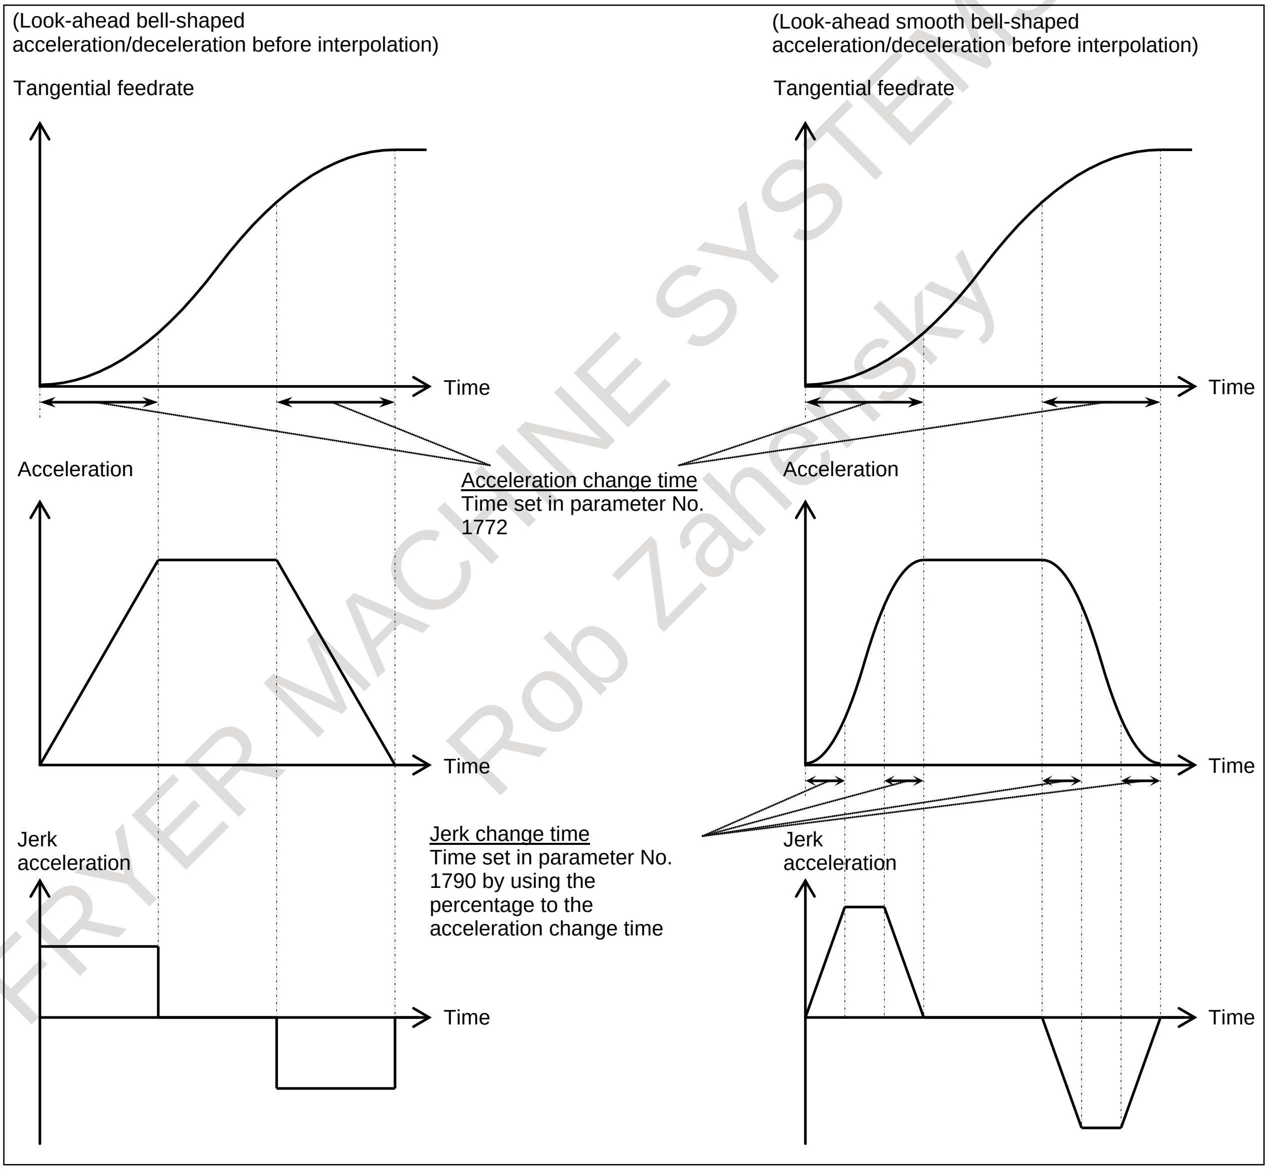
7.3.2 Look-Ahead Smooth Bell-Shaped Acceleration/Deceleration before Interpolation

Overview

In look-ahead bell-shaped acceleration/deceleration before interpolation performs smooth acceleration/deceleration by changing the acceleration at a constant rate in specified acceleration change time.

In look-ahead smooth bell-shaped acceleration/deceleration before interpolation, the jerk change time is specified in parameter No. 1790 by using the percentage to the acceleration change time for look-ahead bell-shaped acceleration/deceleration before interpolation, and change of acceleration is also controlled so that the change is bell-shaped.

This enables smoother acceleration/deceleration, therefore it reduces machine vibration and shock due to acceleration/deceleration.



Explanation

- Setting the jerk change time

The jerk change time is set in parameter No. 1790 by using the percentage to the acceleration change time.
The actual jerk change time is represented by the percentage to the acceleration change time set in parameter No. 1772.
The jerk change time must be within a half of the acceleration change time, so the value to be set in the parameter ranges 0 to 50 (percent).
If 0 or a value beyond the specifiable range is specified in parameter No. 1790, look-ahead smooth bell-shaped acceleration/deceleration before interpolation is not available.

- Acceleration/deceleration before interpolation for linear type rapid traverse

When look-ahead bell-shaped acceleration/deceleration is used in look-ahead acceleration/
deceleration before interpolation for linear type rapid traverse, enabling look-ahead smooth bell-shaped acceleration/deceleration before interpolation applies smooth bell-shaped acceleration/deceleration to acceleration/deceleration before interpolation for linear type rapid traverse.
In this case, the jerk change time is represented by the percentage set in parameter No. 1790 to the acceleration change time set in parameter No. 1672.

- Optimum torque acceleration/deceleration

When bell-shaped acceleration/deceleration is used in optimum torque acceleration/deceleration, enabling look-ahead smooth bell-shaped acceleration/deceleration before interpolation applies smooth bell-shaped acceleration/deceleration to optimum torque acceleration/
deceleration.
In this case, the jerk change time is represented by the percentage set in parameter No. 1790 to the acceleration change time set in parameter No. 1672.

Parameter

1790	Ratio of change time of the rate of change of acceleration in smooth bell-shaped acceleration/deceleration before interpolation

[Input type] Parameter input
[Data type] Byte path
[Unit of data] %
[Valid data range] 0 to 50

Set the ratio of the change time of the rate of change of acceleration to the change time of acceleration(*1) by percentage (%) in smooth bell-shaped acceleration/deceleration before look-ahead interpolation.
If 0 is set in this parameter or a value not within the valid data range is specified in this parameter, look-ahead smooth bell-shaped acceleration/ deceleration before interpolation is not performed.

(*1) Parameter No. 1772 for look-ahead acceleration/deceleration before interpolation (cutting feed).
Parameter No. 1672 for look-ahead acceleration/deceleration before interpolation in linear rapid traverse, or for optimum torque acceleration/ deceleration.

8 MULTI-PATH CONTROL

8.1 MULTI-PATH CONTROL

Overview

The multipath control function is designed to control the independent simultaneous machining with up to 2 paths, and the peripheral device such as a loader for performing a non-machining operation. (machining path up to 2, loader path up to 2, up to 4 paths in total). This function is applicable to lathes and automatic lathes which perform cutting simultaneously with multiple tool posts, combined machine tools which perform turning and milling simultaneously with multiple paths, and machines which require additional control paths such as a loader control path.

For multipath simultaneous machining, each machining program is stored in a directory in program memory for each path. When automatic operation is to be performed, each path is activated after selecting a program for machining with path 1 and programs for machining with paths 2 from the programs stored in the respective directories in program memory. Then the programs selected for the tool posts are executed independently at the same time. When tool post 1 and tool post 2 need to wait for each other during machining, the waiting function is available.

Other available functions specific to multipath control include interference check for each path, balance cut, synchronization control, composite control, path spindle control, and memory common to paths.

Just one LCD/MDI is provided for the all paths. Before operation and display on the LCD/MDI, the path selection signal is used to switch between the paths.

- For a system with two paths

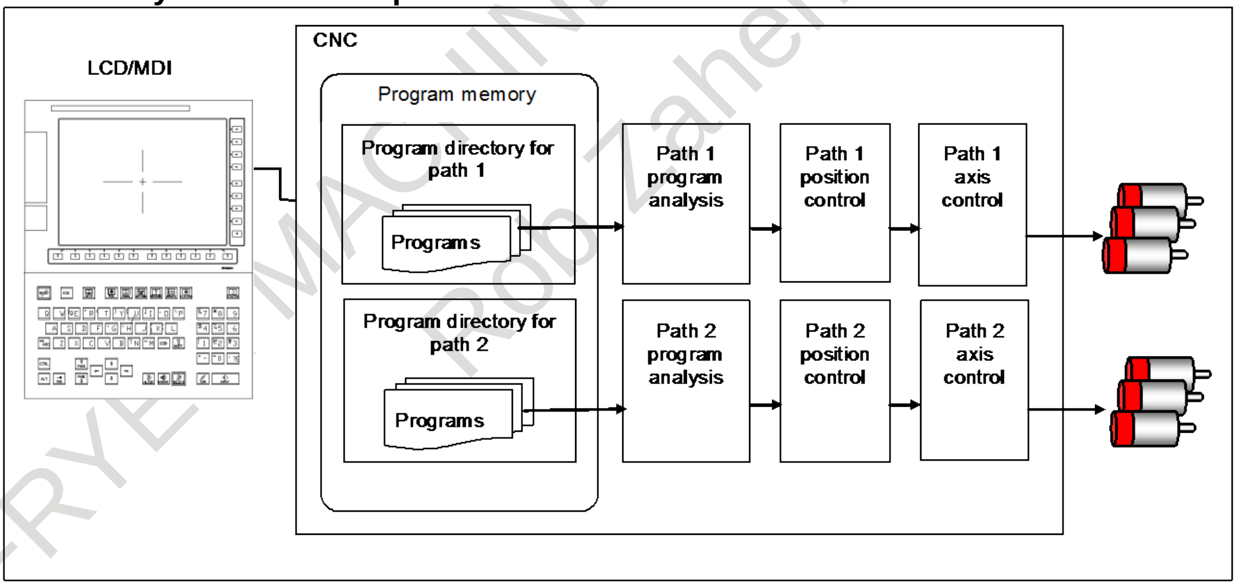


Fig.8.1 (a)

Explanation

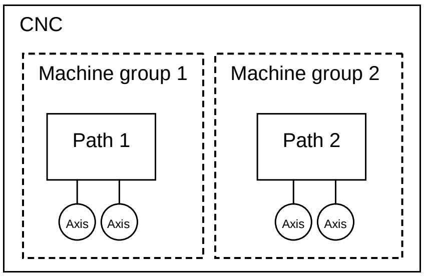
- System configuration

In multi-path control, multiple paths are combined into a single machine group, and such multiple machine groups, in turn, make up a single system.

Each of the elements making up multi-path control is explained below.

Example)

Configuration of multi-path control



- Machine group

If you have multiple paths, you can combine some of them into a group, so that, for example, you can share data in that group and if an alarm is generated in a certain path, you can stop other paths in that group. A group that is made up of such paths is called a machine group.
Up to three groups are available, depending on the type of the CNC system.
The main items that depend on the machine group are shown below.

- Emergent stop signal *ESP <X0008.4,X0008.0,X0008.1>
- MDI reset key
- Operation during the occurrence of an alarm

- Path

A path refers to a group of axes controlled by the same CNC program command.
Up to 2 paths are available for machining, and up to 2 paths are available for loader control. Up to 4 paths in total are available.
You can specify which machine group a certain path is to belong to, using parameter No. 0980 for that path. In addition.

NOTE
The number of the machine group to which each path can belong differs depending on the machine used. For details, refer to the manual issued by the machine tool builder.

- Controlled axes

The number of control axes witch used throughout the entire system is specified with parameter No.0987.
You can specify which path each controlled axis is to be assigned, using parameter No. 0981.
You can assign each path to any controlled axis, provided that you follow the maximum allowable number of controlled axes.

Example)
For a system with 2 paths and a total of 6 controlled axes:
Settings that cause the system to become a 2-path system with the first path consisting of 3 controlled axes and the second consisting of 3 controlled axes

Parameter No. 0981	Setting value	Application
Logical, axis 1	1	Path 1, axis 1
Logical, axis 2	1	Path 1, axis 2
Logical, axis 3	1	Path 1, axis 3
Logical, axis 4	2	Path 2, axis 1
Logical, axis 5	2	Path 2, axis 2
Logical, axis 6	2	Path 2, axis 3

> **NOTE**
> 1 If the setting of parameter No. 0981 is 0, that controlled axis will belong to the first path.
> 2 Any path having no controlled axis cannot be set.

- Spindle

The number of spindle which used throughout the entire system is specified with parameter No.0988.
You can specify which path each spindle is to be assigned, using parameter No. 0982.
You can assign each path to any controlled axis, provided that you follow the maximum allowable number of spindles.
Example)

For a system with 2 paths and a total of 6 spindles:
Settings that cause the system to become a 2-path system with the first path consisting of 3 spindles and the second consisting of 3 spindles

Parameter No. 0982	Setting value	Application
Logical, spindle 1	1	Path 1, spindle 1
Logical, spindle 2	1	Path 1, spindle 2
Logical, spindle 3	1	Path 1, spindle 3
Logical, spindle 4	2	Path 2, spindle 1
Logical, spindle 5	2	Path 2, spindle 2
Logical, spindle 6	2	Path 2, spindle 3

> **NOTE**
> If the setting of parameter No. 0982 is 0, that spindle will belong to the first path.

Example

- Example of a system configuration (2 path and loader path)

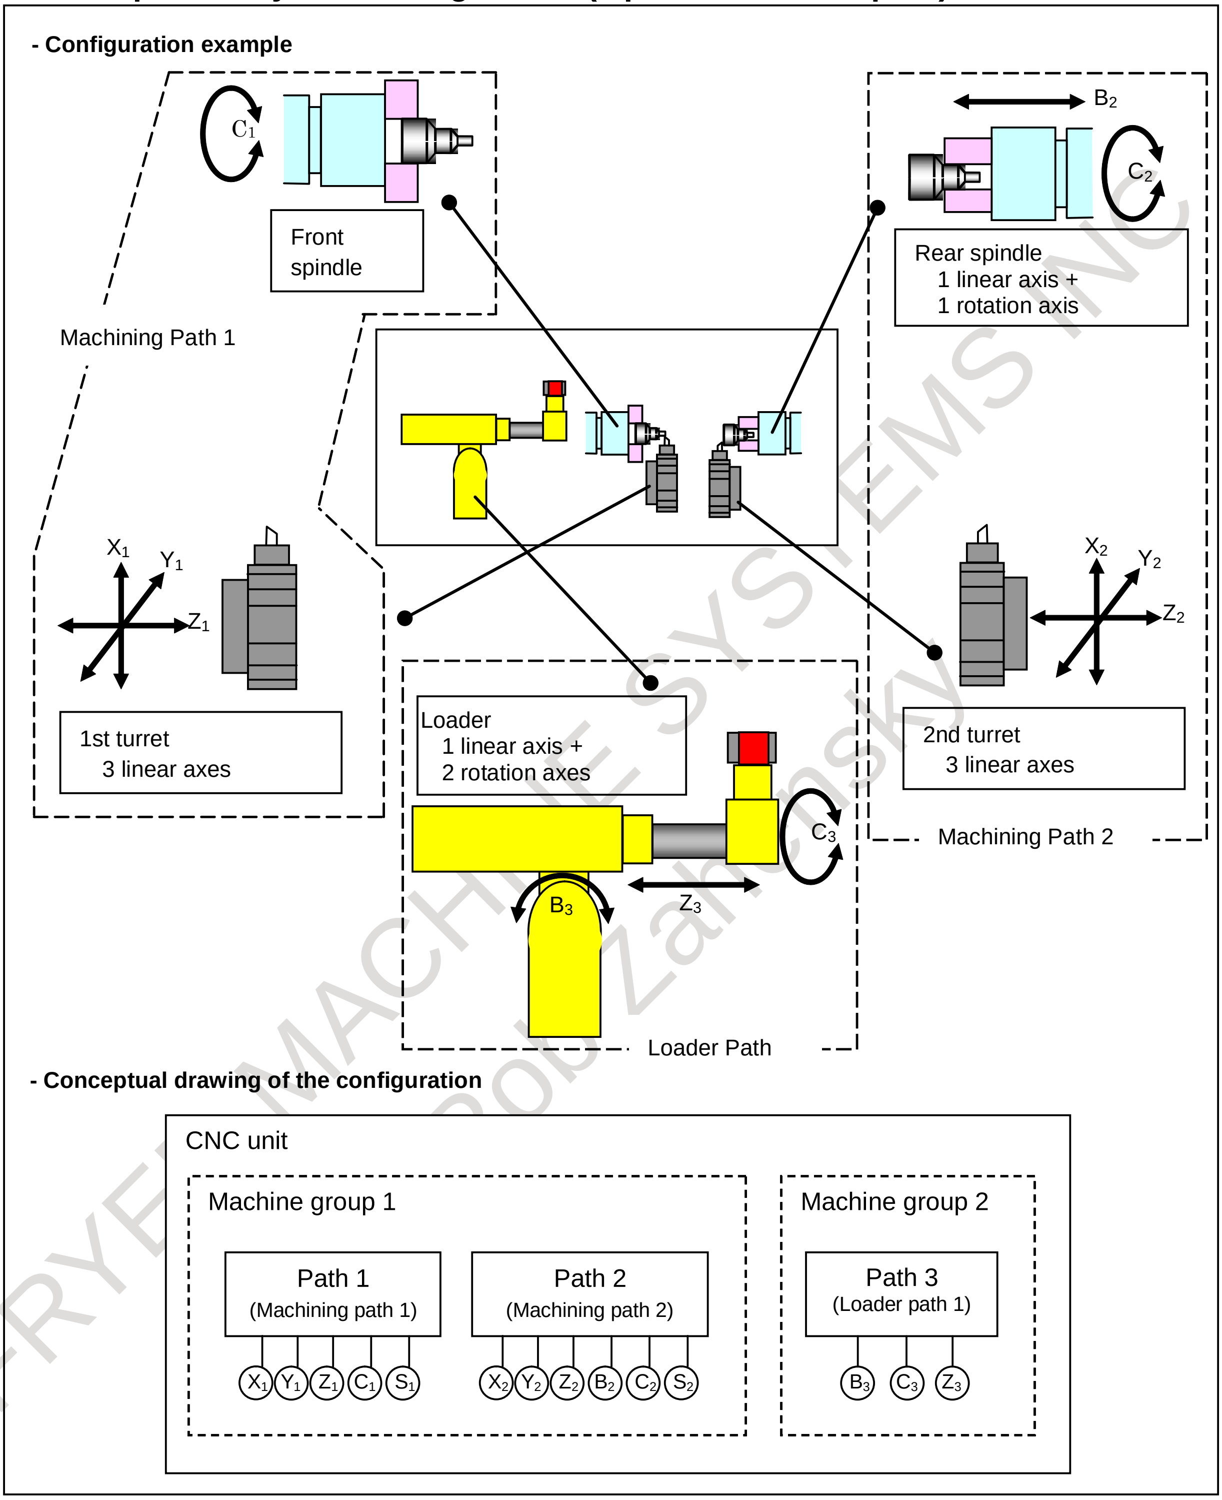


Fig. 8.1 (b)

In the system configuration example shown in the example, Fig. 8.1 (a), paths 1 and 2 are of lathe systems, path 3 is of a machining center system, and path 4 is the loader control path in a lathe system. The machine control type is com y ined system. The parameter settings that accomplish that system configuration are as follows.

Machine Group to Which Each Path Is to Belong (Parameter No. 0980)

	Setting value
Path 1	1
Path 2	1
Path 3 (Loader control)	2

Number of the Path to Which Each Axis Is to Belong (Parameter No. 0981)

	Setting value
Logical, axis 1 (X_1)	1
Logical, axis 2 (Y_1)	1
Logical, axis 3 (Z_1)	1
Logical, axis 4 (C_1)	1
Logical, axis 5 (X_2)	2
Logical, axis 6 (Y_2)	2
Logical, axis 7 (Z_2)	2
Logical, axis 8 (B_2)	2
Logical, axis 9 (C_2)	2
Logical, axis 10 (X_3)	3
Logical, axis 11 (Y_3)	3
Logical, axis 12 (Z_3)	3

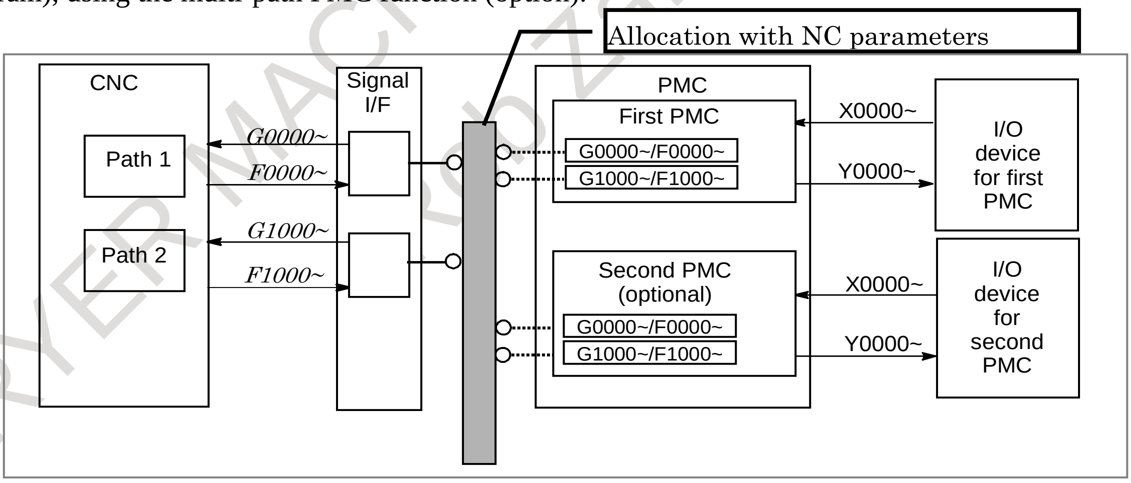
Number of the Path to Which Each Spindle Is to Belong (Parameter No. 0982)

	Setting value
Logical, spindle 1 (S_1)	1
Logical, spindle 2 (S_2)	2

- DI/DO

In a multi-path system, the interface signal address relations between the CNC and the PMCs are as shown in the figure.

You can control all paths with a single PMC (Ladder program), or control each path with a PMC (Ladder program), using the multi-path PMC function (option).



NOTE
1. In a multi-path PCM system, each PMC has an independent signal area. The F, G, X, and Y signal addresses of each PMC are allocated, starting with address 0. In contrast, the F and G signal addresses as seen from the CNC are fixed addresses in the same order as that of the path numbers. The F and G signal addresses programmed by each Ladder program differ from the F and G signal addresses as seen from the CNC.
2. The signal addresses relations between the CNC and the PMCs of each path can be set with CNC parameters Nos. 11920 to 11929. For details of how to do this, refer to Chapter 1 of the PMC Programming Manual.

Specific Setting Example for the Previous Example

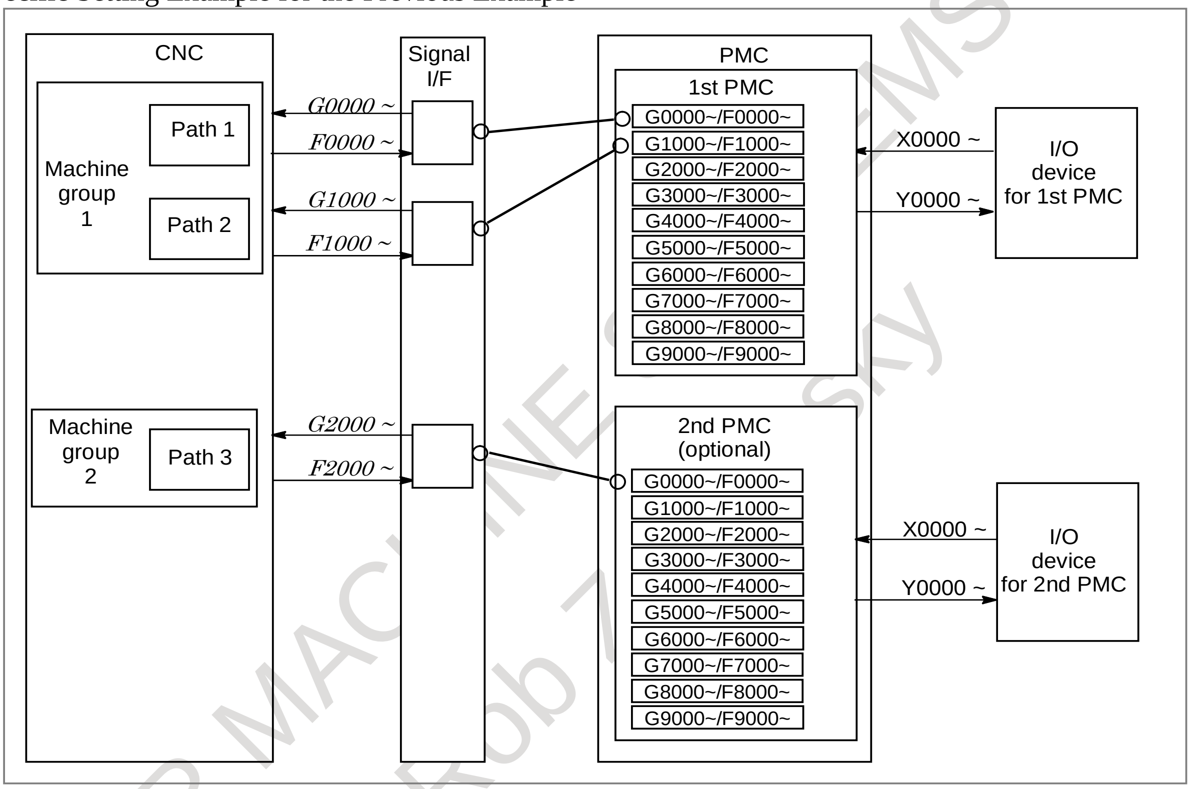


Fig. 8.1 (c)

NOTE
As with the loader control function of the Series 16*i*/18*i*/21*i*, if the PMC (Ladder program) specifically for loaders is used, assign a single PMC path as the loader path, using the multi-path PMC function as in the Fig. 8.1 (c).

Setting Examples for the Interface Between the NC and the PMCs

Parameter No.	Setting value	Application
11920	100	F0000 to F0767/G0000 to G0767 of the 1st PMC
11921	101	F1000 to F1767/G1000 to G1767 of the 1st PMC
11922	102	F2000 to F2767/G2000 to G2767 of the 1st PMC
11923	200	F0000 to F0767/G0000 to G0767 of the 2nd PMC
11924	0	
11925	0	
11926	0	
11927	0	
11928	0	

Parameter No.	Setting value	Application
11929	0	

In general, the address for each path as seen from the NC section is assigned as in the table below.

Signal Address for Each Path

Signal address	Description
G0000 to G0767	Signal for path 1 (PMC→CNC)
F0000 to F0767	Signal for path 1 (CNC→PMC)
G1000 to G1767	Signal for path 2 (PMC→CNC)
F1000 to F1767	Signal for path 2 (CNC→PMC)

The following signals follow separate settings from the above:
- Signals common to paths. (There are those arranged on path 1.)
- Signals for each controlled axis and for each spindle
- Signals for each group in PMC axis control

- Signals common to paths

These signals are common to paths.

Path select

Path select signal HEAD<G0063.0>

Auto screen clear function

Auto screen clear invalidation signal *CRTOF<G0062.1>

Screen hard copy function

Hard copy cancellation request signal HCABT<G0067.6>
Hard copy cancellation request acceptance signal HCAB2<F0061.2>
Hard copy execution request signal HCREQ<G0067.7>
Hard copy under execution signal HCEXE<F0061.3>

External key input function

External key input mode select signal ENBKY<G0066.1>
Key code read signal EKSET<G0066.7>
Key code signal EKC0 to EKC7<G0098.0to G0098.7>
Program screen display in progress signal PRGDPL<F0053.1>
Key code read completion signal EKENB<F0053.7>
Key input nullification signal INHKY<F0053.0>

NOTE
The signal area is common to paths. Key input is made on the currently selected screen.

Memory protection function

Memory protection signal KEY1 to KEY4<G0046.3 to G0046.6>
Memory protect signal KEYO<F0075.6>

8.1.1 CNC Data Display, Setup, and Input/Output

There are offsets and custom macro variables for each path. For the path selected from the display unit, you can perform data display, setup, and input/output using a medium such as a memory card.
As for custom macro variables, you can change some or all of common variables into those for common use by paths, through appropriate parameter settings.
As for offsets, you can change them into those for common use by paths, through appropriate parameter settings.
As for input/output, you can rename the files to be input and output for each path, through appropriate parameter settings.

8.1.2 Multi-path Functions

The functions specific to multi-path control are as listed below.

Waiting M codes
Path interference check
Balance cutting
Synchronous/Composite control
Superimposed control
Path spindle control
Memory common to paths
Path single block check function
Path selection/arbitrary path name display

NOTE
The functions waiting M code, memory common to paths, and path selection/arbitrary path name display are valid for all machine groups. For example, waiting can be performed across machine groups 1 and 2. The other functions are valid only within the same machine group. For example, synchronous control cannot be performed across machine groups 1 and 2.

The following provides an outline of each of the functions.

- Waiting M codes

You use an M code if you want to achieve synchronization in the middle of the machining program for a path.
By specifying a waiting M code in the machining program for each of multiple paths, you can synchronize these paths. If, during automatic operation, a waiting M code is specified for one path, the program waits for the same M code to be specified for another path, then starts executing the next block.
You must specify the range of M codes that can be used as waiting M codes in advance, using an appropriate parameter.
For details, see Section, "WAITING M CODES".

T

- Path interference check

If you machine a single workpiece on two tool posts at the same time, the portions of these tool posts may come close to each other exceedingly. If these two tool posts come into contact due to a program error or other setting error, this will cause grave consequences such as the damage of the tool or the damage of the machine itself.
The "Interference check for each path" refers to the function whereby if a command that will cause two tool posts to interfere with each other as described above is specified, these two tool posts are both decelerated to a stop before they actually come into contact.
For details, see Section, "INTERFERENCE CHECK FOR EACH PATH".

T

- **Balance cutting**

If turning a thin workpiece, you can machine it from both of its sides at the same time by using a cutting tool, thereby preventing the workpiece from deflection, which can occur if it is machined from a single side only, and achieving higher precision. Unless the movements of the two tools are synchronized with each other well, the workpiece will vibrate, making correct machining impossible. By using this function, you can easily synchronize the movements of the tool posts and execute machining.
For details, see Section, "BALANCE CUTTING" in this chapter.

- **Synchronous/Composite control**

Usually, in 2-path control, the tool moves along the axes (X1, Z1, and C1) belonging to tool post 1 in accordance with the move commands for tool post 1 and along the axes (X2, Z2, and C2) belonging to tool post 2 in accordance with the move commands for tool post 2 (independent control for each tool post). The synchronous/composite control function allows you to move the tool along any of the axes of one tool post in synchronization with any of the axes of the other tool post (synchronous control). The function also allows you to replace the move command for any of the axes of one tool post and that for anys of the axes of the other tool post with other to move the tool along these axes with these commands (composite control).
For details, see Section, "SYNCHRONOUS/COMPOSITE CONTROL" in this chapter.

- **Superimposed control**

Usually, in 2-path control, the tool moves along the axes (X1, Z1, and C1) belonging to tool post 1 in accordance with the move commands for tool post 1 and along the axes (X2, Z2, and C2) belonging to tool post 2 in accordance with the move commands for tool post 2 (independent control for each tool post). The superimposed control function allows you to move the tool along any of the axes of one tool post and along any of the axes of the other tool post by superimposing the amount of travel.
For details, see Section, "SUPERIMPOSED CONTROL" in this chapter.

- **Path spindle control**

This function allows the spindle belonging to one path to follow the spindle command of another specific path.
It allows you to specify that a path is to incorporate the position coder feedback data for any of the spindles belonging to any path. This achieves control using a spindle of another path, for example, threading or feed per revolution in path 1, using a spindle belonging to path 2.
For details, see Section, "PATH SPINDLE CONTROL".

- **Memory common to paths**

In a machine with multiple paths, this function allows you to make common the independent custom macro common variables and tool compensation memory of a path, through appropriate parameter settings.

- **Custom macro common variables**

Part or all of common variables #100 to #149 and #500 and #531 of custom macros can be made into those for common use by paths (variables that permit reading or writing by either of both paths).

- **Tool compensation memory**

The tool compensation memory of path 1 can be accessed by path 2 as well, for data reference and setting.
The requirement is that the settings for tool compensation (such as the number of sets, the number of digits, and the unit system) must be the same in both paths 1 and 2.

For details, see Section, "MEMORY COMMON TO PATHS" in this chapter.

- Path single block check function

If one path enters the single block stop state, this function allows another path to enter the feedhold stop state, enabling single block operation with the path machining programs being nearly synchronized.
For details, see the Section, "PATH SINGLE BLOCK CHECK FUNCTION".

- Path selection/arbitrary path name display

Path selection/arbitrary path name display
This function is used to select a path targeted for an operation that is performed for a specified path, for example, displaying and setting various types of data (tool compensation or the like) for each path, inputting the command program in MDI mode, or editing the machining program in program memory.
In addition, the name of each path can be changed by setting the parameter.
For details, see Section, "PATH SELECTION/ARBITRARY PATH NAME DISPLAY" in this chapter.

8.1.3 Cautions on Multi-path Control

- Parameter

> ⚠ **WARNING**
> If you attempt to change parameters in MDI mode in a certain path, it is probable that other paths are in MEM or other modes even if that path is in MDI mode. Before changing parameters, check to see if this will not affect the operations in the other paths.
> During axial movement, in particular, use great caution not to change those parameters related to axes and spindles.

- MDI reset key

> ⚠ **CAUTION**
> Only a single LCD/MDI set is provided for all paths. You use the path selection signal to specify which path the operations and displays on the LCD/MDI are for. The RESET key on the MDI panel is, however, effective to all paths, regardless of the path selection signal.
> Note, however, that you can make the key effective to the path selected with the path selection signal or the machine group, by appropriately setting bit 0 (RST) of parameter No. 8100 or bit 0 (MGR) of parameter No. 8106).

- Alarms during automatic operation

> ⚠ **CAUTION**
> If, during automatic operation, an alarm occurs in a certain path, all paths in that machine group will enter the feedhold state and stop.
> You can let them continue to operate, disregarding the alarm, by appropriately setting bit 1 (IAL) of parameter No. 8100.

- Assignment of signals

> ⚠ **CAUTION**
> 1 When there are four or more paths
> Input signals by the X address for each path are assigned to up to three paths. Therefore, when there are four or more paths, the signals must be assigned by bit 2 (XSG) of parameter No. 3008.

⚠ CAUTION

2 When there are nine or more axes for one path
The X address of the reference position return deceleration signal (*DECx) for each axis is assigned to up to three paths (up to eight axes for each path). Therefore, when there are four or more paths or there are nine or more axes for one path, the signals must be assigned by setting bit 2 (XSG) of parameter No. 3008, parameter No. 3013, and parameter No. 3014.
The input signal (G signal) and output signal (F signal) for each axis are assigned to up to eight axes for each path. Therefore, when there are nine or more axes for one path, the signals must be assigned by setting parameter No. 3021.

Parameter

0980	Machine group number to which each path belongs

NOTE
When this parameter is set, the power must be turned off before operation is continued.

[Input type] Parameter input
[Data type] Byte path
[Valid data range] 1 to 3
Set the machine group number to which each path belongs.

NOTE
When 0 is set, each path is assumed to belong to machine group 1.

0981	Absolute path number to which each axis belongs

NOTE
When this parameter is set, the power must be turned off before operation is continued.

[Input type] Parameter input
[Data type] Byte axis
[Valid data range] 1 to 4
Set the path to which each axis belongs.

NOTE
When 0 is set, each axis is assumed to belong to path 1.

0982	Absolute path number to which each spindle belongs

NOTE
When this parameter is set, the power must be turned off before operation is continued.

[Input type] Parameter input
[Data type] Byte spindle
[Valid data range] 1 to 4
Set the path to which each spindle belongs.

NOTE
When 0 is set, each spindle is assumed to belong to path 1.

0983	Path control type of each path

NOTE
When this parameter is set, the power must be turned off before operation is continued.

[Input type] Parameter input
[Data type] Byte path
[Valid data range] 0 to 1
Set the path control type of each path.
The following two path control types are available:
T series (lathe system) : 0
M series (machining system): 1

	#7	#6	#5	#4	#3	#2	#1	#0
3008						XSG		

[Input type] Parameter input
[Data type] Bit path

NOTE
When this parameter is set, the power must be turned off before operation is continued.

#2 XSG A signal assigned to an X address is:
0: Fixed at the address.
1: Able to be reassigned to an arbitrary X address.

NOTE
When this parameter is set to 1, set parameters Nos. 3013, 3014, 3012, and 3019. If parameters Nos. 3013 and 3014 are not set, the deceleration signal for reference position return is assigned to bit 0 of <X0000>. If parameters Nos. 3012 and 3019 are not set, the skip signal, the PMC axis control skip signal, the measurement position arrival signal, the interlock signal for each axis direction, and the tool compensation value write signal are assigned to <X0000>.

3012	Skip signal assignment address

NOTE
When this parameter is set, the power must be turned off before operation is continued.

[Input type] Parameter input
[Data type] Word path
[Valid data range] 0 to 727
Set an X address to which the skip signal SKIPn is to be assigned.

NOTE

This parameter is valid when bit 2 (XSG) of parameter No. 3008 is set to 1.
Depending on the configuration of the I/O Link, the actually usable X addresses are:
<X0000 to X0127>, <X0200 to X0327>, <X0400 to X0527>, <X0600 to X0727>

3013	X address to which the deceleration signal for reference position return is assigned

NOTE

When this parameter is set, the power must be turned off before operation is continued.

[Input type] Parameter input
[Data type] Word axis
[Valid data range] 0 to 727

Set an address to which the deceleration signal *DECx for reference position return for each axis is to be assigned.

NOTE

This parameter is valid when bit 2 (XSG) of parameter No. 3008 is set to 1.
Depending on the configuration of the I/O Link, the actually usable X addresses are:
<X0000 to X0127>, <X0200 to X0327>, <X0400 to X0527>, <X0600 to X0727>

3014	Bit position of an X address to which the deceleration signal for reference position return is assigned

NOTE

When this parameter is set, the power must be turned off before operation is continued.

[Input type] Parameter input
[Data type] Byte axis
[Valid data range] 0 to 7

Set a bit position to which the deceleration signal for reference position return *DECx for each axis is to be assigned.

NOTE

This parameter is valid when bit 2 (XSG) of parameter No. 3008 is set to 1.

3019	Address to which the PMC axis control skip signal and measurement position arrival signals are assigned

NOTE

When this parameter is set, the power must be turned off before operation is continued.

[Input type] Parameter input
[Data type] Word path
[Valid data range] 0 to 727

Set an X address to which the PMC axis control skip signal ESKIP and the measurement position arrival signals (XAE, YAE, and ZAE (Machining Center series) or XAE and ZAE (Lathe series)) are to be assigned.

Example 1. When No.3012 is set to 5 and No.3019 is set to 6

When bit 2 (XSG) of parameter No. 3008 is 1, the PMC axis control skip signal, and measurement position arrival signal are allocated to X0006 and the skip signal is allocated to X0005.

	#7	#6	#5	#4	#3	#2	#1	#0	
X005	SKIP	SKIP6	SKIP5	SKIP4	SKIP3	SKIP2	SKIP8	SKIP7	(T series)
	SKIP	SKIP6	SKIP5	SKIP4	SKIP3	SKIP2	SKIP8	SKIP7	(M series)

	#7	#6	#5	#4	#3	#2	#1	#0	
X006		ESKIP					ZAE	XAE	(T series)
		ESKIP				ZAE	YAE	XAE	(M series)

Example 2. When No.3012 is set to 5 and No.3019 is set to 5

When bit 2 (XSG) of parameter No. 3008 is 1, the PMC axis control skip signal, measurement position arrival signal, and skip signal are allocated to X0005.

	#7	#6	#5	#4	#3	#2	#1	#0	
X005	SKIP	ESKIP					ZAE	XAE	(T series)
		SKIP6	SKIP5	SKIP4	SKIP3	SKIP2	SKIP8	SKIP7	

	#7	#6	#5	#4	#3	#2	#1	#0	
	SKIP	ESKIP	SKIP5	SKIP4	SKIP3	ZAE	YAE	XAE	(M series)
		SKIP6				SKIP2	SKIP8	SKIP7	

NOTE
This parameter is valid when bit 2 (XSG) of parameter No. 3008 is set to 1.
Depending on the configuration of the I/O Link, the actually usable X addresses are:
X0000 to X0127, X0200 to X0327, X0400 to X0527, X0600 to X0727

3021	Address to which an axis signal is assigned

NOTE
When this parameter is set, the power must be turned off before operation is continued.

[Input type] Parameter input
[Data type] Byte axis
[Valid data range] 0 to 7, 10 to 17, 20 to 27, ... , 90 to 97

For each axis of the CNC, set a PMC interface address.
Set a value according to the tables below.

Value of parameter No. 3021 (the second digit)

Setting value	Input signal address	Output signal address
0	G0000 to G0767	F0000 to F0767
1	G1000 to G1767	F1000 to F1767
2	G2000 to G2767	F2000 to F2767
3	G3000 to G3767	F3000 to F3767

Value of parameter No. 3021 (the first digit)

Setting value	Input signal address	Output signal address
0	#0	#0
1	#1	#1
	:	
7	#7	#7

[Example of setting]

Axis number	No. 3021	Signal allocation
1	0	+J1<G0100.0>, -J1<G0102.0>, ZP1<F0090.0>, ...
2	1	+J2<G0100.1>, -J2<G0102.1>, ZP2<F0090.1>, ...
3	2	+J3<G0100.2>, -J3<G0102.2>, ZP3<F0090.2>, ...
4	10	+J4<G1100.0>, -J4<G1102.0>, ZP4<F1090.0>, ...
5	11	+J5<G1100.1>, -J5<G1102.1>, ZP5<F1090.1>, ...

If eight or less axes are used per path, the following signal allocation results when 0 is set for all axes:

Axis 1 of path 1 = Setting equivalent to 0
Axis 2 of path 1 = Setting equivalent to 1
:
Axis 1 of path 2 = Setting equivalent to 10
:

> **NOTE**
> Set this parameter when more than eight axes are used per path.
> The valid data range varies, depending on the system software.

	#7	#6	#5	#4	#3	#2	#1	#0
8100		DSB					IAL	RST

[Input type] Parameter input
[Data type] Bit machine group

#0 RST The pressing of the RESET key on the MDI panel is:

0: Valid for all paths.
1: Valid only for the path selected by the path selection signal.

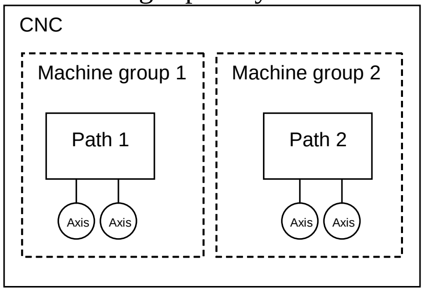
The RESET key on the MDI panel functions for all machine groups. So, in machine groups for which this parameter is set to 0, a reset can be performed for all paths. In machine groups for which this parameter is set to 1, a reset can be performed only for the path that is selected by the path select signal.

> **NOTE**
> The path by which reset becomes actually effective depends on the combination with bit 0 (MGR) of parameter No.8106 setting and this parameter.

So, operations are performed as indicated in the example below.

[Example]

Suppose that the following 3-path system is used.



(1) When RST (machine group 1) = 0 and RST (machine group 2) = 0 are set, the reset key is valid for all paths.

Reset operation when the MDI key is pressed

Signal HEAD	0 (Path 1 selected)	1 (Path 2 selected)
Path 1	Resetting valid	Resetting valid
Path 2	Resetting valid	Resetting valid

(2) When RST (machine group 1) = 1 and RST (machine group 2) = 1 are set, the reset key is valid for a path selected by the path selection signal.

Reset operation when the MDI key is pressed

Signal and HEAD	0	1
Path 1	Resetting valid	Resetting invalid
Path 2	Resetting invalid	Resetting valid

(3) When RST (machine group 1) = 1 and RST (machine group 2) = 0 are set, the following operation is performed:

Reset operation when the MDI key is pressed

Signal HEAD	0	1
Path 1	Resetting valid	Resetting invalid
Path 2	Resetting valid	Resetting valid

#1 IAL Choice of an option concerning operation continuation when an alarm is issued, and choice of an option concerning the start of automatic operation in alarm state:

0: - When an alarm is issued, the operation is stopped with the other path(s) in same group placed in hold state.
- When the other path or paths in same group are placed in alarm state, automatic operation cannot be started.

1: - Even when an alarm is issued, the operation is continued without stopping the other path(s).
- Even when the other path or paths in same group are placed in alarm state, automatic operation can be started.

#6 DSB The inter-path single block check function is:

0: Disabled.
When a single block stop occurs with a path, no single block stop occurs with the other path(s).

1: Enabled.
When a single block stop occurs with a path, a feed hold stop occurs with all paths in the same machine group.

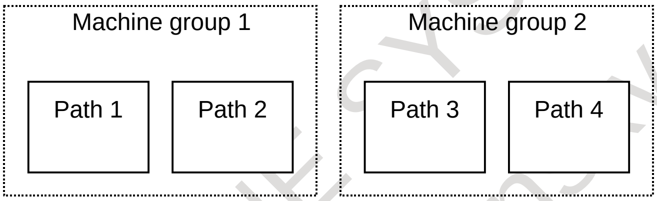
	#7	#6	#5	#4	#3	#2	#1	#0
8106								MGR

[Input type] Parameter input
[Data type] Bit

 # 0 MGR When the RESET key on the MDI panel is pressed,
0: All machine groups are reset.
1: Only the machine groups to which the path selected by the path selection signal belongs are reset.

> **NOTE**
> The path by which reset becomes actually effective depends on the combination with bit 0 (RST) of parameter No. 8100 setting and this parameter.

[Example]
Suppose that the following 2-machine-group with 4-path system is used.



[Example 1]
When the bit 0 (MGR) of parameter No. 8106 is set to 0:
When the RESET key on the MDI panel is pressed, all paths are reset regardless of which path is selected.

[Example 2]
When the bit 0 (MGR) of parameter No. 8106 is set to 0 and path 1 is selected:
When the RESET key on the MDI panel is pressed, machine group 1 (paths 1 and 2) to which path 1 belongs is reset. Machine group 2 (paths 3 and 4) is not reset.

Bit 0 (MGR) of parameter No. 8106 can be used together with bit 0 (RST) of parameter No. 8100. The following table lists the path or paths to be reset when the RESET key on the MDI panel is pressed, according to the setting of bit 0 (RST) of parameter No. 8100 used when bit 0 (MGR) of parameter No. 8106 is set to 1 for the machine group in the above example.

No.	Bit 0 (RST) of parameter No. 8100 (Machine group 1)	Bit 0 (RST) of parameter No. 8100 (Machine group 2)	Selected path			
			Path 1	Path 2	Path 3	Path 4
			Path(s) to be reset			
1	0	0	1, 2	1, 2	3, 4	3, 4
2	0	1	1, 2	1, 2	3	4
3	1	0	1	2	3, 4	3, 4
4	1	1	1	2	3	4

Signal address

Alarm and message

Number	Message	Description
PS0365	TOO MANY MAXIMUM SV/SP AXIS NUMBER PER PATH	The maximum control axis number or maximum control spindle number which could be used within a path was exceeded.
PW0001	X-ADDRESS(*DEC) IS NOT ASSIGNED.	The X address of the PMC could not be assigned correctly. This alarm may occur in the following case: - During the setting of parameter No. 3013, the X address could not be assigned correctly for the deceleration dog (*DEC) for a return to the reference position. When there are four or more paths or there are nine or more axes for one path, the signals must be assigned by setting bit 2 (XSG) of parameter No. 3008, parameter No. 3013, and parameter No. 3014.
PW0002	PMC address is not correct(AXIS).	The address to assign the axis signal is incorrect. This alarm may occur in the following case: - The parameter No. 3021 setting is incorrect.

8.2 WAITING M CODES

Overview

Control based on M codes is used to cause one path to wait for the other during machining. When an M code for waiting is specified in a block for one path during automatic operation, the other path waits for the same M code to be specified before staring the execution of the next block.

A range of M codes used as M codes for waiting is to be set in the parameters Nos. 8110 and 8111 beforehand. Waiting can be ignored using a signal.

Address P to be specified in the same block as that containing a waiting M code can be set in either of two ways:

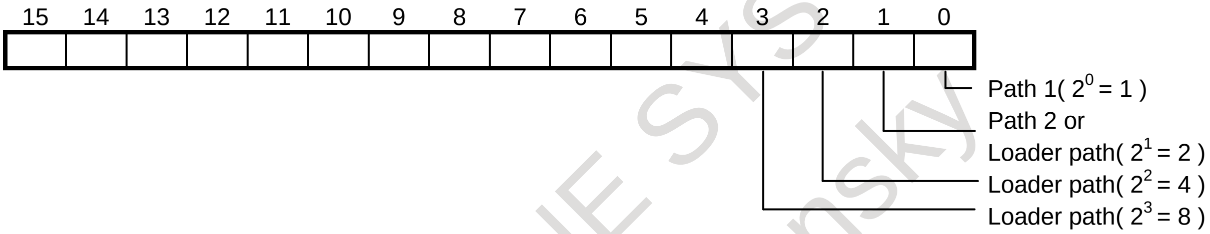
- When the bit 1 (MWP) of parameter No. 8103 is set to 0 :
  Waiting with a binary value specification
- When the bit 1 (MWP) of parameter No. 8103 is set to 1 :
  Waiting with a path number combination specification

- Waiting specified with binary values

When bit 1 (MWP) of parameter No. 8103 is set to 0, the value specified at address P is assumed to be obtained using binary values. The following table lists the path numbers and corresponding binary values.

Path number	Binary value (decimal number)
1	1
2 or Loader path 1(1 control path)	2
Loader path 1 (2 control paths) or Loader path 2(1 control path)	4
Loader path 2 (2 control paths)	8

The bit position of each path in binary representation is shown below.



To make all of paths 1, 2, and 3 wait for one another, the P value is obtained as follows:

Binary value of path 1	1 (0000 0000 0000 0001)
Binary value of path 2	2 (0000 0000 0000 0010)
Binary value of path 3	4 (0000 0000 0000 0100)
Sum	7 (0000 0000 0000 0111)

All of the three paths can be made to wait for one another by specifying P7 together with an M code for waiting.

- Waiting specified with a combination of path numbers

When bit 1 (MWP) of parameter No. 8103 is set to 1, the value specified at address P is assumed to be a combination of path numbers. The following table lists the path numbers and corresponding values.

Path number	Value (decimal number)
1	1
2 or Loader path 1(1 control path)	2
Loader path 1 (2 control paths) or Loader path 2(1 control path)	3
Loader path 2 (2 control paths)	4

To make all of paths 1, 2, and 3 wait for one another, the P value is a number consisting of 1, 2, and 3.
Example) P123
There are no restrictions on the order in which the numeric characters are specified, the following six possible values can be specified:

P123, P132, P213, P231, P312, P321

Path numbers specified in combination in different orders for different paths are effective as long as the numbers of the relevant paths are specified.

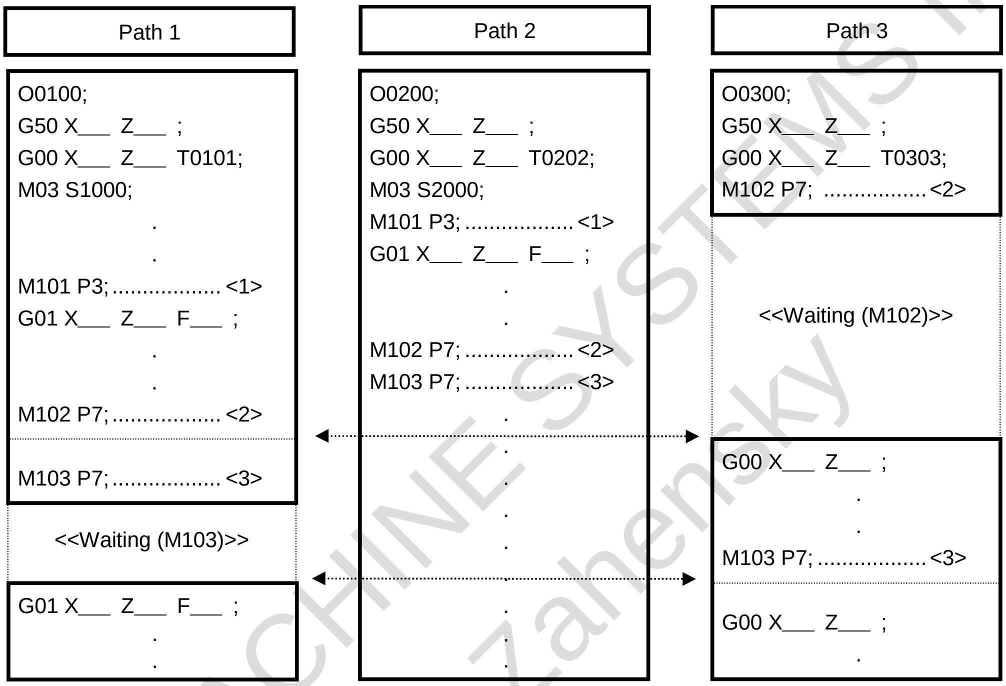
Example)

The following are treated as the same P value and these paths can be made to wait for one another:
M200P123 for path 1, M200P231 for path 2, and M200P321 for path 3

Program example

- When the value specified at P is obtained using binary values

Assume that the no-wait signal NOWT <G0063.1> for path 2 (NMWT<G1063.7> for a system with three or more paths) is set to "1" and M101 to M103 (parameter No. 8110 = 101 and parameter No. 8111 = 103) are set as M codes for waiting. In this case, programs O100, O200, and O300 for individual paths are executed as follows:



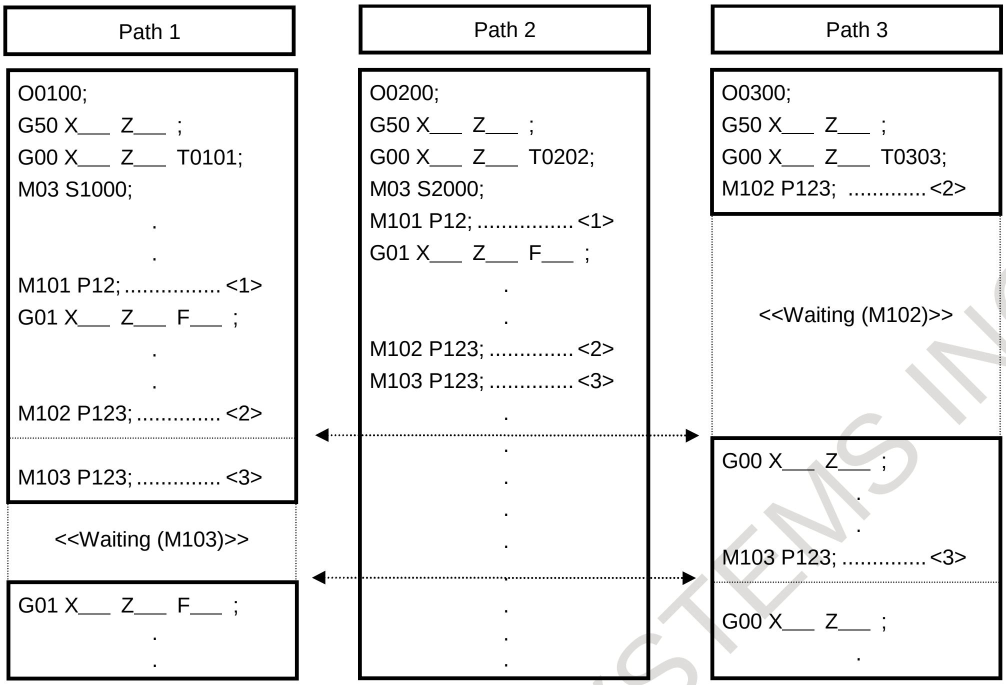
<1> M101 P3; (making paths 1 and 2 wait for each other)
When the no-wait signal for path 2 is set to "0", paths 1 and 2 wait for each other. Because the signal is set to "1", however, paths 1 and 2 ignore the M code for waiting and immediately execute the next block.

<2> M102 P7; (making paths 1, 2, and 3 wait for one another)
In this example, path 3 waits for processing on paths 1 and 2 to terminate. Because the no-wait signal for path 2 is set to "1", however, path 3 assumes that waiting is completed when processing on path 1 terminates, and executes the next block.

<3> M103 P7; (making paths 1, 2, and 3 wait for one another)
In this example, paths 1 and 2 wait for processing on path 3 to terminate. Because the no-wait signal for path 2 is set to "1", however, path 2 does not wait for processing on path 3 to terminate and executes the next block, but path 1 waits for path 3.

- When the value specified at P is obtained using path numbers in combination

Assume that the no-wait <G0063.1> signal for path 2 (NMWT<G1063.7> for a system with three or more paths) is set to "1" and M101 to M103 (parameter No. 8110 = 101 and parameter No. 8111 = 103) are set as M codes for waiting. In this case, programs O100, O200, and O300 for individual paths are executed as follows:



<1> M101 P12; (making paths 1 and 2 wait for each other)
When the no-wait signal for path 2 is set to "0", paths 1 and 2 wait for each other. Because the signal is set to "1", however, paths 1 and 2 ignore the M code for waiting and immediately execute the next block.

<2> M102 P123; (making paths 1, 2, and 3 wait for one another)
In this example, path 3 waits for processing on paths 1 and 2 to terminate. Because the no-wait signal for path 2 is set to "1", however, path 3 assumes that waiting is completed when processing on path 1 terminates, and executes the next block.

<3> M103 P123; (making paths 1, 2, and 3 wait for one another)
In this example, paths 1 and 2 wait for processing on path 3 to terminate. Because the no-wait signal for path 2 is set to "1", however, path 2 does not wait for processing on path 3 to terminate and executes the next block, but path 1 waits for path 3.

Signal

You can invalidate waiting by using the no-wait signal.
The waiting M code of a path for which the no-wait signal is "1" is ignored by other paths, thereby invalidating waiting. You use this signal if you are to perform automatic operation with a program containing a waiting M code, but you want to keep a certain path stopped while performing automatic operation in the other paths. For the path that you want to keep stopped, set the no-wait signal to "1".

No-wait signal

NOWT<G0063.1>(for path common signal interface)
NMWT<Gn063.7>(for path individual signal interface)

[Classification] Input signal

[Function] Specifies whether to synchronize the paths by the waiting M code.

[Operation] When this signal turns to "1" the paths are not synchronized by the M code. The M code for waiting specified in a machining program is ignored.
When this signal turns to "0", the paths are synchronized by the M code. When the M code for waiting is specified for one path, the CNC waits for the corresponding M code of another path to be issued, then starts executing the next block.

Waiting signal
WATO<F0063.6>(for path common signal interface)
WATO<Fn063.6>(for path individual signal interface)

[Classification] Output signal

[Function] Indicates that the M code is waiting for a path.

[Output cond.] These signals are "1" as long as:

- One path is waiting for another path. That is, the signal stays "1" for the period from when the M code for waiting is issued to one path to when the corresponding M code is issued to another path.

This signal is "0" as long as:

- Neither of the paths are waiting for the other.

> **NOTE**
> When the path common signal interface (bit 0 (MWT) of parameter No. 8103 = 1) is used, F0063.6=1 results even if path 2 is placed in the wait state.
> So, when the wait state needs to be checked with each path, use the path individual signal interface (bit 0 (MWT) of parameter No. 8103 = 0).

Signal address

- For path common signal interface

	#7	#6	#5	#4	#3	#2	#1	#0
G0063							NOWT	
F0063		WATO						

- For path individual signal interface

	#7	#6	#5	#4	#3	#2	#1	#0
Gn063	NMWT							
Fn063		WATO						

Parameter

	#7	#6	#5	#4	#3	#2	#1	#0
8103							MWP	MWT

[Input type] Parameter input

[Data type] Bit

> **NOTE**
> When at least one of these parameters is set, the power must be turned off before operation is continued.

#0 MWT As the signal interface for the waiting M code:

0: The path individual signal interface is used.

1: The path common signal interface is used.

This parameter can be selected only when 2-path control is used.

#1 MWP To specify a P command for the waiting M code/balance cut:

0: A binary value is used as conventionally done.

1: A path number combination is used.

8110	**Waiting M code range (minimum value)**
8111	**Waiting M code range (maximum value)**

[Input type] Parameter input
[Data type] 2-word
[Valid data range] 0 ,100to99999999

A range of M code values can be set by specifying a minimum waiting M code value (parameter No. 8110) and a maximum waiting M code value (parameter No. 8111).
(parameter No. 8110) ≤ (waiting M code) ≤ (parameter No. 8111)
Set 0 in these parameters when the waiting M code is not used.

Alarm and message

Number	Message	Description
PS0160	MISMATCH WAITING M-CODE	<1> When different M codes are specified for path 1 and path 2 as waiting M codes without a P command. <2> When the waiting M codes are not identical even though the P commands are identical <3> When the waiting M codes are identical and the P commands are not identical (This occurs when a P command is specified with binary value.) <4> When the number lists in the P commands contain a different number even though the waiting M codes are identical (This occurs when a P command is specified by combining path numbers.) <5> When a waiting M code without a P command (2-path waiting) and a waiting M code with a P command (3-or-more-path waiting) were specified at the same time <6> When a waiting M code without a P command was specified for 3 or more paths.
PS0161	ILLEGAL P OF WAITING M-CODE	<1> When address P is negative <2> When a P value inappropriate for the system configuration was specified <3> When a waiting M code without a P command (2-path waiting) was specified in the system having 3 or more paths.

An alarm occurs in all the paths in which an alarm-related waiting M code has been executed, bringing them into a single block stop and placing them in the automatic operation stop state.
At this time, the paths other than the alarm-related ones are stopped immediately, entering the automatic operation idle state.

Caution

⚠ **CAUTION**

1 Be sure to specify a waiting M code in an independent block.
2 Unlike other M codes, waiting M codes are not output to PMCs.
3 If you want to independently operate one path only, you need not delete that waiting M code. Using the no-wait signal (NOWT for a 2-path system and NMWT for a 3-path system), you can invalidate the waiting M code specified in the machining program. For details, refer to the manual issued by the machine tool builder.
4 To use a waiting M code in mode for multiple M commands in a single block, the M code must be specified as the first M code.

Reference item

Manual name	Item name
OPERATOR'S MANUAL (B-64694EN)	WAITING FUNCTION FOR PATHS

8.3 WAITING M CODES OF HIGH-SPEED TYPE

Overview

Waiting M codes of high-speed type are useful function to reduce the cycle time of a program operation.

Specification

In order to use Waiting M codes of high-speed type, it is necessary to set the range of the M codes to parameters Nos.8114 and 8115.
The usage of these type M codes is similar to normal waiting M codes. For instance, the ways to set a path by address P and to use a no-wait signal or so on are the same.

Format

M m (P p) ;

m : Number of an M code for waiting
p : (1) In the binary value specification mode, specify the sum of the binary values corresponding to the numbers of paths which are to wait for one another.
(2) In the path number specification mode, specify the numbers of all paths that are to wait for one another in combination.

NOTE
1 Specify a waiting M code only in a block.
2 The irrelevant command, which is specified with a waiting M code in a block, is ignored.

Detail

Specifying the path by address P

The way to specify the path by address P is the same as normal waiting M codes.

Waiting signal

Waiting signal WATO<F0063.6> (for path common signal interface) and WATO<Fn063.6> (for path individual signal interface) are output like normal waiting M codes.

No-wait signal

No-wait signal NOWT<G0063.1> (for path common signal interface) and NMWT<Gn063.7> (for path individual signal interface) are effective like normal waiting M codes.

Waiting M codes of high-speed type invalid signal

Waiting M codes of high-speed type are treated as normal waiting M codes when waiting M codes of high-speed type invalid signal NHSW<G0579.6> is set to "1".

Limitation

Display of the currently executing program

Instead of the block of waiting M code, the block before waiting M code is displayed as the currently executing program during waiting of high-speed type.

Function code signal and strobe signal

As for waiting M code of high-speed type, the function code signal and strobe signal are not output.

Modal display

Waiting M codes of high-speed type are not displayed as the information of M code modal.

Condition to treat waiting M codes of high-speed type as normal waiting M codes

When one of the following conditions is satisfied, waiting M codes of high-speed type are treated as normal waiting M codes.

- Waiting M codes of high-speed type invalid signal is set to "1".
- The single-block operation is enabled.
- Waiting M codes of high-speed type are specified in the same block as the program number.
- In manual handle retrace function, the checking mode synchronizing an operation with a manual handle pulse is selected.
- Animation or path drawing of dynamic graphic display is operated.

NOTE

1 Waiting between waiting M codes of high-speed type and waiting M codes of high-speed type treated as normal waiting M codes cannot be executed when setting bit 7 (HMA) of parameter No.11279 to 0. In this case, alarm (PS0160) “MISMATCH WAITING M-CODE” occurs.
Example)
When either path 1 or path 2 is under the single block operation and waiting by "waiting M code of high-speed type" is executed between path 1 and path2, alarm (PS0160) occurs.

2 Waiting between waiting M codes of high-speed type and waiting M codes of high-speed type treated as normal waiting M codes can be executed when setting bit 7 (HMA) of parameter No.11279 to 1. And, waiting M codes of high-speed type can be specified during Relation of cutter compensation by setting bit 7 (HMA) of parameter No.11279 to 1. In this case, waiting M codes of high-speed type are not work at a high-speed, waiting M codes of high-speed type are treated as normal waiting M codes, and the processing time of waiting M codes of high-speed type is equal with normal waiting M codes.

Auxiliary function output in moving axis

Waiting is not executed even if waiting M code of high-speed type is specified, when Auxiliary function output in moving axis (G50.9) is given in the same block. In this case, M code is treated as a normal auxiliary function.

Manual handle retrace function

In Manual handle retrace function, a backward movement cannot be executed while the block of waiting M codes of high-speed type is executing. The backward movement ends when an operation enters the next block of waiting M code of high-speed type during the backward movement. And ‘RVED’ is displayed.
However, in the checking mode synchronizing with a manual handle pulse, the backward movement can be executed when waiting M code of high-speed type was executed once during forward movement, because the M code is treated as a normal M code in this case.

Retrace

The backward movement cannot be executed by Retrace function in the block of waiting M codes of high-speed type. The backward movement ends when the next block of waiting M code of high-speed type just starts executing during the backward movement. And ‘RVED’ is displayed.

Waiting function by specifying start point

Waiting M codes of high-speed type cannot act as a waiting function by specifying start point. Alarm (PS0160) occurs when such a command is specified. Use normal waiting M codes to use waiting function by specifying start point.

Relation of cutter compensation

Waiting M codes of high-speed type cannot be specified during the following cutter compensation functions. Alarm (PS0160) occurs when such a command is specified. Set the bit 7 (HMA) of parameter No.11279 to 1, or use normal waiting M codes during the following cutter compensation functions.
- Cutter compensation and tool nose radius compensation

> **NOTE**
>
> Waiting M codes of high-speed type cannot be specified just after the cancel command of cutter compensation, tool nose radius compensation. Moreover, waiting M codes of high-speed type cannot be specified while the vector of cutter compensation is being held.

Multiple repetitive canned cycle

Waiting M codes of high-speed type cannot be specified during Multiple repetitive canned cycle G70 to G73. Alarm (PS0160) occurs when such a command is specified. Use normal waiting M codes during Multiple repetitive canned cycle G70 to G73.

Chamfering and corner R, Optional chamfering and corner R and Direct drawing dimension programming

In the condition to treat waiting M codes of high-speed type as normal waiting M codes, alarm (PS0051) “MISSING MOVE AFTER CNR/CHF” occurs when waiting M codes of high-speed type are specified during Chamfering and corner R or Optional chamfering and corner R. And alarm (PS0312) “ILLEGAL COMMAND IN DIRECT DRAWING DIMENSIONS PROGRAMMING” occurs when waiting M codes of high-speed type are specified during Direct drawing dimension programming.

Quick program restart

When the program is interrupted by reset or etc. while executing waiting of high-speed type, the previous block of waiting M codes is regarded as the last restart point, instead of the block of waiting M codes.

Output to the PMC

Waiting M codes are not output to the PMC unlike the other M codes.

Occurring alarm while waiting

The state of cycle start lamp signal STL<Fn000.5> is as follows when an alarm occurs while waiting.

	Cycle start lamp signal STL<Fn000.5>	
	When alarms PS, SR or IO occurs.	**When other alarms occurs.**
Waiting M codes of normal	STL = 1	STL = 0
Waiting M codes of high-speed type	STL = 0	STL = 0

Block start interlock signal

Block start interlock signal *BSL<Gn008.3> is invalid for waiting M codes of high-speed type. However, block start interlock signal *BSL<Gn008.3> is valid in the condition to treat waiting M codes of high-speed type as normal waiting M codes.

Real-time custom macro

Execution timing of each real time macro statement is delayed compared with normal waiting M codes when real time macro command is executed during the waiting by waiting M codes of high-speed type.
Please use normal waiting M codes for the waiting which is executed with real time macro command at the same time.

Signal

Waiting M codes of high-speed type invalid signal NHSW<G0579.6>

[Classification] Input signal

[Function] Waiting M codes of high-speed type are invalidated.

[Operation] When this signal becomes "1":
M codes setting by parameters Nos.8114 and 8115 are treated as normal waiting M codes.
When this signal becomes "0":
M codes setting by parameters Nos.8114 and 8115 are treated as waiting M codes of high-speed type.

> **NOTE**
> This signal cannot be changed during operating a program.
> The state of signal at cycle start is kept.

No-wait signal
NOWT<G0063.1> (for path common signal interface)
NMWT<Gn063.7> (for path individual signal interface)

[Classification] Input signal

[Function] Specifies whether to synchronize the paths by the waiting M code or not.

[Operation] When this signal turns to "1", inter-path synchronization by the M code is not performed. The waiting M code specified in a machining program is ignored.
When this signal turns to "0", inter-paths synchronization by the M code is performed. When the waiting M code is specified in one path, the CNC waits for the corresponding M code of another path to be issued, then starts executing the next block.

Waiting signal
WATO<F0063.6> (for path common signal interface)
WATO<Fn063.6> (for path individual signal interface)

[Classification] Output signal

[Function] Indicates that the M code is waiting for another path.

[Output cond.] These signals are "1" as long as:

- A path is waiting for another path. That is, the signal stays "1" for the period from when the path issues the M code for waiting to when another path issues the corresponding M code.

This signal is "0" as long as:

- Neither of the paths is waiting for the other.

> **NOTE**
> 1 Waiting signal might not be output when waiting is released in a very short time.
> 2 Waiting signal might keep being output at 16ms or less, just after waiting has been released.

Parameter

8114	Top number of waiting M codes of high-speed type

[Input type] Parameter input
[Data type] 2-word
[Valid data range] 0, 100 to 99999999

Set the top number of waiting M codes of high-speed type.
Waiting M codes of high-speed type cannot be used when the setting value is 0 or out of range.

8115	Number of waiting M codes of high-speed type

[Input type] Parameter input
[Data type] word
[Valid data range] 0 to 32767

Set the number of waiting M codes of high-speed type.
Waiting M codes of high-speed type cannot be used when the setting value is 0 or out of range.

> **NOTE**
> Set the range of waiting M codes of high-speed type not to overlap with the range of other waiting M codes. The M codes are regarded as waiting M codes of high-speed type if overlapping.

	#7	#6	#5	#4	#3	#2	#1	#0
11279	HMA							

[Input type] Parameter input
[Data type] Bit

#7 HMA When waiting M codes of high-speed are specified during Relation of cutter compensation, :
0: alarm occurs.
1: alarm not occurs.

> **NOTE**
> 1 Processing time of waiting M codes of high-speed type during Relation of cutter compensation is equal with waiting M codes setting by parameter No.8110 and 8111 when setting this parameter to 1.
> 2 Waiting M codes of high-speed type during Relation of cutter compensation are treated with non-buffering and non-movement block when setting this parameter to 1. Please note enough about the function which changes operation by the non-movement block (For example, cutter compensation and tool nose radius compensation or etc.)

Alarm and message

Number	Message	Description
PS0051	MISSING MOVE AFTER CNR/CHF	Improper movement or the move distance was specified in the block next to the chamfering or corner R block. Modify the program.
PS0160	MISMATCH WAITING M-CODE	1. When different M codes were specified in path 1 and path 2 as waiting M codes without a P command. 2. When the waiting M codes were not the same even though the P commands were the same. 3. When the waiting M codes were the same and the P commands were not the same (This case occurs when a P command was specified with binary value.) 4. When the number lists in the P commands contain a different number even though the waiting M codes were the same (This case occurs when a P command was specified by combining path numbers.) 5. When a waiting M code without a P command (2-path waiting) and a waiting M code with a P command (3-or-more-path waiting) were specified at the same time 6. When a waiting M code without a P command was specified for 3 or more paths. 7. When waiting was executed between waiting M codes of high-speed type and waiting M codes of high-speed type which are treated as normal waiting M codes. 8. When waiting M codes of high-speed type were specified as waiting function by specifying start point.
PS0161	ILLEGAL P OF WAITING M-CODE	1. When the value of address P was negative. 2. When a P value inappropriate for the system configuration was specified. 3. When a waiting M code without a P command (2-path waiting) was specified in the system having 3 or more paths.
PS0312	ILLEGAL COMMAND IN DIRECT DRAWING DIMENSIONS PROGRAMMING	Direct input of drawing dimensions was commanded in an invalid format. An attempt was made to specify an invalid G code during direct input of drawing dimensions. Two or more blocks not to be moved exist in consecutive commands that specify direct input of drawing dimensions. Although non-use of commas (,) (bit 4 of parameter No. 3405 = 1) was specified for direct input of drawing dimensions, a comma was specified.

8.4 INTERFERENCE CHECK FOR EACH PATH

T

Overview

When tool posts on individual paths machine the same workpiece simultaneously, the tool posts can approach each other very closely. If the tool posts interfere with each other due to a program error or any other setting error, a serious damage such as a tool or machine destruction can occur.
The function "interference check for each path" decelerates and stops the tool posts on individual paths before they actually make contact with each other if a command is issued and they will interfere with each other as the result.

Bit 7 (IFP) of parameter No. 8140 can be used to specify whether to make a two-path interference check or multipath interference check.

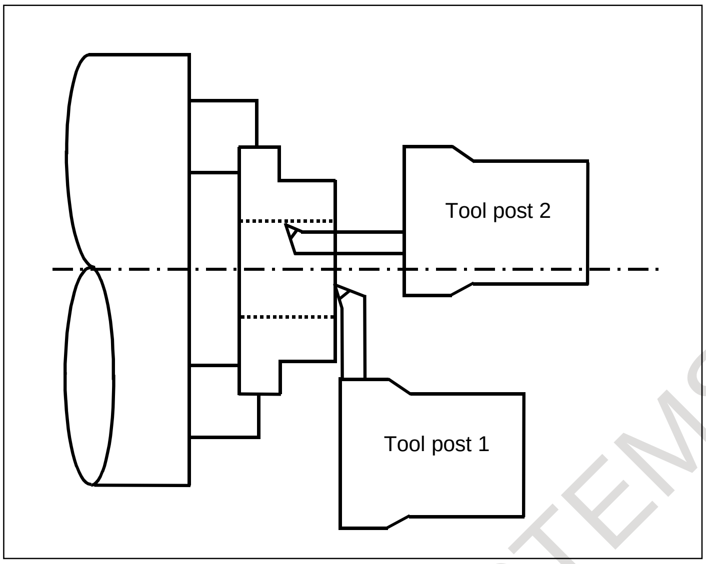


Fig. 8.4 (a)

The contours and shapes of the tool posts on individual paths are checked to determine whether or not interference occurs.

Explanation

- Data Setting for the Interference check for each path

To make a path interference check, data including the relationships between the tool posts on individual paths and interference forbidden areas (that is, tool shapes) needs to be set. The method of such data setting is described below.

- Setting the positions for reference points of tool posts on individual paths

X described below is the axis for which 1 (X-axis of the three basic axes) is set in parameter No. 1022 and Z is the axis for which 3 (Z-axis of the three basic axes) is set in the parameter. If an invalid value is set in this parameter, a path interference check is not made.

(1) Setting the reference points for a two-path interference check

When bit 7 (IFP) of parameter No. 8140 is set to 0, a two-path interference check is made.
When reference point return operation is completed with all axes (X1, Z1, X2, Z2), the reference point of tool post 1 is set at the origin of the ZX plane coordinate system. At this time, the position of the reference point of tool post 2 is set in a parameter.

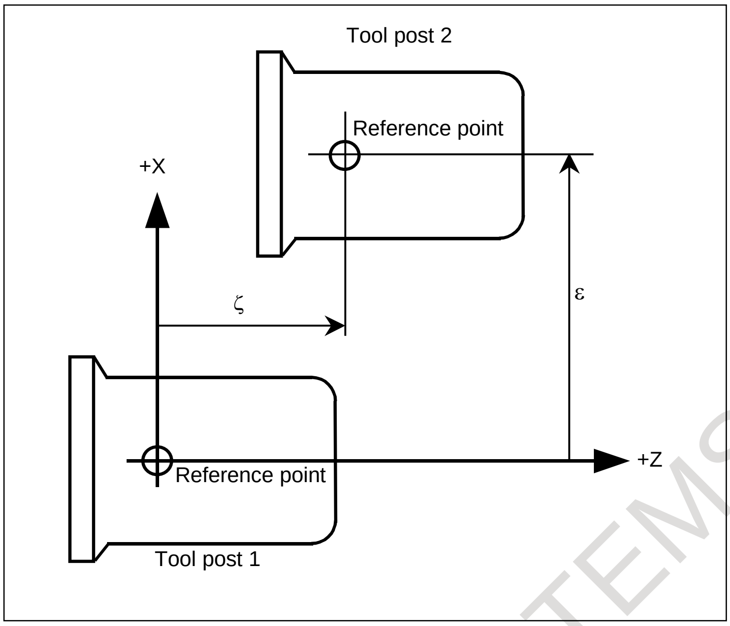

Fig. 8.4 (b)

In the ZX plane coordinate system at the origin of which the reference point of tool post 1 is set, set the X coordinate (ε) of the reference point of tool post 2 in parameter No. 8151, and its Z coordinate (ζ) in parameter No. 8152.
The unit of setting is the least command increment. For an axis subject to diameter specification, a diameter value is to be specified.
Measure (ε) and (ζ) when reference point return operation is completed with the four axes (X1, Z1, X2, Z2) (when the tools are in their reference points). When relative coordinate parameters Nos. 8151 and 8152 of the tool posts are to be updated, reference point return operation must always be completed with the four axes beforehand. Otherwise, the internally memorized relational positions of the tool posts are not updated to new parameter values.

- Setting the relationship between the coordinate systems for a two-path interference check

Set the relationship between the coordinate systems of the two tool posts using TY0 and TY1 (bits 0 and 1 of parameter No. 8140), with tool post 1 used as the reference.

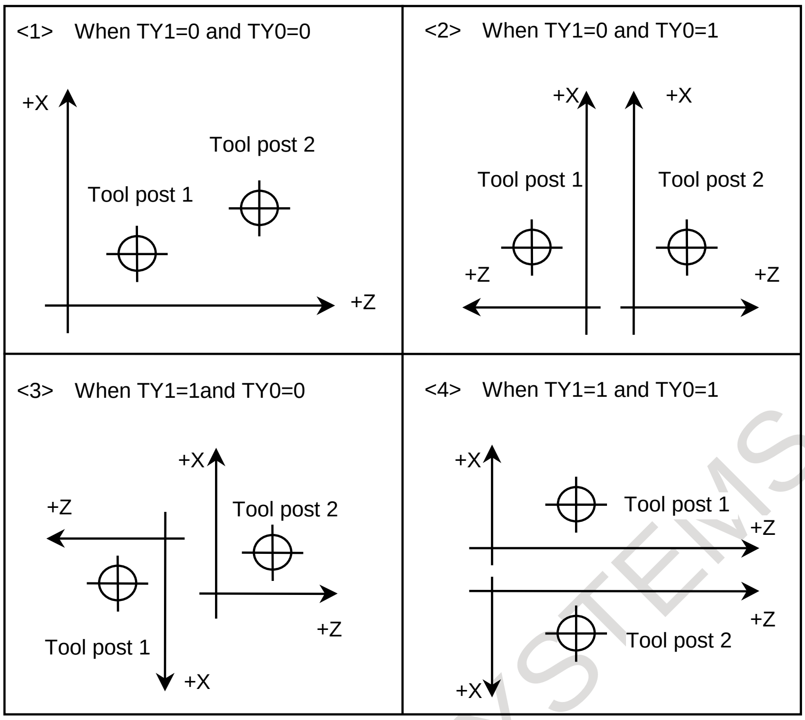

Fig. 8.4 (c)

(2) Setting the reference points for a multipath interference check

When bit 7 (IFP) of parameter No. 8140 is set to 1, multipath specifications are used, with which a multipath interference check is made. When reference position return operation is completed with all axes on all paths belonging to the same machine group, set the reference point of the tool post on path 1 belonging to the machine group as the origin of the ZX plane coordinate system. Also set the position of the reference point of the tool post on each of other paths in the coordinate system in parameters Nos. 8141 and 8143 (parameters for the X- and Z-axes are provided for each path).

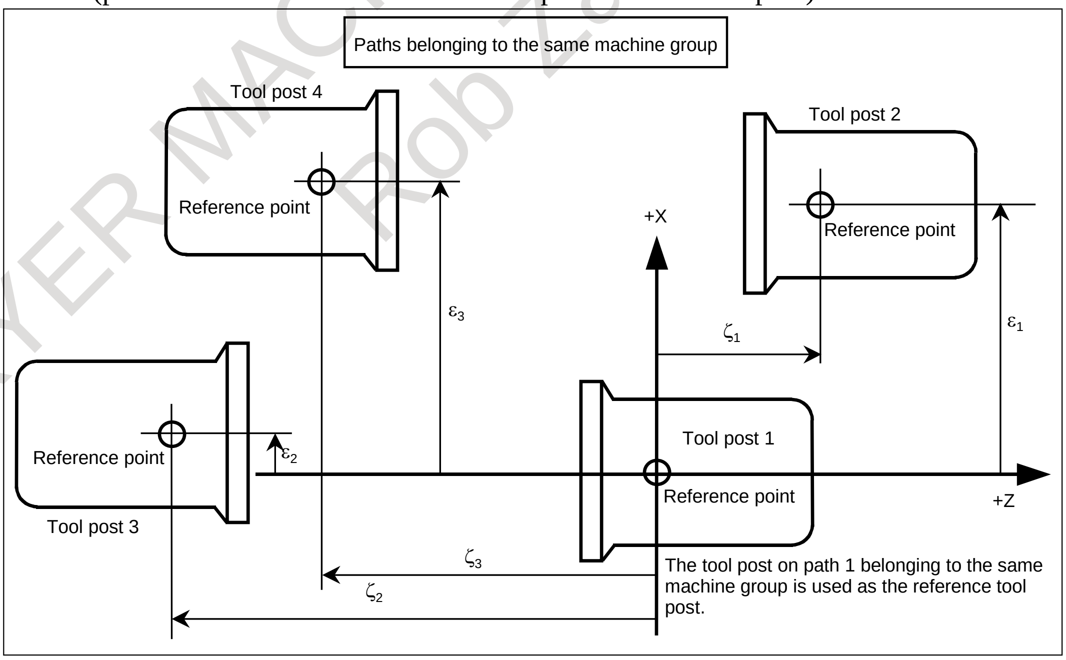

Fig. 8.4 (d)

In the example, Fig. 8.4 (d), there are the tool posts for four paths belonging to the same machine group. In the ZX plane coordinate system in which the reference point of tool post 1 on path 1 belonging to the same machine group is used as the origin, set the X coordinate (ε_1) of the reference point of tool post 2 on path 2 in parameter No. 8141 for path 2, and its Z coordinate (ζ_1) in parameter No. 8143.
In the same way, in the ZX plane coordinate system in which the reference point of tool post 1 is used as the origin, set the X coordinate (ε_2) of the reference point of tool post 3 on path 3 in parameter No. 8141 for path 3, and its Z coordinate (ζ_2) in parameter No. 8143. In the ZX plane coordinate system, set the X coordinate (ε_3) of the reference point of tool post 4 on path 4 in parameter No. 8141 for path 4, and its Z coordinate (ζ_3) in parameter No. 8143.
The unit of setting is the least input increment. For an axis subject to diameter specification, specify a diameter value.
Measure (ε_1, ζ_1), (ε_2, ζ_2), and (ε_3, ζ_3) when reference position return operation is completed with all axes (when the tools are in their reference positions). When updating a value of parameter No. 8141 or 8143 for each path, always perform reference position return operation with all axes on all paths. Otherwise, the internally stored relational positions of the tool posts are not updated to new parameter values.

- Setting the relationship between the coordinate systems for a multipath interference check

Select one of the following four relationships as the relationship between the coordinate system based on the reference point of the tool post on path 1 belonging to the same machine group and the position of each tool post and set it in parameter No. 8158 for the relevant path. The parameter setting indicates the positional relationship among the tool posts on the paths belonging to the same machine group.

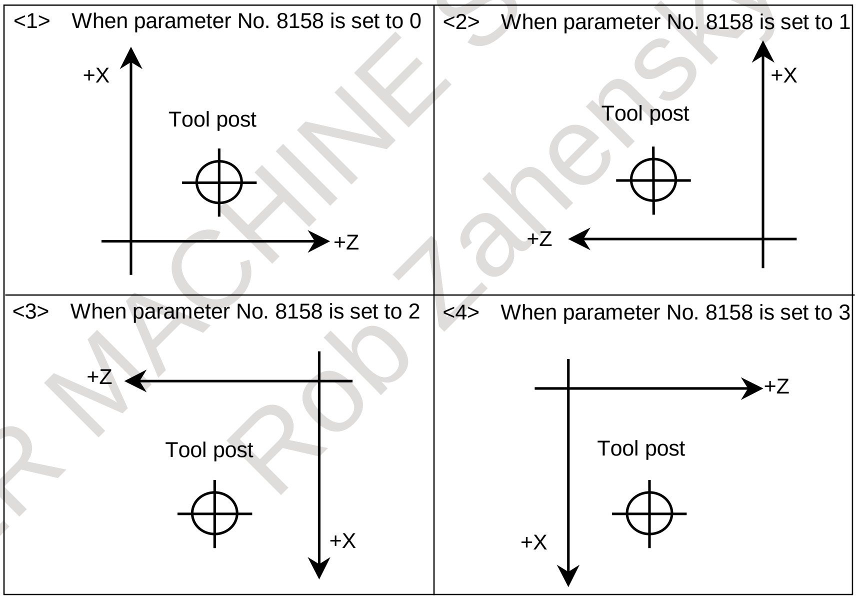

Fig. 8.4 (e)

For example, the parameter values are set as follows for each of the machine configurations in which the coordinate systems shown below are used.

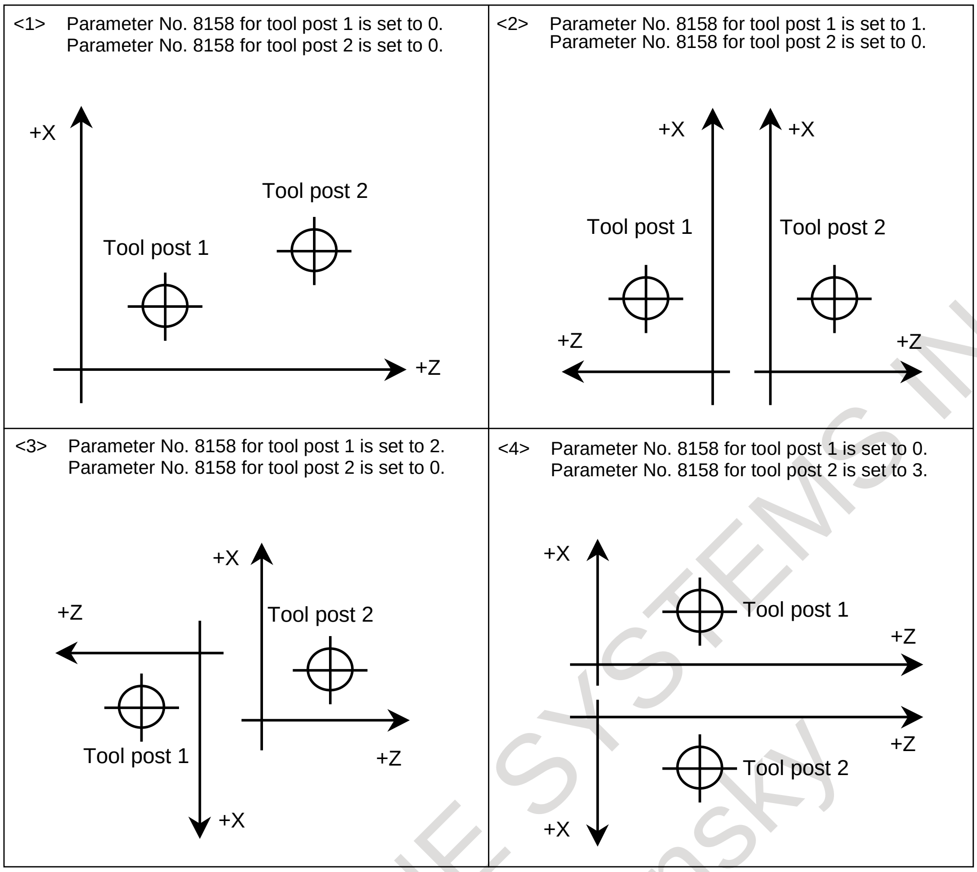

Fig. 8.4 (f)

- Specifying paths for which a multipath interference check is to be made

The following signals can be used to specify whether to make an interference check for the corresponding paths.

	#7	#6	#5	#4	#3	#2	#1	#0
Gn406					**ITF04**	**ITF03**	**ITF02**	**ITF01**

[Classification] Input signal

For these signals, the number assigned to each bit name indicates a path number.

These signals are available for individual paths (n = 0 to3, an area for signals for 4 paths is reserved). For each path, specify whether to make an interference check for each of other paths. To make an interference check, set the bit corresponding to a target path and the bit corresponding to the local path to 1.

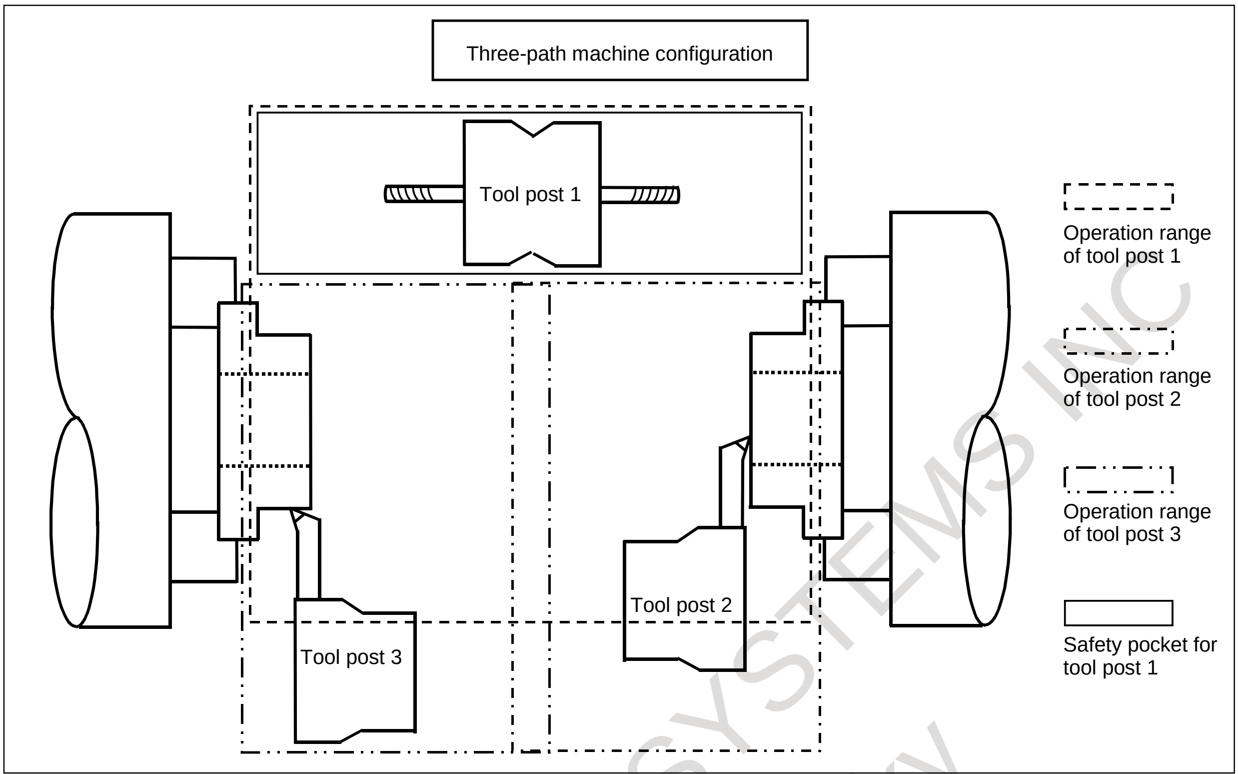

Fig. 8.4 (g)

For example, Fig. 8.4 (g), when the operation range of tool post 1 on path 1 overlaps with that of tool post 2 on path 2 and that of tool post 3 on path 3 as shown above, an interference check is required. In this sample machine configuration, however, tool post 1 is always positioned within the safety pocket in which the tool post does not interfere with path 2 or 3 when tool post 2 or 3 operates. In this case, for signals Gn406 for path 1, set the signals corresponding to paths 2 and 3 to 1 because an interference check must be made for the paths.

Path 1 Gn406 = 00000111

Paths 2 and 3 do not interfere with path 1, but the operation ranges of tool posts 2 and 3 overlap each other. In this case, an interference check is required and the setting is as follows:

Path 2 Gn406 = 00000110
Path 3 Gn406 = 00000110

- Setting the interference forbidden area (setting common to conventional and multipath specifications)

An interference forbidden area is set using a combination of two rectangular areas. The examples are shown below.

(Example 1)

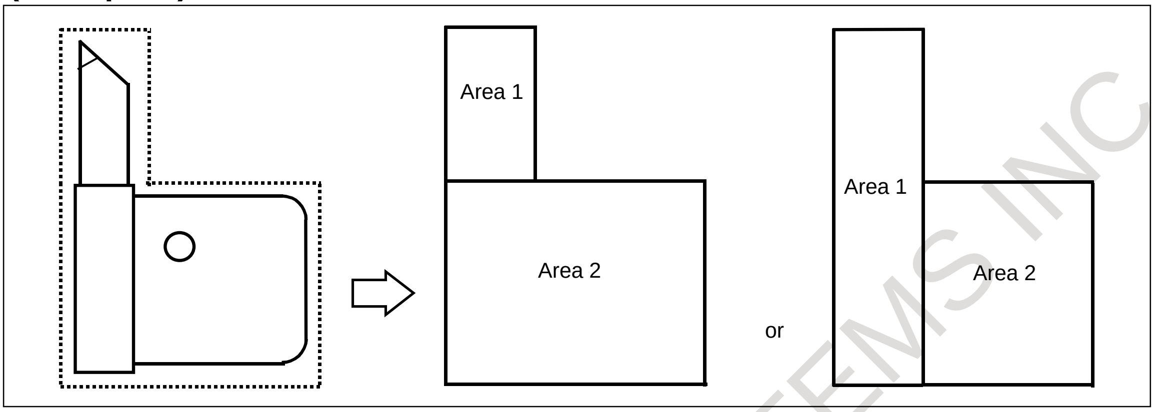

Fig. 8.4 (h)

(Example 2)

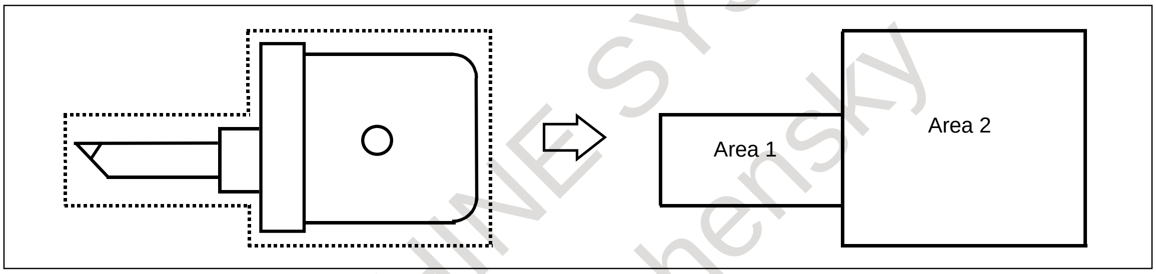

Fig. 8.4 (i)

The relative coordinates of the upper and lower ends (points A and B and points C and D shown below) of each of two rectangles are set, with the reference position of the tool post set as the origin.

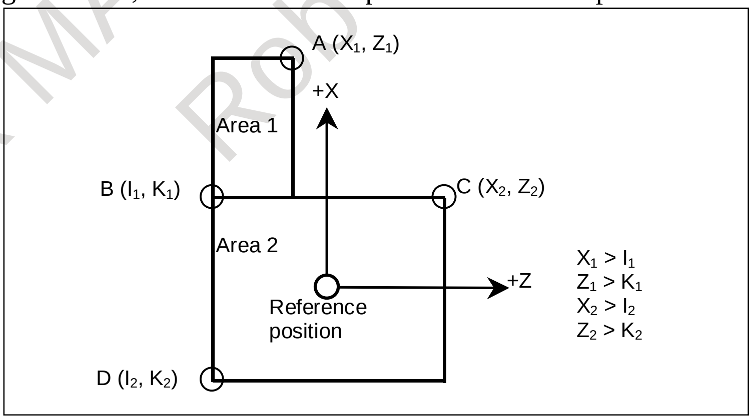

Fig. 8.4 (j)

Display and setting of an interference forbidden area in a multipath interference check

Display and set tool figure data (interference forbidden area) by performing the following operations:

(1) With the path selection signal, select a path for which an interference forbidden area is to be displayed and set in a multipath interference check.

(2) Press the function key .

(3) Press the chapter selection soft key [TOOL FIGURE].

(4) Display the screen including a tool number for which data is to be set.
Method 1: Switch the screen display by pressing the page key or cursor key.
Method 2: Enter a tool number to be set then press the [NO.SRH] soft key.

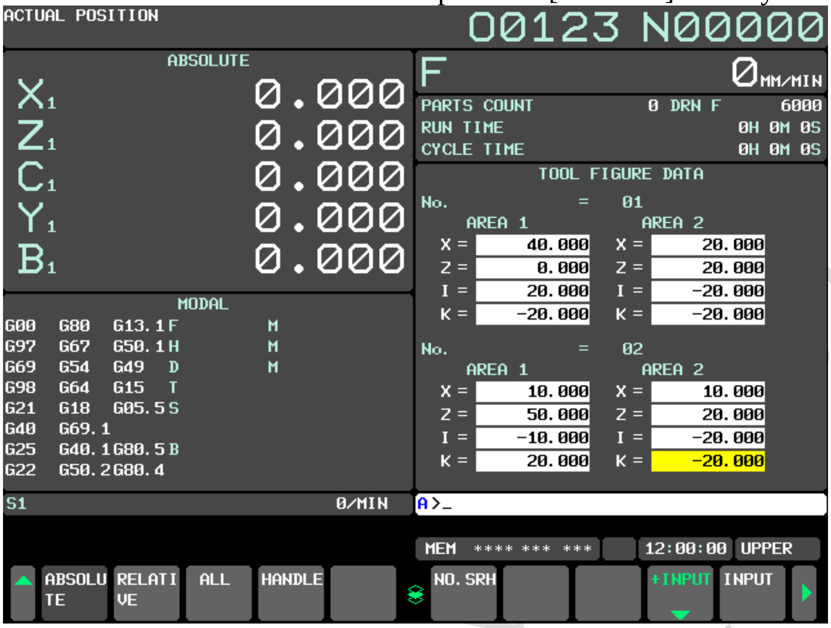

Fig. 8.4 (k)

(5) With the cursor keys, move the cursor to data to be set.
(When setting data for point A, move the cursor to X and Z. When setting data for point B, move the cursor to I and K.)

(6) Enter the coordinate values of point A or point B by using numeric keys.
(The decimal point can also be entered.)
Enter the coordinate values of point A or point B by using numeric keys.
(The decimal point can also be entered.)

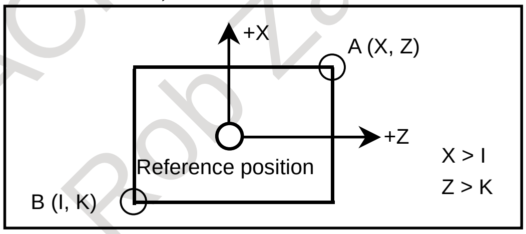

Fig. 8.4 (l)

(7) By pressing the soft key [INPUT], the entered coordinate values are set.
(To add an entered value to the already set data, press the soft key [+INPUT].)

NOTE

Tool number

Tool figure data needs to be set for each tool number. A tool number used here means an offset number. When both of geometry offset and wear offset are used, a tool number corresponds to a wear offset number. When multiple offset numbers are used for the same tool, the same data needs to be set as tool figure data.

- Conditions for Making a Path Interference Check

A path interference check is made when conditions listed below are satisfied.

(1) Common conditions

- Bit 4 (IFE) of parameter No. 8140 for enabling the path interference check function is set to 0.
- The X- and Z-axes of the three basic axes are set for parameter No. 1022 for individual paths for which a path interference check is to be made.
- After power is turned on, reference point return operation is completed with all axes. (When an absolute-position detector is used, the matching between a machine position and absolute-position detector position must be completed.)
- Offset numbers other than 0 are specified using T codes for tool posts on the paths for which a path interference check is made.
- Values are input in either one or both of the areas of the tool shape data corresponding to the specified tool number and the relationships among the values are X > I and Z > K.
- When manual mode is used, bit 3 (IFM) of parameter No. 8140 for enabling the interference check for each path function in manual mode is set to 1.

(2) Conditions for a multipath interference check

A multipath interference check is made when the conditions below as well as the common conditions are satisfied:

- Bit 7 (IFP) of parameter No. 8140 for enabling the multipath interference check function is set to 1.
- The path associated with each signal of Gn406 for each path exists.

(3) When the interference check conditions are satisfied

When all conditions for making a path interference check are satisfied, the path-interference-check-in-progress signal is output to the PMC.

> ⚠ **WARNING**
> To make a path interference check, the tool number for which tool shape data is input must agree with the programmed tool number. An interference check cannot be made correctly if the tool is selected by manual operation or if no tool select command is specified at power-on.

Signal

- For a check for interference between two paths

Path interference check in progress signal TICHK<F0064.6>

[Classification] Output signal

[Function] Informs whether a path interference check is in progress.

[Output cond.] This signal goes to "1" when:

- All conditions necessary to perform a path interference check on the tool posts of the first and second paths have been satisfied.

This signal goes to "0" when:

- Any one of the conditions necessary to perform a path interference check on the tool posts of the first and second paths have not been satisfied.

Path interference alarm signal TIALM<F0064.7>

[Classification] Output signal

[Function] Informs whether an alarm has occurred due to a path interference check.

[Output cond.] This signal goes to "1" when:

- The two tool posts are judged to interfere with each other while a path interference check is in progress on the tool posts of the first and second paths.

This signal goes to "0" when:

- The two tool posts are judged not to interfere with each other while a path interference check is in progress on the tool posts of the first and second paths.
- A path interference check is not performed (the path interference check signal TICHK is "0")

- For a multi-path interference check

Path interference check association signal ITF01 to ITF04 <Gn406>

[Classification] Input signal

[Function] Specifies the path subject to a path interference check.

ITFx

x : 01 Performs a path interference check with the tool post of the first path.
02 Performs a path interference check with the tool post of the second path.
03 Performs a path interference check with the tool post of the third path.
04 Performs a path interference check with the tool post of the fourth path.

[Operation] Performs a path interference check with the path for which "1" is set.
Be sure to set the bit corresponding to the local path to "1".

Path interference check in progress signal TICHK<Fn064.6>

[Classification] Output signal

[Function] Notifies whether a path interference check is in progress.

[Output cond.] This signal goes to "1" when:

- At least one of the paths associated by means of the Gn406 signals enters a state in which it can be subject to a path interference check with the tool post of the local path.

  Example)

  Assuming that the setting of the Gn406 signal of the 1st path is 00001101, and other settings are such that an interference check is to be performed with the tool posts of the third and fourth paths, F0064.6 of the first path will become "1" when the first path and either the third or fifth path enter the state in which they can be subject to a path interference check.

  If, at this time, the setting of the Gn406 signal of the third path is 00001100, and other settings are such that an interference check is to be performed with the tool post of the fourth path only, F2064.6 of the third path will become "1" when the third and fifth path enter the state in which they can be subject to a path interference check.

  As described above, ON/OFF timing differs depending on the settings of the Gn406 signals of each path.

This signal goes to "0" when:

- At least one of the conditions necessary to perform a path interference check on the too posts of the path associated by means of the Gn406 and Gn407 signals and of the local path is not satisfied.

Path interference alarm signal TIALM <Fn064.7>

[Classification] Output signal

[Function] Notifies whether an alarm has occurred due to a check for path interference.

[Output cond.] This signal goes to "1" when:

- The signal of the local path, Fn064.7 goes "1" if, while a path interference check is in progress on the tool posts of the paths associated by means of the Gn406 signals and of the local path, at least one of the associated paths is judged to have interfered because the tool post of the local path moved.

This signal goes to "0" when:

- While a path interference check is in progress on the tool posts of the paths associated by means of the Gn406 signals and of the local path, none of the associated paths is judged to have interfered.
- A path interference check is not in progress (the path interference check signal TICHK is "0")

Signal address

- For a 2-path interference check

	#7	#6	#5	#4	#3	#2	#1	#0
F0064	TIALM	TICHK						

- For a multi-path interference check

	#7	#6	#5	#4	#3	#2	#1	#0
Gn406					ITF04	ITF03	ITF02	ITF01

	#7	#6	#5	#4	#3	#2	#1	#0
Fn064	TIALM	TICHK						

Caution

- Items common to both 2-path interference and multi-path interference checks

NOTE

1 If an alarm occurs due to a path interference check, first switch to manual mode, manually retract the tool post of the path in which the alarm occurred to a position without interference, then perform a reset to cancel the alarm on the control unit. By manually retracting the tool post, the TIALM signal <G0064.7> will become "0" at the point when the tool post associated with the interference is judged not to interfere. (This can be used as a guideline: If, after a tool post has interfered, retracting it manually, you have only to retract it until the TIALM signal <G0064.7> becomes "0".)

2 If an alarm occurs due to a path interference check, the axis and direction of movement that were assumed at that time will be stored, so that the tool can no longer be moved in the stored direction along the stored axis until the alarm on the control unit is canceled with a reset. (Any start that will result in further interference will be prohibited.)

3 If an interference alarm occurs, the tool post will stop before the interference position if bit 7 (BFA) of parameter No. 1300 is set to 1.
If this parameter is set to 0, the CNC and the machine system will stop somewhat later than the correct time, the positions at which they actually stop will be closer to the other tool post that the interference position specified in tool figure data. For safety, therefore, the tool figure data must be somewhat larger than necessary. The excess distance L may be calculated from the rapid traverse rate.
L = (Rapid traverse rate) x 1/7500
If, for example, the rapid traverse rate is 15 m/min, the figure data must be larger by about 2 mm.

- Item for a 2-path interference check only

NOTE

Besides the common items, there is a note on a 2-path interference check only. If, during a path interference check, the tool posts of the two paths are judged to have interfered with each other, both the paths are decelerated to a stop and the control unit enters the alarm state. If this occurs, the path interference alarm signal TIALM <F0064.7> is set to "1" to notify that an alarm has occurred in a path interference check.

- Item for a multi-path interference check only

> **NOTE**
> Besides the common items, there is a note on a multi-path interference check only.
> If, during a path interference check, the tool posts of the paths associated with the Gn406 signals of each path are judged to have interfered with each other, all the paths associated are decelerated to a stop, and the paths related to the interference (paths in which movement was in progress) enter the alarm state. Other associated paths enter the operation pause state. If this occurs, the tool post interference alarm signal TIALM <Fn064.7> of the path related to the interference is set to "1" to notify that a check has occurred in a path interference check.

Parameter

	#7	#6	#5	#4	#3	#2	#1	#0
1300	BFA							

[Input type] Setting input
[Data type] Bit path

#7 BFA When the stored stroke check 1, 2, or 3 alarm is issued, an interference alarm is issued with the inter-path interference check function (lathe system), or a chuck/tail stock barrier (lathe system) alarm is issued:
0: The tool stops after entering the prohibited area.
1: The tool stops before the prohibited area.

> **NOTE**
> 1. This parameter is valid even in AI contour control.
> 2. This parameter is invalid for the slave axis under axis synchronous control.

	#7	#6	#5	#4	#3	#2	#1	#0
8140	IPF		ZCL	IFE	IFM	IT0	TY1	TYO

[Input type] Parameter input
[Data type] Bit

#0 TY0
#1 TY1 This parameter sets the coordinate system relationship between two tool posts based on the tool post of path 1.
This parameter is used for checking the interference between two paths when bit 7 (IPF) of parameter No. 8140 is set to 0.

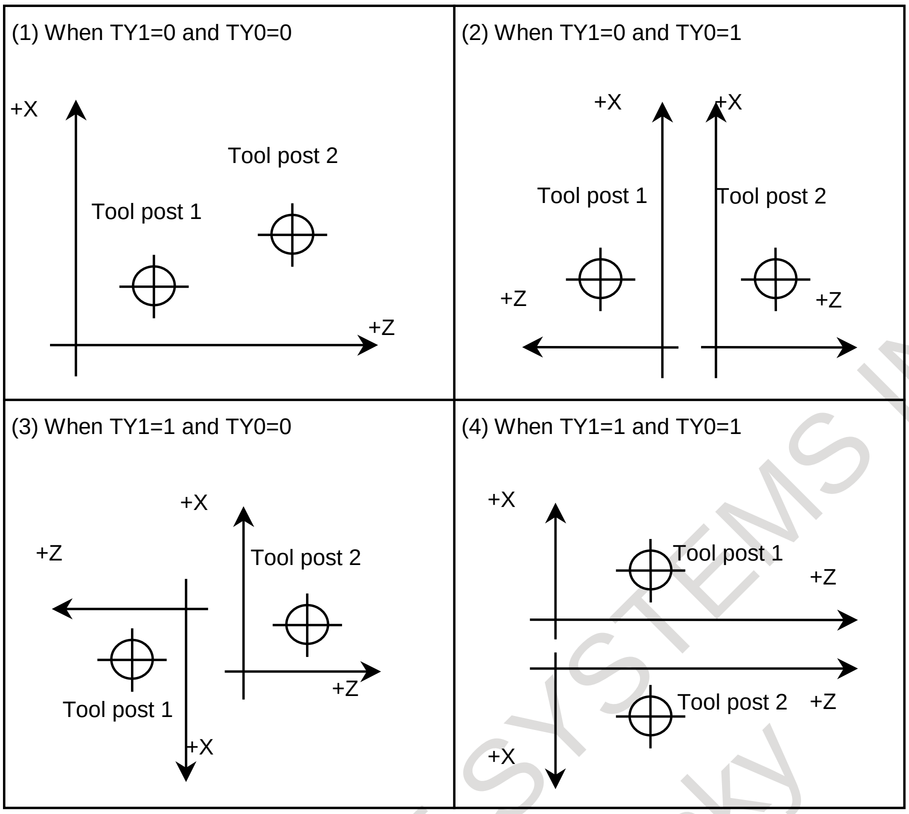

Fig. 8.4 (m)

#2 IT0 When offset number 0 is specified by the T code,
- 0: Checking interference between paths is stopped until an offset number other than 0 is specified by the next T code.
- 1: Checking interference between paths is continued according to the previously specified offset number.

#3 IFM In manual mode, a interference check between paths is:
- 0: Not performed.
- 1: Performed.

#4 IFE Interference check between paths is:
- 0: Performed.
- 1: Not performed.

#5 ZCL Specifies whether interference along the Z axis is checked while checking interference between paths.
- 0: Checked.
- 1: Not checked (Only interference along the X axis is checked.)

#7 IPF In inter-path interference checking:
- 0: The interference between two paths is checked.
- 1: The interference among multiple paths is checked.

Even in two-path control, the specification of a multi-path interference check can be applied.

If this parameter is set to 0 when three or more paths are controlled, a two-path interference check is made only with path 1 and path 2.

8141	Distance along the X axis between the reference positions of tool post 1 and tool post n in the same machine group

8143	Distance along the Z axis between the reference positions of tool post 1 and tool post n in the same machine group

[Input type] Parameter input
[Data type] Real path
[Unit of data] mm, inch (machine unit)
[Min. unit of data] Depend on the increment system of the applied axis
[Valid data range] 9 digit of minimum unit of data (refer to standard parameter setting table (A))
(When the increment system is IS-B, -999999.999 to +999999.999)

Each of these parameters sets the distance between the reference positions of the tool post of path 1 and tool post of each path in the same machine group.
Set 0 in parameters Nos. 8141 and 8143 for tool post 1 of each machine group.
For the lathe system, only a Z-X coordinate system based on parameters Nos. 8141 and 8143 is used for setting.

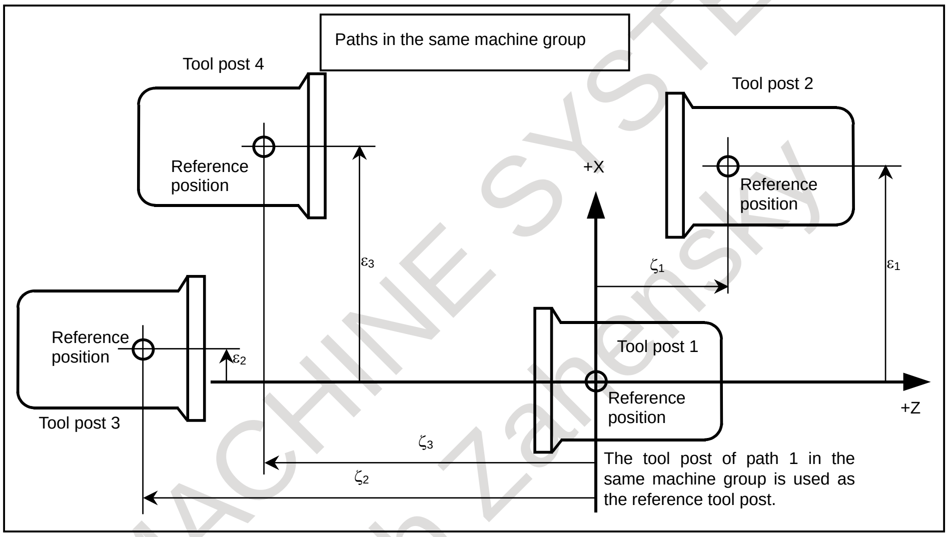

Fig. 8.4 (n)

In the example above (Fig. 8.4 (n), the same machine group contains tool posts for four paths. In the ZX plane coordinate system with its origin placed at the reference position of tool post 1 of path 1 in the same machine group, the position of the reference position of tool post 2 of path 2 is specified by setting the value ε_1 of the X component in parameter No. 8141 for path 2 and by setting the value ζ_1 of the Z component in parameter No. 8143 for path 2.
Similarly, In the ZX plane coordinate system with its origin placed at the reference position of tool post 1, the position of the reference position of tool post 3 of path 3 is specified by setting the value ε_2 of the X component in parameter No. 8141 for path 3 and by setting the value ζ_2 of the Z component in parameter No. 8143 for path 3. In the ZX plane coordinate system with its origin placed at the reference position of tool post 1, the position of the reference position of tool post 4 of path 4 is specified by setting the value ε_3 of the X component in parameter No. 8141 for path 4 and by setting the value ζ_3 of the Z component in parameter No. 8143 for path 4.
The unit of setting is the least input increment. For an axis based on diameter specification, make a setting using a diameter value.

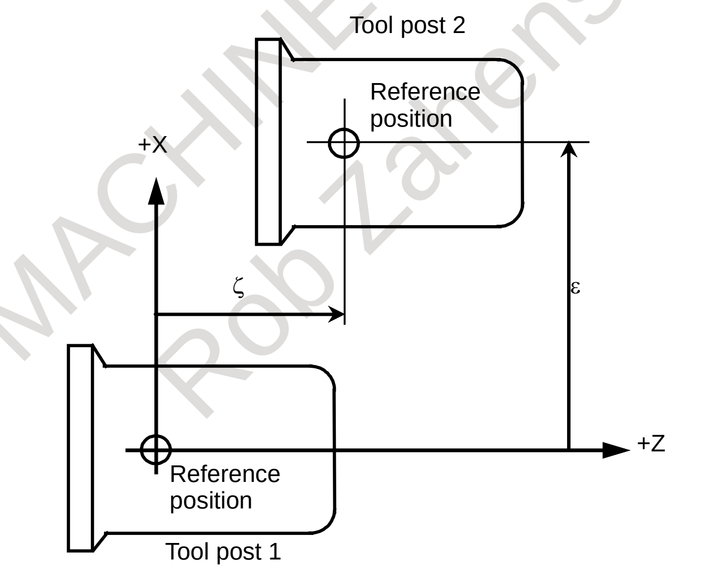
> ⚠ **WARNING**
> Measure (ε_1, ζ_1), (ε_2, ζ_2), and (ε_3, ζ_3) in the state where reference position return operation is completed for all axes (the tool is at the reference position.)
> After modifying parameters Nos. 8141 and 8143 for each path, be sure to perform a reference position return operation along all axes in all paths. Otherwise, the internally stored positional relationships of the tool posts are not updated to the newly set parameter values.

8151	**Distance along the X axis between the reference positions of tool posts 1 and 2**

8152	**Distance along the Z axis between the reference positions of tool posts 1 and 2**

[Input type] Parameter input
[Data type] Real
[Unit of data] mm, inch (machine unit)
[Min. unit of data] Depend on the increment system of the applied axis
[Valid data range] 9 digit of minimum unit of data (refer to standard parameter setting table (A))
(When the increment system is IS-B, -999999.999 to +999999.999)

These parameters are used for checking the interference between two paths when bit 7 (IPF) of parameter No. 8140 is set to 0.
Each of these parameters sets the distance between the tool posts of two paths.



In the Z-X plane coordinate system with its origin at the reference position of tool post 1, set the X component value ε of the reference position of tool post 2 in parameter No. 8151 and set the Z component value ζ in parameter No. 8152.

Fig. 8.4 (o)

> ⚠ **WARNING**
> After modifying the parameter values, perform a manual reference position return operation for both tool posts. Otherwise, the internally stored positional relationships of the two tool posts are not updated to the newly set parameter values.

8158	Coordinate system pattern with the reference position based on the tool post of path 1 in the same machine group

[Input type] Parameter input
[Data type] Byte path
[Valid data range] 0 to 3

This parameter is used for checking the interference among multiple paths when bit 7 (IPF) of parameter No. 8140 is set to 1.
This parameter sets a coordinate system pattern with the reference position based on the tool post of path 1 in the same machine group.

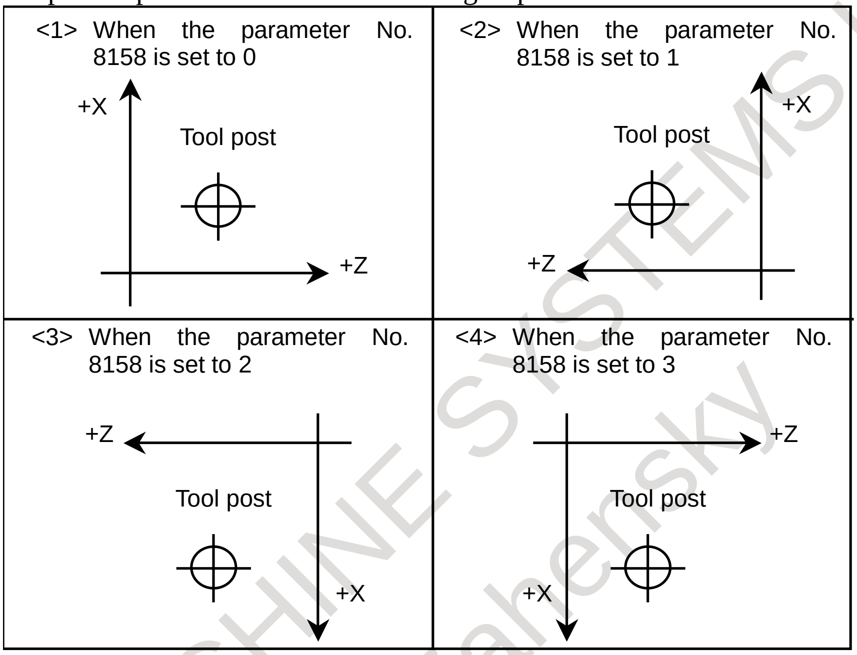


Fig. 8.4 (p)

Alarm and message

Number	Message	Description
PS0169	ILLEGAL TOOL GEOMETRY DATA	Incorrect tool figure data in interference check. Set correct data, or select correct tool figure data.
OT0508	INTERFERENCE:+	A tool moving in the positive direction along the n axis has fouled another tool post.
OT0509	INTERFERENCE:-	A tool moving in the negative direction along the n axis has fouled another tool post.

Alarms will occur individually for the axes associated with interference.

WARNING

⚠ WARNING

After setting parameters for the interference check function, tool figure data (contact prohibited area), etc., be sure to enter manual mode (parameter settings must be such that an interference check is enabled even in manual mode), let the tool post of each path interfere in all directions and confirm that a normal interference area has been set.

8.5 BALANCE CUTTING

T

Overview

When a thin workpiece is to be machined as shown below, a precise machining can be achieved by machining each side of the workpiece with a tool simultaneously; this function can prevent the warpage of the workpiece that can result when only one side is machined at a time (see the Fig. 8.5). When both sides are machined at the same time, the movement of one tool must be in phase with that of the other tool. Otherwise, the workpiece can vibrate, resulting in poor machining. With this function, the movement of one tool post can be easily synchronized with that of the other tool post.

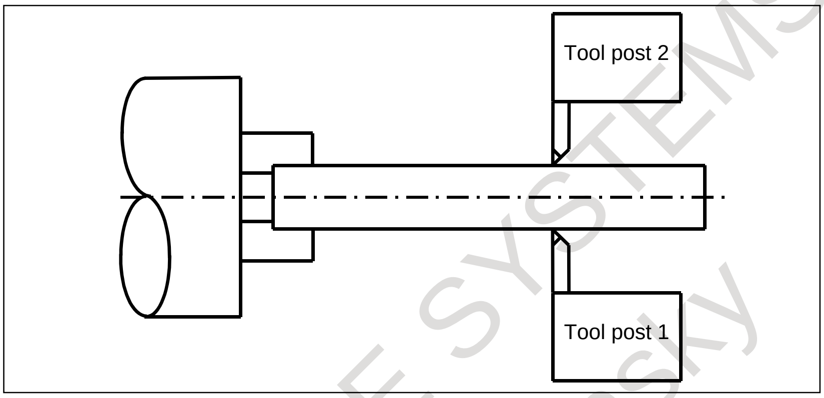

Fig. 8.5

Specifying G68, which turns balance cutting mode on, causes balance cutting to be performed with the tool post of path 1 and that of path 2. Alternatively, specifying address P in the same block as that containing the G64 command causes balance cutting to be performed between any tool posts.
Address P to be specified in the same block as G68, which turns balance cutting mode on can be set in either of two ways:

- When the bit 1 (MWP) of parameter No. 8103 is set to 0 :
  Balance cutting with a binary value specification
- When the bit 1 (MWP) of parameter No. 8103 is set to 1 :
  Balance cutting with a path number combination specification

NOTE
1 Balance cutting is not performed in dry run or machine lock state. G68 or G69 specified for one tool post is synchronized with G68 or G69 specified for the other tool post, however.
2 In the balance cut mode, G68 specified for one tool post is not synchronized with G68 specified for the other tool post. In the balance cut cancel mode, G69 specified for one tool post is not synchronized with G69 specified for the other tool post.
3 Balance cutting is not performed in a block in which 0 is specified for the travel distance.
4 Balance cutting is not performed when rapid traverse is specified.

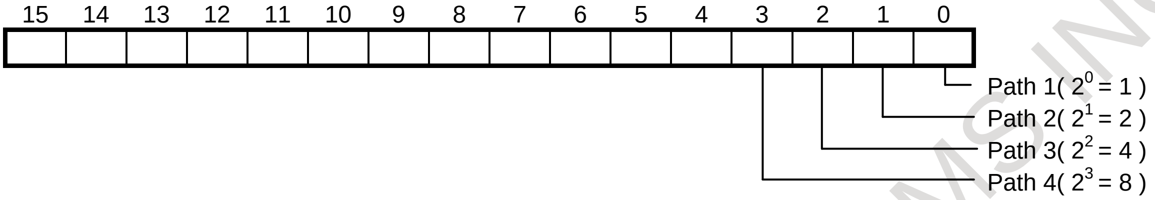
- Balance cut specified with binary values

When bit 1 (MWP) of parameter No. 8103 is set to 0, the value specified at address P is assumed to be obtained using binary values. The Table 8.5 (a) lists the path numbers and corresponding binary values.

Table 8.5 (a)

Path number	Binary value (decimal number)	Path number	Binary value (decimal number)
1	1	6	32
2	2	7	64
3	4	8	128
4	8	9	256
5	16	10	512

The bit position of each path in binary representation is shown below.



To perform balance cutting for all of paths 1, 2, and 3, the P value is obtained as follows:

Binary value of path 1	1 (0000 0000 0000 0001)
Binary value of path 2	2 (0000 0000 0000 0010)
Binary value of path 3	4 (0000 0000 0000 0100)
Sum	7 (0000 0000 0000 0111)

Balance cutting can be performed for all of the five paths by specifying P341 together with the balance cut G code (G68).

- Balance cut specified with a combination of path numbers

When bit 1 (MWP) of parameter No. 8103 is set to 1, the value specified at address P is assumed to be a combination of path numbers. The Table 8.5 (b) lists the path numbers and corresponding values.

Table 8.5 (b)

Path number	Value (decimal number)	Path number	Value (decimal number)
1	1	6	6
2	2	7	7
3	3	8	8
4	4	9	9
5	5	10	0

To perform balance cutting for all of paths 1, 2, and 3, the P value is a number consisting of 1, 2, and 3.
Example) P123
There are no restrictions on the order in which the numeric characters are specified, the following six possible values can be specified:

P123, P132, P213, P231, P312, P321

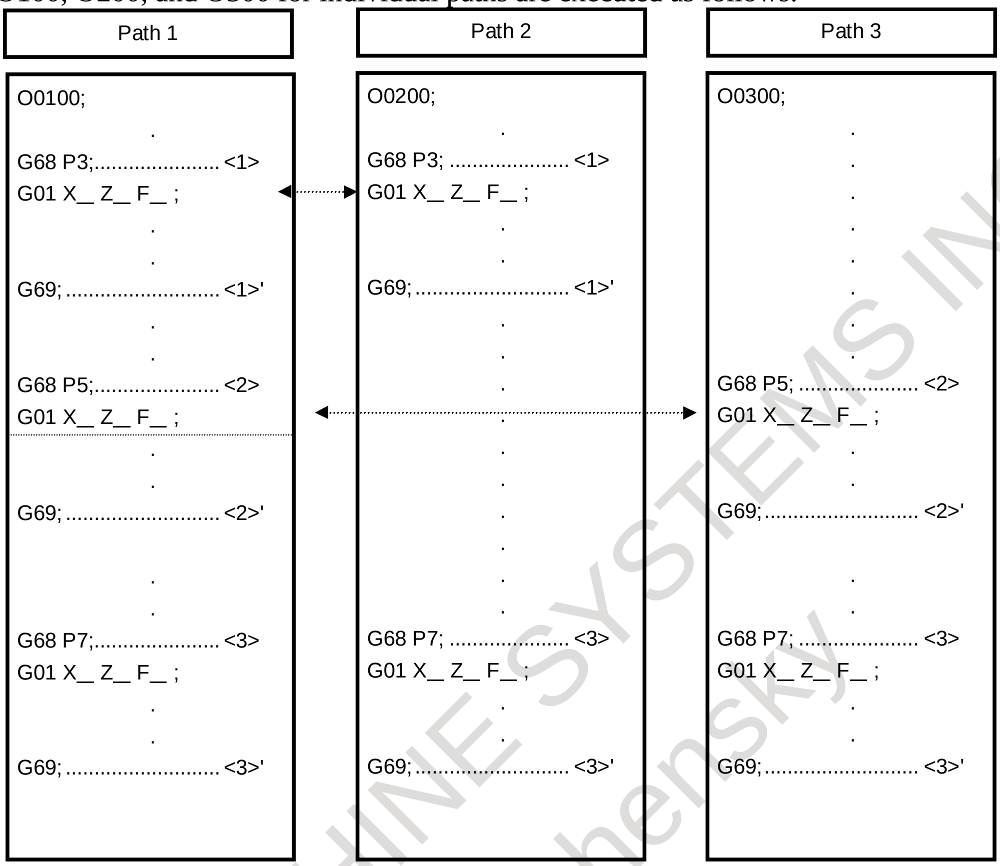
Path numbers specified in combination in different orders for different paths are effective as long as the numbers of the relevant paths are specified.
Example)

The following are treated as the same P value
M200P123 for path 1, M200P231 for path 2, and M200P321 for path 3

Program example

- When the value specified at P is obtained using binary values

Programs O100, O200, and O300 for individual paths are executed as follows:



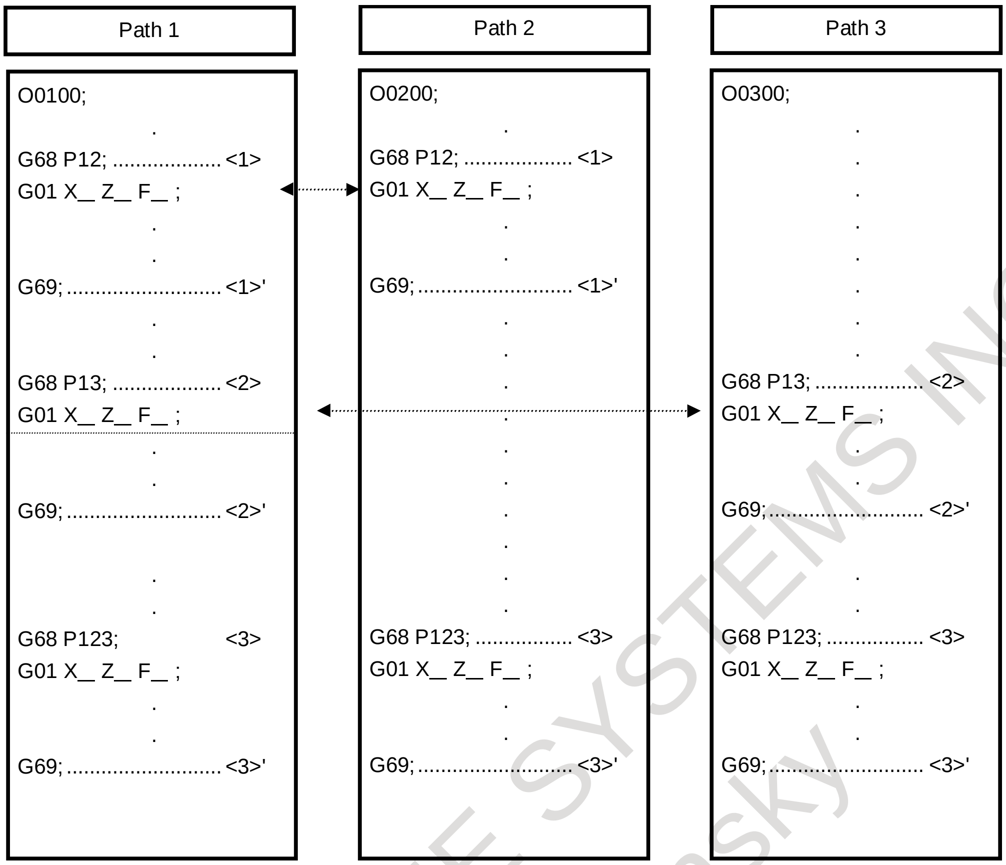
<1> G68 P3; (balance cut for paths 1 and 2)
Performs balance cutting for paths 1 and 2.
Balance cutting is performed according to the cutting feed commands between <1> and <1>'.

<2> G68 P5; (balance cut for paths 1 and 3)
Performs balance cutting for paths 1 and 3.
Balance cutting is performed according to the cutting feed commands between <2> and <2>'.

<3> G68 P7; (balance cut for paths 1, 2, and 3)
Performs balance cutting for paths 1, 2, and 3.
Balance cutting is performed according to the cutting feed commands between <3> and <3>'.

- When the value specified at P is obtained using path numbers in combination

Programs O100, O200, and O300 for individual paths are executed as follows:



<1> G68 P12; (balance cut for paths 1 and 2)
Performs balance cutting for paths 1 and 2.
Balance cutting is performed according to the cutting feed commands between <1> and <1>'.

<2> G68 P13; (balance cut for paths 1 and 3)
Performs balance cutting for paths 1 and 3.
Balance cutting is performed according to the cutting feed commands between <2> and <2>'.

<3> G68 P123; (balance cut for paths 1, 2, and 3)
Performs balance cutting for paths 1, 2, and 3.
Balance cutting is performed according to the cutting feed commands between <3> and <3>'.

Parameter

	#7	#6	#5	#4	#3	#2	#1	#0
8103							MWP	

[Input type] Parameter input
[Data type] Bit

> **NOTE**
> When this parameter is set, the power must be turned off before operation is continued.

#1 MWP To specify a P command for the waiting M code/balance cut:
0: A binary value is used as conventionally done.
1: A path number combination is used.

Caution

> ⚠ **CAUTION**
> 1 Balance cuting only starts cutting feed on both tool posts at the same time; it does not maintain synchronization thereafter. To synchronize all the movements of both tool posts, the setting for both tool posts, such as the travel distance and feedrate, must be the same. Override and interlock can be applied independently to both tool posts. The settings for both tool posts that are related to override and interlock must also be the same to perform balance cutting.
> 2 After feed hold is applied during execution of balance cutting for both tool posts, balance cutting is not performed at the restart. Balance cutting is performed when the next move command is executed for both tool posts.

Note

> **NOTE**
> 1 Time delay before the pulse distribution of both tool posts is started is 2 msec or shorter.
> 2 Overlap is invalid. In the balance cut mode, synchronization is established at the start of each move block in which cutting is specified, so movement can momentarily stop.
> 3 In the balance cut mode, continuous thread cutting overlap is also invalid. Perform continuous thread cutting in the balance cut cancel mode.
> 4 To establish synchronization at the start of pulse distribution in a block in which thread cutting is specified, the same PC must be selected.
> 5 The cancel mode (G69) is unconditionally set by a reset.
> 6 When the mirror image for double turrets is selected, the balance cut function cannot be used.

Alarm and message

Number	Message	Description
PS0163	ILLEGAL COMMAND IN G68/G69	G68 and G69 are not independently commanded in balance cut. An illegal value is commanded in a balance cut combination (address P).

8.6 SYNCHRONOUS/COMPOSITE CONTROL

Overview

Multi-path control, which has multiple independent control paths built in, is used for such purposes as controlling multiple turrets of a complex lathe. The axes (such as X1-and Z1-axes) belonging to path 1 are controlled by commands in path 1, and the axes (such as X2- and Z2-axes) belonging to path 2 are controlled by commands in path 2.

- Independent control in each path

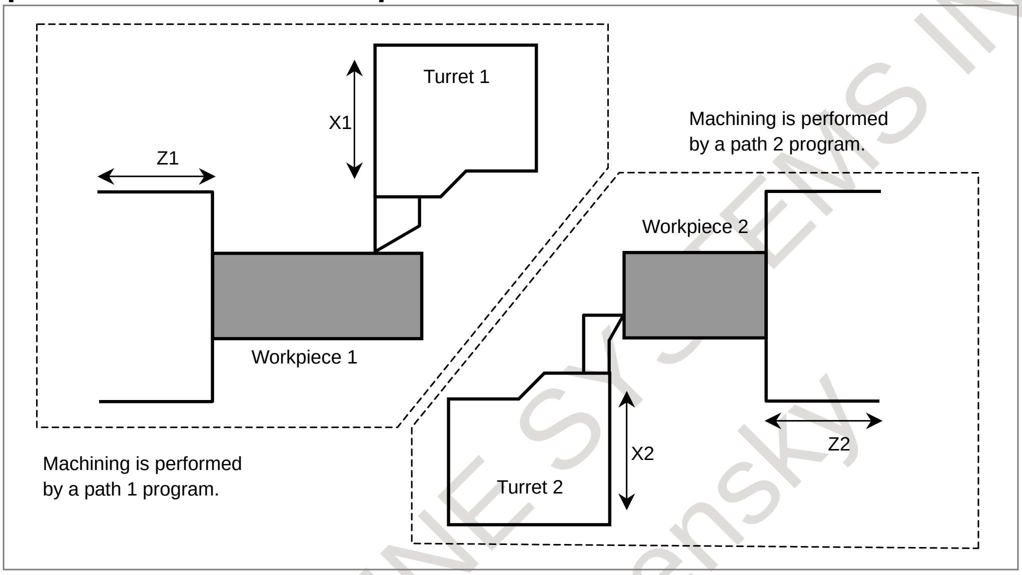


Fig. 8.6 (a)

This function enables synchronous control between paths or within a path, composite control between paths, and superimposed control between paths, as explained below.

- Synchronous control

- Synchronization of an axis in one path with an axis in another path
  (Example)
  Synchronization of the Z1-axis (master) with the Z2-axis (slave)

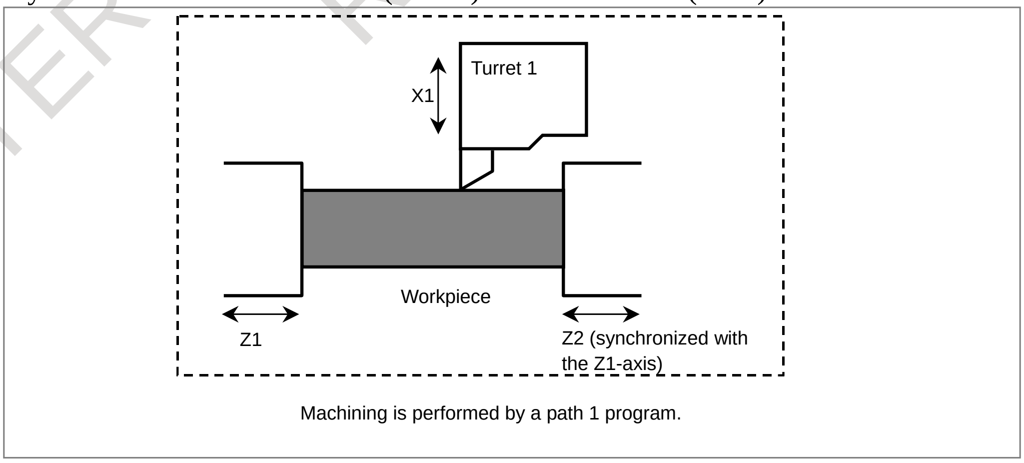

Fig. 8.6 (b)

- Synchronization of an axis in one path with another axis in the same path
  (Example)
  Synchronization of the Z1-axis (master) with the B1-axis (slave)

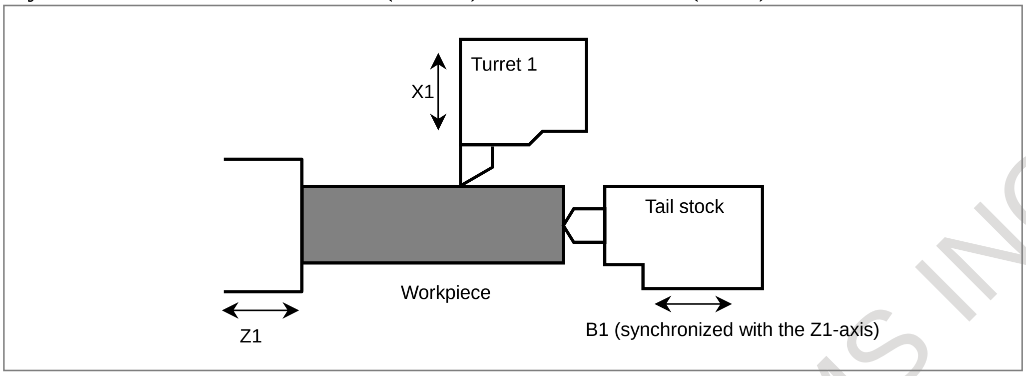

Fig. 8.6 (c)

- Composite control

- Interchanging move commands for an axis in one path with those for an axis in another path.
  (Example)
  Interchanging commands between the X1- and X2-axes
  → Control both X2- and Z1-axes by commands in a path 1 program
  Control both X1- and Z2-axes by commands in a path 2 program

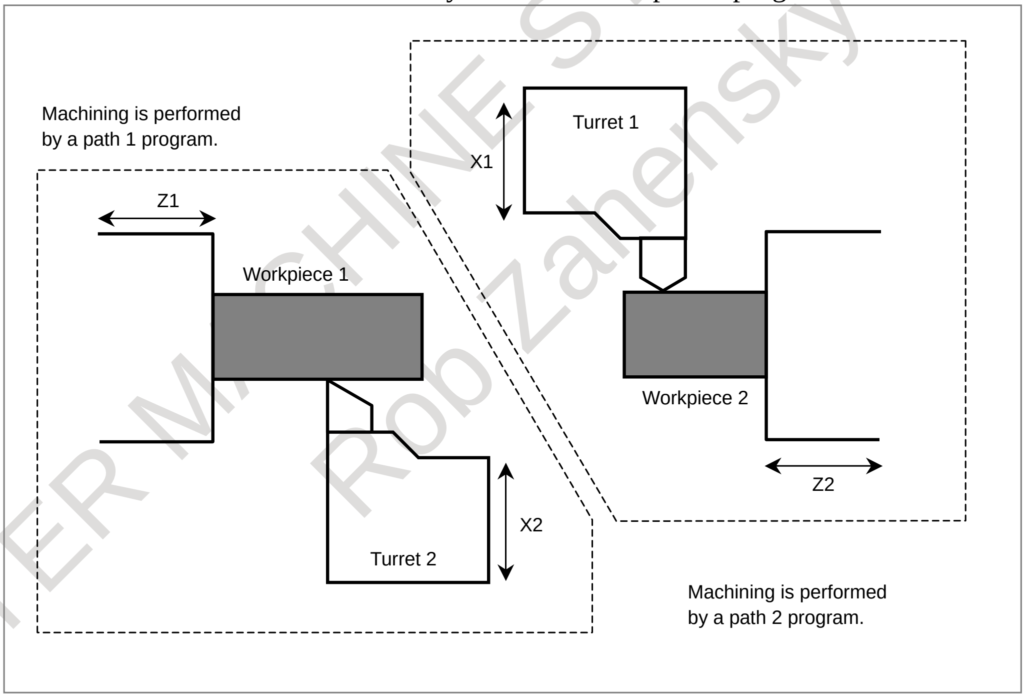

Fig. 8.6 (d)

8.6.1 Synchronous Control

An axis in one path can be synchronized with another axis in the same path or an axis in another path. This is done by issuing the same move commands for one axis (synchronous master axis) to another axis (synchronous slave axis). Using bit 0 (SMRx) of parameter No. 8162 can cause the slave axis to move in the direction opposite to that of the master axis. It is possible to place either the master or slave axis in a parking state, which means to discontinue giving move commands to a servo system. No coordinates are updated in the parking state. However, the absolute and relative coordinates can be updated using bit 2 (PKUx) of parameter No. 8162.

Explanation

- Setting

Specify which axis is to be the synchronous master axis, with parameter No. 8180, using the path number and the axis number.

(Example)

For an axis configuration in which all paths consist of X, Z, and Y axes

To synchronize the Z4-axis (slave) with the Z1-axis (master):

Parameter No. 8180z of path 4 = 102

To synchronize the X8-axis (slave) with the X5-axis (master):

Parameter No. 8180x of path 8 = 501

To synchronize the Y1-axis (slave) with the X1-axis (master):

Parameter No. 8180y of path 1 = 101

- Programming

Both before and after the M codes for a start and a cancellation of synchronous control, specify a waiting M code.

Master axis path	Slave axis path	
:	:	
M100P12;	M100P12;	Waiting
	M200;...........................	Start of synchronous control
M101P12;	M101P12;	Waiting
:	:	
Independent operation	Independent operation	
:	:	
M100P12;	M100P12;	Waiting
	M201;	Cancellation of synchronous control
M101P12;	M101P12;	Waiting
:	:	

- Signal operation

When synchronization begins or ends (when an M code is issued, for example), the synchronous control axis selection signals SYNC1 to SYNC8<Gn138> for the slave axis (from the PMC to the CNC) are changed from "0" to "1" (to begin synchronization) or from "1" to "0" (to terminate synchronization). To place an axis in a parking state, a parking signal PK1 to PK8<Gn122> is set to "1" for the target axis.

- Examples of applications

The following operations can be performed by using the synchronization functions together with the parking function, which causes move commands for an axis to be ignored and keeps the axis at a rest.

(1) Moving an axis in one path in synchronization with an axis in another path (Both master and slave axes move.)

Example 1)

Synchronizing the Z2-axis (slave) with the Z1-axis (master) (machining with both ends of a workpiece chucked)

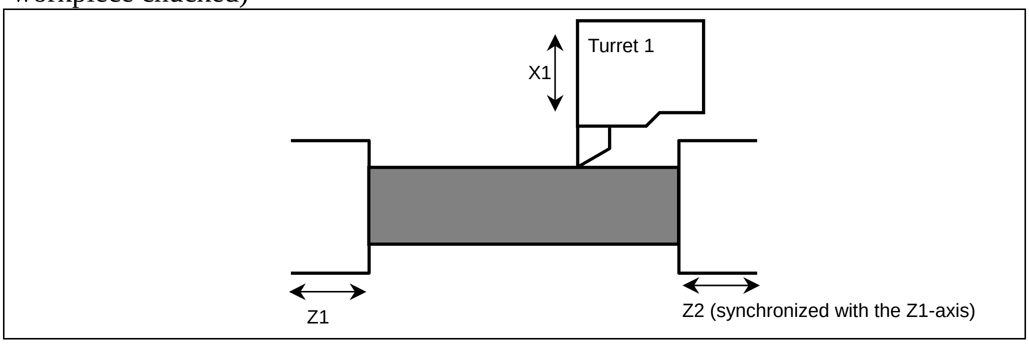

Fig. 8.6.1 (a)

Example 2)

Synchronizing the X2- and Z2-axes (master) with the X1- and Z1-axes (slave) (balance cutting)

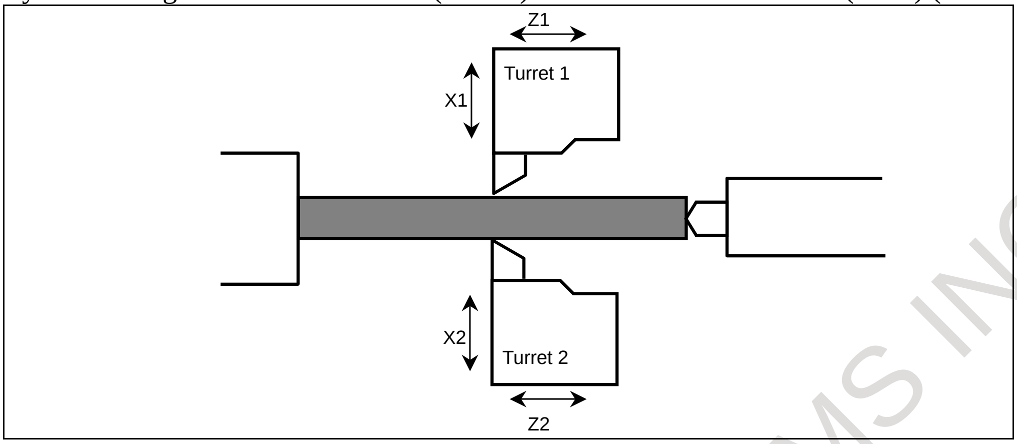

Fig. 8.6.1 (b)

Example 3)

Synchronizing the B1-axis (slave) (tail stock axis) with the Z1-axis (master)

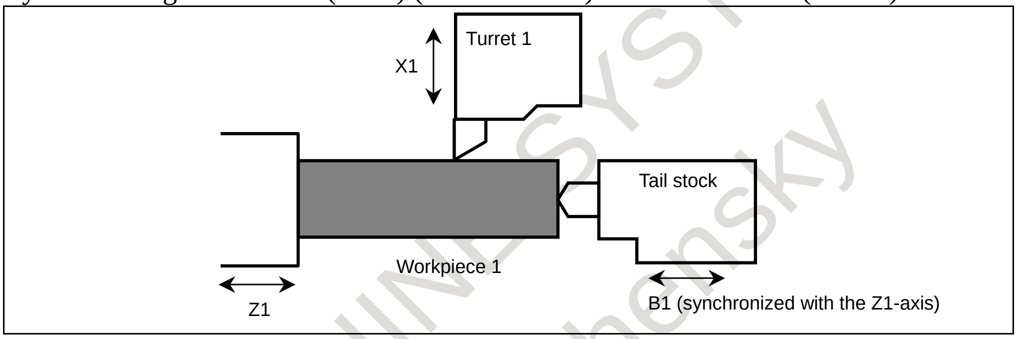

Fig. 8.6.1 (c)

(2) Placing the movement along the synchronous master axis in the stopped state using a parking signal is referred to as master parking. In this state, the tool will move along the slave axes only. In contrast, placing the synchronous slave axes in the stopped state is referred to as slave parking. In this state, the tool will move along the master axis only. This makes it possible to control a single motor from both paths 1 and 2.

Example 4)

Sharing one motor with the Z1- and Z2-axes (assuming that the motor is linked to the Z1-axis)

Master axis parking

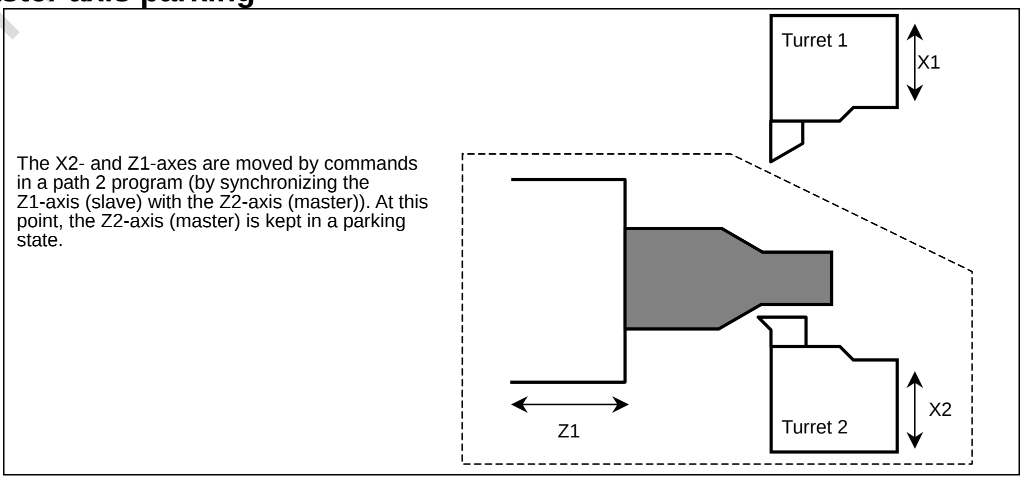

Fig. 8.6.1 (d)

Slave axis parking

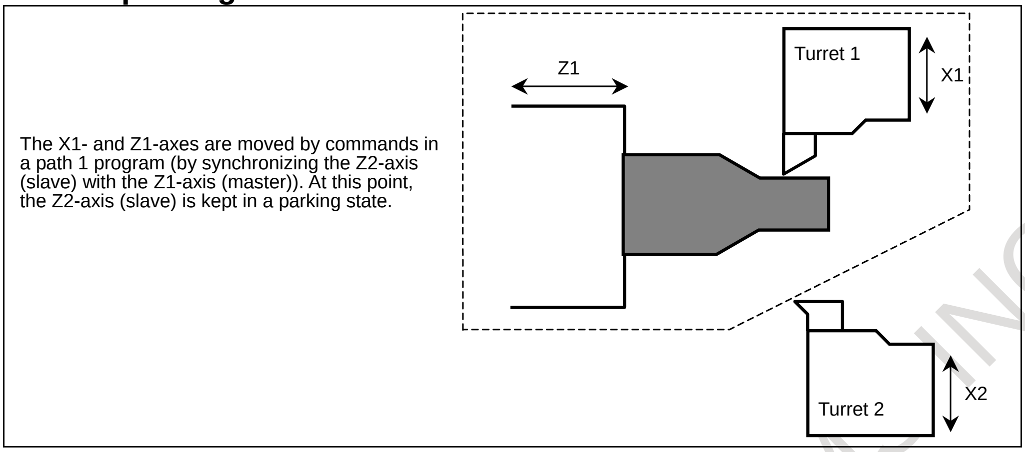

Fig. 8.6.1 (e)

Parking causes the positional relations between machine, absolute, and relative coordinates to shift. After reference position return, therefore, set the workpiece coordinate system.

- Reference position return and its check during synchronous control

If a reference position return command is issued for a synchronous master axis during synchronous control, it is executed normally for the master axis, but the slave axis does not return to its reference position (the slave axis only moves in synchronization with the reference position return of the master axis).
An exception is for automatic reference position return (G28) issued when the master axis is in a parking state, in which the amount of movement is calculated so that the slave axis returns to its reference position. In this case, a reference position return has been carried for the slave axis. If the reference position of the slave axis has not been established, alarm PS0354 “THE G28 WAS INSTRUCTED IN WITH THE REF POS NOT FIXED IN SYNC MODE” will result.

If, in Cs axis synchronous control, the master axis is not in the parking state and the reference position of the master axis has not been established, a reference position return operation will be performed in reference to the master axis machine position, with the G28 command for the master axis.
If the master axis is in the parking state and the reference position of the slave axis has not been established, a reference position return operation will be performed in reference to the slave axis machine position, with the G28 command for the master axis.

If more than one slave axis belongs to one master axis, a reference position return command is executed so that the lowest-numbered slave axis returns to its reference position. If the master axis in one path is subjected to both synchronization with an axis in the same path and synchronization with an axis in the other path simultaneously, the lowest-numbered slave axis in the two paths is moved to the reference position.

A return to the second (third or fourth) reference position by the G30 command works in the same way as G28. In other words, usually only the master axis moves to the second (third or fourth) reference position. If the master axis is parking, the lowest-numbered axis is caused to move to its second (third or fourth) reference position.
If a reference position return check (G27) is specified during synchronous control, the master and slave axes move to the specified position. Upon completion of movement, a check is made to see whether the master axis is at its reference position (no check is made for the salve axes) unless the master axis is in a parking state, in which case a check is made upon completion of positioning to see whether the lowest-numbered slave axis is at its reference position.

- Out-of-synchronization detection

The term synchronous control used here only refers to an operation in which the same move command is issued to multiple different servo systems at one time. Note that synchronous control does not involve out-of-synchronization compensation, in which the positional deviation between multiple servo motors is constantly checked and one of the servo motors is subjected to compensation to reduce the deviation. However, using bit 1 (SERx) of parameter No. 8162 can specify detection of out-of-synchronization.
When the out-of-synchronization state is detected, the synchronization mode is canceled immediately using bit 6 (SESx) of parameter No. 8169, alarm SV0407, “EXCESS ERROR” is issued and the servo ready signal is turned off, or the excess synchronization error signal SEO <Fn559> is output.

- Automatic setting of a workpiece coordinate system

When synchronous control is started in a workpiece coordinate system, it is possible to specify the workpiece coordinate system automatically. When synchronous control for a workpiece coordinate system is terminated, it is possible to return the workpiece coordinate system to ordinary machining (not synchronous control). The explanation of the workpiece coordinate system used during synchronous control follows. When synchronous control is used to move an axis differently from the way originally specified, for example, the master axis may be placed in a parking state, while the slave axis is allowed to move. In such a case, it will be convenient if a coordinate system that indicates the current position of the slave axis is used as a workpiece coordinate system for the master axis. Conventionally, this workpiece coordinate system must be specified by program when synchronous control is started, because the workpiece coordinate system does not originally belong to the master axis. This automatic workpiece coordinate system setting function for synchronous control sets up this workpiece coordinate system automatically. This function can also resume the original workpiece coordinate system for the master axis automatically. Note that the workpiece coordinates of a salve axis can be automatically set through appropriate parameter setting at the end of synchronous control only.

- Setting and commands

In addition to setting ordinary synchronous control, parameters must be specified as follows:

(1) To set up a workpiece coordinate system for synchronous control automatically when starting synchronous control
Set bit 1 (SPMx) of parameter No. 8163 to 1.
Set parameter No. 8185 with the coordinates of the slave axis reference position relative to the coordinates of the master axis when the master axis is at the reference position.

(2) To resume the ordinary workpiece coordinate system automatically when terminating synchronous control
Set bit 2 (SPSx) of parameter No. 8163 to 1. (Only the parameter of the master axis.)
Set parameter No. 1250 with the master axis coordinates in the workpiece coordinate system when the master axis is at the reference position.
This synchronous control can be specified using the synchronous control axis selection signals (SYNC1 to SYNC8) similarly to the ordinary synchronous control. When the signals are raised to start synchronous control, a workpiece coordinate system for the master axis is automatically set up. When the signals are dropped to terminate synchronous control, the original workpiece coordinate system for the master axis is resumed automatically.

- Workpiece coordinate calculation method

(1) Workpiece coordinate system for synchronous control
(Master axis workpiece coordinate value) = (parameter No. 8185 for the master axis)
± (slave axis machine coordinate value) .... <1>
+ (master axis machine coordinate value)............ <2>

<1> +: Bit 4 (SCDx) of parameter No. 8163 for the master axis = 0
-: Bit 4 (SCDx) of parameter No. 8163 for the master axis = 1

<2> Bit 3 (SCMx) of parameter No. 8163 for the master axis = 1 only

(2) Workpiece coordinate system for ordinary operation
(Master axis workpiece coordinate value)
= (parameter No. 1250 for the master axis) +(master axis machine coordinate value)

Caution

⚠ CAUTION
The same least command and input increments must apply to both master and slave axes.

Note

NOTE

1. If more than one slave axis is synchronized with one master axis, the master axis is set with the workpiece coordinate system that corresponds to the current position of the first slave axis that is synchronized with the master axis.
2. A coordinate system can also be set with consideration given to tool offset, through appropriate parameter settings. So, the coordinate system is set up normally even when tool geometry compensation is applied.

8.6.2 Composite Control

Move commands can be interchanged between an axis in one path and an axis in another path. In other words, when a machining program is executed for one path, actual machining can be performed with an axis in the other path. Coordinate systems can also be switched automatically between independent control and composite control.

Explanation

- Setting

Specify which axis is to interchange with which axis, with parameter No. 8183, using the path numbers and the axis numbers.

Example)

For an axis configuration in which all paths consist of X, Z, and Y axes
Between the Z1- and Z4-axes:

Parameter No. 8183z of path 4 = 102	Between the X5- and X8-axes:
Parameter No. 8183x of path 8 = 501	Between the X1- and Y2-axes:
Parameter No. 8183y of path 2 = 101	

To set up coordinate systems automatically when composite control begins or ends, set bits 4 (MPMx) and 5 (MPSx) of parameter No. 8162 to 1, and specify the positional relationship between the coordinate systems in parameter No. 8184.

- Programming

Both before and after the M codes for a start and a cancellation of composite control, specify a waiting M code.

Composite control source	Composite control destination
:	:
M100P12;	M100P12; ....Waiting
	M210;....................................Start of composite control
M101P12;	M101P12; ....Waiting
:	:
Independent operation	Independent operation
:	:

```
M100P12;            M100P12; ...............................Waiting
                    M211;  ..................................Cancellation of composite control
M101P12;            M101P12; ...............................Waiting
  :                   :
```

- Signal operation

When you want to start or cancel composite control (when you specify an M code, for example), change the composite control axis select signal between MIX1 and MIX8<Gn128> for the axis subject to composite control that is specified with parameter No. 8183 (the signal being sent from the PMC to the CNC) from "0" to "1" (to start composite control) and from "1" to "0" (to cancel composite control).

- Examples of applications

Suppose that a machine has the X1- and Z1-axes belonging to path 1 and the X2- and Z2-axes belonging to path 2 and that a workpiece moves along the Z1- and Z2-axes as directed by move commands. The following examples interchange commands between the X1- and X2-axes.

(1) Independent control

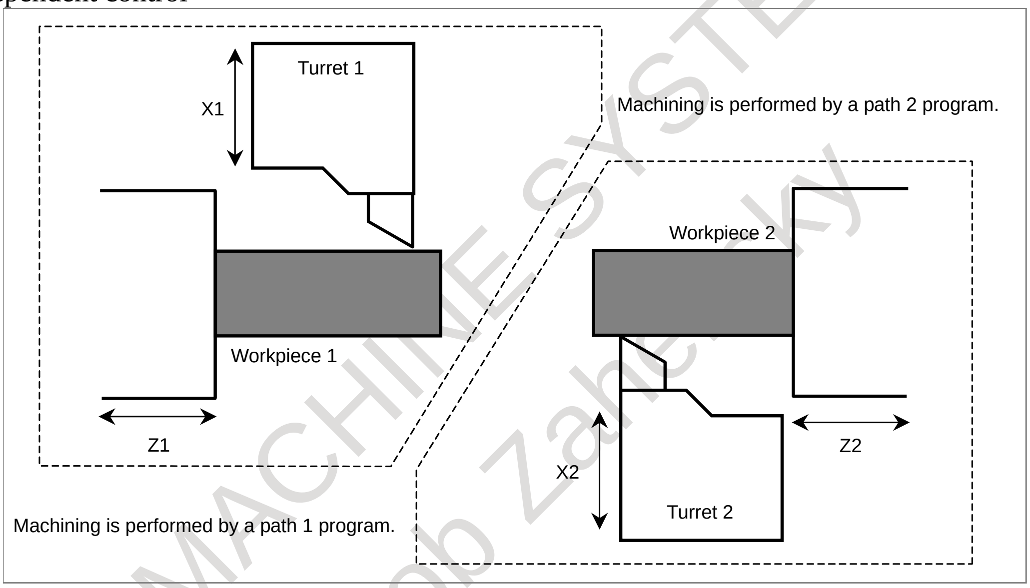

Fig. 8.6.2 (a)

(2) Composite control

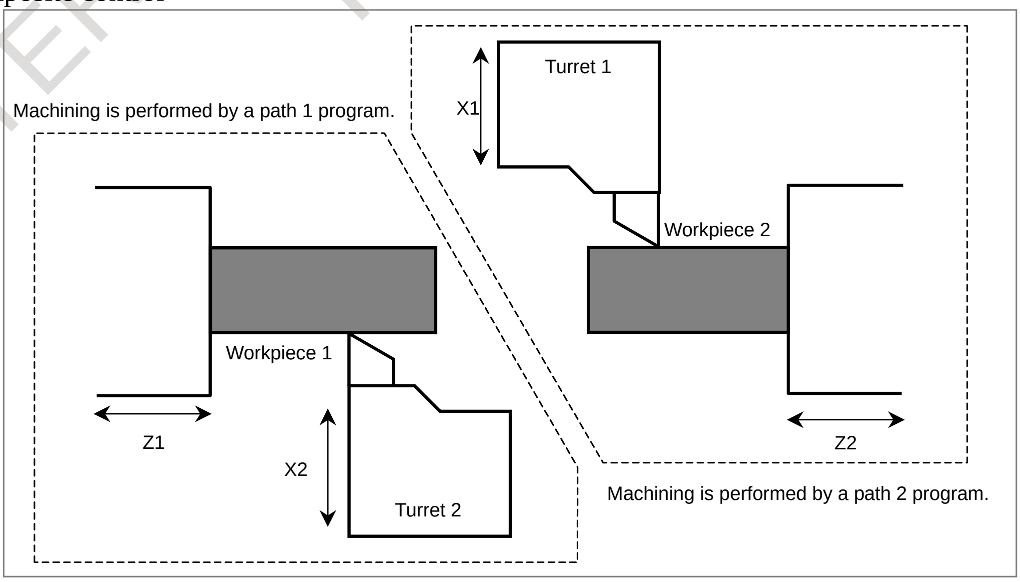

Fig. 8.6.2 (b)

During composite control, the X2- and Z1-axes are moved by a path 1 program, and the workpiece coordinates of the X-axis in path 1 indicates the position of turret 2. Similarly, the X1- and Z2-axes are moved by a path 2 program, and the workpiece coordinates of the X-axis in path 2 indicates the position of turret 1.

- Spindle control

The composite control function does not switch the spindle speed command or the feed per rotation command based on feedback pulses from the position coder. Therefore, the spindle speed command and feedback pulses should be switched using the spindle command selection signals and spindle feedback selection signals.

- Tool offset during composite control

At the time of a switch between independent control and composite control, the preset offset value, tool nose radius compensation/cutter compensation/tool length amounts will not be changed. After a control switch, you must issue a new T/D/H code command to set an offset value again, if required.

- Reference position return during composite control

If G28 is issued to specify an automatic reference position return for an axis in one path during composite control, an amount of movement is calculated so that the associated axis in the other path can move to the reference position. In this case, the reference position for that axis must have already been established. If the reference position of the axis of the other path subject to composite control has not been established, alarm PS0359 “THE G28 WAS INSTRUCTED IN WITH THE REF POS NOT FIXED IN COMP MODE” will result.
A manual reference position return is not allowed.
However, that during Cs axis composite control, a manual reference position return is allowed. If, after the establishment of a reference position and before a switch to composite control, you want to enter the state in which no reference position is established, set bit 5 (CRZ) of parameter No. 8161 to 1.

- Automatic workpiece coordinate system setting

By parameter setting, a workpiece coordinate system to be used during composite control can be automatically set when composite control is started. When composite control is terminated, the workpiece coordinate system can be automatically returned to the workpiece coordinate system used for ordinary machining not under composite control.
A workpiece coordinate system to be used during composite control is explained below. For example, when a movement is made on axes other than the specified axes by using composite control, it is convenient to use a coordinate system that indicates the current position on the movement axes, as a workpiece coordinate system for the specified axes. Such a workpiece coordinate system differs from the original workpiece coordinate system for the specified axes, so that the coordinate system needs to be set by programming when composite control is started. Moreover, the workpiece coordinate system needs to be returned to the original workpiece coordinate system for the specified axes when composite control is terminated. With this function, these coordinate systems can be set automatically.

Setting, command

When composite control is started, a workpiece coordinate system to be used during composite control is automatically set for axes with bit 4 (MPMx) of parameter No. 8162 set to 1. When composite control is terminated, the workpiece coordinate system can be automatically returned to the workpiece coordinate system used for ordinary machining not under composite control in connection with the axes with bit 5 (MPSx) of parameter No. 8162 set to 1.

To specify this function, the composite control axis change selection signals MIX1 to MIX32 are used as in the case of ordinary composite control. When composite control is started by turning on signals, a workpiece coordinate system for the composite axes is automatically set. Similarly, when composite control is canceled by turning off signals, a workpiece coordinate system for the composite axes is automatically set.

Workpiece coordinate calculation method

1) When no workpiece coordinate system (G54 to G59, including additional workpiece coordinate systems) is used, a coordinate value calculated from the coordinate value (parameter No. 8184) of the reference position on the composite control target axis in the workpiece coordinate system of the local axis and the machine coordinate value of the composite control target axis is set in a coordinate system at composite control start time.
In a coordinate system at composite control termination time, a coordinate value calculated from the coordinate value (parameter No. 1250) of the reference position used for automatic coordinate system setting on the local axis and the machine coordinate value on the local axis is set.
The method of coordinate value calculation is described below.

(Example)

Composite control where the X1-axis and X2-axis are replaced with each other

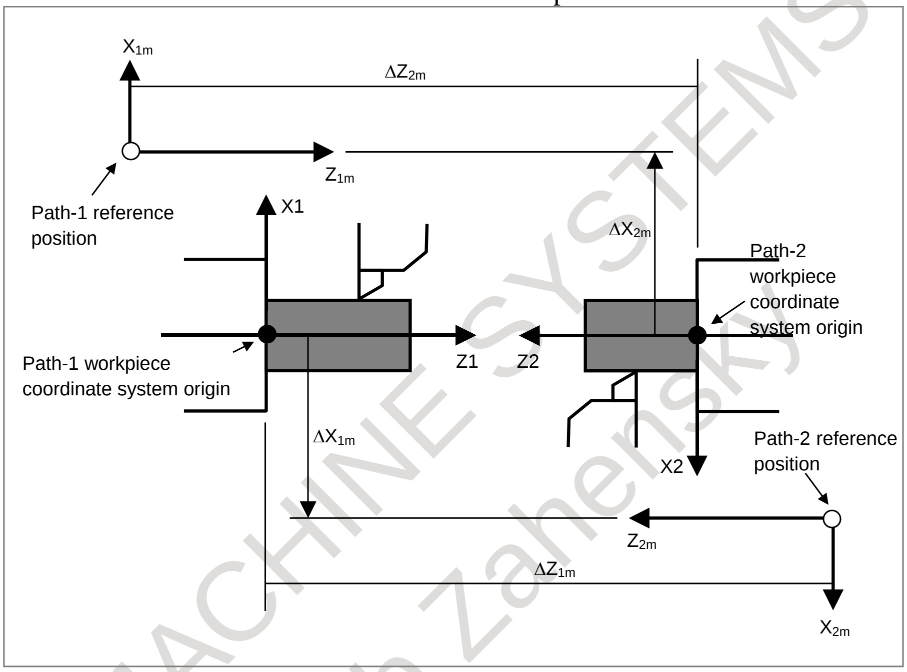

Fig. 8.6.2 (c)

The reference position of path 2 in the workpiece coordinate system of path 1 is at (ΔX1m,ΔZ1m). The reference position of path 1 in the workpiece coordinate system of path 2 is at (ΔX2m,ΔZ2m). Set ΔX1m in parameter No. 8184x for path 1. Set ΔX2m in parameter No. 8184x for path 2.

When composite control is started, a workpiece coordinate system is set to satisfy the following:
X1 = (Path-1 X-axis setting) ± (X2 machine coordinate value)
+ when bit 6 (MCDx) of parameter No. 8162 for path 1 = 0
– when bit 6 (MCDx) of parameter No. 8162 for path 1 = 1
X2 = (Path 2 X-axis setting) ± (X1 machine coordinate value)
+ when bit 6 (MCDx) of parameter No. 8162 for path 2 = 0
– when bit 6 (MCDx) of parameter No. 8162 for path 2 = 1

When composite control is terminated, a workpiece coordinate system is set to satisfy the following:
X1 = (Parameter No. 1250 for path 1) + (X1 machine coordinate value)
X2 = (Parameter No. 1250 for path 2) + (X2 machine coordinate value)

2) When a workpiece coordinate system (G54 to G59, including additional workpiece coordinate systems) is used, workpiece coordinate system preset operation (equivalent to G92.1 IP 0) is used for setting as described below, instead of coordinate values based on the calculation method of 1) above.
   When composite control is started, the workpiece coordinate system based on specified axes is preset to a workpiece coordinate system shifted on the specified axes by the currently valid workpiece origin offset values from the machine origin on the movement axes.
   When composite control is terminated, the workpiece coordinate system based on composite axes is preset to a workpiece coordinate system shifted on the local axes by the currently valid workpiece origin offset values from the machine origin on the local axes.

- Composite control between Cs contour control axes

When bit 4 (SMT) of parameter No. 8165 is set to 1, when composite control is executed between axes of Cs contour control, torque limit skipping is possible in the state of torque limit command signal TLMH and load detection signal LDT1 of the Cs contour control axis of the composite control destination.
The torque limit skip command (G31 P98 / P99) is commanded by composite control source.
For details of the torque limit skip for the Cs contour control, refer to "Cs Contour Control Torque Limit Skip".

For signal TLMH and signal LDT1, refer torelevant manuals such as "FANUC Spindle Motor α *i* series PARAMETER MANUAL" (B-65280EN).

Signals

Synchronous control axis selection signals SYNC1 to SYNC8<Gn138>

[Classification] Input signal
[Function] These signals perform synchronous control.
[Operation] When one of these signals becomes "1", the control unit:
Begins synchronous control in such a way that the corresponding axis becomes a slave axis.
The axis with which the slave axis is synchronized is determined by parameter No. 8180.

Parking signals PK1 to PK8<Gn122>

[Classification] Input signal
[Function] These signals place each axis in a parking state.
[Operation] When one of these signals becomes "1", the control unit:
- Places the corresponding axis in a parking state.
  If the corresponding axis is under synchronous control, it enters a parking state immediately regardless of whether the axis is moving. If a parking signal is set to "1" without specifying synchronous control, it is ignored.

Composite control axis change selection signals MIX1 to MIX8<Gn128>

[Classification] Input signal
[Function] These signals perform composite control.
[Operation] When one of these signals becomes "1", the control unit:
- Begins composite control over the corresponding axis.
  The axis with which the corresponding axis is controlled together is determined by parameter No. 8183.

> **NOTE**
> For bit 1 (MIX) of parameter No. 8166, only a single signal for path 1 is available.

Synchronous/composite/superimposed control under way signals SYN1O to SYN8O<Fn118>

[Classification] Output signal

[Function] These signals indicate each axis is being subjected to ssynchronous, composite, or superimposed control.

[Output cond.] These signals become "1" under the following condition:

- The corresponding axis is under synchronous, composite, or superimposed control.

These signals become "0" under the following condition:

- The corresponding axis is not under synchronous, composite, or superimposed control.

> ⚠ **CAUTION**
> Whether each axis is under synchronous or composite control does not always match whether the corresponding selection signal (synchronous control axis selection or composite control axis selection) has been issued or not. For example, if these signals are set to "1" during an alarm, they are ignored. If a servo alarm occurs during these types of control, they are terminated automatically. Before attempting to perform these types of control, always check the state of these signals.

Synchronous master axis confirmation signals SYCM1 to SYCM8<Fn341>

[Classification] Output signal

[Function] These signals notify whether the corresponding axes are synchronous master axes.

[Output cond.] These signals become "1" under the following condition:

- The corresponding axes are synchronous master axes.

These signals become "0" under the following condition:

- The corresponding axes are released from synchronous control.

Synchronous slave axis confirmation signals SYCS1 to SYCS8<Fn342>

[Classification] Output signal

[Function] These signals notify whether the corresponding axes are synchronous slave axes.

[Output cond.] These signals become "1" under the following condition:

- The corresponding axes are synchronous slave axes.

These signals become "0" under the following condition:

- The corresponding axes are released from synchronous control.

Composite axis confirmation signals MIXO1 to MIXO8<Fn343>

[Classification] Output signal

[Function] These signals notify whether the corresponding axes are composite control axes.

[Output cond.] These signals become "1" under the following condition:

- The corresponding axes are composite control axes.

These signals become "0" under the following condition:

- The corresponding axes are released from composite control.

Parking axis confirmation signals SMPK1 to SMPK8<Fn346>

[Classification] Output signal

[Function] These signals notify whether the corresponding axes are parking axes in synchronous control.

[Output cond.] These signals become "1" under the following condition:

- The corresponding axes are parking axes in synchronous control.

These signals become "0" under the following condition:

- The corresponding axes are released from synchronous control or from parking.

Excess synchronization error signals SEO1 to SEO8<Fn559>

[Classification] Output signal
[Function] These signals indicate whether excess synchronization error is detected.
[Operation] These signals become "1" under the following condition:
- Synchronization error exceeds the allowable range specified in parameter No. 8181.

These signals become "0" under the following condition:
- Synchronization error is within the allowable range specified in parameter No. 8181.

NOTE
1 These signals are valid when bit 1 (SERx) of parameter No. 8162 is set to 1 and bit 6 (SESx) of parameter No. 8169 is set to 1.
2 These signals are output to the slave axis.

Parameter

	#7	#6	#5	#4	#3	#2	#1	#0
8160	NRS	SPE	NCS					

[Input type] Parameter input
[Data type] Bit path

#5 NCS If an overtravel alarm is issued for an axis under synchronous, composite, or superimposed control, synchronous, composite, or superimposed control is:
0: Released.
1: Not released.

NOTE
If this parameter is 1 for any one of the paths in a machine group, it is assumed to be 1 for all the paths.

#6 SPE The synchronization deviation is:
0: The difference between the positioning deviation of the master axis and that of the slave axis.

1: The difference between the positioning deviation of the master axis and that of the slave axis plus the acceleration/deceleration delay.

> **NOTE**
> 1 When the master and slave axes have different acceleration/deceleration time constants, set 1.
> 2 SPE is valid when bit 1 (SERx) of parameter No. 8162 is set to 1. SPE is used to find a synchronization deviation for comparison with parameter No. 8181.

#7 NRS When the system is reset, synchronous, composite, or superimposed control is:
0: Released.
1: Not released.

	#7	#6	#5	#4	#3	#2	#1	#0
8161	NSR		CRZ					NMR

[Input type] Parameter input
[Data type] Bit

#0 NMR When an axis subject to composite control is placed in servo-off state:
0: Composite control is stopped
1: Composite control is not stopped, provided bit 0 (FUP) of parameter No. 1819 is set to 1 to disable follow-up for the axis.

#5 CRZ If the state of the composite control signal is switched in composite control on two axes under Cs contour control, the reference position establishment state of the two axes in composite control is:
0: Maintained. (The unestablished state is not assumed.)
1: Assumed to be unestablished.

#7 NSR When servo-off occurs with an axis in synchronous control:
0: Synchronous control is canceled.
1: Synchronous control is not canceled if follow-up operation is disabled for the axis (with bit 0 (FUPx) of parameter No. 1819 set to 1).

	#7	#6	#5	#4	#3	#2	#1	#0
8162	MUMx	MCDx	MPSx	MPMx		PKUx	SERx	SMRx

[Input type] Parameter input
[Data type] Bit axis

#0 SMRx Synchronous mirror-image control is:
0: Not applied. (The master and slave axes move in the same direction.)
1: Applied. (The master and slave axes move in opposite directions.)

#1 SERx The synchronization deviation is:
0: Not detected.
1: Detected.

> **NOTE**
> When both master and slave axes move in synchronization, the positioning deviations of the corresponding axes are compared with each other. If the difference is greater than or equal to the value specified in parameter No. 8181, an alarm occurs. When either axis is in the parking or machine-locked state, however, the synchronization deviation is not detected.

#2 PKUx In the parking state,

0: The absolute, relative, and machine coordinates are not updated.
1: The absolute and relative coordinates are updated. The machine coordinates are not updated.

> **NOTE**
> 1 With an axis for which polar coordinate interpolation (T series) is specified, set this parameter to 1. If this parameter is set to 0, a coordinate shift can occur when a single block stop or feed hold is performed in the polar coordinate interpolation mode (T series).
> 2 With an axis that is set to function as a synchronous master axis and synchronous slave axis at the same time (with bit 1 (SYWx) of parameter No. 8167), set this parameter to 1.
> 3 With an axis specified in the 3-dimensional coordinate conversion mode, set this parameter to 1. If this parameter is set to 0, the alarm PS0367 ”3-D CONV. WAS COMMANDED IN SYNC MODE AS THE PARAMETER PKUx(NO.8162#2) IS 0.” is issued.
> 4 When specify the G53 command during master parking, set this parameter to 1.

#4 MPMx When composite control is started, the workpiece coordinate system is:

0: Not set automatically.
1: Set automatically.

> **NOTE**
> When the workpiece coordinate system is automatically set at the start of composite control, it is calculated from the following:
> Current machine coordinates and the workpiece coordinates at the reference point of each axis (parameter No. 8184).
> When a workpiece coordinate system (G54 to G59, including additional workpiece coordinate systems) is used, however, instead of the coordinate value obtained by the above calculation, the workpiece coordinate value obtained by workpiece coordinate system presetting (equivalent to G92.1 IP 0) in the machine coordinate system of the other axis in composite control is set.

#5 MPSx When composite control is terminated, the workpiece coordinate system is:

0: Not set automatically.
1: Set automatically.

> **NOTE**
> When the workpiece coordinate system is automatically set at the end of composite control, it is calculated from the following: Current machine coordinates and the workpiece coordinates at the reference point of each axis under composite control (parameter No. 1250)
> When a workpiece coordinate system (G54 to G59, including additional workpiece coordinate systems) is used, however, instead of the coordinate value obtained by the above calculation, the workpiece coordinate value obtained by workpiece coordinate system presetting (equivalent to G92.1 IP 0) in the machine coordinate system of the local axis is set.

#6 MCDx The axes to be replaced with each other under composite control have the coordinate systems placed:

0: In the same direction. Simple composite control is applied. (A movement is made in the same direction along the corresponding axis.)

1: In opposite directions. Mirror-image composite control is applied. (A movement is made in the reverse direction along the corresponding axis.)

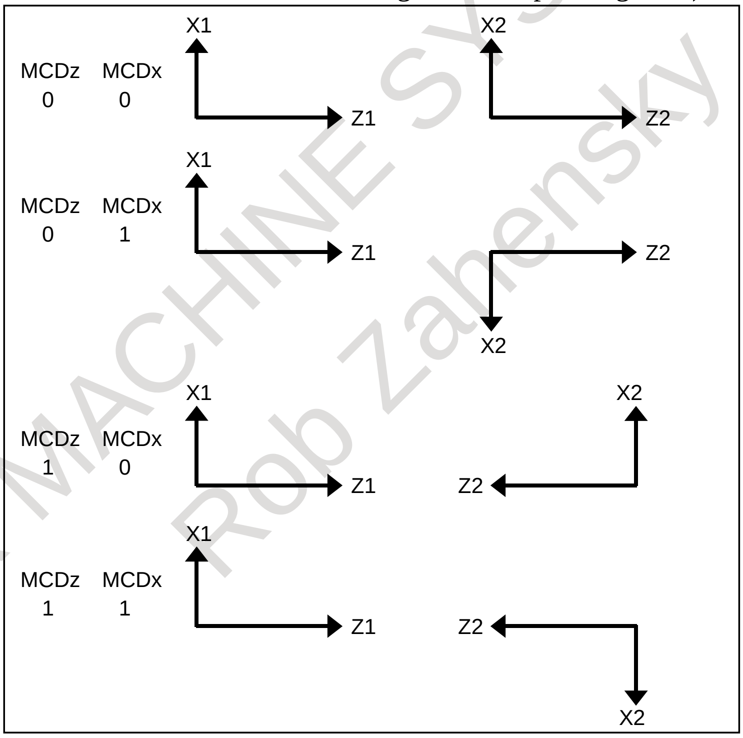

Fig. 8.6.2 (d)

#7 MUMx In composite control, a move command for the axis:

0: Can be specified.

1: Cannot be specified.

> **NOTE**
> Upon the execution of a move command along an axis for which MUMx is set to 1 during mixed control, alarm PS0353 is issued. For example, when axis X1 and axis X2 are placed under composite control, and a command for axis X2 (motor for axis X1) is to be disabled, set MUMx for path 2 to 1.

	#7	#6	#5	#4	#3	#2	#1	#0
8163	NUMx	MMIx	SMIx	SCDx	SCMx	SPSx	SPMx	

[Input type] Parameter input
[Data type] Bit axis

#1 SPMx When synchronous control is started, automatic workpiece coordinate system setting for the master axis is
0: Not Performed.
1: Performed.

> **NOTE**
> When a workpiece coordinate system is automatically set at the start of synchronous control, the workpiece coordinate system is calculated from the current machine coordinates and the workpiece coordinates of each axis at the reference position set in parameter No. 8185.

#2 SPSx When synchronous control terminates, automatic workpiece coordinate system setting for the master axis is:
0: Not performed.
1: Performed.

> **NOTE**
> When a workpiece coordinate system is automatically set at the end of synchronous control, the workpiece coordinate system is calculated from the current machine coordinates and the workpiece coordinates for each axis at the reference position set in parameter No. 1250.

#3 SCMx When workpiece coordinates are calculated in synchronous control:
0: The workpiece coordinates are calculated from the machine coordinates of the slave axis.
1: The workpiece coordinates are calculated from the machine coordinates of the master axis and slave axis.

#4 SCDx The positive (+) directions of the master axis and slave axis in the coordinate system in synchronous control are:
0: Identical.
1: Opposite.
Set the parameters SPMx, SPSx, SCMx, and SCDx for the master axis. These settings are referenced during automatic workpiece coordinate setting for the master axis at the start of synchronous control.

#5 SMIx In synchronous control, the manual handle interruption amount for the master axis or the mirror image mode is:
0: Reflected in the slave axis.
1: Not reflected in the slave axis.

When this bit (SMIx) is set to 0
Manual handle interruption :
To the travel distance along the slave axis, the interruption amount of the master axis is also added.
Mirror image :
When mirror image is applied to the master axis, mirror image is also applied to the slave axis.

When this bit (SMIx) is set to 1
Manual handle interruption :
To the travel distance along the slave axis, the interruption amount of the master axis is not added.
Mirror image :
Even when mirror image is applied to the master axis, mirror image is not applied to the slave axis.

#6 MMIx For a composite control axis, manual handle interruption under composite control is:
0: Enabled.
1: Disabled.

#7 NUMx When neither synchronous control nor composite control is applied, a move command for the axis is:
0: Not disabled.
1: Disabled.

> **NOTE**
> If a move command is specified for an axis with NUMx set to 1 when neither synchronous control nor composite control is applied, alarm PS0353 is issued.

	#7	#6	#5	#4	#3	#2	#1	#0
8164					MCEx	MCSx	MWEx	MWSx
					MCEx	MCSx		

[Input type] Parameter input
[Data type] Bit axis

#0 MWSx In automatic workpiece coordinate system setting, performed when composite control is started, a workpiece shift and position offset are:
0: Not considered.
1: Considered.

> **NOTE**
> When bit 4 (MPMx) of parameter No. 8162 is set to 1 and workpiece coordinate system (G54 to G59, including additional workpiece coordinate system) is not used, MWSx is enabled.

#1 MWEx In automatic workpiece coordinate system setting, performed when composite control is canceled, a workpiece shift and position offset are:
0: Not considered.
1: Considered.

> **NOTE**
> When bit 5 (MPSx) of parameter No. 8162 is set to 1 and workpiece coordinate system (G54 to G59, including additional workpiece coordinate system) is not used, MWEx is enabled.

#2 MCSx In automatic workpiece coordinate system setting, performed when composite control is started:
0: Parameter No. 8184 and the machine coordinate system of the composite control target path are used.
1: The absolute coordinate system of the composite control target path is used.

> **NOTE**
> When bit 4 (MPMx) of parameter No. 8162 is set to 1 and workpiece coordinate system (G54 to G59, including additional workpiece coordinate system) is not used, MCSx is enabled.

#3 MCEx In automatic workpiece coordinate system setting, performed when composite control is canceled:
0: Parameter No. 1250 and the machine coordinate system of the composite control target path are used.
1: The absolute coordinate system of the composite control target path is used.

> **NOTE**
> When bit 5 (MPSx) of parameter No. 8162 is set to 1 and workpiece coordinate system (G54 to G59, including additional workpiece coordinate system) is not used, MCEx is enabled.

	#7	#6	#5	#4	#3	#2	#1	#0
8165				SMT				

[Input type] Parameter input
[Data type] Bit

#4 SMT In composite control between Cs contour control axes, torque limit skip is:
0: Disabled
1: Enabled

	#7	#6	#5	#4	#3	#2	#1	#0
8166							MIX	

[Input type] Parameter input
[Data type] Bit

> **NOTE**
> When this parameter is set, the power must be turned off before operation is continued.

#1 MIX For composite control:
0: An interface for three paths or more is used. In this case, set the composite control axis selection signals MIX1 to MIX8 for the axis that is placed under composite control by parameter No. 8183, from “0” to “1” or from “1” to “0”.

1: The conventional 2-path interface is used. (Composite control on three paths or more is disabled.) In this case, set parameter No. 8183 for path 2, and use the composite control axis selection signals of path 1.

	#7	#6	#5	#4	#3	#2	#1	#0
8167		SPVx	SWSx	SWMx	SGSx	SGMx	SYWx	
		SPVx					SYWx	

[Input type] Parameter input
[Data type] Bit axis

#1 SYWx The axis is:
0: Not used as a master axis and slave axis at the same time.
1: Used as a master axis and slave axis at the same time.

#2 SGMx In automatic workpiece coordinate system setting at the start of synchronous control, a tool offset is:
0: Considered.
1: Not considered.

> **NOTE**
> SGMx is enabled when bit 1 (SPMx) of parameter No. 8163 is set to 1.

#3 SGSx In automatic workpiece coordinate system setting at the end of synchronous control, a tool offset is:
0: Considered.
1: Not considered.

> **NOTE**
> SGSx is enabled when bit 2 (SPSx) of parameter No. 8163 or bit 6 (SPVx) of parameter No. 8167 is set to 1.

#4 SWMx In automatic workpiece coordinate system setting at the start of synchronous control, a workpiece shift is:
0: Not considered.
1: Considered.

> **NOTE**
> SWMx is enabled when bit 1 (SPMx) of parameter No. 8163 is set to 1.

#5 SWSx In automatic workpiece coordinate system setting at the end of synchronous control, a workpiece shift is:
0: Not considered.
1: Considered.

> **NOTE**
> SWSx is enabled when bit 2 (SPSx) of parameter No. 8163 or bit 6 (SPVx) of parameter No. 8167 is set to 1.

#6 SPVx At the end of synchronous control, automatic workpiece coordinate system setting for the slave axis is:
0: Not performed.
1: Performed.

> **NOTE**
> When a workpiece coordinate system is automatically set at the end of synchronous control, the workpiece coordinate system is calculated from the current machine coordinates and the workpiece coordinates for each axis at the reference position set in parameter No. 1250.

	#7	#6	#5	#4	#3	#2	#1	#0
8168		WST		MWR		SVF	MSO	MPA

[Input type] Parameter input
[Data type] Bit

#0 MPA If an alarm concerning synchronous control, composite control, or superimposed control is issued:
0: All paths of the machine group to which the alarm occurrence path belongs are placed in feed hold state.
1: Only the path including the axis placed under synchronous control, composite control, or superimposed control is placed in the feed hold state.

#1 MSO When one of the following events occurs in synchronous control, composite control or superimposed:
- The emergency stop signal *ESP <Gn008.4> is turned off.
- The servo-off signals SVF1 to SVF8 <Gn126.0 to Gn126.7> are turned on.
- A servo alarm is issued.

0: The synchronous, composite control or superimposed control mode is canceled and follow-up operation is not performed.
For the operation to be performed when the servo-off signal is turned on, however, the setting of bit 7 (NSR) of parameter No. 8161 is used in synchronous control or the setting of bit 0 (NMR) of parameter No. 8161 is used in composite control.
1: The synchronous, composite control or superimposed control mode is not canceled.
The following operation is performed to perform follow-up operation:
When the emergency stop signal *ESP is turned off, the relevant path is determined and operation is performed so that the emergency stop signal *ESP is virtually turned off for the determined path.
When the servo-off signals SVF1 to SVF8 are turned on, the relevant axis is determined and operation is performed so that the servo-off signals SVF1 to SVF8 are virtually turned on for the determined axis.
When a servo alarm is issued, the relevant axis is determined and the alarm SV0003, “SYNCHRONOUS/COMPOSITE/SUPERIMPOSED CONTROL MODE CAN'T BE CONTINUED” is issued for the determined axis to stop moving the tool along the axis. When bit 2 (SVF) of parameter No. 8168 is set to 1, this servo-off specification follows the SVF setting.

> **NOTE**
> 1 This setting is valid also during operation. For all axes placed under synchronous, composite control or superimposed control, the emergency stop signal is turned off, the servo-off signal is turned on, or a servo alarm is issued.
> 2 If the servo-off signal is turned on, alarm DS1933 "NEED REF RETURN (SYNC:MIX:OVL)" will be generated in superimposed control.
> After canceling alarm, perform a manual reference position return.

#2 SVF When an axis under composite control is placed in the servo-off state:
0: Composite control is canceled.
1: Composite control is not canceled.

Follow-up specification follows the setting of bit 0 (FUPx) of parameter No. 1819.
When bit 2 (SVF) of parameter No. 8168 is set to 1, bit 0 (NMR) of parameter No. 8161 is invalid. Bit 1 (MSO) of parameter No. 8168, specification for servo-off, is also invalid.

> **NOTE**
> If a composite control axis is placed in the servo-off state when stopped, set this parameter to 1.

#4 MWR When the synchronous control, composite control, or superimposed control is started or ended and the automatic setting of a workpiece coordinate system is executed, the tool offset number is:
0: Canceled.
1: Not canceled.

> **NOTE**
> This parameter is valid when the workpiece coordinate system (bit 0 (NWZ) of parameter No.8136 is set to 0) is enabled.

#6 WST When a workpiece coordinate system is automatically set up for a slave axis at the end of synchronous control, workpiece coordinate system presetting is:
0: Not performed.
1: Performed.

> **NOTE**
> This parameter is valid when the workpiece coordinate system (bit 0 (NWZ) of parameter No.8136 is set to 0) is enabled, and bit 6 (SPV) of parameter No. 8167 is set to 1.

	#7	#6	#5	#4	#3	#2	#1	#0
8169		SESx				MRFx	MVMx	MDMx

[Input type] Parameter input
[Data type] Bit axis

#0 MDMx As machine coordinates in composite control:
0: Coordinates for the local path are displayed.
1: Coordinates for the other path in composite control are displayed.

#1 MVMx In composite control, machine coordinates (#5021 and above) to be read are:
0: Machine coordinates of the local path.
1: Machine coordinates of the other path in composite control.

#2 MRFx In composite control, the rapid traverse rate is:
0: The rapid traverse rate for the specified axis.
1: The rapid traverse rate for the axis along which a movement is made.

#6 SESx If a synchronization error is out of the tolerable range (specified with parameter No. 8181):
0: Alarm SV0407, “EXCESS ERROR”, is issued.
1: No alarm is issued. Instead, the excess synchronization error signal SEO<Fn559> is output.

SESx is valid when bit 1 (SERx) of parameter No. 8162 is 1. Specify the value of this parameter for the slave axis.

8180	Master axis with which an axis is synchronized under synchronous control

[Input type] Parameter input
[Data type] Word axis
[Valid data range] 101, 102, 103, . . . , (path number)*100+(intra-path relative axis number) (101, 102, 103, . . . , 201, 202, 203, . . . , 1001, 1002, 1003, . . .)
This parameter sets the path number and intra-path relative axis number of the master axis with which each axis is synchronized. When zero is specified, the axis does not become a slave axis and is not synchronized with another axis. When an identical number is specified in two or more parameters, one master axis has two or more slave axes.

8181	Synchronization error limit of each axis

[Input type] Parameter input
[Data type] 2-word axis
[Unit of data] Detection unit
[Valid data range] 0 to 99999999
When the synchronization deviation detected (bit 1 (SERx) of parameter No. 8162 is set to 1), this parameter specifies the limit of the difference between the positioning deviation of the slave axis and that of the master axis. Set this parameter to the slave axis.

8183	Composite control axis of the other path in composite control for each axis

[Input type] Parameter input
[Data type] Word axis
[Valid data range] 101, 102, 103, . . . , (path number)*100+(intra-path relative axis number) (101, 102, 103, . . . , 201, 202, 203, . . . , 1001, 1002, 1003, . . .)
This parameter sets with which axis each axis is to be placed under composite control. When zero is specified, control of the axis is not replaced under composite control. An identical number can be specified in two or more parameters, but composite control cannot be exercised for all of them at a time.

NOTE
When the two-path interface is used (bit 1 (MIX) of parameter No. 8166 is set to 1), set this parameter for path 2.

8184	Coordinates of the reference point of an axis on the coordinate system of another axis under composite control

[Input type] Parameter input
[Data type] Real axis
[Unit of data] mm, inch, deg (input unit)
[Min. unit of data] Depend on the increment system of the applied axis
[Valid data range] 9 digit of minimum unit of data (refer to standard parameter setting table (A))
(When the increment system is IS-B, -999999.999 to +999999.999)

This parameter specifies the coordinates of the reference point of an axis on the coordinate system of another axis under composite control.

> **NOTE**
> This parameter is valid when bit 4 (MPMx) of parameter No. 8162 is set to 1, and workpiece coordinate systems (G54 to G59, including additional workpiece coordinate systems) are not used.

8185	Workpiece coordinates on each axis at the reference position

[Input type] Parameter input
[Data type] Real axis
[Unit of data] mm, inch, deg (input unit)
[Min. unit of data] Depend on the increment system of the applied axis
[Valid data range] 9 digit of minimum unit of data (refer to standard parameter setting table (A))
(When the increment system is IS-B, -999999.999 to +999999.999)

This parameter sets the workpiece coordinates on each master axis, subject to synchronous control, when the master and slave axes are at the reference position. This parameter is enabled when bit 1 (SPMx) of parameter No. 8163 is set to 1. Set this parameter for the master axis.

	#7	#6	#5	#4	#3	#2	#1	#0
11284						NCA		

[Input type] Parameter input
[Data type] Bit

#2 NCA When the inside of the specified area on stored stroke check 2,3 is defined as the forbidden area, the combination of axes that composes the forbidden area on Composite control mode is:

0: Exchanged according to the exchanging of axes on Composite control. (Conventional specification)
1: Not exchanged. (Compatible specification with FS0*i*-TTC)

Example) In the following machine compositions,

Path 1	**Path 2**
- X1 axis	- X2 axis
- Z1 axis (Master axis of Composite control)	- Z2 axis (Slave axis of Composite control)

1. In case of bit 2 (NCA) of parameter No.11284 is set to 0 (Conventional specification)

The forbidden area is composed from the axes actually controlled according to the exchanging of Z axes on Composite control, as shown in Fig. 8.6.2 (e).

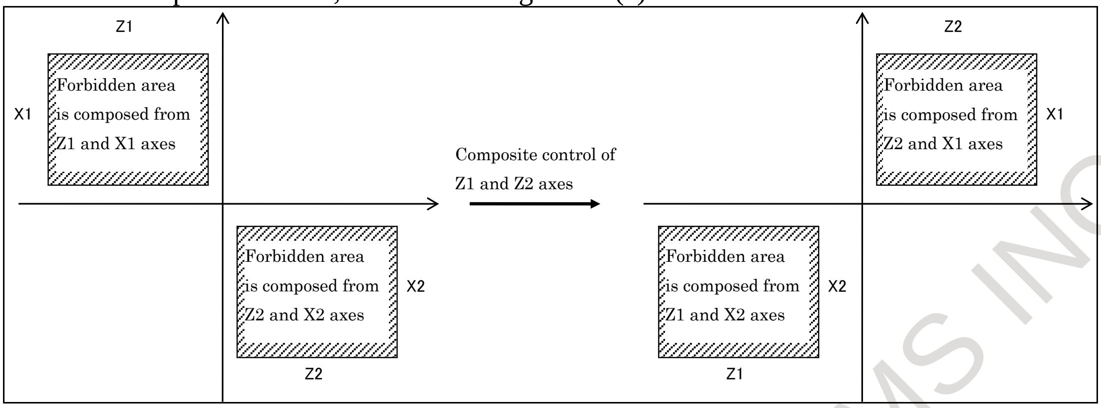

Fig. 8.6.2 (e) Composite control and the inside forbidden area (Existing specification)

2. In case of bit 2 (NCA) of parameter No.11284 is set to 1 (Compatible specification with FS0*i*-TTC)

The forbidden area is kept even if Composite control is executed, as shown in Fig. 8.6.2 (f).

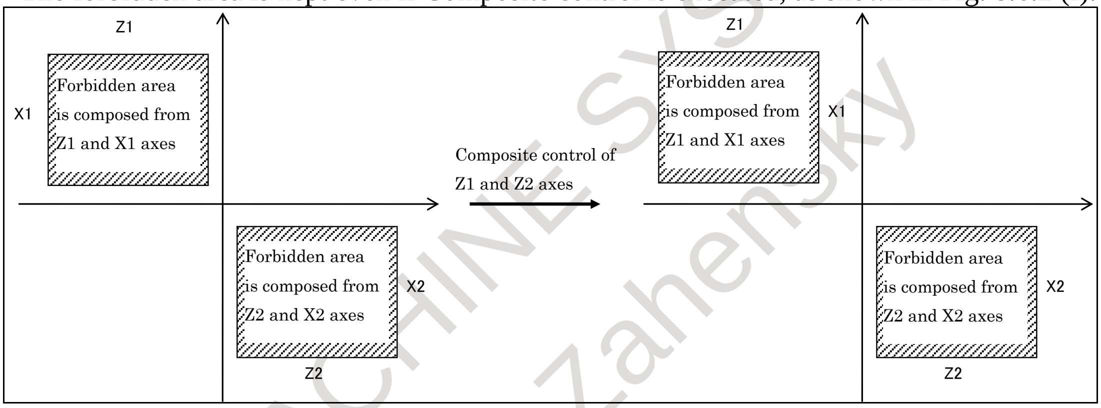

Fig. 8.6.2 (f) Composite control and the inside forbidden area (Compatible specification with FS0*i*-TTC's)

Diagnosis data

The diagnosis data displays synchronous errors.

3502	Display of synchronous error for each axis

[Unit of data] Detection unit

[Meaning] Displays the difference between the master and slave axes in position deviation if synchronous deviation detection is performed (bit 1 (SERx) of parameter No. 8162 =1).

The positional deviation difference is:

(positional deviation of the master axis) ± (positional deviation of the slave axis)

+ if a mirror image is applied to the synchronization command.
- if no mirror image is applied to the synchronization command.

Alarm and message

If any of the following alarms occurs, synchronous or composite control will be canceled for all axes.

- P/S alarm

Number	Message	Description
PS0350	PARAMETER OF THE INDEX OF THE SYNCHRONOUS CONTROL AXIS SET ERROR.	An illegal synchronization control axis number (parameter No. 8180) is set.
PS0351	BECAUSE THE AXIS IS MOVING, THE SYNC CONTROL IS CAN'T BE USED.	While the axis being subject to synchronization control was moving, an attempt was made to start or cancel the synchronization control by a synchronization control axis selection signal.
PS0352	SYNCHRONOUS CONTROL AXIS COMPOSITION ERROR.	This error occurred when: 1) An attempt was made to perform synchronization control for the axis during a synchronization, composition, or superposition. 2) An attempt was made to synchronize a further great-grandchild for a parent-child-grandchild relation. 3) An attempt was made to operate synchronization control although a parent-child-grandchild relation was not set.
PS0353	THE INSTRUCTION WAS DONE FOR THE AXIS WHICH WAS NOT ABLE TO MOVE.	This error occurred when: - For synchronization 1) A move command was issued to the axis for which bit 7 (NUMx) of parameter No. 8163 is set to 1. 2) A move command was issued to the slave axis. - For composition 1) A move command was issued to the axis for which bit 7 (NUMx) of parameter No. 8163 is set to 1. 2) A move command was issued to the axis for which bit 7 (MUMx) of parameter No. 8162 is set to 1.
PS0354	THE G28 WAS INSTRUCTED IN WITH THE REF POS NOT FIXED IN SYNC MODE	This error occurred when G28 was specified to the master axis being parking during synchronization control, but an axis reference position is not set for the slave axis.
PS0355	PARAMETER OF THE INDEX OF THE COMPOSITE CONTROL AXIS SET ERROR.	An illegal composite control axis number (parameter No. 8183) is specified.
PS0356	BECAUSE THE AXIS IS MOVING, THE COMP CONTROL IS CAN'T BE USED.	While the axis being subject to composite control was moving, an attempt was made to start or cancel the composite control by a composite control axis selection signal.
PS0357	COMPOSITE CONTROL AXIS COMPOSITION ERROR.	This error occurred when an attempt was made to perform composite control for the axis during a synchronization, composition, or superposition.
PS0359	THE G28 WAS INSTRUCTED IN WITH THE REF POS NOT FIXED IN COMP MODE	This error occurred when G28 was specified to the composite axis during composite control, but a reference position is not set to the other part of the composition.
PS0367	3-D CONV. WAS COMMANDED IN SYNC MODE AS THE PARAMETER PKUx(NO.8162#2) IS 0.	A 3-dimensional coordinate conversion was commanded during synchronization control when the bit 2 (PKUx) of parameter No. 8162 was 0.

- D/S alarm

Number	Message	Description
DS1933	NEED REF RETURN(SYNC:MIX:OVL)	The relation between a machine coordinate of an axis in synchronization, composition, or superposition control, and the absolute, or relative coordinate was displaced. Perform the manual return to the reference position.

- Servo alarm

Number	Message	Description
SV0407	EXCESS ERROR	The difference value of the amount of positional deviation for the synchronization axis exceeded the setting value. (during synchronization control only)

Caution

- Items common to synchronous control and composite control

⚠ **CAUTION**

1 At the start or end of synchronous or composite control, the tool must be stopped on the axis subject to that control.

2 Before or after an M code for starting or canceling synchronous or composite control during automatic operation, be sure to specify a waiting M code (M code without buffering). When exercising synchronous or composite control in a path, be sure to prohibit look-ahead operation by specifying an M code without buffering before or after an M code for starting or canceling synchronous or composite control.

3 The axes under synchronous or composite control must match in least command increment, Detection unit, and diameter/radius specification. Otherwise, the amounts of travel will not be equal.

4 In synchronous or composite control, do not change the parameters related to it (including axis control, increment system, feedrate, and acceleration/deceleration control).

5 Before starting synchronous or composite control, make sure that the axes subject to it has undergone a reference position return after the power was turned on or that a reference position has been established with an absolute pulse coder.

6 If an emergency stop or servo off is performed or if a servo alarm occurs, the coordinates will change due to synchronous or composite control. If this occurs alarm DS1933, “NEED REF RETURN (SYNC:MIX:OVL)" will be generated. After canceling the emergency stop, canceling servo off, or restoring from the servo alarm, perform a reference position return and coordinate system setting first, then start synchronous or composite control.

7 Acceleration/deceleration control, pitch error compensation, backlash compensation, and stored stroke check are performed independently, regardless of synchronous or composite control.

8 The following servo software functions cannot be used with synchronous or composite control:
- Abnormal load detection and switching function for each of cutting and rapid traverse
- Fine acceleration/deceleration and switching function for each of cutting and rapid traverse

9 The following functions cannot be used in synchronous or composite control:
- Electronic gear box
- Spindle positioning
- Manual numeric command

10 During synchronous or composite control, reference position establishment based on "linear scale with absolute address reference mark" or "linear scale with absolute address zero point" is impossible.

NOTE
1. This function is an option function.
2. You can place more than one axis under synchronous or composite control at the same time. You cannot, however, synchronize an axis to multiple axes at the same time, synchronize the interchanging axis under composite control to another axis, or duplicate an interchange.
3. Synchronous or composite control cannot be performed on a linear axis and a rotation axis.

- **Items related to synchronous control only**

⚠ **CAUTION**
1. In synchronous control, you cannot issue a move command for the synchronous axis on the synchronous slave.
2. The axes under synchronous control must match in acceleration/deceleration time constant and servo parameters, insofar as possible. If their settings greatly differ, the actual machine movement will deviate.
3. Even if you perform operations that do not move the machine but change the workpiece coordinate system only, such as workpiece coordinate system setting/shifting and geometric offset commands, on the synchronous master, this will not be reflected in the workpiece coordinate system on the slave.
4. If you perform workpiece coordinate system setting/wear offset commands, tool nose radius compensation, or cutter compensation on the synchronous master, the travel path on the synchronous slave will shift by the offset, but the offset will not be set as an offset amount. (No offset vector will be created.)
5. The synchronous or composite control and axis synchronous control can be specified at the same time. In this case, the master axis subject to axis synchronous control can be set as the master axis subject to synchronous control. The master axis subject to axis synchronous control cannot be used as the slave axis subject to synchronous control, and the slave axis subject to axis synchronous control cannot be used as the master or slave axis subject to synchronous control.
6. If you want to perform a tool retract and recover operation for axes in the synchronous control mode, perform the operation for the master axis. In the same way as in ordinary synchronous control, the master and slave axes move together.

- **Items related to composite control only**

⚠ **CAUTION**
1. If you want to place a tapping axis under composite control, place it under composite control first, and then issue a rigid tapping command. In rigid tapping mode, you must not switch the composite control axis selection signal; be sure to do this in the rigid tapping canceled state.
2. If you place a tapping axis under composite control, rigid tapping will be performed using the time constant, loop gain, in-position width, and the positional deviation limits during stoppage/travel of the interchanging axis in composite control.

> ⚠ **CAUTION**
> 3 In composite control, the loop gain may be switched depending on the switching of the Cs contour control switching signal and of the composite control axis selection signal. For this reason, switch the signals in the state in which the tool has stopped on the related axis. If you change the loop gain while the tool is moving along an axis, shock may result.
> 4 The synchronous or composite control and axis synchronous controlcan be specified at the same time. An axis used for movement under composite control can be selected as the master axis for axis synchronous control, but cannot be specified as a slave axis for axis synchronous control.
> 5 If you want to perform a tool retract and recovery operation for axes in the composite control mode, perform the operation for the composite control source axis. In the same way as in ordinary composite control, the composite control destination axis moves.

Limitation

- Limitations on synchronous control and composite control

Function	In synchronous control	In composite control
Acceleration/deceleration control	The synchronous slave axis is subject to acceleration/deceleration of the same type as the synchronous master axis. As the time constants, those specific to the axes are used.	The acceleration/deceleration type of the specified path is used. As the time constants, those specific to the axes are used (3).
Look-ahead acceleration/deceleration before interpolation	The synchronous slave axis is subject to the same acceleration/deceleration as the synchronous master axis.	The acceleration/deceleration settings of the specified path are used.
Cutting feedrate clamp	Clamping is performed on the synchronous master.	Clamping is performed on the specified path (4).
Reference position return	Possible on the synchronous master axis if the axis is not in parking. Only automatic reference position return (G28) is possible if the synchronous master axis is in parking.	Possible on axes not related to composite control. Only automatic reference position return (G28) is possible on an axis under composite control.
2nd, 3rd, 4th reference position return	Same as above.	Same as above.
Reference position return check	Same as above.	Same as above.
PMC axis control	Possible on axes other than the synchronous slave axis. (If a slave axis is specified as a PMC control axis, alarm PS0130 is issued.)	Possible.
Polar coordinate interpolation (T series), Cylindrical interpolation	Possible.	Possible. (In polar coordinate interpolation (T series) or cylindrical interpolation mode, composite control cannot be turned ON/OFF.)
Handle interruption	See bit 5 (SMI) of parameter No. 8163.	Possible with bit 6 (MMI) of parameter No. 8163
Mirror image	See bit 5 (SMI) of parameter No. 8163.	Signals in the specified path are effective (4).
Machine lock	Signals in the individual paths are effective (1).	Signals in the specified path are effective (4).
Inter lock	Signals on the synchronous master side are valid for the synchronous slave axis.(2)	Signals in the specified path are effective (4).

Function	In synchronous control	In composite control
Override	Signals on the synchronous master side are valid for the synchronous slave axis.(2)	Signals in the specified path are effective (4).
External deceleration	Signals on the synchronous master side are valid for the synchronous slave axis.(2)	Signals in the specified path are effective (4).
Skip function	Not possible on the synchronous slave axis.	Possible on axes not related to composite control.
Automatic tool offset	Not possible on the synchronous slave axis.	Possible on axes not related to composite control.
Follow-up	Not possible during synchronization.	Not possible during composite control.
Program restart	Not possible with a program containing synchronous control.	Not possible with a program containing composite control.
Cs contour control	Synchronous control possible (5).	Composite control possible (5).
Spindle positioning	Synchronous control does not possible	Composite control does not possible
EGB function	Synchronous control does not possible	Composite control does not possible
Servo off	Synchronous control does not possible	Possible unless the interchanging axis in composite control is in the servo off state.

(1) Processed after synchronous pulses are transferred to the slave.
(2) Processed on the master, then transfers synchronous pulses.
(3) Transfers composite control pulses and the acceleration/ deceleration type. As the time constant, uses that on the slave.
(4) Processed on the master, then transfers composite control pulses.
(5) Limited to combinations of Cs axes.

- Reading of coordinates in synchronous or composite control

In synchronous or composite control, the reading of custom macro system variable positional information or of current coordinates from the PMC window is as follows:

Positional information type	In synchronous control	In composite control
Absolute coordinate	Reading possible.	Reading possible.
Machine coordinate	Reading possible.	Reading possible.
End point of each block	Reading possible on the master only.	Reading possible.
Skip signal position	Reading possible on the master only.	Reading not possible.

- Canceling synchronous or composite control

Synchronous or composite control is canceled in the event of the following, as well as when the synchronous/composite control axis selection signal becomes 0.
(1) Emergency stop
(2) Reset
(3) Servo alarm
(4) Servo off *1
(5) Overtravel *2
(6) Alarm related to synchronous or composite control
(7) Alarm PW0000

If one of the above events occurs in either path, all paths will be released from synchronous or composite control. If one of the above events occurs in either path in synchronous or composite control, the other path will automatically be placed in feedhold state (during automatic operation) or in interlock state (during manual operation).

*1: By setting bit 0 (NMR) of parameter No. 8161 to 1, you can prohibit the composite control axis from release from the synchronous or composite control state even if the axis enters the servo off state.

By setting bit 7 (NSR) of parameter No. 8161 to 1, you can prohibit the synchronous control axis from release from the synchronous or composite control even if the axis enters the servo off state.

*2: By setting bit 5 (NCS) of parameter No. 8160 to 1, you can prohibit the synchronous or composite control axis from release from the synchronous or composite control state even if the axis enters the overtravel state.

- Axis state output signals in synchronous or composite control

State output signal	In synchronous control	In composite control
Axis moving signals MVn <Fn102>	- During movement along the master or slave axis, the master axis signal goes 1. - The slave axis signal is always 0 (1).	- On the axis on which a move command is executed, the signal goes 1. The signal on the axis along which the tool is actually moving does not turn to 1 (1).
Axis moving direction signals MVDn <Fn106>	- On the master axis, the moving direction of the master axis. - On the slave axis, moving direction after mirror image processing.	- Actual moving direction on the axis (moving direction after mirror image processing in composite control).
In-position signals INPn <Fn104>	- The master axis signal goes 1 when both the master and slave axes are in the in-position state. - The slave axis signal is always 1.	- The signal in the specified path reflects the state of the moving axis with that specification.
Reference position establishment signal ZRFn <Fn120>	- The signal on the axis for which the reference position has been established turns to 1.	- The signal on the axis for which the reference position has been established turns to 1.
Reference position return completion signal ZPn <Fn094>	- After completion of reference position return of the master axis, the signal on the master axis turns to 1. - The slave axis is synchronized with movement of the master axis, but is not subjected to reference position return. The signal turns to 0. - When the master axis is parking, the slave axis is subjected to reference position return. The signal on the slave axis turns to 1.	- The signal on the axis along which the tool is actually moving turns to 1.

(1) In a positional deviation check, regardless of the states of these signals, parameter No. 1828 is used if move command pulses are sent to the motor (regardless of whether the axis is the master or slave) as the limit, and parameter No. 1829 if none are sent.

Examples of Use

- Examples of independent control and of synchronous control on the Z1 and Z2 axes

(1) Machine configuration

(a) Independent control

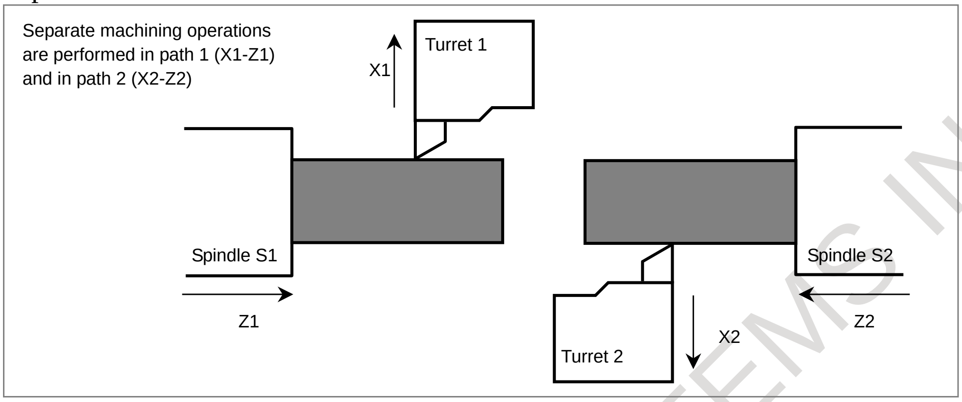

Fig. 8.6.2 (g)

(b) Z1-Z2 axis synchronous control

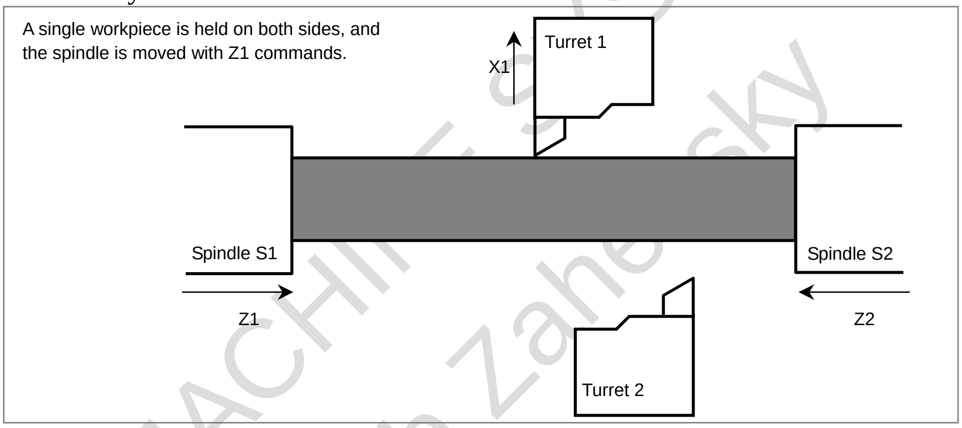

Fig. 8.6.2 (h)

(2) Parameter settings

- To synchronize the Z2 (slave) axis with the Z1 (master) axis, set parameter No. 8180z of path 2 to "102".
- Because the plus directions of the Z1 (master) and Z2 (slave) axes are opposite, perform synchronization with a mirror image applied. To that end, set bit 0 (SMRz) of parameter No. 8162 of path 2 to 1.
- Because the movements along the Z1 (master) and Z2 (slave) axes must be equal, perform synchronous error detection. Set bit 1 (SERz) of parameter No. 8162 of path 2 to 1. Set the synchronous error limit in parameter No. 8181z of path 2, in the range of 100 to 1000. (The setting differs with each machine.)
- During synchronization, the difference between the Z1 (master) axis and the Z2 (slave) axis in positional deviation is displayed as No. 3502 on the diagnosis data of path 2.

(3) Signal operation

- To start synchronous movement along the Z1 (master) axis and the Z2 (slave) axis, set signal SYNC2 <G1138.1> to 1.
- To cancel synchronization, set signal SYNC2 <G1138.1> to 0.
- When an emergency stop, NC reset, or alarm occurs, set signal SYNC2 <G1138.1> to 0.
- Set signals other than signal SYNC2 <G1138.1> to 0.

(4) Program example

Path 1		Path 2		
N1000	. . .	N2000	. . .	Independent machining of each path
N1010	Z80.0 ;	N2010	Z150.0 ;	Move the workpiece and the chuck to position
N1020	M200 P12 ;	N2020	M200 P12 ;	Waiting
		N2030	M61 ;	Workpiece clamping and start of synchronization
N1040	M201 P12 ;	N2040	M201 P12 ;	Waiting
N1050	M3 S800 ;			Forward spindle rotation
N1060	Z- 25.0 ;			Movement along the Z1 axis
N1070	. . .			Machining along the X1 and Z1 axes
N1080	M200 P12 ;	N2080	M200 P12 ;	Waiting
		N1090	M62 ;	Cancellation of synchronization and unclamping of workpiece
N1100	M201 P12;	N2100	M201 P12;	Waiting
N1110	. . .	N2110	. . .	Independent machining of each path

where
M61 is an M code that clamps the workpiece and sets signal SYNC2 <G1138.1> to 1, and
M62 is an M code that sets signal SYNC2 <G1138.1> to 0 and unclamps the workpiece.

NOTE

1. An operation to make the speeds of spindles S1 and S2 identical is required. To do this, issue a spindle command of path 1 to both S1 and S2.
2. A waiting M code is an M code without buffering.

- Examples of independent control and interpolation on the X1 and Z2 axes

(1) Machine configuration

(a) Independent control

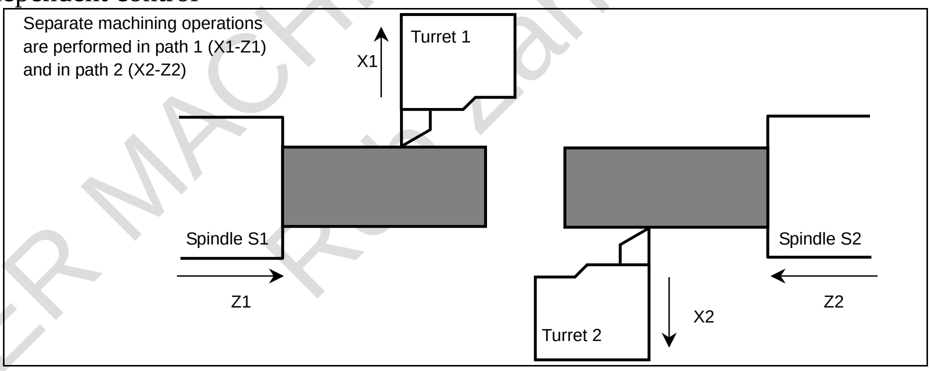

Fig. 8.6.2 (i)

(b) Interpolation on the X1 and Z2 axes

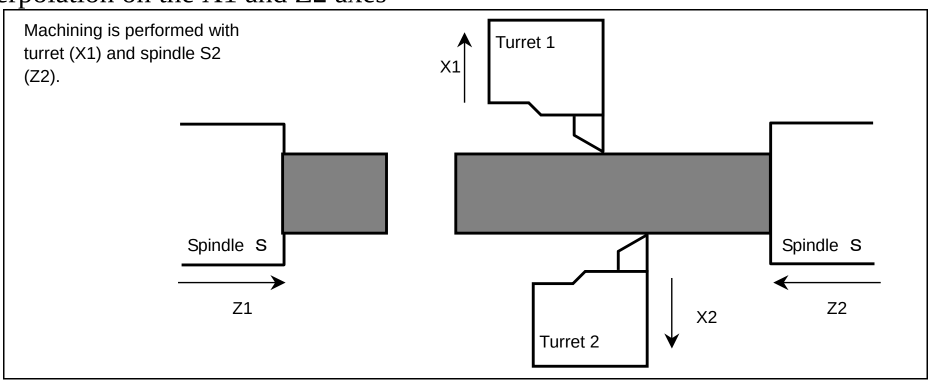

Fig. 8.6.2 (j)

There are two ways to perform interpolation on the X1 and Z2 axes.

1. Use the program of path 2 to issue a command to the X2 and Z2 axes to synchronize the X1 (slave) axis to the X2 (master) axis and to park the X2 (master) axis. For path 1, do not issue a move command.
2. Perform composite control to let the X1 and X2 axes interchange between paths. For path 1, do not issue a move command.

The following explains the ways using synchronous control and composite control separately.

If using synchronous control

(1) Parameter settings

- To synchronize the X1 (slave) axis to the X2 (master) axis, set parameter No. 8180x of path 1 to "201".
- For both X1 (slave) and X2 (master) axes, no mirror image is required because the direction away from the center of the workpiece is the plus direction of coordinates.
- Do not perform synchronous error detection because the X2 (master) axis is parked.
- During synchronization, the difference between the X2 (master) and X1 (slave) axes in positional deviation is displayed as No. 3502 on the diagnosis data of path 1.

(2) Signal operation

- To start synchronous control on the X2 (master) axis and the X1 (slave) axis, set signals SYNC1 <G0138.0> and PK1 <G1122.0> to 1.
- To cancel synchronization, set signals SYNC1 <G0138.0> and PK1 <G1122.0> to 0.
- When an emergency stop, NC reset, or alarm occurs, set SYNC1 <G0138.0> and PK1 <G1122.0> to 0.
- Set signals other than SYNC1 <G0138.0> and PK1 <G1122.0> to 0.

(3) Program example

Path 1		Path 2		
N1000	. . .	N2000	. . .	Independent machining of each path
N1010	Z0 ;	N2010	Z20.0 ;	Move each workpiece to position
N1020	X120.0 ;	N2020	X120.0 ;	Move each X axis to the synchronization start position (X1=X2)
N1030	M200 P12;	N2030	M200 P12 ;	Waiting
		N2040	M55 ;	Synchronize the X2 and X1 axes and start parking on the X2 axis
N1050	M201 P12 ;	N2050	M201 P12 ;	Waiting
		N2060	T0212 ;	Set the offset for turret 1
		N2070	S1000 M4 ;	Reverse spindle rotation
		N2080	G0 X30.0 Z55.0 ;	
		N2090	G1 F0.2 W-15.0 ;	Machining along the X1 and Z2 axes
		N2100	. . .	
N1110	M200 P12 ;	N2110	M200 P12 ;	Waiting
		N2120	M56 ;	Cancellation of synchronization and parking
N1130	M201 P12 ;	N2130	M201 P12 ;	Waiting
N1140	. . .	N2140	. . .	Independent machining of each path

where

M55 is an M code to start the control of turret 1 with the program of path 2, and M56 is an M code that cancel the control of turret 1 with the program of path 2.

> **NOTE**
> During synchronous control on the X axis, no move command can be issued from path 1 to the X1 (slave) axis, but movement along the Z1 axis is possible.

If using composite control

(1) Parameter settings

- To perform composite control by letting the X1 and X2 axes interchange, set parameter No. 8183x of path 2 to "101".
- Because the direction of the coordinates on the X1 axis is opposite from that of the coordinates on the X2 axis, set bit 6 (MCDx) of parameter No. 8162 of path 2 to 1.
- To automatically set the position of turret 1 in the workpiece coordinate system of path 2 at the start of composite control, set bit 4 (MPMx) of parameter No. 8162 of path 2 to 1.
- To automatically set the position of turret 1 in the workpiece coordinate system of path 1 at the end of composite control, set bit 5 (MPSx) of parameter No. 8162 of path 1 to 1.
- Assuming that the X coordinate of the reference position of turret 1 in the workpiece coordinate system of path 2 is -150.0 mm as shown in the figure below, set parameter No. 8184x of path 2 to "-150000" to automatically set the coordinate system.

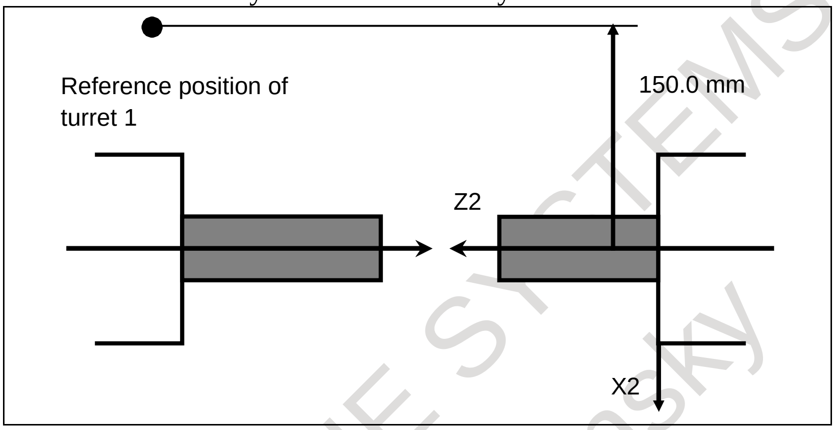

Fig. 8.6.2 (k)

(2) Signal operation

- To start composite control on the X2 and X1 axes, set signal MIX1 <G1128.0> to 1.
- To cancel composite control, set signal MIX1 <G1128.0> to 0.
- When an emergency stop, NC reset, or alarm occurs, set MIX1 <G1128.0> to 0.
- Set signals other than MIX1 <G1128.0> to 0.

(3) Program example

Path 1		Path 2		
N1000	. . .	N2000	. . .	Independent machining of each path
N1010	Z0 ;	N2010	Z20.0 ;	Move each workpiece to position
		N2020	X120. ;	Move along the X2 axis to a non-interference position
N1030	M200 P12 ;	N2030	M200 P12 ;	Waiting
		N2040	M55 ;	Start composite control on the X2 and X1 axes (perform automatic coordinate system setup)
N1050	M201 P12 ;	N2050	M201 P12 ;	Waiting
		N2060	T0212 ;	Set the offset for turret 1
		N2070	S1000 M4 ;	
		N2080	G0 U10.0 W- 20.0 ;	Machining along the X1 and Z2 axes
		N2090	G1 F0.2 W- 15.0 ;	
		N2100	. . .	
N1110	M200 P12 ;	N2110	M200 P12 ;	Waiting
		N2120	M56 ;	Cancel composite control (perform automatic coordinate system setup)
N1120	M201 P12 ;	N2120	M201 P12 ;	Waiting
N1130	. . .	N2130	. . .	Independent machining of each path

where
M55 is an M code to start the control of turret 1 with the program of path 2, and
M56 is an M code that cancel the control of turret 1 with the program of path 2.

NOTE

1 At the start and end of composite control, you do not necessarily perform automatic setup of the coordinate system. If you do not perform automatic setting, the program will set an appropriate one internally.
2 During composite control on the X axis, you can issue a move command for the X axis in path 1 to move the tool along the X2 axis.
3 With the parameter settings above, turret 1 will be positioned on the minus side of the X coordinates in the workpiece coordinate system of path 2. For this reason, specify with the opposite sign as usual, such as U+10.0 and U-10.0 to move turret 1 toward the center of the workpiece and move it away from it, respectively.
   If this is inconvenient, specify the following parameter settings:
   Bit 6 (MCDx) of parameter No. 8162 = 0
   Parameter No. 8184x = 150000
   These settings cause turret 1 to exist on the plus side of the X coordinates virtually.

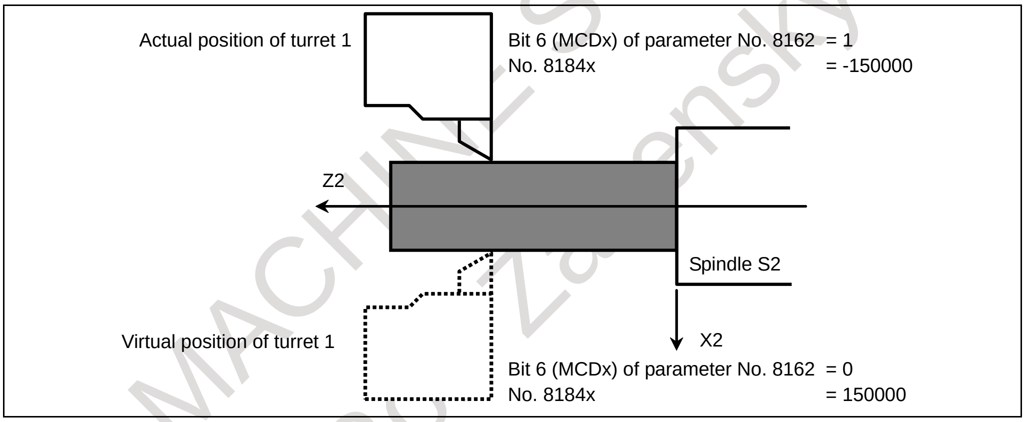

Fig. 8.6.2 (l)

- Examples of independent control and of interpolation on X1-Z2 and X2-Z1

(1) Machine configuration

(a) Independent control

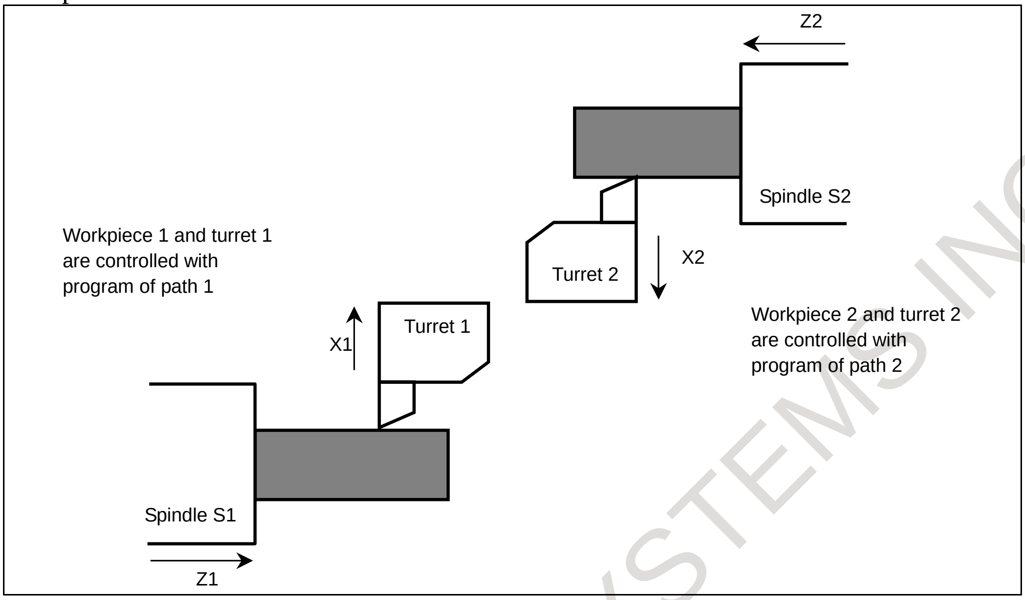

Fig. 8.6.2 (m)

(b) X1-Z2 and X2-Z1 interpolation

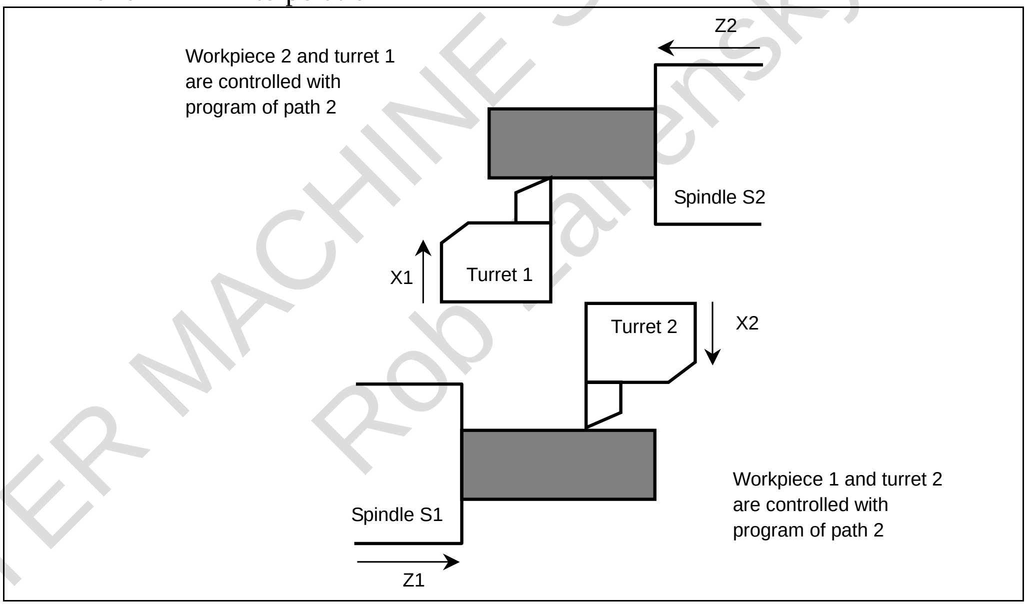

Fig. 8.6.2 (n)

(2) Parameter settings

- To perform composite control by letting the X1 and X2 axes interchange, set parameter No. 8183x of path 2 to "101".
- Because the direction of the coordinates on the X1 axis is opposite from that of the coordinates on the X2 axis, set bit 6 (MCDx) of parameter No. 8162 of path 2 to 1.
- To automatically set the position of the remote turret in the workpiece coordinate system of each path at the start of composite control, set bit 4 (MPMx) of parameter No. 8162 of each of paths 1 and 2 to 1.
- To automatically set the position of the local turret in the workpiece coordinate system of each path at the end of composite control, set bit 5 (MPSx) of parameter No. 8162 of each of paths 1 and 2 to 1.

- Assuming that the relations between the workpiece coordinates of each path and the reference position are as shown in the figure below, set parameter No. 8184x of path 1 to "200000" and No. 8184x of path 2 to "180000".

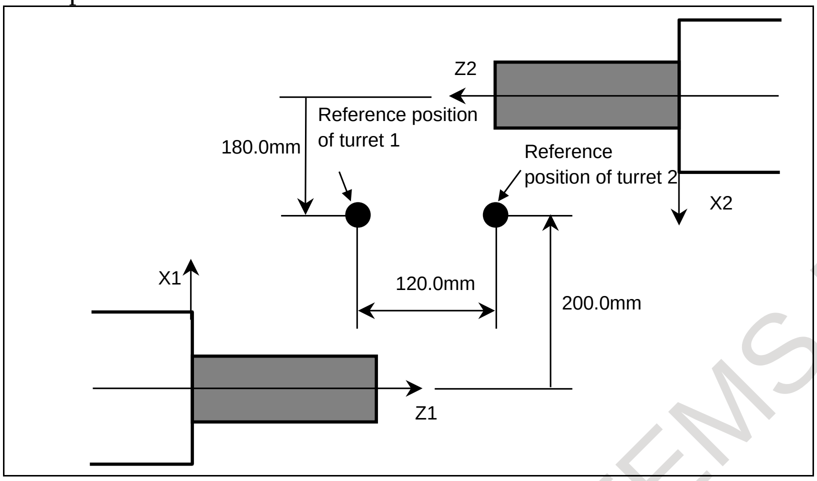

Fig. 8.6.2 (o)

(3) Signal operation

- To start composite control on the X2 and X1 axes, set signal MIX1 <G1128.0> to 1.
- To cancel composite control, set signal MIX1 <G1128.0> to 0.
- When an emergency stop, NC reset, or alarm occurs, set signal MIX1 <G1128.0> to 0.
- Set signals other than signal MIX1 <G1128.0> to 0.

(4) Program example

Path 1	Path 2	
N1000 . . .	N2000 . . .	Independent machining of each path
N1010 M200 P12 ;	N2010 M200 P12 ;	Waiting

N1140 . . .	N2140 . . .	Independent machining of each path

where

M55 is an M code to start composite control (set signal MIX1 <G1128.0> to 1), and
M56 is an M code to cancel composite control (set signal MIX1 <G1128.0> to 0).

> **NOTE**
> At the start and end of composite control, you do not necessarily perform automatic setup of the coordinate system. If you do not perform automatic setting, the program will set an appropriate one internally.

Others

- In the preceding explanation, a single synchronous control or composite control operation is explained. In reality, however, you can select multiple synchronous control or composite control operations and execute them at the same time: Set all necessary parameters in advance, and specify which synchronous or composite control to perform, using appropriate signals. Make sure that a single axis is not subject to multiple synchronous/composite control operations at the same time.
- You can set only a single set of axes subject to synchronous or composite control. If you require multiple sets, use the programmable parameter input function (G10) to change the parameter settings in the program. Before changing parameters, make sure that the associated synchronous or composite control has been canceled. If parameters are changed during Synchronous control or Composite control, the changes will not take effect immediately. For the changes made to the parameters to take effect, it is necessary to turn off synchronous or composite control mode and turn it back on.

  (Example)

  Change parameter settings to synchronize the Z2 (slave) axis to the Y1 (master) axis.
  (To set parameter No. 8180z of path 2 to "103", execute a program such as that shown below.)

  ```
  N0200   . . .
  N0210   G10   L50   ;              Start of parameter settings
  N0220   N8180   P2   R103   ;      Set parameter No. 8180z to "103".
  N0230   G11   ;                    End of parameter settings
  N0240   . . .
  ```

  Execute blocks G10 and G11 while the Y1 and Z2 axes are not subject to synchronous or composite control.

Troubleshooting

1. Unable to start synchronous or composite control. (No alarm occurs.)
   (1) The correct synchronous or composite control have not been set up.
   → To perform synchronous or composite control, you must set up the correct.
   (2) The synchronous/composite control axis selection signals <Gn128> or <Gn138> is not changed from 0 to 1.
   → Synchronous or composite control starts when the synchronous/composite control axis selection signal <Gn128> or <Gn138> is changed from 0 to 1. After synchronous or composite control ends due to a reset or alarm, merely canceling the reset or alarm cause will not cause synchronous or composite control to restart. After canceling the reset or alarm cause, you must make the signal rise again.
   (3) The axis number of the axis subject to synchronous or composite control is not set in the appropriate parameter.
   → To perform synchronous control, set the axis number of the master axis in parameter No. 8180. To perform composite control, set the axis number of the interchanging axis in parameter No. 8183. If using a 2-path interface, use the parameter of path 2.
   (4) Synchronous or composite control cannot be started if the NC unit is one of the following states:
   - Emergency stop
   - Reset
   - Servo alarm
   - Alarm PW0000
   - Alarm related to synchronous or composite control

Synchronous or composite control cannot be started, either, if the axis on which synchronous or composite control is to start is either of the following states:

- Servo off
- Overtravel

2. An attempt to raise a synchronous or composite start signal results in an alarm.
   (1) An attempt is made to use an axis already under synchronous or composite control for another synchronous or composite signal operation. (Alarms PS0352 and PS0357)
      → You cannot use a single axis for a combination of multiple synchronous or composite control operations. Note, however, that the synchronous master axis can be the master of multiple synchronous slave axes at the same time. You can add additional slave axes while synchronous control is in progress.
   (2) The axis number set in a parameter is greater than the number of controllable axes. (Alarms PS0350 and PS0355)
      → The number of the synchronous master axis and that of the interchanging axis subject to composite control must not exceed the number of axes controllable in the remote path (or the local path if you are to perform synchronous control in that path).
   (3) The tool is moving along the axis that you want to control. (Alarms PS0351 and PS0356)
      → At the start of synchronous or composite control, the tool must be stopped on the axis subject to that control. That the tool is stopped on an axis means that the speed specified after acceleration/deceleration is zero.
   (4) An axis on which you want to perform synchronous or composite control belongs to another machine group. (Alarms PS0350 and PS0355)
      → The axes on which you want to perform synchronous or composite control must be of the same machine group.

3. An attempt to cancel synchronous or composite control results in alarms PS0351 and PS0356.
   (1) The tool is moving along the axis on which the control you want to cancel.
      → To cancel synchronous or composite control, the tool must be stopped on the axis on which to cancel it. That the tool is stopped on an axis means that the speed specified after acceleration/deceleration is zero. Before canceling, make sure that the movement in progress signal Fn102 has changed to 0.

4. During synchronous control or composite control, an alarm occurs.
   (1) A move command is issued for a synchronous slave axis. (Alarm PS0353)
      → No move command can be issued for a synchronous slave axis, whether it be automatic or manual.
   (2) A move command is issued for an axis under composite control for which bit 7 (MUMx) of parameter No. 8162 is set to 1. (Alarm PS0353)
      → During composite control, no move command can be issued for an axis for which bit 7 (MUMx) of parameter No. 8162 is set to 1, whether it be automatic or manual.
   (3) During synchronous control, an automatic reference position return command with G28 is issued for a parking master axis. (Alarm PS0354)
      → In this case, a reference position return is performed on the slave axis, requiring that the reference position of the slave axis be established.
   (4) During composite control, an automatic reference position return command with G28 is issued. (Alarm PS0359)
      → In this case, a reference position return is performed on the remote interchanging axis, requiring that the reference position of the interchanging axis be established.
   (5) During synchronous control, a 3-dimensional coordinate conversion is specified. (Alarm PS0367)
      → For the synchronous master axis to be specified in 3-dimensional coordinate conversion mode, set bit 2 (PKUx) of parameter No. 8162 to 1.

5. During synchronous control, servo alarm SV0407 occurs.
   (1) The difference between the synchronous master and slave axes in positional deviation is too large.
   → When the difference between synchronous master and slave axes in positional deviation exceeds the parameter (No.8181) while checking the synchronous error, alarm (SV0407) occurs. In general, this alarm occurs if the difference between the synchronous master and slave axes in acceleration/deceleration time constant or servo parameter is large. It can also occur if the actual movement of the machine is not correct (is not correctly synchronized) due to some cause or other.

6. During synchronous control, the machine position deviates.
   (1) The synchronous master and slave axes in acceleration/deceleration time constant or servo parameter (such as loop gain) differs.
   → In this synchronous control, acceleration/deceleration control and servo control are performed in the master and slave independently of each other. (That is, move commands are synchronized.) For this reason, if the master and slave differ in acceleration/ deceleration time constant and servo characteristics, the actual movement of the machine may not fully match.

7. The travel distance is not correct during synchronous or composite control.
   (1) The master and slave axes differ in diameter/radius specification or inch/millimeter setting.
   → In synchronous or composite control, diameter/radius conversion or inch/millimeter conversion is not performed between master and slave. The master and slave must match in least command increment.

8. After a switch to synchronous or composite control, the tool does not move to the specified coordinates.
   (1) After a switch to synchronous or composite control, a move command is issued without waiting (with an M code without buffering).
   → If, during automatic operation, you want to start or cancel synchronous or composite control with automatic coordinate system setting, be sure to perform waiting (with an M code without buffering) before and after that.

9. Synchronous or composite control is canceled although the synchronous/composite control axis selection signal <Gn128> or <Gn138> is not changed from 1 to 0.
   → In synchronous or composite control, synchronous or composite control will be automatically canceled if at least either of the paths enters one of the following states:
   - Emergency stop
   - Reset
   - Servo alarm
   - Alarm PW0000
   - Alarm related to synchronous or composite control

   In addition, if at least one of the axes on which synchronous or composite control is in progress enters either of the following states:
   - Servo off
   - Overtravel

10. Alarm DS1933 occurs.
   → In synchronous or composite control, alarm DS1933 occurs if at least one path enters one of the following states:
   - Emergency stop
   - Servo off
   - Servo alarm

After canceling the emergency stop, after canceling servo off, or after restoring from the servo alarm, first perform a reference position return or coordinate system setting and then start synchronous or composite control.

8.6.3 Hypothetical Cs Axis Control

Overview

This function allows you to add a hypothetical Cs axis to a path to which no serial spindle is actually connected.
Usually, performing composite control on Cs axes in multi-path control requires that both of the axes to be interchanged between paths be Cs axes. Using this function, however, enables composite control in which a hypothetical Cs axis and a Cs axis to which a serial spindle is actually connected interchange with each other. This makes it possible to move the serial spindle with Cs contour control that is connected to another path with a command to move from a path to which a serial spindle is not connected to a hypothetical Cs axis.

Explanation

By setting bit 7 (CDMx) of parameter No. 1014 to 1 and setting a Cs axis in parameter No. 1023, you can add the hypothetical Cs axis to a path to which a serial spindle is not actually connected.

In multi-path control, this enables composite control in which a hypothetical Cs axis and an actual Cs axis connected to another path interchange with each other.

For the hypothetical Cs axis, you need not set up a Cs contour control mode switching signal.

NOTE
1. An attempt to turn ON the Cs contour control mode switching signal for a hypothetical Cs axis results in alarm SP0752.
2. If a program issues a move command for a hypothetical Cs axis for which composite control is OFF or for a hypothetical Cs axis and a Cs axis under composite control, alarm PS0197 will occur.

Example of control in which a hypothetical Cs axis and composite control are combined

1) Control in which a Cs contour control axis (a single serial spindle) is used in two paths

[Machining pattern]
Usually, machining is performed in path 1, using X1-Z1-C1.
By performing composite control on C1-C2, you can operate C1 (Cs axis) with a C2 command in path 2, thereby enabling machining using X2-Z2-C1.

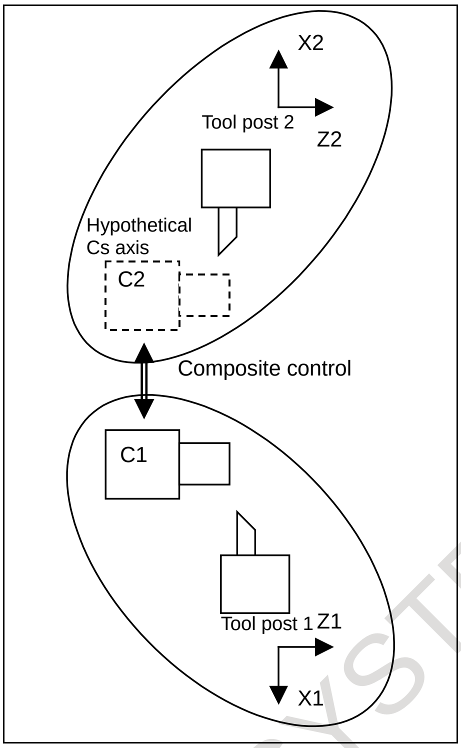

Fig. 8.6.3 (a)

Axis configuration

Path 1	Path 2
X1 (servo axis)	X2 (servo axis)
Z1 (servo axis)	Z2 (servo axis)
C1 (Cs-axis)	C2 (hypothetical Cs axis)

Parameter setting

		Parameter No. 1023 (servo axis number)	Bit 7 of parameter No. 1014 (Hypothetical Cs axis setting)
1st axis	Path 1, axis 1, X1	1	0
2nd axis	Path 1, axis 2, Z1	2	0
3rd axis	Path 1, axis 3, C1	-1	0
4th axis	Path 2, axis 1, X2	3	0
5th axis	Path 2, axis 2, Z2	4	0
6th axis	Path 2, axis 3, C2	-2	1

		Parameter No. 3717 (spindle motor number)
1st spindle	Path 1, spindle 1	1
2nd spindle	Path 2, spindle 1	0

2) Control in which Cs contour control axes (two serial spindle) are used in two paths

[Machining pattern]
Usually, machining is performed in path 1, using X1-Z1-C1, and in path 2, using X2-Z2-C2.
By performing composite control on B1-C2, you can operate C2 (Cs axis) with a B1 command in path 1, thereby enabling machining using X1-Z1-C2.
By performing composite control on C1-B2, you can operate C1 (Cs axis) with a B2 command in path 2, thereby enabling machining using X2-Z2-C1.

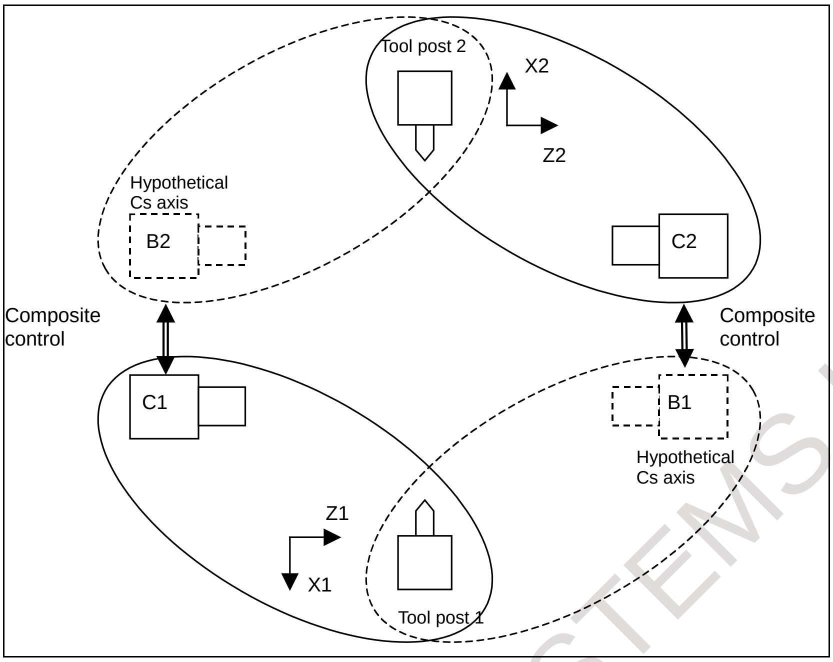

Fig. 8.6.3 (b)

Axis configuration

Path 1	Path 2
X1 (servo axis)	X2 (servo axis)
Z1 (servo axis)	Z2 (servo axis)
C1 (Cs-axis)	C2 (Cs-axis)
B1 (hypothetical Cs axis)	B2 (hypothetical Cs axis)

Configuration in which by using a hypothetical Cs axis, the addresses of commands for the Cs axis in the remote path are set separately from those of commands for the Cs axis in the local path.

Parameter

	#7	#6	#5	#4	#3	#2	#1	#0
1014	CDMx							

[Input type] Parameter input
[Data type] Bit axis

> **NOTE**
> When this parameter is set, the power must be turned off before operation is continued.

#7 CDMx The Cs contour control axis is:
0: Not a virtual Cs axis
1: Virtual Cs axis

1023	Number of the servo axis for each axis

> **NOTE**
> When this parameter is set, the power must be turned off before operation is continued.

[Input type] Parameter input

[Data type] Byte axis
[Valid data range] 0 to 80

This parameter associates each control axis with a specific servo axis. Specify values 1+8n, 2+8n, 3+8n, 4+8n, 5+8n, and 6+8n (n = 0, 1, 2, …, 9) like 1, 2, 3, 4, 5, …, 77, and 78.
The control axis number is the order number that is used for setting the axis-type parameters or axis-type machine signals
With an axis for which Cs contour control/spindle positioning is to be performed, set -(spindle number) as the servo axis number.
Example)
When exercising Cs contour control on the fourth controlled axis by using the first spindle, set -1.

3717	Spindle amplifier number to each spindle

> **NOTE**
> When this parameter is set, the power must be turned off before operation is continued.

[Input type] Parameter input
[Data type] Byte spindle
[Valid data range] 0 to Maximum number of controlled axes

Set a spindle amplifier number to be assigned to each spindle.
0: No spindle amplifier is connected.
1: Spindle motor connected to amplifier number 1 is used.
2: Spindle motor connected to amplifier number 2 is used.
to
n: Spindle motor connected to amplifier number n is used.

Alarm and message

Number	Message	Description
PS0197	C-AXIS COMMANDED IN SPINDLE MODE	The program specified a movement along the Cs-axis when the Cs contour control switching signal was off.
SP0752	SPINDLE MODE CHANGE ERROR	This alarm is generated if the system does not properly terminate a mode change. The modes include the Cs contour control, spindle positioning, rigid tapping, and spindle control modes. The alarm is activated if the spindle control unit does not respond correctly to the mode change command issued by the NC.

Caution

> ⚠ **CAUTION**
> 1 Set the necessary parameters such as feedrate for the hypothetical Cs axis as well. You need not set serial spindle parameters (such as Nos. 4000 to 4799).
> 2 For Cs contour control, see the explanation of each function.

Note

NOTE

This function requires the following functions.
- Serial spindle
- Cs contour control (bit 2 (SCS) of parameter No.8133 is set to 1)
- Synchronous/composite control

In the number of controlled axes specification and the number of controlled spindles specification, you must include the hypothetical Cs axis. (The maximum number of controllable axes and the maximum number of controllable spindles in the system or in each path must not be exceeded.)

8.7 SUPERIMPOSED CONTROL

Overview

The superimposed control function adds the amount of movement of an axis (superimposed control master axis) in one path to an axis (superimposed control slave axis) on the other path for which ordinary move commands are being executed. This function is similar to synchronous control but differs from it in that move commands can be issued not only for the master axis but also for the slave axis. The slave axis moves by the sum of the amount of movement specified by its own move commands and the amount of movement specified by move commands for the master axis. Appropriate setting of bit 3 (OMRx) of parameter No. 8162 can reverse the direction in which the master and slave axes move.

- Independent control of each path

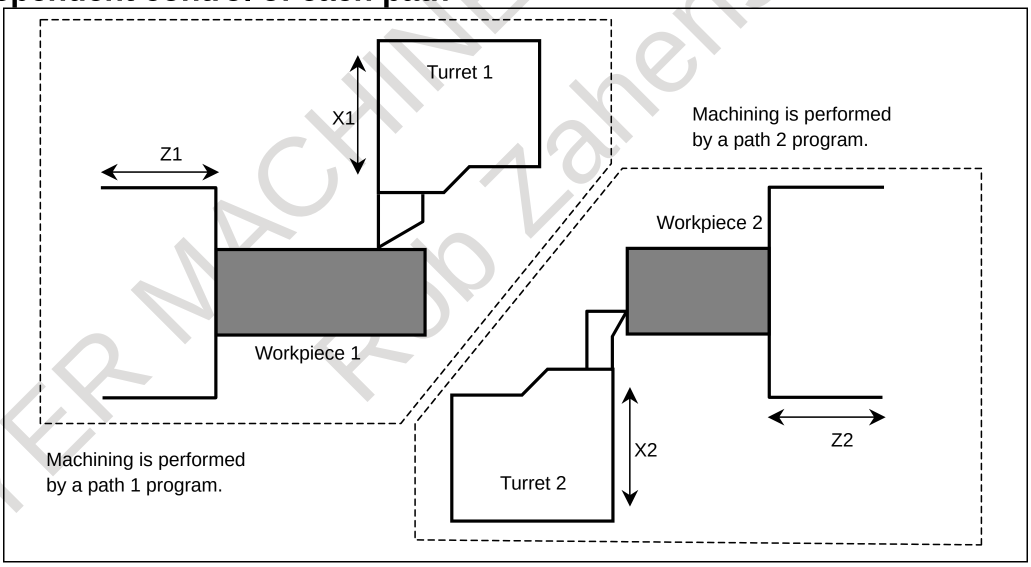

Fig. 8.7 (a)

This function enables superimposed control between paths and in a single path, as described below.

- Superimposed control

The move command for any axis is superimposed on an axis of another path.

(Example)

Superimpose the movement along the Z1 (master) axis on the Z2 (slave) axis.

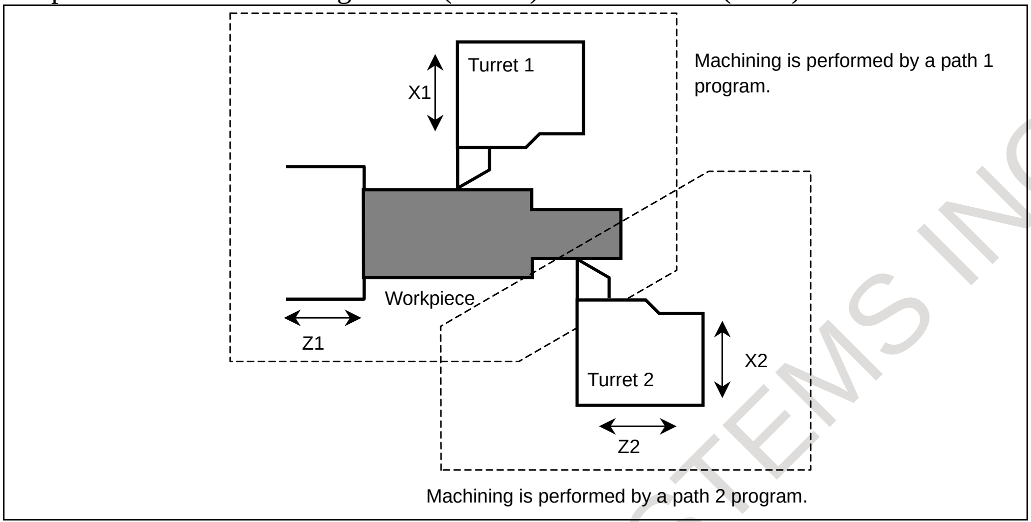

Fig. 8.7 (b)

Explanation

- Setting

Specify which axis is to be the master axis to be under superimposed control, with parameter No. 8186, using the path number and the axis number.

Example)

For an axis configuration in which all paths consist of X, Z, and Y axes
To superimpose the movement of the Z1-axis (master) to that of the Z2-axis (slave) :
Parameter No. 8186z of path 2 = 102
To superimpose the movement of the X3-axis (master) to that of the Z4-axis (slave) :
Parameter No. 8186z of path 4 = 301
To superimpose the movement of the X1-axis (master) to that of the Y1-axis (slave) :
Parameter No. 8186y of path 1 = 101

- Programming

Both before and after the M codes for a start and a cancellation of superimposed control, specify a waiting M code.

Master axis path	Slave axis path	
:	:	
M100P12;	M100P12;	Waiting
	M220;	Start of superimposed control
M101P12;	M101P12;	Waiting
:	:	
Independent operation	Independent operation	
:	:	
M100P12;	M100P12;	Waiting
	M221;	Cancellation of superimposed control
M101P12;	M101P12;	Waiting
:	:	

- Signal operation

When superimposed control begins or ends (when an M code is issued), the superimposed control axis selection signals OVLS1 to OVLS8 <Gn190> for the target slave axis (from the PMC to the CNC) are changed from "0" to "1" (to begin superimposed control) or from "1" to "0" (to terminate superimposed control).

- Examples of applications

Suppose that a workpiece on the spindle (Z1-axis) that moves along the axis is to be cut with a tool in path 1 and a tool in path 2 simultaneously. This example superimposes the amount of movement of the Z1-axis (master) on that of the Z2-axis (slave).

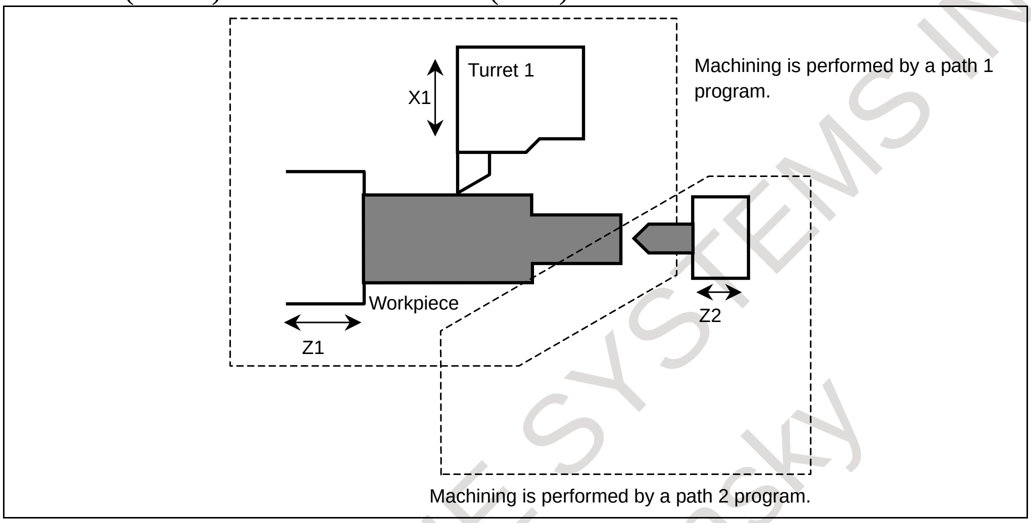

Fig. 8.7 (c)

- Feedrate

Because the amount of movement of the master axis is added to that of the slave axis, the resulting speed of the slave axis may become much larger than a normal speed.

- Differences between superimposed control and ordinary synchronous control

- Neither out-of-synchronization compensation nor detection is performed between the master and slave axes during superimposed control.
- A parking signal is ineffective for axes under superimposed control.
- A reference position return cannot be specified for the salve axis under superimposed control.

Signal

Superimposed control axis selection signals OVLS1 to OVLS8 <Gn190>

[Classification] Input signal

[Function] These signals perform superimposed control.

[Operation] When one of these signals becomes "1", the control unit:

- Begins superimposed control over the corresponding axis.
  The master axis is selected according to parameter No. 8186.

Synchronous/composite/superimposed control under way signals SYN1O to SYN8O <Fn118>

[Classification] Output signal

[Function] These signals indicate each axis is being subjected to synchronous, composite, or superimposed control.

[Output cond.] These signals become "1" under the following condition:

- The corresponding axis is under synchronous, composite, or superimposed control.

These signals become "0" under the following condition:

- The corresponding axis is not under synchronous, composite, or superimposed control.

> ⚠ **CAUTION**
> Whether each axis is under superimposed control does not always match whether the superimposed control axis selection signal has been issued or not. For example, if these signals are set to 1 during an alarm, they are ignored. If a servo alarm occurs during superimposed control, they are terminated automatically. Before attempting to perform superimposed control, always check the state of these signals.

Superimposed control master axis confirmation signals OVMO1 to OVMO8 <Fn344>

[Classification] Output signal

[Function] These signals notify whether the corresponding axes are superimposed control master axes.

[Output cond.] These signals become "1" under the following condition:

- The corresponding axes are superimposed control master axes.

These signals become "0" under the following condition:

- The corresponding axes are released from superimposed control.

Superimposed control slave axis confirmation signals OVSO1 to OVSO8 <Fn345>

[Classification] Output signal

[Function] These signals notify whether the corresponding axes are superimposed control slave axes.

[Output cond.] These signals become "1" under the following condition:

- The corresponding axes are superimposed slave axes.

These signals become "0" under the following condition:

- The corresponding axes are released from superimposed control.

Signal address

	#7	#6	#5	#4	#3	#2	#1	#0
Gn190	OVLS8	OVLS7	OVLS6	OVLS5	OVLS4	OVLS3	OVLS2	OVLS1

	#7	#6	#5	#4	#3	#2	#1	#0
Fn118	SYN8O	SYN7O	SYN6O	SYN5O	SYN4O	SYN3O	SYN2O	SYN1O
Fn344	OVMO8	OVMO7	OVMO6	OVMO5	OVMO4	OVMO3	OVMO2	OVMO1
Fn345	OVSO8	OVSO7	OVSO6	OVSO5	OVSO4	OVSO3	OVSO2	OVSO1

Parameter

	#7	#6	#5	#4	#3	#2	#1	#0
8160	NRS		NCS	AXS				

[Input type] Parameter input

[Data type] Bit path

#4 AXS When the axis moving signals MV1 to MV8<Fn102> or the axis moving direction signals MVD1 to MVD8<Fn106> of the slave axis in superimposed control is output:

0: State output is performed according to the result of adding superimposed move pulses.

1: State output is performed according to the result of movement along each axis instead of superimposed move pulses.

#5 NCS If an overtravel alarm is issued for an axis under synchronous, composite, or superimposed control, synchronous, composite, or superimposed control is:
0: Released.
1: Not released.

> **NOTE**
> If this parameter is set to 1 for any one of the paths in a machine group, it is assumed to be set to 1 for all the paths.

#7 NRS When the system is reset, synchronous, composite, or superimposed control is:
0: Released.
1: Not released.

	#7	#6	#5	#4	#3	#2	#1	#0
8162					OMRx			

[Input type] Parameter input
[Data type] Bit axis

#3 OMRx Superimposed mirror-image control is:
0: Not applied. (The superimposed pulse is simply added.)
1: Applied. (The inverted superimposed pulse is added.)

	#7	#6	#5	#4	#3	#2	#1	#0
8164		SOKx	OPSx					

[Input type] Parameter input
[Data type] Bit axis

#5 OPSx When superimposed control is canceled, control in which an amount of movement along a master axis subject to superimposed control is added to the workpiece coordinate of a slave axis is:
0: Not applied.
1: Applied.

> **NOTE**
> When the workpiece coordinate system is enabled (bit 0 of parameter No.8136 is 0), workpiece coordinate system presetting (equivalent to G92.1IP0) is performed to set up a coordinate system.

#6 SOKx If a master axis subject to superimposed control is also subject to synchronous control:
0: An alarm is issued when superimposed control is started during synchronous control.
1: No alarm is issued when superimposed control is started during synchronous control.

	#7	#6	#5	#4	#3	#2	#1	#0
8168				MWR			MSO	MPA

[Input type] Parameter input

[Data type] Bit

#0 MPA If an alarm concerning synchronous control, composite control, or superimposed control is issued:

0: All paths of the machine group to which the alarm occurrence path belongs are placed in feed hold state.

1: Only the path including the axis placed under synchronous control, composite control, or superimposed control is placed in the feed hold state.

#1 MSO When one of the following events occurs in synchronous control, composite control or superimposed control:

- The emergency stop signal *ESP <Gn008.4> is turned off.
- The servo-off signals SVF1 to SVF8 <Gn126.0 to Gn126.7> are turned on.
- A servo alarm is issued.

0: The synchronous, composite control or superimposed control mode is canceled and follow-up operation is not performed.
For the operation to be performed when the servo-off signal is turned on, however, the setting of bit 7 (NSR) of parameter No. 8161 is used in synchronous control or the setting of bit 0 (NMR) of parameter No. 8161 is used in composite control.

1: The synchronous, composite control or superimposed control mode is not canceled. The following operation is performed to perform follow-up operation:
When the emergency stop signal *ESP is turned off, the relevant path is determined and operation is performed so that the emergency stop signal *ESP is virtually turned off for the determined path.
When the servo-off signals SVF1 to SVF8 are turned on, the relevant axis is determined and operation is performed so that the servo-off signals SVF1 to SVF8 are virtually turned on for the determined axis.
When a servo alarm is issued, the relevant axis is determined and the alarm SV0003, "SYNCHRONOUS/COMPOSITE/SUPERIMPOSED CONTROL MODE CAN'T BE CONTINUED" is issued for the determined axis to stop moving the tool along the axis. When bit 2 (SVF) of parameter No. 8168 is set to 1, this servo-off specification follows the SVF setting.

> **NOTE**
> 1 This setting is valid also during operation. For all axes placed under synchronous, composite control or superimposed control, the emergency stop signal is turned off, the servo-off signal is turned on, or a servo alarm is issued.
> 2 If the servo-off signal is turned on, alarm DS1933 "NEED REF RETURN (SYNC:MIX:OVL)" will be generated in superimposed control.
> After canceling alarm, perform a manual reference position return.

#4 MWR When the synchronous control, composite control, or superimposed control is started or ended and the automatic setting of a workpiece coordinate system is executed, the tool offset number is:

0: Canceled.

1: Not canceled.

> **NOTE**
> This parameter is valid when the workpiece coordinate system is enabled (bit 0 of parameter No.8136 is 0).

8186	Master axis under superimposed control

[Input type] Parameter input
[Data type] Word axis
[Valid data range] 101, 102, 103,…, path number *100 + intra-path relative axis number (101, 102, 103,…, 201, 202, 203,…, 1001, 1002, 1003,….)

This parameter sets the path number and intra-path relative axis number of a superimposed master axis for each axis when superimposed control is exercised. When zero is specified, the axis does not become a slave axis under superimposed control and the move pulse of another axis is not superimposed.
An identical number can be specified in two or more parameters to exercise superimposed control simultaneously. This means that superimposed control with one master axis and multiple slave axes is possible.
A slave axis may function as the master axis of another axis to allow three-generation superimposed control: parent (master axis) - child (slave axis/master axis) - grandchild (slave axis).

In this case, a movement along the child is made by its travel distance plus the travel distance of the parent, and a movement along the grandchild is made by its travel distance plus the travel distance of the child plus the travel distance of the parent.

Example of the relationship of parent (X1 of path 1) - child (X2 of path 2) - grandchild (X3 of path 3):
The travel distance of X1 is superimposed on X2, and the travel distances of X1 and X2 are further superimposed on X3.
Parameter No. 8186 (X axis) of path 2 = 101
Parameter No. 8186 (X axis) of path 3 = 201

	#7	#6	#5	#4	#3	#2	#1	#0
11284								SSH

[Input type] Parameter input
[Data type] Bit

 # 0 SSH During superimposed control, manual handle interruption to the slave axis is:
0: Disabled.
1: Enabled.

Alarm and message

If any of the following alarms occurs, superimposed control will be released for all axes.

- P/S alarm

Number	Message	Description
PS0360	PARAMETER OF THE INDEX OF THE SUPERPOS CONTROL AXIS SET ERROR.	An illegal superimposed control axis number (parameter No. 8186) is specified.
PS0361	BECAUSE THE AXIS IS MOVING, THE SUPERPOS CONTROL IS CAN'T BE USED.	While the axis being subject to superimposed control was moving, an attempt was made to start or cancel the superimposed control by a superimposed control axis selection signal.

Number	Message	Description
PS0362	SUPERPOSITION CONTROL AXIS COMPOSITION ERROR.	This error occurred when: 1) An attempt was made to perform superimposed control for the axis in synchronization, composition, or superimposed. 2) An attempt was made to synchronize a further great-grandchild for a parent-child-grandchild relation.
PS0363	THE G28 WAS INSTRUCTED IN TO THE SUPERPOS CONTROL SLAVE AXIS.	This error occurred when G28 was specified to the superimposed control slave axis during superimposed control.
PS0364	THE G53 WAS INSTRUCTED IN TO THE SUPERPOS CONTROL SLAVE AXIS.	In superimposed control, this error occurs if G53 is specified to the slave axis during movement along the master axis.

- D/S alarm

Number	Message	Description
DS1933	NEED REF RETURN(SYNC:MIX:OVL)	The relation between a machine coordinate of an axis in synchronization, composition, or superimposed control, and the absolute, or relative coordinate was displaced. Perform the manual return to the reference position.

Caution

⚠ CAUTION

1 At the start or end of superimposed control, the tool must be stopped on the axis subject to that control.
2 Before or after an M code for starting or canceling superimposed control during automatic operation, be sure to specify a waiting M code (M code without buffering). When exercising superimposed control in a path, be sure to prohibit look-ahead operation by specifying an M code without buffering before or after an M code for starting or canceling superimposed control.
3 The axes under superimposed control must match in least command increment, detection unit, and diameter/radius specification. Otherwise, the amounts of travel will not be equal.
4 In superimposed control, do not change the parameters related to it (including axis control, increment system, feedrate, and acceleration/deceleration control).
5 Before starting superimposed control, make sure that the axes subject to it has undergone a reference position return after the power was turned on or that a reference position has been established with an absolute pulse coder.
6 If an emergency stop or servo off is performed or if a servo alarm occurs, the coordinates will change due to superimposed. If this occurs, alarm DS1933, "NEED REF RETURN (SYNC:MIX:OVL)" will be generated. After canceling the emergency stop, canceling servo off, or restoring from the servo alarm, perform a reference position return and coordinate system setting first, then start superimposed control.
7 In superimposed control, pitch error compensation, backlash compensation, and stored stroke check are performed on the position resulting from adding superimposing pulses.

⚠ **CAUTION**

8 The following servo software functions cannot be used with superimposed control:
- Feed forward function(*)
- Advance preview feed forward function(*)
- Fine acceleration/deceleration
- Abnormal load detection and switching function for each of cutting and rapid traverse
- Fine acceleration/deceleration and switching function for each of cutting and rapid traverse
- Cutting/rapid velocity gain switching function
- Electric current 1/2 and PI switching function for each of cutting and rapid traverse
- Torque command filter switching function for each of cutting and rapid traverse

9 The following functions cannot be used in superimposed control:
- Electronic gear box
- AI contour control I/II(*)
- Tool retract and recover

10 During superimposed control, reference position establishment based on "linear scale with absolute address reference mark" or "linear scale with absolute address zero point" is impossible.

(*) Please refer the section of "SUPERIMPOSED CONTROL AVAILABLE IN THE AI CONTOUR CONTROL MODE".

Note

NOTE

1 You can place more than one axis under superimposed control at the same time. You cannot, however, place an axis subject to synchronous or composite control under superimposed control.

2 Superimposed control cannot be performed on a linear axis and a rotation axis.

3 The superimposed control and axis synchronous control option can be specified at the same time. In this case, the master axis for superimposed control can be specified as the master axis for axis synchronous control.

Limitation

- Limitations on superimposed control

Function	In superimposed control
Acceleration/deceleration control	The move pulses of the superimposed control master axis after acceleration/deceleration are added to those of the slave axis after acceleration/deceleration.
Reference position return	Not allowed for a superimposed slave axis.
2nd, 3rd, 4th reference position return	Not allowed for a superimposed slave axis.
Reference position return check	Not allowed for a superimposed slave axis.
Machine coordinate system selection	Not allowed for a superimposed slave axis. (3)
PMC axis control	Allowed.
Polar coordinate interpolation, Cylindrical interpolation	Allowed.
Handle interruption	Not allowed for a superimposed control axis. (4)
Mirror image	Only master signals are effective to superimposing pulses. (1)
Machine lock	Only master signals are effective to superimposing pulses. (1)

Function	In superimposed control
Inter lock	Only master signals are effective to superimposing pulses. (1)
Override	Only master signals are effective to superimposing pulses. (1)
External deceleration	Only master signals are effective to superimposing pulses. (1)
Skip function	Allowed.
Automatic tool offset	Not allowed for a superimposed slave axis.
Follow-up	Not allowed in superimposed control.
Program restart	Not allowed for program containing superimposed control.
Cs contour control	Superimposed control is possible. (2)
Spindle positioning	Superimposed control is impossible.
EGB function	Not allowed in superimposed control.
Servo off	Superimposed control is impossible.

(1) For the move commands inherent to the master and slave, these functions are processed as usual; for superimposed pulses from the master axis, these functions are not applied to the slave.
(2) Limited to combinations of Cs axes. Switch to Cs mode and perform a reference position return first, then start superimposed control.
(3) If there are no superimposed pulses from the master axis, the machine coordinate system selection command can be specified on the path containing the slave axis.
Example)
If X1 is a master axis, and X2 is a slave axis

Path 1	Path 2	
M120P12;	M120P12;	Waiting
G01Z100.0;	G53X50.0;	X1 (master axis)-X2 (slave axis) superimposed control
M121P12;	M121P12;	Waiting

In this case, alarm PS0364 is not issued because there is no command for X1, which is the master axis of X2 on path 2.
(4) If bit 0 (SSH) of parameter No. 11284 is set to 1, handle interrupt can be performed on the slave axis.

- Reading of coordinates in superimposed control

In superimposed control, the reading of custom macro system variable positional information or of current coordinates from the PMC window is as follows:

Positional information type	In superimposed control
Absolute coordinate	Reading possible. (*1)
Machine coordinate	Reading possible.
End point of each block	Reading possible. (*1)
Skip signal position	Reading possible. (*1)

(*1) Superimposing pulses are not added.

- Canceling superimposed control

Superimposed control is canceled in the event of the following, as well as when the synchronous/composite/superimposed control axis selection signal becomes "0".
(1) Emergency stop
(2) Reset
(3) Servo alarm
(4) Servo off
(5) Overtravel *1
(6) Alarm related to superimposed control
(7) Alarm PW0000
If one of the above events occurs in either path, all paths will be released from superimposed control. If one of the above events occurs in either path in superimposed control, the other path will automatically be placed in feedhold state (during automatic operation) or in interlock state (during manual operation).

*1: By setting bit 5 (NCS) of parameter No. 8160 to 1, you can prohibit the superimposed control axis from release from the superimposed control state even if the axis enters the overtravel state.

- Axis state output signals in superimposed control

State output signal	In superimposed control
Axis moving signals MVn <Fn102>	- On the master axis, as usual. - The slave axis reflects the travel state with the command on the slave, regardless of superimposed control pulses. (*1)(*2).
Axis moving direction signals MVDn <Fn106>	- On the master axis, the moving direction of the master axis. - For the slave axis, the moving direction after superimposed control pulses are added. (*2).
In-position signals INPn <Fn104>	- On the master axis, as usual. - The slave axis signal is always "1".
Reference position establishment signal ZRFn <Fn120>	- The signal on the axis for which the reference position has been established turns to "1".
Reference position return completion signal ZPn <Fn094>	- The signal value for each axis depends on the state of the axis.

(*1) In a positional deviation check, regardless of the states of these signals, parameter No. 1828 is used if move command pulses are sent to the motor (regardless of whether the axis is the master or slave) as the limit, and parameter No. 1829 if none are sent.

(*2) Using bit 4 (AXS) of parameter No. 8160, you can switch the slave axis state output between results with superimposed control pulses added and results of individual axial movements.

Examples of Use

- Examples of independent control and of superimposed control on the Z1 and Z2 axes

(1) Machine configuration

(a) Independent control

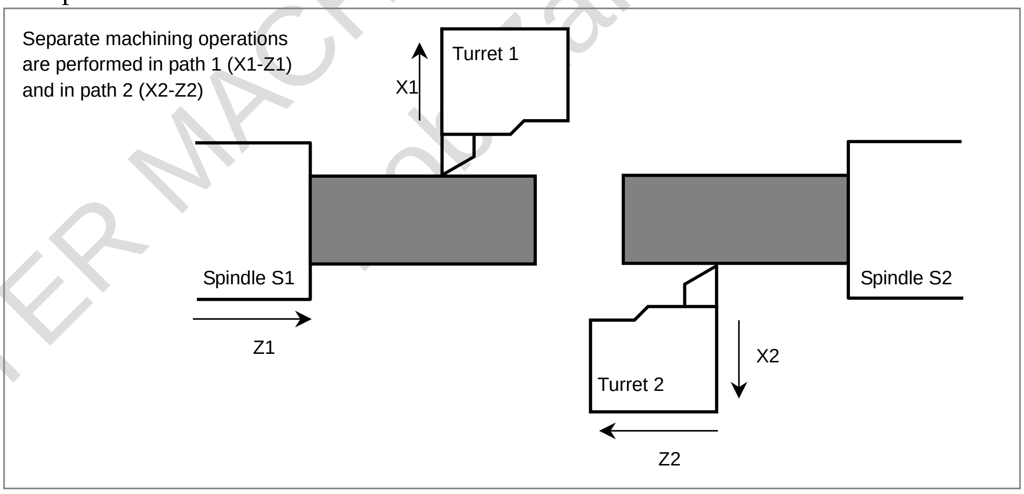

Fig. 8.7 (d)

(b) Z1-Z2 axis superimposed control

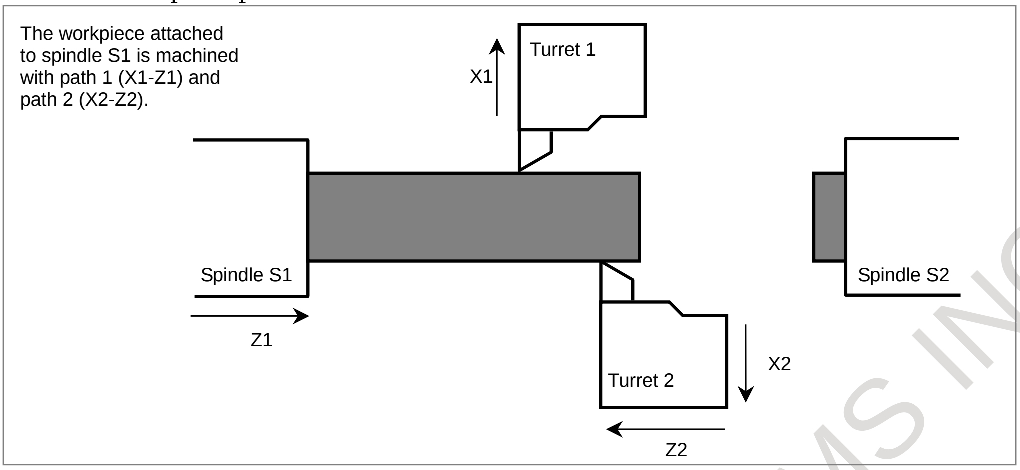

Fig. 8.7 (e)

(2) Parameter setting

- To superimpose the move command for the Z1 (master) axis on that of the Z2 (slave) axis, set parameter No. 8186z of path 2 to "102".
- Since the plus directions of the Z1 (master) and Z2 (slave) axes are opposite from each other, perform superimposed control with a mirror image applied. To do this, set bit 3 (OMRz) of parameter No. 8162 of path 2 to 1.

(3) Signal operation

- To start superimposed movement along the Z1 (master) axis and the Z2 (slave) axis, set signal OVLS2 <G1190.1> to "1".
- To cancel superimpose, set signal OVLS2 <G1190.1> to "0".
- When an emergency stop, NC reset, or alarm occurs, set signal OVLS2 <G1190.1> to "0".
- Set signals other than signal OVLS2 <G1190.1> to "0".

(4) Program example

Path 1		Path 2		
N1000	. . .	N2000	. . .	Independent machining of each path
N1010	M200 P12 ;	N2010	M200 P12 ;	Waiting
		N2020	M55 ;	Start of superimposed control from the Z1 axis to the Z2 axis
N1030	M201 P12 ;	N2030	M201 P12 ;	Waiting
		N2040	T0414 ;	Selection of a superimposed control tool and setting of an offset
N1050	S1000 M3 ;

N1010	M201 P12 ;	N2010	M201 P12 ;	Waiting
N1120	. . .	N2120	. . .	Independent machining of each path

where
M55 is an M code to start superimposed control, and
M56 is an M code to cancel superimposed control.

> ⚠ **CAUTION**
> If performing constant surface speed control, you must determine the spindle command in which path is currently effective to spindle S1.

> **NOTE**
> Input the speed of spindle S1 (feedback pulses from the position coder) to both paths 1 and 2.

Troubleshooting

1. Unable to start superimposed control. (No alarm occurs.)
   (1) The correct superimposed control have not been set up.
   → To perform superimposed control, you must set up the correct
   (2) The superimposed control axis selection signals OVLS1 to OVLS8 <Gn190> is not set to "1".
   → Superimposed control starts when the superimposed control axis selection signals OVLS1 to OVLS8 <Gn190> is changed from "0" to "1". After superimposed control ends due to a reset or alarm, merely canceling the reset or alarm cause will not cause superimposed control to restart. After canceling the reset or alarm cause, you must make the signal rise again.
   (3) The axis number of the axis subject to superimposed control is not set in the appropriate parameter.
   → To perform superimposed control, set the axis number of the master axis in parameter No. 8186.

(4) Superimposed control cannot be started if the NC unit is one of the following states:
- Emergency stop
- Reset
- Servo alarm
- Alarm PW0000
- Alarm related to superimposed control

Superimposed control cannot be started, either, if the axis on which superimposed control is to start is either of the following states:
- Servo off
- Overtravel

2. An attempt to raise a superimposed start signal results in PS alarm.
   (1) An attempt is made to use an axis already under superimposed control for another superimposed signal operation. (Alarm PS0362)
       → You cannot use a single axis for a combination of multiple superimposed control operations.
   (2) The axis number set in a parameter is greater than the number of controllable axes. (Alarm PS0360)
       → The number of the superimposed master axis and that of the interchanging axis subject to superimposed control must not exceed the number of axes controllable in the remote path (or the local path if you are to perform superimposed control in that path).
   (3) The tool is moving along the axis that you want to control. (Alarm PS0361)
       → At the start of superimposed control, the tool must be stopped on the axis subject to that control. That the tool is stopped on an axis means that the speed specified after acceleration/deceleration is zero.
   (4) An axis on which you want to perform superimposed control belongs to another machine group. (Alarm PS0360)
       → The axes on which you want to perform superimposed control must be of the same machine group.

3. An attempt to cancel superimposed control results in alarm PS0361.
   (1) The tool is moving along the axis on which the control you want to cancel.
       → To cancel superimposed control, the tool must be stopped on the axis on which to cancel it. That the tool is stopped on an axis means that the speed specified after acceleration/deceleration is zero. Before canceling, make sure that the axis moving signals MV1 to MV8 <Fn102> has changed to "0".

4. In superimposed control, the amount of travel is not correct.
   (1) The master and slave axes differ in diameter/radius specification or in inch/millimeter setting.
       → In superimposed control, diameter/radius conversion or inch/millimeter conversion is not performed between master and slave. The master and slave must match in least command increment.

5. In superimposed control, alarm PS0363 occurs.
   (1) In superimposed control, a reference position return is performed on the slave axis.
       → No reference position return can be performed on the slave axis under superimposed control.

6. Superimposed control is canceled although the superimposed control axis selection signals OVLS1 to OVLS8 <Gn190> is not changed from "1" to "0".
   → In superimposed control, superimposed control will be automatically canceled if at least either of the paths enters one of the following states:
   - Emergency stop
   - Reset
   - Servo alarm
   - Alarm PW0000
   - Alarm related to superimposed control

   In addition, if at least one of the axes on which superimposed control is in progress enters either of the following states:
   - Servo off
   - Overtravel

7. Alarm DS1933 occurs.
   → In superimposed control, alarm DS1933 occurs if at least one path enters one of the following states:
   - Emergency stop
   - Servo off
   - Servo alarm

   After canceling the emergency stop, after canceling servo off, or after restoring from the servo alarm, first perform a reference position return or coordinate system setting and then start superimposed control.

8.8 SUPERIMPOSED CONTROL(WITH SPEED CONTROL)

For a slave axis under superimposed control, a travel distance specified by the program for the master axis path is added to a travel distance specified by the program for the slave axis path. So, the actual speed on a slave axis is excessively higher than ordinary speed ("ordinary speed" means a speed such as a parameter-set rapid traverse rate).
To prevent this, feedrates and a linear acceleration/deceleration time constant in rapid traverse can be set for use only during superimposed control with this function.

The parameters for feedrates and a time constant usable only during superimposed control are indicated below.

-	Rapid traverse rate	Parameter No. 8190
-	F0 velocity of rapid traverse override	Parameter No. 8191
-	Linear acceleration/deceleration time constant in rapid traverse	Parameter No. 8192
-	Maximum cutting feedrate	Parameter No. 8194
(-	Manual rapid traverse rate	Value of parameter No. 8190 or 1424, whichever smaller)

During superimposed control, each of the master and slave axes uses these separately set parameters.
Set proper values, considering a feedrate after addition of a travel distance.

Parameter

8190	Rapid traverse rate of an axis under superimposed control

[Input type] Parameter input
[Data type] Real axis
[Unit of data] mm/min, inch/min, deg/min (machine unit)
[Min. unit of data] Depend on the increment system of the applied axis
[Valid data range] Refer to standard parameter setting table (C) (See “PREFACE” in this manual.)
(When the increment system is IS-B, 0 to +999000.0)

Set a rapid traverse rate for each of the axes when the rapid traverse override of the axes (master and slave axes) under superimposed control is 100%. The manual rapid traverse rate set in this parameter or the manual rapid traverse rate set in parameter No. 1424, whichever smaller, is used.
If this parameter is set to 0, the normal rapid traverse rate (parameter No. 1420) is used.

8191	F0 velocity of rapid traverse override of an axis under superimposed control

[Input type] Parameter input
[Data type] Real axis
[Unit of data] mm/min, inch/min, deg/min (machine unit)
[Min. unit of data] Depend on the increment system of the applied axis
[Valid data range] Refer to standard parameter setting table (C) (See “PREFACE” in this manual.)
(When the increment system is IS-B, 0 to +999000.0)
Set the F0 velocity of rapid traverse override of an axis under superimposed control (each of the master and slave axes).
If this parameter is set to 0, the F0 velocity of rapid traverse override in normal operation (parameter No. 1421) is used.

8192	Linear acceleration/deceleration time constant in rapid traverse of an axis under superimposed control

[Input type] Parameter input
[Data type] Word axis
[Unit of data] msec
[Valid data range] 0 to 4000
This parameter specifies the linear acceleration/deceleration time constant in rapid traverse for each of the axes (master and slave axes) under superimposed control.

8194	Maximum cutting feedrate in superimposed control

[Input type] Parameter input
[Data type] Real axis
[Unit of data] mm/min, inch/min, deg/min (machine unit)
[Min. unit of data] Depend on the increment system of the applied axis
[Valid data range] Refer to standard parameter setting table (C) (See “PREFACE” in this manual.)
(When the increment system is IS-B, 0 to +999000.0)
Set the maximum cutting feedrate that can be applied under superimposed control.
If this parameter is set to 0, the maximum cutting feedrate in normal operation (parameter No. 1430) is used.

8.9 SYNCHRONOUS, COMPOSITE, AND SUPERIMPOSED CONTROL BY PROGRAM COMMAND

Overview

Synchronous control, composite control, and superimposed control can be started or canceled using a program command instead of a DI signal.
Synchronous control, composite control, and superimposed control based on a DI signal is also possible.
For the basic operations of synchronous control, composite control, and superimposed control, see Section "SYNCHRONOUS / COMPOSITE CONTROL", and "SUPERIMPOSED CONTROL".

Format

G51.4 P_ Q_ (L_) ; Start synchronous control (L_ can be omitted)
G50.4 Q_ ; Cancel synchronous control

P: Number to identify synchronous master axis
Q: Number to identify synchronous slave axis
L: Parking state command
1: Master parking (slave parking cancel)
2: Slave parking (master parking cancel)
0: No parking (parking cancel)
(When L is omitted, the specification of L0 is assumed.)

G51.5 P_ Q_ ; Start composite control
G50.5 P_ Q_ ; Cancel composite control

P: Number to identify composite axis 1
Q: Number to identify composite axis 2

G51.6 P_ Q_ ; Start superimposed control
G50.6 Q_ ; Cancel superimposed control

P: Number to identify superimposed master axis
Q: Number to identify superimposed slave axis

Identification numbers are unique values that set into parameter No. 12600 in order to identify each axes.

NOTE
1 These commands are one-shot G code.
2 These commands must be specified in a single block.
3 When P,Q or L command is out of range, the alarm PS5339"ILLEGAL FORMAT COMMAND IS EXECUTED IN SYNC/MIX/OVL CONTROL." occurs.

Explanation

- Synchronous control

Synchronous control is exercised by the G51.4/G50.4 commands instead of the synchronous control axis selection signals (SYNC1 to SYNC8<Gn138.0-7>, n=0 to 9).

- Composite control

Composite control is exercised by the G51.5/G50.5 commands instead of the composite control axis change selection signals (MIX1 to MIX8<Gn128.0-7>, n=0 to 9).

- Superimposed control

Superimposed control is exercised by the G51.6/G50.6 commands instead of the superimposed control axis selection signals (OVLS1 to OVLS8<Gn190.0-7>, n=0 to 9).

Parameter

12600	Identification Number for synchronous, composite, and superimposed control by program command

[Input type] Parameter input
[Data type] Word axis
[Valid data range] 0,1 to 32767

Set identification numbers that can be specified with P,Q addresses.
The axis whose identification number is 0 cannot become under synchronous, composite, and superimposed control by program command.
The same identification number cannot be set to two or more axes through all paths.
When the same identification number is set, alarm PS5339 occurs at G50.4/G50.5/G50.6/G51.4/G51.5/G51.6 commands.

Alarm and message

Number	Message	Description
PS5339	ILLEGAL FORMAT COMMAND IS EXECUTED IN SYNC/MIX/OVL CONTROL.	1. The value of P, Q, or L specified by G51.4/G50.4/G51.5/G50.5/G51.6/G50.6 is invalid. 2. A duplicate value is specified by parameter No. 12600.

Note

NOTE

1 If a G code (G50.4/G50.5/G50.6) for canceling synchronous, composite, or superimposed control based on a program command is specified using a DI signal for an axis under synchronous, composite, or superimposed control, synchronous, composite, or superimposed control is canceled.

2 If the synchronous control axis selection signal/composite control axis change selection signal/superimposed control axis selection signal is set to 1 from 0 and to 0 from 1 for an axis under synchronous, composite, or superimposed control based on a program command, synchronous, composite, or superimposed control is canceled.
For an axis under synchronous, composite, or superimposed control based on a program command, if the synchronous control axis selection signal/composite control axis change selection signal/superimposed control axis selection signal is set to 1 from 0, the state of synchronous, composite, or superimposed control isn't influenced.

8.10 SUPERIMPOSED CONTROL AVAILABLE IN THE AI CONTOUR CONTROL MODE

Overview

This function enables superimposed control in the AI contour control mode.
Moreover, advance preview feed forward function becomes effective by the AI contour control when the parameters about advance preview feed forward function are set.

Explanation

To use superimposed control and AI contour control simultaneously during automatic operation, it is necessary to set the AI contour control permission signal OVLN to 1 and place the CNC in the advanced superimposition mode.

NOTE

1. To use superimposed control in the AI contour control mode, set the AI contour control permission signal for the master and slave axis paths to 1. If superimposed control is started when the advanced superimposition mode is off, AI contour control is turned off. Moreover, lowering of the precision or the shock might occur when the advanced superimposition mode for the one of paths is off.
2. Setting the AI contour control permission signal to 1 immediately after power-on can place the master and slave axis paths in the advanced superimposition mode without specifying a superimposed control mode on command in the program.

See the following example for the program sequence for specifying M codes for the advanced superimposition mode and superimposed control.

Program example)

Path of master axis	Path of slave axis
M100P12; ----- Waiting M210; ----- Advanced superimposition mode on. (Note 1) M101P12; ----- Waiting G05.1Q1; ----- AI contour control mode on. (Note 2) ~	M100P12; ----- Waiting M212; ----- Advanced superimposition mode on. M60; ----- Starts superimposed control. M101P12; ----- Waiting G05.1Q1; ----- AI contour control mode on. ~
: ------ Master axis move commands	~
~ M102P12; ----- Waiting M211; ----- Advanced superimposition mode off. (Note 1) M103P12; ----- Waiting	~ M102P12; ----- Waiting M61; ----- Cancels superimposed control. M213; ----- Advanced superimposition mode off. M103P12; ----- Waiting

NOTE

1. Turn the advanced superimposition mode on or off after canceling superimposed control for the slave path.
2. The AI contour control mode can be turned on by setting bit 0 (SHP) of parameter No. 1604 to 1 instead of using G05.1Q1;.

(1) Specify the waiting M code before and after the M codes for starting advanced superimposition and superimposed control.
  (a) Starts advanced superimposed control.
  Set the AI contour control permission signal OVLN to 1 and confirm that the advanced superimposition mode signal OVLNS is changed to 1.
  (b) Starts superimposed control.
  Set the superimposed control axis selection signal OVLS1 to OVLS8 for the slave axis of superimposed control to 1 (start of superimposed control) and confirm that the superimposed control under way signal SYN1O to SYN8O is changed to 1.

(2) Specify the waiting M code before and after the M codes for canceling advanced superimposition and superimposed control.
  (a) Cancels superimposed control.
  Set the superimposed control axis selection signal OVLS1 to OVLS8 for the slave axis of superimposed control to 0 (cancel of superimposed control) and confirm that the superimposed control under way signal SYN1O to SYN8O is changed to 0.
  (b) Cancels advanced superimposed control.
  Set the AI contour control permission signal OVLN to 0 and confirm that the advanced superimposition mode signal OVLNS is changed to 0.

Functions for which the advanced superimpositon mode cannot be specified

For any path for which the advanced superimposition mode is on, the following functions cannot be specified.
If any of the following functions is specified in the advanced superimposition mode, alarm PS0502 is issued.

- Reference position return in Cs contour control (G00,G28)
- Skip function (G31)
- Automatic tool length measurement / Automatic tool offset
- Low-speed type automatic reference position return (G28)
- High-speed program check

These functions can be specified after the advanced superimposition mode and superimposed control are turned off.
See the following example for the program sequence for specifying M codes for the advanced superimposition mode and superimposed control when a function that cannot be specified in the advanced superimposition mode is used.

Program example) (specifying G31 for the slave axis)

Path of master axis	Path of slave axis
M100P12; ----- Waiting M210; ----- Advanced superimposition mode on. M101P12; ----- Waiting G05.1Q1; ----- AI contour control mode on. ~	M100P12; ----- Waiting M212; ----- Advanced superimposition mode on. M60; ----- Starts superimposed control. M101P12; ----- Waiting G05.1Q1; ----- AI contour control mode on. ~
: ------ Master axis move commands	~
~ M102P12; ----- Waiting M211; ----- Advanced superimposition mode off. M103P12; ----- Waiting	~ M102P12; ----- Waiting M61; ----- Cancels superimposed control. M213; ----- Advanced superimposition mode off. M103P12; ----- Waiting
~	G31;
M104P12; ----- Waiting M210; ----- Advanced superimposition mode on. M105P12; ----- Waiting ~	M104P12; ----- Waiting M212; ----- Advanced superimposition mode on. M60; ----- Starts superimposed control. M105P12; ----- Waiting ~
: ------ Master axis move commands	~
~ M106P12; ----- Waiting M213; ----- Advanced superimposition mode off. M107P12; ----- Waiting	~ M106P12; ----- Waiting M61; ----- Cancels superimposed control. M213; ----- Advanced superimposition mode off. M107P12; ----- Waiting

NOTE

1. Start and cancel superimposed control for the slave axis. Specify the M code for starting or canceling superimposed control in a block without specifying other commands.
2. Use an unbuffered M code as the M code for turning the advanced superimposition mode on or off. (parameters Nos. 3411 to 3420)
3. Do not specify any move or PMC axis control command between the M code for turning the advanced superimposition mode on or off and a waiting M code.

Sequence of advanced superimposition and superimposed control start command

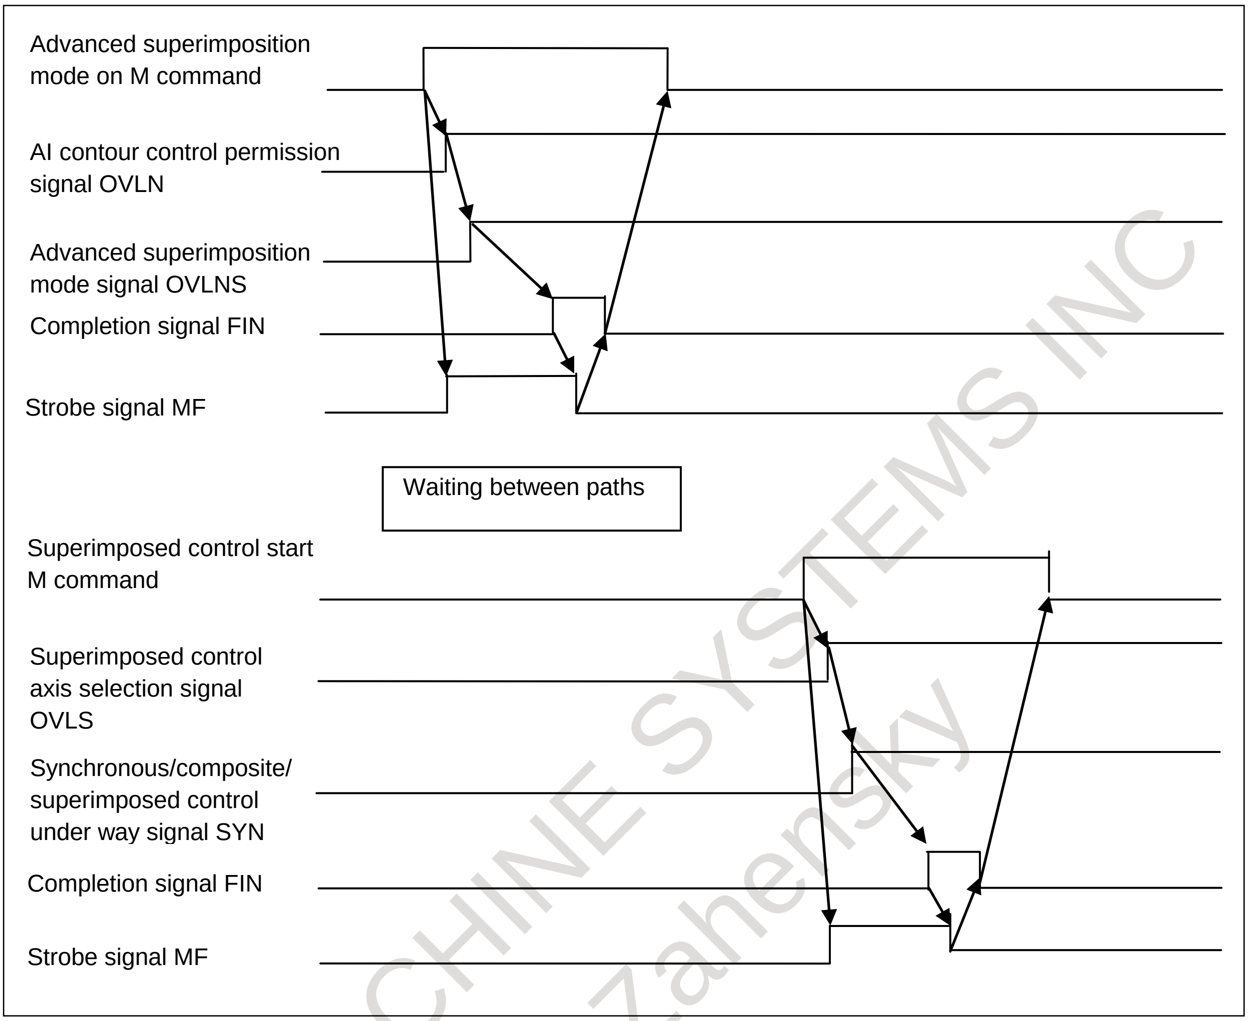

Fig. 8.10 (a)

1. When the M code for turning the advanced superimposition mode on is specified and the AI contour control permission signal OVLN is set to 1, the advanced superimposition mode signal OVLNS becomes 1.
2. The completion signal FIN is operated for completion.
3. The waiting M code is specified in both the master and slave axis paths.
4. When the M code for starting superimposed control is specified, and the superimposed control axis selection signal OVLS is set to 1, superimposed control starts. And, the superimposed control under way signal SYN becomes 1.
5. When the superimposed control under way signal SYN becomes 1, the completion signal FIN is operated for completion.

Sequence of advanced superimposition and superimposed control cancel command

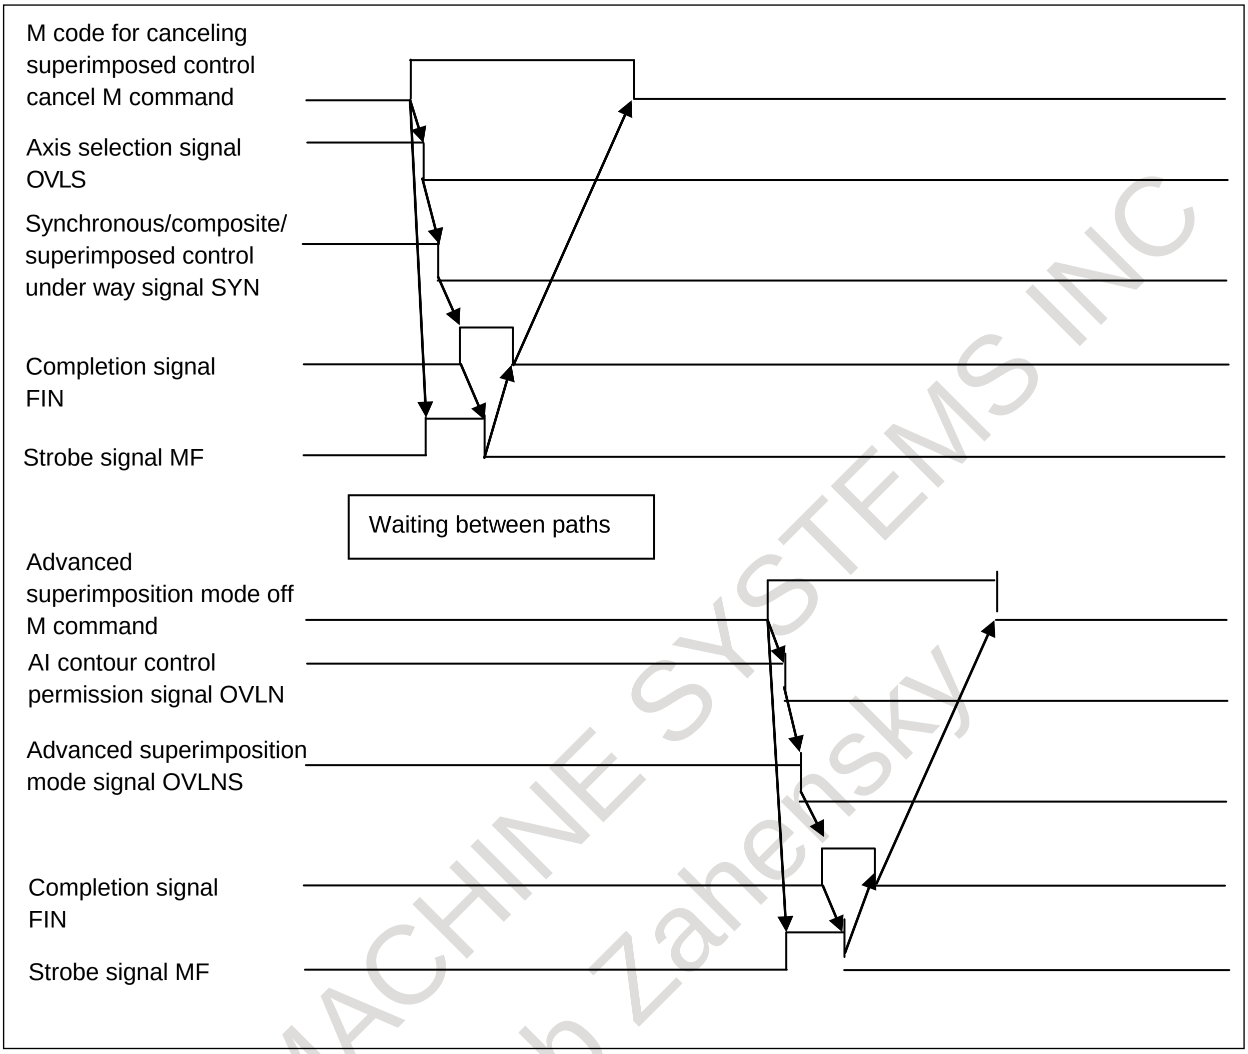

Fig. 8.10 (b)

1. When the M code for canceling superimposed control is specified and the superimposed control axis selection signal OVLS is set to 0, superimposed control is canceled.
2. When the superimposed control axis selection signal becomes 0, the completion signal FIN is operated for completion.
3. The waiting M code is specified in both the master and slave axis paths.
4. When the M code for turning the advanced superimposition mode off is specified and the AI contour control permission signal OVLN is set to 0, the advanced superimposition mode signal OVLNS becomes 0.
5. When the AI contour control permission signal OVLN becomes 0, the completion signal FIN is operated for completion.

Parameter

	#7	#6	#5	#4	#3	#2	#1	#0
8004					G8C			

[Input type] Parameter input
[Data type] Bit path

#3 G8C In PMC axis control, advanced preview feed forward is :
0: Disabled.
1: Enabled.

Signal

Superimposed control axis selection signals OVLS1 to OVLS8 <Gn190>

[Classification] Input signal
[Function] These signals perform superimposed control.
[Operation] When one of these signals becomes 1, the control unit operates as follows:
- Starts superimposed control with using the corresponding axis as the slave axis. Uses an axis as the master axis following the setting in parameter No. 8186.

Synchronous/composite/superimposed control under way signals SYN1O to SYN8O <Fn118>

[Classification] Output signal
[Function] These signals indicate that each axis is in the synchronous, composite, or superimposed control mode.
[Output cond.] These signals become 1 under the following condition:
- The corresponding axis is in the superimposed control mode.

These signals become 0 under the following condition:
- The corresponding axis is not in the superimposed control mode.

AI contour control permission signal OVLN <Gn531.4>

[Classification] Input signal
[Function] This signal enables superimposed control in the AI contour control mode by advanced superimposition.
[Operation] When this signal becomes 1, the control unit operates as follows:
- The corresponding path enters the advanced superimposition mode.

When the AI contour control permission signal is changed to 1 or 0, the tool must stop along all axes (other than PMC axes) in the target path. If the tool moves along any axis, alarm DS0071 is issued.

Advanced superimposition mode signal OVLNS <Fn545.1>

[Classification] Output signal
[Function] This signal indicates the advanced superimposition mode.
[Output cond.] This signal becomes 1 under the following condition:
- The corresponding path is in the advanced superimposition mode.

This signal becomes 0 under the following condition:
- The corresponding path is not in the advanced superimposition mode.

Alarm and message

Number	Message	Description
PS0502	ILLEGAL G-CODE (SUPERIMPOSED AHEAD)	A G code unavailable in the advanced superimposition mode was specified.
DS0071	START OR RELEASE OF SUPERIMPOSED AHEAD CANNOT BE DONE	To start or cancel the advanced superimposition mode, the tool must be stopped along all axes.
DS0072	MANUAL REFERENCE RETURN CANNOT BE DONE	In the advanced superimposition mode, manual reference position return cannot be performed.

Limitation

- Manual reference position return

In the advanced superimposition mode, manual reference position return cannot be performed. If an attempt is made to perform manual reference position return in the advanced superimposition mode, alarm DS0072 is issued.

- PMC axis control

In a system in which this function (AI contour control permission signal OVLN <Gn531.4>) is used, to use PMC axis control, it is necessary to set bit 3 (G8C) of parameter No.8004 to 1. For details, refer to "ADVANCED PREVIEW FEED FORWARD FOR PMC AXIS CONTROL".

- Others

The limitations on superimposed control and AI contour control are applied to this function. For basic specifications of and limitations on superimposed control and AI contour control, see the explanation of superimposed control and AI contour control in this manual.

8.11 PATH SPINDLE CONTROL

Overview

This function allows a workpiece attached to one spindle to be machined simultaneously with two tool posts and each of two workpieces attached to each of two spindles to be machined simultaneously with each of two tool posts.

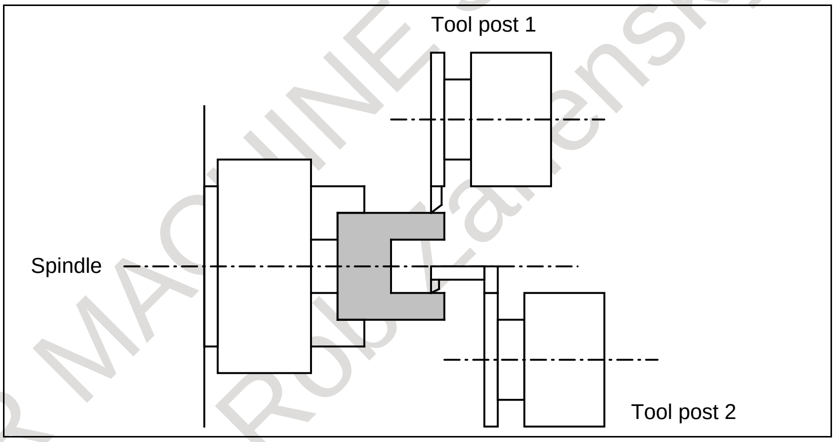

Fig. 8.11 (a) Application to a lathe with one spindle and two tool posts

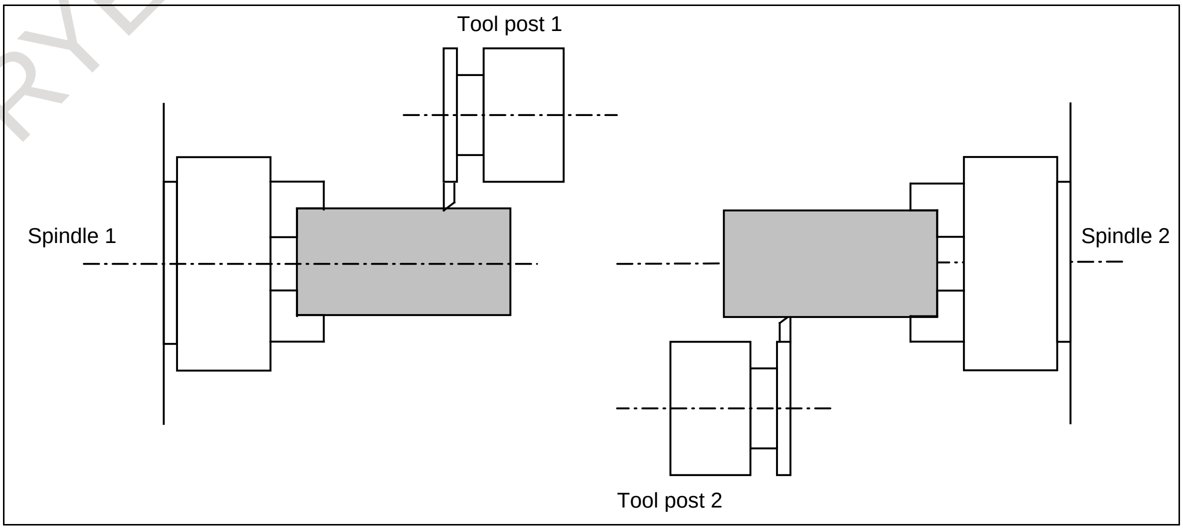

Fig. 8.11 (b) Application to a lathe with two spindles and two tool posts

The spindle belonging to each path can generally be controlled by programmed commands for the path. With path spindle command selection signals, programmed commands for any path can control the spindle belonging to any path.

When feed per revolution is performed on each path, the feedback pulses from the position coder attached on the spindle belonging to the path are generally used. With path spindle feedback selection signals, feed per revolution can be performed using the feedback pulses from the position coder attached on the spindle belonging to any path.

NOTE
1 The spindle speed is changed by spindle commands from multiple paths because path spindle command selection signals switch to spindle commands from relevant paths. Create a PMC sequence which determines whether spindle commands programmed for each path can be executed and switches over to another path spindle command selection signal.
2 When multiple paths share one analog spindle, during execution of a thread cutting command for a path, a function (such as thread cutting or feed per revolution) which uses the feedback pulses from the spindle on another path cannot be executed normally. Put restrictions so that during execution of thread cutting on a path, feed per revolution and other functions are not executed for the tool post on another path.

Explanation

- Selecting spindle commands
  Each path spindle command selection signal (input) can be used to switch over to spindle commands for the relevant path that the spindle belonging to each path follows.

- Selecting the feedback pulses from a position coder
  When a serial spindle is used, each path spindle feedback selection signal (input) can be used to switch over to the feedback pulses from the position coder attached on the spindle belonging to the relevant path that each path uses in the NC. Thread cutting and feed per revolution using the spindle belonging to a different path can be performed.

The following two signal types are available as selection methods using signals and each type is specified by parameter setting as follows.

Bit 0 (2P2) of parameter No. 3703	Signal type
0	Signal type A
1	Signal type B

The using method and meaning of signals differ depending on the signal type. For details, see the explanation of signals.

Each signal type is applicable to the following spindle configurations.

Signal type	Controlling the spindle belonging to path 1 from path 1 or 2	Controlling the spindle belonging to path 1 or 2 from path 1 or 2
Signal type A	○	×
Signal type B	○	○

> **NOTE**
> When the path spindle control function is used, the spindle gear selection method must be the T type.
> For a machining center system, set bit 4 (GTT) of parameter No. 3706 to 1 to select the T type as the spindle gear selection method.

- When multiple spindles belong to individual paths

Multi-spindle control can be used simultaneously to issue spindle commands to any spindle belonging to individual paths.
When multi-spindle control is not used, path spindle control is valid only for the 1st spindle belonging to individual paths.

The following two methods are available for selecting spindle commands in multi-spindle control:
1) Selecting spindle commands using signals (Bit 3 (MPP) of parameter No. 3703 is set to 0.)
2) Selecting spindle commands using address P (Bit 3 (MPP) of parameter No. 3703 is set to 1.)

When spindle commands are selected using address P, processing including path spindle command selection is performed in a multipath system. For this reason, spindle command selection using signals is invalid (this selection is made by spindle selection signals SWS1 to SWS4 <Gn027.0 to Gn027.2 and Gn026.3> and path spindle command selection signals SLSPA <Gn063.2>, SLSPB <Gn063.3>, SLSPC <Gn404.0>, and SLSPD <Gn404.1>).
Only one address P can be specified together with a spindle command and there is a one-to-one correspondence between address P values and spindles. For this reason, a spindle command in the same block cannot control multiple spindles simultaneously.

Selecting the feedback pulses from a position coder
The simultaneous use of multi-spindle control enables feed per revolution using the feedback pulses from the position coder on any spindle belonging to each path. Use signals (combination of position coder selection signal and path spindle feedback selection signal) to select the feedback pulses from a position coder.

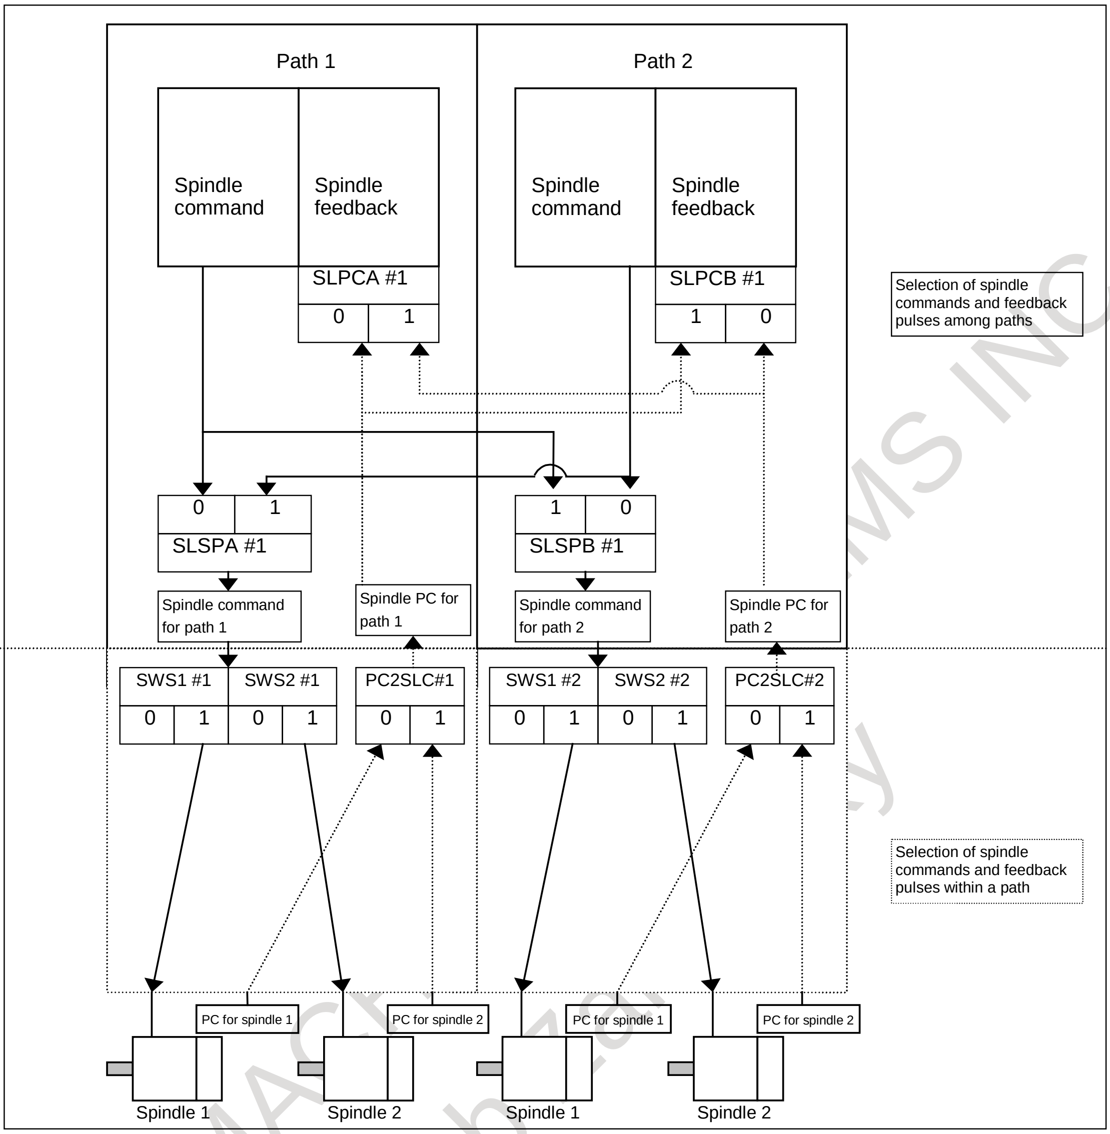

Fig. 8.11 (c) Configuration in which four spindles belonging to paths 1 and 2 are shared between the two paths (Path spindle control (signal type B) + multi-spindle control)

Signal

There are three signal types, which are selected with appropriate parameter settings.

Bit 2 (MPM) of parameter No. 3703	Bit 0 (2P2) of parameter No. 3703	Signal type
0	0	Signal type A
0	1	Signal type B
1	0/1	Signal type C

- Signal type A

Path spindle command selection signal SLSPA <G0063.2>

[Classification] Input signal

[Function] This signal specifies the path of the program commands to be effective to the spindles belonging to path 1.

[Operation]

Signal input SLSPA<G0063.2>	Program command to be effective to the spindle belonging to path m (= n + 1)
0	Spindle command of path 1
1	Spindle command of path 2

Path spindle feedback selection signal SLPCA<G0064.2>,SLPCB<G0064.3>

[Function] You need not control the path spindle feedback selection signal because the spindle feedback signal of path 1 is always effective to paths 1 and 2.

Path spindle command confirmation signal COSP <F0064.5>

[Classification] Output signal

[Function] This signal notifies which path the spindle command last specified came from.

[Output cond.] This signal becomes 1 under the following condition:

- A spindle command is issued from path 2.

This signal becomes 0 under the following condition:

- A spindle command is issued from path 1, or no spindle command is issued from either path.

In the state in which spindle commands for both paths 1 and 2 are effective to the spindles belonging to path 1, this signal allows you to determine which path the spindle command last specified came from.

> **NOTE**
> Spindle commands refer to S code commands, maximum speed command (G50S), M03/M04/M05, and commands for the constant surface speed control (G96 and G97).

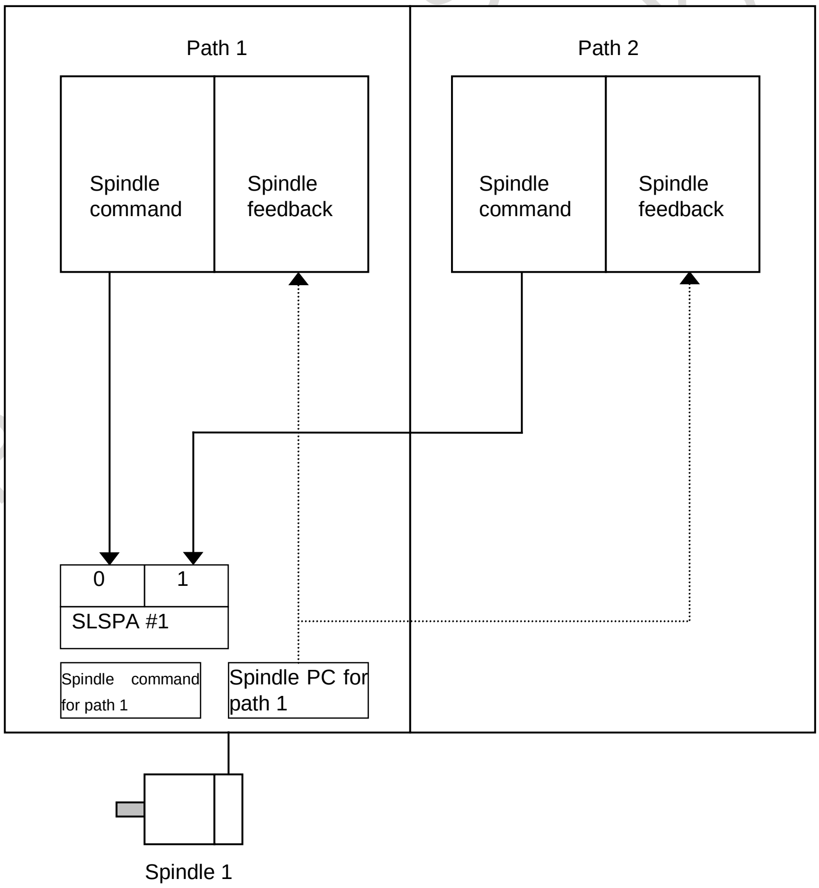

Fig. 8.11 (d) Configuration in which the spindle of path 1 is shared by 2 paths

- Signal type B

Path spindle command selection signal SLSPA<G0063.2>,SLSPB<G0063.3>

[Classification] Input signal

[Function] This signal specifies the path of the program commands to be effective to the spindles belonging to paths 1 and 2.

[Operation]

Signal input	Program command to be effective to the spindle belonging to path 1
SLSPA<G0063.2>	
0	Spindle command of path 1
1	Spindle command of path 2

Signal input	Program command to be effective to the spindle belonging to path 2
SLSPB<G0063.3>	
0	Spindle command of path 2
1	Spindle command of path 1

Path spindle feedback selection signal SLPCA<G0064.2>,SLPCB<G0064.3>

[Classification] Input signal

[Function] In paths 1 and 2, this signal specifies the path to which the spindle to which position coder feedback pulses are to be effective belongs.

[Operation]

Signal input	In path 1, the path to which the spindle to which position coder feedback pulses are to be effective belongs
SLPCA<G0064.2>	
0	Spindle PC of path 1
1	Spindle PC of path 2

Signal input	In path 2, the path to which the spindle to which position coder feedback pulses are to be effective belongs
SLPCB<G0064.3>	
0	Spindle PC of path 2
1	Spindle PC of path 1

Path spindle command confirmation signal COSP<F0064.5>

[Classification] Output signal

[Function] This signal notifies which path the spindle command last specified came from.

[Output cond.] This signal becomes 1 under the following condition:

- A spindle command is issued from path 2.

This signal becomes 0 under the following condition:

- A spindle command is issued from path 1, or no spindle command is issued from either path.

In the state in which spindle commands for both paths 1 and 2 are effective to the spindles belonging to path 1, this signal allows you to determine which path the spindle command last specified came from.

> **NOTE**
> Spindle commands refer to S code commands, maximum speed command (G50S), M03/M04/M05, and commands for the constant surface speed control (G96 and G97).

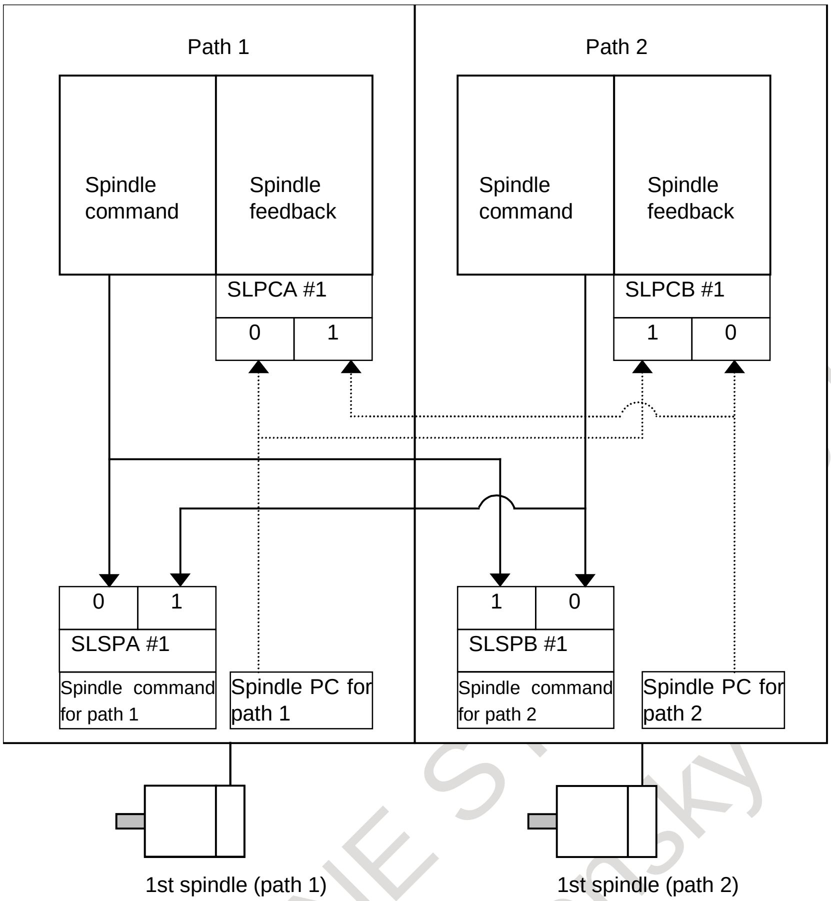

Fig. 8.11 (e) Configuration in which the spindles in paths 1 and 2 are shared by 2 paths

Signal address

	#7	#6	#5	#4	#3	#2	#1	#0
Gn063					SLSPB	SLSPA		
Gn064					SLPCB	SLPCA		

	#7	#6	#5	#4	#3	#2	#1	#0
Fn064			COSP					

Parameter

	#7	#6	#5	#4	#3	#2	#1	#0
3702							EMS	

[Input type] Parameter input
[Data type] Bit path

#1 EMS The multi-spindle control is:
0: Used.
1: Not used.

NOTE
1 Set this parameter for a path that does not require multi-spindle control in a 2-path control system.
2 To use this parameter requires enabling multi-spindle control (setting bit 3 (MSP) of parameter No. 8133).

	#7	#6	#5	#4	#3	#2	#1	#0
3703					**MPP**	**MPM**		**2P2**

[Input type] Parameter input
[Data type] Bit

> **NOTE**
> When at least one of these parameters is set, the power must be turned off before operation is continued.

#0 2P2 When a multi-path system is used, inter-path spindle control allows:
0: Configuration where the spindle that belongs to one path only is shared between path 1 and path 2.
1: Configuration where the spindles that belong to path 1 and 2 are shared between the two paths.

#3 MPP In multi-spindle control, a spindle selection using a programmed command instead of using Spindle selection signals (SWS1 to SWS4<G027.0 to 2, G026.3>) is:
0: Not made.
1: Made.

> **NOTE**
> When this parameter is set to 1, set parameter No. 3781 at the same time.

	#7	#6	#5	#4	#3	#2	#1	#0
3706					**PCS**			

[Input type] Parameter input
[Data type] Bit path

#3 PCS When a multi-path system is used, and multi-spindle control is enabled with each path, as the position coder signals (PC2SLC<Gn028.7>, PC3SLC<Gn026.0>, PC4SLC<Gn026.1>) for selecting the position coder of a spindle among the multiple spindles that belong to a path selected by the inter-path spindle feedback selection signals:
0: The signals of the path selected by the inter-path spindle feedback selection signal are used.
1: The signals of the local path are used.

Suppose that path x is selected by the inter-path spindle feedback selection signals (SLPCA<Gn064.2>, SLPCB<Gn064.3>, SLPCC<Gn403.4>, SLPCD<Gn403.5>). Then, the following position coder is selected in path x by the position coder selection signals:
n = m(path number)-1
y = x(path number selected by the spindle feedback selection signals)-1

When bit 3 (PCS) of parameter No. 3706 is set to 0

Position coder selected in path m	Selected path Position coder selection signals (path x)			Selecting path Position coder selection signals (path m)		
	PC2SLC <Gy028.7>	PC3SLC <Gy026.0>	PC4SLC <Gy026.1>	PC2SLC <Gn028.7>	PC3SLC <Gn026.0>	PC4SLC <Gn026.1>
PC1 of path x	0	0	0	-	-	-
PC2 of path x	1	0	0	-	-	-
PC3 of path x	0	1	0	-	-	-

Position coder selected in path m	Selected path Position coder selection signals (path x)			Selecting path Position coder selection signals (path m)

3781	P code for selecting the spindle in multi-spindle control

[Input type] Parameter input
[Data type] Word spindle
[Valid data range] 0 to 32767

If bit 3 (MPP) of parameter No. 3703 is set to 1, set the P code to select each spindle under multi-spindle control. Specify the P code in a block containing the S command.

[Example] If the P code value for selecting the second spindle is set to 3,
S1000 P3;
causes the second spindle to rotate at S1000.

NOTE
1 This parameter is valid if bit 3 (MPP) of parameter No. 3703 is set to 1.
2 If this parameter is set to 0, the corresponding spindle cannot be selected by a P code.
3 Under multi-path control, the P code specified here is valid for each path.
For instance, if the P code to select the first spindle of path 2 is set to 21, specifying S1000 P21; in path 1 causes the first spindle of path 2 to be rotated at S1000.
4 Identical P code values cannot be used for different spindles. (Identical P code values cannot be used even if the paths are different.)
5 When this parameter is used (when bit 3 (MPP) of parameter No. 3703 is set to 1), the spindle command selection signal is invalid.
6 To use this parameter, enable multi-spindle control (bit 3 (MSP) of parameter No. 8133 is 1).

	#7	#6	#5	#4	#3	#2	#1	#0
8133					MSP			

> **NOTE**
> When this parameter is set, the power must be turned off before operation is continued.

[Input type] Parameter input
[Data type] Bit

#3 MSP Multi-spindle is
0: Not Used.
1: Used.

Alarm and message

Number	Message	Description
PS5305	ILLEGAL SPINDLE NUMBER	In a spindle select function by address P for a multiple spindle control, 1) Address P is not specified. 2) Parameter No. 3781 is not specified to the spindle to be selected. 3) An illegal G code which cannot be commanded with an S_P_; command is specified. 4) The multi spindle cannot be used because the bit 1 (EMS) of parameter No. 3702 is 1. 5) The spindle amplifier number of each spindle is not set in parameter No. 3717. 6) A prohibited command for a spindle was issued (parameter No. 11090). 7) An invalid value is set in parameter No. 11090.

Note

> **NOTE**
> Signals used to operate the spindle control unit are not influenced by path spindle command selection signals; process them with a PMC Ladder program, if required.
> (Example: SFRA<G0070.5> is always a forward rotation command to the first serial spindle control amplifier of path 1.)

OPERATOR’S MANUAL (B-64694EN)	SPINDLE CONTROL BETWEEN EACH PATH

8.12 MEMORY COMMON TO PATHS

Overview

In a multipath system, this function enables data within the specified range to be accessed as data common to all paths. The data includes tool compensation memory and custom macro common variables.

Explanation

- Tool compensation memory

Part or all of tool compensation memory for individual paths can be used as common data by setting parameter No. 5029.

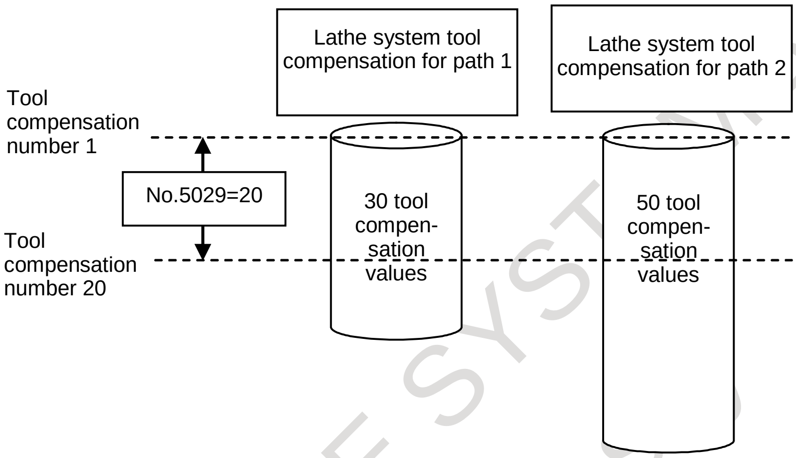

Fig. 8.12 (a)

> **NOTE**
> 1 Set a value less than the number of tool compensation values for each path for parameter No. 5029.
> 2 If the value set for parameter No. 5029 is greater than the number of tool compensation values for each path, the minimum number of tool compensation values for individual paths is assumed.

- Custom macro common variables

All or part of custom macro common variables #100 to #149 (or #199) and #500 to #599 (or #999) can be used as common data by setting parameters Nos. 6036 (#100 to #149 (, #199, or #499)) and 6037 (#500 to #599 (or #999)).

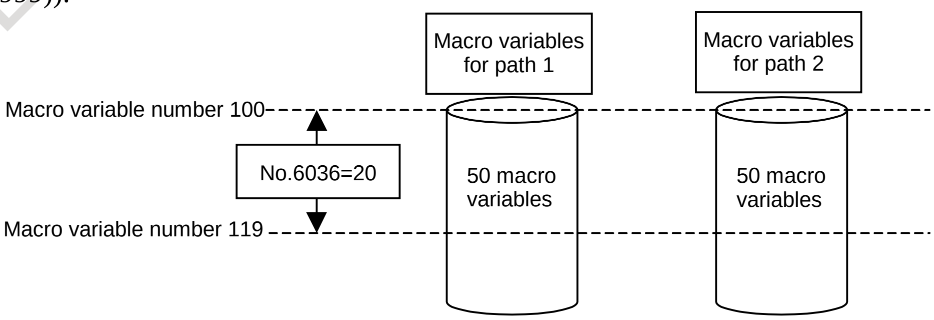

Fig. 8.12 (b)

> **NOTE**
> If the value of parameter No. 6036 or 6037 exceeds the maximum number of macro common variables, the maximum number of macro common variables is assumed.

Parameter

5024	Number of tool compensation values

> **NOTE**
> When this parameter is set, the power must be turned off before operation is continued.

[Input type] Parameter input
[Data type] Word path
[Valid data range] 0 to 999

Set the maximum allowable number of tool compensation values used for each path.
Ensure that the total number of values set in parameter No. 5024 for the individual paths is within the number of compensation values usable in the entire system. The number of compensation values usable in the entire system depends on the option configuration.
If the total number of values set in parameter No. 5024 for the individual paths exceeds the number of compensation values usable in the entire system, or 0 is set in parameter No. 5024 for all paths, the number of compensation values usable for each path is a value obtained by dividing the number of compensation values usable in the entire system by the number of paths.
Tool compensation values as many as the number of compensation values used for each path are displayed on the screen. If tool compensation numbers more than the number of compensation values usable for each path are specified, alarm PS0115 “VARIABLE NO. OUT OF RANGE” is issued.
For example, 64 tool compensation sets are used, 20 sets may be allocated to path 1, 30 sets to path 2, and 14 sets to path 3. All of 64 sets need not be used.

5029	Number of tool compensation value memories common to paths

> **NOTE**
> When this parameter is set, the power must be turned off before operation is continued.

[Input type] Parameter input
[Data type] Word
[Valid data range] 0 to 999

When using memories common to paths, set the number of common tool compensation values in this parameter.
Ensure that the setting of this parameter does not exceed the number of tool compensation values set for each path (parameter No. 5024).

[Example 1] When parameter No. 5029 = 10, parameter No. 5024 (path 1) = 15, and parameter No. 5024 (path 2) = 30 in a 2-path system, tool compensation numbers 1 to 10 of all paths are made common.

[Example 2] When parameter No. 5029 = 20 and the other conditions are the same as for Example 1, tool compensation numbers 1 to 15 are made common.

> **NOTE**
> 1 Ensure that the setting of parameter No. 5029 does not exceed the number of tool compensation values for each path (parameter No. 5024). If the setting of parameter No. 5029 exceeds the number of compensation values of a path, the least of the numbers of compensation values in all paths is made common.

> **NOTE**
> 2 When 0 or a negative value is set, memories common to paths are not used.

6036	Number of custom macro variables common to tool path (for #100 to #199 (#499))

> **NOTE**
> When this parameter is set, the power must be turned off before operation is continued.

[Input type] Parameter input
[Data type] Word
[Valid data range] 0 to 400

When the memory common to paths is used, this parameter sets the number of custom macro common variables to be shared (custom macro variables common to paths). Common variables #100 to #199 may be shared. Ensure that the maximum number of usable macro common variables is not exceeded.

[Example] When 20 is set in parameter No. 6036
#100 to #119: Shared by all paths
#120 to #149: Used by each path independently

> **NOTE**
> 1 To use from #160 to #199, enable Custom macro common variables(bit 6 (NCV) of parameter No.8135 is 0).
> 2 When 0 or a negative value is set, the memory common to paths is not used.

6037	Number of custom macro variables common to path (for #500 to #999)

> **NOTE**
> When this parameter is set, the power must be turned off before operation is continued.

[Input type] Parameter input
[Data type] Word
[Valid data range] 0 to 500

When the memory common to paths is used, this parameter sets the number of custom macro common variables to be shared (custom macro variables common to paths). Common variables #500 to #999 may be shared. Ensure that the maximum number of usable macro common variables is not exceeded.

[Example] When 50 is set in parameter No. 6037
#500 to #549: Shared by all paths
#550 to #599: Used by each path independently

> **NOTE**
> 1 To use from #600 to #999, enable Custom macro common variables(bit 6 (NCV) of parameter No.8135 is 0).
> 2 When 0 or a negative value is set, the memory common to paths is not used.

OPERATOR’S MANUAL (B-64694EN)	COMMON MEMORY BETWEEN EACH PATH

8.13 PATH SINGLE BLOCK CHECK FUNCTION

Overview

In multi-path control, each of the paths has single block command signals, so that their respective automatic operation programs can be brought to a single block stop. Even if, however, the single block command signals of the respective paths are set to 1, the times at which the programs will stop may not match, depending on the difference among command programs.

Example

Assuming that the following programs are started to perform SBK operation at the position of X0.0 in both paths

Path 1
```
O0001;
N1 G01 X10.0 F100 ;
N2 X20.0 ;
   :
```

Path 2
```
O0002;
N1 G01 X20.0 F100 ;
   :
   :
```

In the above example, path 1 enters the single block stop state after the completion of the movement by "X10.0", while in path 2, the movement by "X20.0" will be executed immediately.
This function prevents such an event from occurring; as soon as one path enters the single block stop state, this function places other paths in the feedhold stop states. This function enables single block operation while making sure that the machining programs of multiple paths have nearly been synchronized.
Because the single block command signals of the individual paths remain effective, so that uses such as the following are possible:

<1> Single block operation in which the single block command signal of path 1 only is set to 1 to follow the program of path 1

<2> Single block operation in which the single block command signals of multiple paths are set to 1 to follow the end of a specified block in one of the paths.

⚠ WARNING

If one of the paths is in the single block prohibited state or in the feedhold prohibited state due to threading, etc, the paths will not enter the stop state until that state is canceled. However, the paths enter the stop state if the single block prohibited state is set by the custom macro system variable #3003.

⚠ CAUTION

No operations such as synchronous processing on paths are performed. In an example such as that shown above, therefore, path 2 enters the feedhold stop state after the completion of the movement by "X10.0", but the stop position will be near "X10.0".

Parameter

	#7	#6	#5	#4	#3	#2	#1	#0
8100		DSB						

[Input type] Parameter input
[Data type] Bit machine group

#6 DSB The inter-path single block check function is:
0: Disabled.
When a single block stop occurs with a path, no single block stop occurs with the other path(s).
1: Enabled.
When a single block stop occurs with a path, a feed hold stop occurs with all paths in the same machine group.

8.14 PATH SELECTION/DISPLAY OF OPTIONAL PATH NAMES

Overview

Path selection specifies whether operations performed using the MDI unit is for each path.
The operations, as used here, include displaying and setting data items (such as tool compensation values), entering command programs in MDI mode, and editing machining programs in program memory.
Also note that the name of each path can be changed by parameter.

Signal

Path selection signals (Tool post selection signal)
HEAD<G063.0>

[Classification] Input signal
[Function] These signals select the path the MDI unit is to be for.
[Operation] Operations from the MDI unit will be on the path specified with HEAD. The relations between path selection signal combinations and selectable paths are as given in the table below.

Path selection signal HEAD G063.0	Path to be selected
0	Path 1
1	Path 2

Signal address

	#7	#6	#5	#4	#3	#2	#1	#0
G063								HEAD

Parameter

	#7	#6	#5	#4	#3	#2	#1	#0
8100							IAL	RST

[Input type] Parameter input
[Data type] Bit machine group

#0 RST The pressing of the 

key on the MDI unit is:
0: Valid for all paths in same machine group.
1: Valid only for the path selected by the path selection signal.

The  key on the MDI unit functions for all machine groups. So, in machine groups for which this parameter is set to 0, a reset can be performed for all paths. In machine groups for which this parameter is set to 1, a reset can be performed only for the path that is selected by the path select signal.

#1 IAL Choice of an option concerning operation continuation when an alarm is issued, and choice of an option concerning the start of automatic operation in alarm state:

0: When an alarm is issued, the operation is stopped with the other path(s) in same machine group placed in hold state.
When the other path or paths in same group are placed in alarm state, automatic operation cannot be started.

1: Even when an alarm is issued, the operation is continued without stopping the other path(s).
Even when the other path or paths in same group are placed in alarm state, automatic operation can be started.

3141	**Path name (1st character)**
3142	**Path name (2nd character)**
3143	**Path name (3rd character)**
3144	**Path name (4th character)**
3145	**Path name (5th character)**
3146	**Path name (6th character)**
3147	**Path name (7th character)**

[Input type] Parameter input
[Data type] Word path
[Valid data range] See the "CHARACTER CODE LIST".
Specify a path name with codes.
Any character string consisting of alphanumeric characters, katakana characters, and special characters with a maximum length of seven characters can be displayed as a series name.

> **NOTE**
> When 0 is set in parameter No. 3141, PATH1(,PATH2...) are displayed as path names.

CHARACTER CODE LIST

Character	Code	Comment	Character	Code	Comment	Character	Code	Comment
	032	Space	6	054		L	076

#5 PSC When the path is switched based on Path selection signal :
0: The screen display is switched to the last selected screen of the path.
1: The same screen as for the path before switching is displayed.

8.15 WAITING FUNCTION BY SPECIFYING START POINT

Overview

Control based on M codes is used to make one path to wait for the other during machining. When an M code for waiting is specified in a block of a path during automatic operation, the other path waits for the same M code to be specified before staring the execution of the next block.
In this function, by specifying a start point with a waiting M code, absolute coordinate value of that path or the other path can be used as the condition for waiting.

Format

M_ P3 L_ IP ;

Format to specify coordinates of a start point.
M : Waiting M code.
IP : Absolute coordinate value of a start point.
L : Specifying type of waiting (0,1).
L0 : This path waits until absolute coordinate on the other path arrives at start point.
L1 : The other path waits until absolute coordinate on this path arrives at start point.
P3 : Be sure to specify P3 (It can't be omitted).
∗The meaning of P command can be switched to "pattern of waiting with path number" by bit 1 (MWP) of parameter No. 8103.
For more detail information, please refer to "WAITING M CODES in this manual".

Note.
Specify absolute coordinate value of start point after M_ P_ L_. If start point is specified before M_ P_ L_, this block is operated as a normal waiting M code.
Specify L in an only one path.
If L is not specified in a block, this block is operated as a normal waiting M code, not the waiting function by specifying start point.

M_ P3 ;

Format not to specify coordinates of start point.

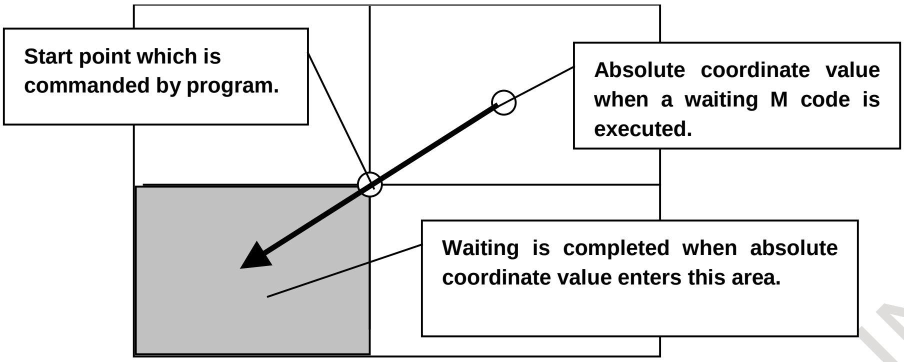
Operation

(1) When a waiting M code is specified on one path during automatic operation, that path waits until other paths execute the same waiting M code on the path with P command.

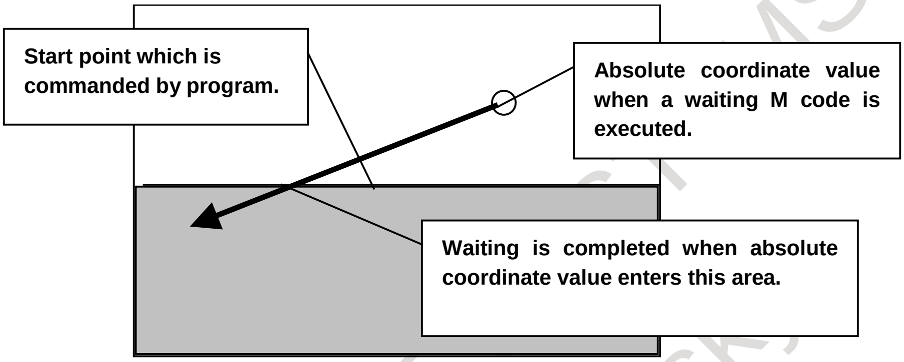
(2) After all related paths execute the same waiting M, The programmed coordinate values is compared with current ones, and a waiting area is decided.

Waiting is completed when absolute coordinate value enters the gray area in the following chart.

When command in coordinates for two axes



When command in coordinates for one axis



(3) If L0 is commanded, the other path executes a next block of a waiting M code, and the path with L0 waits until absolute coordinate value on the other path enters a gray area. If L1 is commanded, a next block of a waiting M code is executed, and the path with L1 makes the other path wait until absolute coordinate value of the path with L1 enters a gray area.

(4) After completing the waiting, the waited path begins to execute a following block of a waiting M code.

Example of program

L0 command

Path 1	Path 2
O0100; G00 X0.0 ; G00 Z0.0 ; : G00 X50.0 Z50.0 ;	O0100; G00 X0.0 Z0.0 ; M103 P3 L0 X10.0 Z10.0 ;
	Waiting for (1).
M103 P3;........................(1)	Path2 begins to wait till other path crosses coordinate values (X≤10.0, Z≤10.0).
X-30.0 Z-30.0 ;...............(2)	Path2 begins to execute a next block because coordinate values of other path crosses (X≤10.0, Z≤10.0) in the middle of block (2).

Path 1	Path 2
O0100; G00 X0.0 ; G00 Z0.0 ; : G00 X50.0 Z50.0 ; M103 P3;......................(1)	O0100; G00 X0.0 Z0.0 ; M103 P3 L0 X10.0 Z10.0 ;
	Waiting for (1)
	Path2 begins to wait till other path crosses coordinate values (X≤10.0, Z≤10.0).
S1000 M03 ; G99 G01 X-30.0 F0.2 ; ..(2) Z-30.0 ;.........................(3)	Path2 keeps waiting because the requirement of Z axis is not met though coordinate value of X axis crosses (X≤10.0) in block (2).
	Path2 begins to execute a next block because coordinate values crosses Z≤10.0 on the way of block (3).

L1 command

Path 1	Path 2
O0100; G00 X0.0 ; G00 Z0.0 ; : G00 X50.0 Z50.0 ; M103 P3;......................(1)	O0100; G00 X0.0 Z0.0 ; M103 P3 L1 X10.0 Z10.0 ; .... Waiting for (1)
Waiting till other path crosses coordinate values (X≥10.0, Z≥10.0)	Path2 begins to execute a next block
Path1 begins to execute a next block because coordinate values crosses (X≥10.0, Z≥10.0) in the middle of block (2).	G00 X50.0 Z50.0 ; ....(2)

Parameter

	#7	#6	#5	#4	#3	#2	#1	#0
3104	DAC	DAL						

[Input type] Parameter input
[Data type] Bit path

#6 DAL The displayed absolute position is
0: The actual position that takes tool length offset into account.
1: The programmed position that does not take tool length offset into account.

NOTE
In lathe systems, whether a tool offset is excluded from displaying absolute position is determined by the setting of bit 1 (DAP) of parameter No.3129.

#7 **DAC** When an absolute position are displayed:
0: Values not excluding the amount of travel based on cutter compensation and tool nose radius compensation are displayed.
1: Values excluding the amount of travel based on cutter compensation and tool nose radius compensation (programmed positions) are displayed.

NOTE
When the parameter DAC is set to 1, in the command like circle interpolation where the cutter compensation vector is changed constantly, an absolute position is not correctly displayed during its interpolation except its start point and its end point.

	#7	#6	#5	#4	#3	#2	#1	#0
3129							DAP	

[Input type] Parameter input
[Data type] Bit path

#1 DAP For absolute coordinate display:
0: The actual position including a tool offset (tool movement) is displayed.
1: The programmed position excluding a tool offset (tool movement) is displayed.

NOTE
In machining center systems, whether the tool length offset is excluded from displaying absolute position is determined according to the setting of bit 6 (DAL) of parameter No.3104

	#7	#6	#5	#4	#3	#2	#1	#0
8101							STW	

[Input type] Parameter input
[Data type] Bit path

#1 STW Waiting function by specifying start point is
0: Not effective.
1: Effective.

8110	Waiting M code range (minimum value)
8111	Waiting M code range (maximum value)

[Input type] Parameter input
[Data type] 2-word
[Valid data range] 0 ,100 to 99999999
A range of M code values can be set by specifying a minimum waiting M code value (parameter No. 8110) and a maximum waiting M code value (parameter No. 8111).

(parameter No. 8110) ≤ (waiting M code) ≤ (parameter No. 8111)

Set 0 in these parameters when the waiting M code is not used.

Signal

No-wait signal
NMWT<Gn063.7>(for path individual signal interface)

[Classification] Input signal

[Function] Specifies whether to synchronize the paths by the waiting M code.

[Operation] When this signal turns to "1" the paths are not synchronized by the M code. The M code for waiting specified in a machining program is ignored.
When this signal turns to "0", the paths are synchronized by the M code. When the M code for waiting is specified for one path, the next block starts executed after the same M code is specified on another path.

> **NOTE**
> Set all signals NMWT <Gn063.7> to "1" for ignoring the waiting when using M code for the waiting function by specifying start point.

Waiting signal
WATO<F0063.6>(for path common signal interface)
WATO<Fn063.6>(for path individual signal interface)

[Classification] Output signal

[Function] Indicates that a waiting M code is being executed.

[Output cond.] These signals are "1" as long as:
- One path is waiting for another path. That is, the signal stays "1" for the period from when the M code for waiting is issued to one path to when the corresponding M code is issued to another path. In addition of the waiting function by specifying start point, the signal stays "1" when one path is waiting for the completion of the axis movement.

This signal is "0" as long as:
- Neither of the paths is waiting for the other.

Auxiliary function code signals M00 to M31<Fn010 to Fn013>

[Classification] Output signal

[Function] These signals report that auxiliary functions are specified.

[Output cond.] When the waiting function by specifying start point is available, these signals are output during waiting for other path M code or the completion of the axis movement.

Signal address

Fn063		WATO						

Alarm and message

Number	Message	Description
PS0003	TOO MANY DIGIT	Data entered with more digits than permitted in the NC instruction word. The number of permissible digits varies according to the function and the word.
PS0009	IMPROPER NC-ADDRESS	An illegal address was specified, or parameter 1020 is not set.
PS0160	MISMATCH WAITING M-CODE	A waiting M-code is in error. <1> When different M codes are specified for path 1 and path 2 as waiting M codes without a P command. <2> When the waiting M codes are not identical even though the P commands are identical <3> When the waiting M codes are identical and the P commands are not identical (This occurs when a P command is specified with binary value.) <4> When the number lists in the P commands contain a different number even though the waiting M codes are identical (This occurs when a P command is specified by combining path numbers.) <5> When a waiting M code without a P command (2-path waiting) and a waiting M code with a P command were specified at the same time <6> When the waiting function by specifying start point and a waiting M code without a P command (2-path waiting) were specified at the same time.
PS0161	ILLEGAL P OF WAITING M-CODE	P in a waiting M-code is incorrect. <1> When address P is negative <2> When a P value inappropriate for the system configuration was specified

Note

Inch / metric switching

Specifying coordinates of the waiting function by specifying start point might be failed when the input unit system is changed by G20/G21 during executing program.

```
O0100;
G20   ; (METRIC)
G00 X0 Z0. ;
  :
G21 ; (INCH)
G00 X50. Z50. ;
M103 P3;......................(1)
X-30. Z-30. ; .................(2)
```

```
O0100;
G00 X0. Z0. ;
M103 P3 L0 X10. Z10. ; .
(When M103 is executed,
the other path is a unit of
metric.)
Coordinates of a different
unit are compared because
the input unit system has
been changed when
waiting M code ends.
```

Current block display

The start position coordinates are not displayed in the current block display and the next block display of the program screen.

Execution macro

The waiting function by specifying start point cannot be used in execution macro (P-code program).
Also, macro cannot be called by M code of the waiting function by specifying start point.

Manual operation during waiting

Even if mode of operation is changed to the manual mode during waiting by specifying start position, waiting is completed when absolute coordinate value enters the specified area.
At this time, please change to JOG mode in only a path which axis moves, and please maintain memory mode in a path that is waiting.

Repetition of waiting command

When both of paths command L0, waiting is not completed and halt because each path waits for the movement of the other path.

Path 1)	Path2)
M_ P_ L0 X_ Z_ ; Halt	M_ P_ L0 X_ Z_ ; Halt

When a path command L1 and another path command L0, waiting of a path with L1 is completed and executes a next block, however waiting of a path with L0 is not completed and halt.

Path 1)	Path2)
M_ P_ L1 X_ Z_ ; Execute a next block	M_ P_ L0 X_ Z_ ; Halt

Amount of tool compensation and current position display

When the absolute coordinate value of the current position display reaches the start position, waiting is completed. Therefore, the start position can be shifted from the program coordinates when the tool compensation (wear-out compensation and tool-nose radius compensation etc.) is effective.

Example)

```
T0101 ; (When the amount wear-out compensation is X = -1.000)
G00 X0.0 ;
M103 P3 L1 X10.0 ;
G00 X20.0 ;
```

- When bit 6 (DAL) of parameter No. 3104 is 0, waiting is completed when absolute coordinate value is X = 10.000 and the amount of distance to go is X = 9.000.
- When bit 6 (DAL) of parameter No. 3104 is 0, waiting is completed when absolute coordinate value is X = 10.000 and the amount of distance to go is X = 10.000.

Manual handle retrace

Forward movement

There is not any restriction in forward movement.

Backward movement

When this function is effective, manual handle retrace function prohibits changing direction at a waiting M code block in backward movement. Continue backward movement until waiting M code is appeared in all paths.

> **NOTE**
> When this function or waiting M code is used with manual handle retrace, please set bit 4 (HMP) of parameter No. 6400 to 1 in the both of paths, and when inversion or backward movement is inhibited in other path, inversion or backward movement is inhibited also for the current executed path.

Flexible path axis assignment

Please do not execute flexible path axis assignment when paths are waiting.

Retrace (M system)

When the waiting function by specifying start point is available, a waiting M code cannot move backward. Only forward movement is possible.

Incremental command

Even if incremental command mode is selected by G91 command in G code system B or C at the path where M code for the waiting function by specifying start point is specified, it is assumed that absolute coordinate value is specified as a start point.
If address U, V or W, that are incremental commands, are specified as start point, the alarm PS0009 occurs.

Rotary axis roll- over

If a rotary axis which has roll-over function is specified as an axis of start point, this coordinate value, to which roll-over function is not applied, is compared with the current absolute coordinate value which is rounded by the angle corresponding to one rotation to judge whether a condition for waiting is met.

Example)
The axis A is the rotary axis and the amount of movement per rotation is 360.000
(Parameter No. 1260 = 360.000)

```
N10 G00 A0.0 ;
N20 M100 P3 L1 A180.0 ;
N30 G00 A-10.0 ;
```

After the end of N30 block, the absolute coordinate value of A axis is 350.0. Therefore, because this value becomes A≥180.0 in the middle of this block, waiting is completed.

8.16 FUNCTION FOR LOADER CONTROL

Overview

The function for loader control is used to control the devices for performing a non-machining operation (peripheral device such as a loader). When this function is valid, the path for performing a loader control is added besides a path for machining.
(In the subsequent explanation, the path which applies the function for loader control is called the loader path, while the other path is called the machining path.)

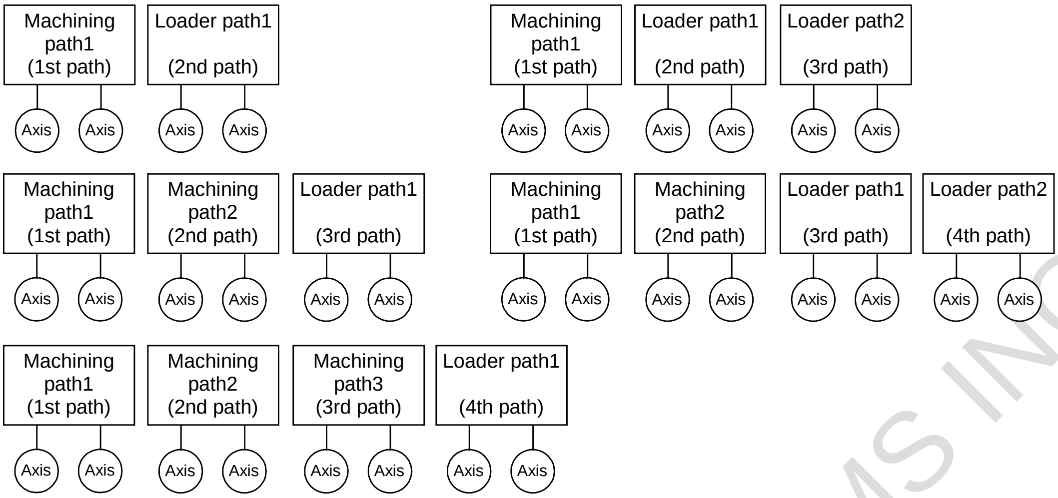
Explanation

- System configuration

When the function for loader control is valid, a combination of paths is as follows.

Machining path 1 + Loader path 1
Machining path 1 + Loader path 1 + Loader path 2
Machining path 1 + Machining path 2 + Loader path 1
Machining path 1 + Machining path 2 + Loader path 1 + Loader path 2
Machining path 1 + Machining path 2 + Machining path 3 + Loader path 2

Loader paths follow machining paths. When a number of machining paths is only 1, loader paths are added as the second or later path. When a number of machining paths is 2, loader paths are added as the third or later path. Loader path can be added up to 2 paths, but the total number of machining paths and loader paths cannot exceed 4.



> **NOTE**
> 1 To use the loader path 2, the addition of loader control path option is required in addition to the function for loader control option.
> 2 The function for loader control cannot be used in the system with more than 4 machining paths.

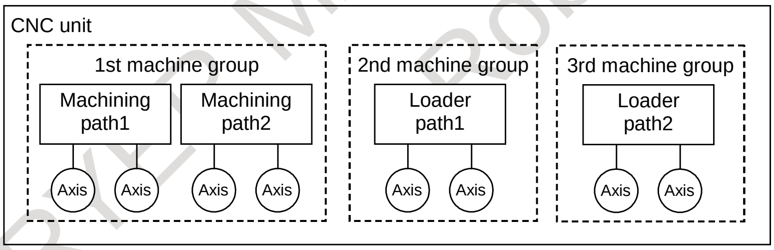
- Machine control type

When lathe system is specified as the machine control type, all paths including loader paths are controlled as a lathe. When machining center system is also specified as same, all paths are controlled as a machining center. When combined system is specified, each path can be selected either lathe system or machining center system. Select either type for a loader path.

- Machine group

A machine group is available on a loader path. Up to 3 groups are available, depending on the type of the CNC system.

Example)



- Number of feed axes

The maximum number of feed axes for the loader path is 4. However, when there are 2 loader paths, the maximum number of feed axes is 3 per path. When a controlled axis is assigned to a loader path, the absolute path number of a loader path is set to parameter No.981.

Example 1)

For a system with 2 paths and a total of 6 controlled axes:
Settings that cause the system to become a 2-path system with the machining path 1 consisting of 3 controlled axes and the loader path 1 consisting of 3 controlled axes.

Setting value of parameter No. 0981	Application
1	Machining path 1 (1st path), axis 1
1	Machining path 1 (1st path), axis 2

Setting value of parameter No. 0981	Application
1	Machining path 1 (1st path), axis 3
2	Loader path 1 (2nd path), axis 1
2	Loader path 1 (2nd path), axis 2
2	Loader path 1 (2nd path), axis 3

Example 2)

For a system with 4 paths and a total of 10 controlled axes:

Settings that cause the system to become a 4-path system with the machining path 1 consisting of 3 controlled axes, the machining path 2 consisting of 3 controlled axes, the loader path 1 consisting of 2 controlled axes and the loader path 2 consisting of 2 controlled axes.

Setting value of parameter No. 0981	Application
1	Machining path 1 (1st path), axis 1
1	Machining path 1 (1st path), axis 2
1	Machining path 1 (1st path), axis 3
2	Machining path 2 (2nd path), axis 1
2	Machining path 2 (2nd path), axis 2
2	Machining path 2 (2nd path), axis 3
3	Loader path 1 (3rd path), axis 1
3	Loader path 1 (3rd path), axis 2
4	Loader path 2 (4th path), axis 1
4	Loader path 2 (4th path), axis 2

- Designation of spindle axes

The loader path does not have a spindle. When the loader path is specified in a parameter No.982, which specifies the path to which each spindle belongs, alarm PS0365, “TOO MANY MAXIMUM SV/SP AXIS NUMBER PER PATH” is issued.

- Part program storage size / Number of registerable programs

A part program storage size and a number of registerable programs for the loader path are included in them of an entire system. Even when the loader path is added, part program storage size / number of registerable programs of an entire system do not change.

- DI/DO

The DI/DO specifications of the loader path confirm to the DI/DO specifications in multi-path control. In the loader path also, therefore, create a ladder program with the same interface as that for the machining path. Addresses of signals for a loader path are as follows.

- In case that a number of machining path is only 1:
  Loader path 1: F1000 to F1767, G1000 to G1767 (the 2nd path in the entire system)
  Loader path 2: F2000 to F2767, G2000 to G2767 (the 3rd path in the entire system)

- In case that a number of machining path is 2:
  Loader path 1: F2000 to F2767, G2000 to G2767 (the 3rd path in the entire system)
  Loader path 2: F3000 to F3767, G3000 to G3767 (the 4th path in the entire system)

- In case that a number of machining path is 3:
  Loader path 1: F3000 to F3767, G3000 to G3767 (the 4th path in the entire system)

- Path selection

When the loader control selection signal LCBS <G0251.1> turns to "1", the reference destination of screen display and MDI operation are switched to a loader path. If the loader path 2 exists, when the loader control 2 selection signal LCB2 <G0251.2> turns to "1", the loader path 2 is subjected to screen display or MDI operation.

When both signals are set to "1", the loader path 1 is selected.

When both the loader control selection signal and the loader control 2 selection signal are set to "0", a selected path can be switched between a machining path and a loader path by MDI key operation. Whenever MDI keys SHIFT and HELP are pressed at the same time, a selected path is switched between a machining path and a loader path alternately. If the loader path 2 exists, when the loader path 1 is selected, the loader path 2 is switched by the MDI key operation. In case of switching from a loader path to a machining path, a machining path which is selected by the path selection signals (HEAD <G0063.0>, H EAD2 <G0062.7>) is switched.

Example)
4-path system (machining path 1, machining path 2, loader path 1, and loader path 2)

- In case of selecting the machining path 1 by the path selection signal (HEAD="0", HEAD2="0") Whenever MDI keys SHIFT and HELP are pressed at the same time, a selected path is switched in the following order.

  Machining path 1 → Loader path 1 → Loader path 2

Path selection by MDI key operation can be disabled by setting bit 3 (SCD) of parameter No.8106.
When the loader path1 is selected, the loader path selection check signal LC1O<F0297.1> turns to "1".
When the loader path 2 is selected, the loader path 2 selection check signal LC2O<F0297.2> turns to "1".

When the loader path is selected, “LC” is displayed at the lower right of the screen. If the loader path 2 exists, “LC1” is displayed on the loader path 1 and “LC2” is displayed on the loader path 2. Optional path name can be displayed by setting parameters Nos. 3141 to 3147. A name of the loader path can be displayed in reverse video by setting bit 1 (LCI) of parameter No.11362.

- Waiting M codes

Waiting M codes are available between the loader path and the machining path. The following two methods for specifying paths which are to wait for one another at address P in the same block in which an M code for waiting is specified are available and can be selected using bit 1 (MWP) of parameter No. 8103. One method is to specify the paths with the sum of their corresponding binary values. The other is to specify them with their path numbers in combination.

- When bit 1 (MWP) of parameter No. 8103 is set to 0:

The sum of the binary values corresponding to the numbers of paths which are to wait for one another is specified with address P.

Path number	Binary value (decimal number)
1	1
2	2
3	4
4	8

Example)
4-path system (machining path 1, machining path 2, loader path 1, and loader path 2)
P5: Machining path 1 and loader path 1 wait for each other. (1+4)
P15: Machining path 1, 2 and loader path 1, 2 wait for one another. (1+2+4+8)

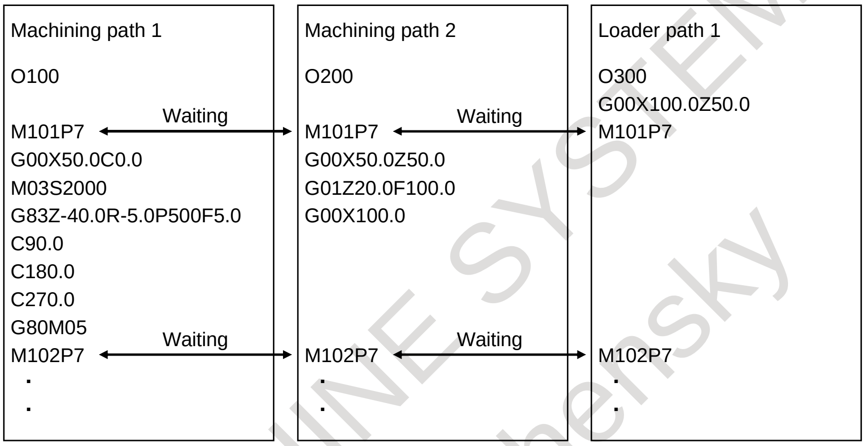
- When bit 1 (MWP) of parameter No. 8103 is set to 1:

A combination of numbers of all paths that are to wait for one another is specified with address P. If command values are different, when they consist of the same numeric characters, they are treated the same command.

Example)
4-path system (machining path 1, machining path 2, loader path 1, and loader path 2)

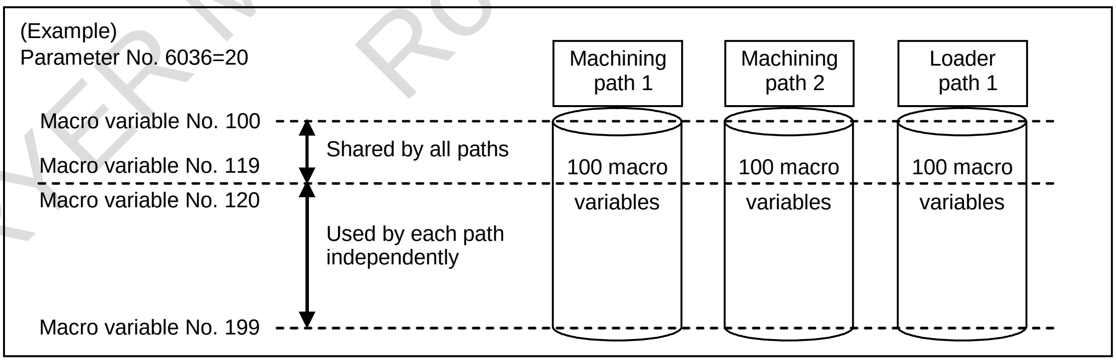
Making machining path 1 and loader path 1 wait for each other: the following 2 commands
P13, P31
Making machining path 1, 2 and loader path 1, 2 wait for one another: the following 24 commands
P1234, P1243, P1324, P1342, P1423, P1432, P2134, P2143, P2314, P2341, P2413, P2431
P3124, P3142, P3214, P3241, P3412, P3421, P4123, P4132, P4213, P4231, P4312, P4321

Example)
In case that M101 and M102 are waiting M codes and parameter MWP is set to 0:



- Custom macro common variables between each path

All or part of custom macro common variables #100 to #199 and #500 to #999 can be used as data common to all paths including the loader path by setting parameter Nos. 6036 (#100 to #199) and 6037 (#500 to #999).



- Position switch

Up to 24 position switch signals can be output in the loader path. 16 position switch signals (PSW01 to PSW16) are output to the conventional signal address. The other position switch signals (PSW17 to PSW24) are output to the address Fn330. The controlled axes corresponding to their position switches are specified in parameters Nos. 6966 to 6973, and the operating ranges are set in parameters Nos. 6974 to 6989. As to the machining path, up to 16 position switch signals is available conventionally.

> **NOTE**
> The position switch signals (PSW17 to PSW24) are available only for the loader path.

- Spindle speed control

The loader path does not have spindle speed control. If an S command is executed in the loader path, the specified value is output directly on the code signals as an auxiliary function.

- Tool functions

The loader path does not have tool functions. If a T command is executed in a loader path, the specified value is output directly on the code signals as an auxiliary function. The loader path does not have a tool offset number and the tool compensation screen.

- C language executer/Macro executer

When a loader path is specified by the C-language executor or the macro executor, use the following path number.

- In case that a number of machining path is only 1:
  Loader path 1: 2 (the 2nd path in the entire system)
  Loader path 2: 3 (the 3rd path in the entire system)

- In case that a number of machining path is 2:
  Loader path 1: 3 (the 3rd path in the entire system)
  Loader path 2: 4 (the 4th path in the entire system)

- In case that a number of machining path is 3:
  Loader path 1: 4 (the 4th path in the entire system)

- Reading of path information by FOCAS2/C language executer

The number of controlled paths (including loader paths) and path attribute can be read by cnc_sysinfo_ex function of the FOCAS2 library and the C language library of C language executor.

Please refer to the subsection of “the function specification” of FANUC FOCAS1/2 library specifications (FWLIB32.HTM) included in “FOCAS1/2 library disk” for details of cnc_sysinfo_ex function of the FOCAS2 library.

Please refer to the subsection of “the CNC/PMC window library” of C language Executor PROGRAMMING MANUAL (B-63943EN-3) for details of cnc_sysinfo_ex function of the C language library of C language executor.

- Notes

(1) In a system with a loader path, the following specifications are also the same as them for a multi-path control system.
  - Alarm
    If, during automatic operation, an alarm occurs in a certain path, all paths in the machine group to which the path belongs will enter the feedhold state and stop. However, the operations in other paths in the same machine group can be continued without generating an alarm, by appropriately setting bit 1 (IAL) of parameter No. 8100.
  - MDI reset key
    The reset key on the MDI unit is effective to all paths. Note, however, that the key can be enabled only for the path selected with the path selection signal, by setting bit 0 (RST) of parameter No. 8100. (The key is also effective for the loader path which is selected by the loader control selection signal or MDI key operation)

(2) Input signals by the X address are not assigned to the 4th path in an entire system. Therefore, when a loader path is the 4th path in an entire system, the signals must be assigned by setting bit 2 (XSG) of parameter No. 3008. If the parameter XSG is set to 0, alarm PW0001, "X-ADDRESS IS NOT ASSIGNED" is issued in the loader path.

- Usable G codes

The following table shows the G codes which are available for a loader path. When the G codes which are not listed in this table are specified in a loader path, alarm PS0010, "IMPRPOER G-CODE" is issued. G code system for a loader path can be set to a different system for a machining path. Which G code system is selected is set using bit 7 (GSC) and 6 (GSB) of parameter No. 3401.

Machining center system	Lathe system G code system			Function
	A	B	C	
G00	G00	G00	G00	Positioning (Rapid traverse)
G01	G01	G01	G01	Linear interpolation (Cutting feed)
G04	G04	G04	G04	Dwell

- Specifications

The following table shows functions which are available for a loader path. The functions which are not listed in this table are not available. Some of the following functions are optional functions. If required options are not specified, these functions cannot be used even on a loader path.

Item	Specifications
Controlled axis	
Max. feed axes/1 path	4 axes(1 path) / 3 axes(2 paths)
Axis control by PMC	
Axis name	
Axis name expansion	
Incremental system (IS-A, IS-B, IS-C)	
HRV2 control	
HRV3 control	
Inch/metric conversion	
Interlock	
Machine lock	
Emergency stop	
Overtravel	
Stored stroke check 1	
Stored stroke check 2,3	
Stroke limit check before move	
Mirror image	
Follow-up	
Servo off/Mechanical handle	
Unexpected disturbance torque detection function	
Position switch	
High speed position switch	
Dual check safety	
Test mode function for Acceptance Test	Dual check safety is required.
Operation	
Automatic operation (memory)	
MDI operation	
Program restart	
Quick program restart	
Manual intervention and return	
Wrong operation prevention	
Dry run	
Single block	
Jog feed	
Manual reference position return	
Manual 2nd/3rd/4th reference position return	
Reference position setting without DOG	
Reference position setting with mechanical stopper	
Reference point setting with mechanical stopper by Grid Method	
Manual handle feed	
High speed program check	
Interpolation functions	
Positioning	G00
Exact stop mode	G61
Tapping mode	G63
Cutting mode	G64
Exact stop	G09

Item	Specifications
Linear interpolation	G01
Dwell	G04, Dwell in seconds
Skip	G31
High-speed skip	
Torque limit skip	
Reference position return	G28
Reference position return check	G27
2nd reference position return	G30
3rd/4th reference position return	
Feed function	
Rapid traverse override	F0, 25, 50, 100% or 0～100%(1% Step)
Feed per minute	
Automatic acceleration/deceleration	
Rapid traverse bell-shaped acceleration/deceleration	
Linear acceleration/deceleration after cutting feed interpolation	
Bell-type acceleration/ deceleration after cutting feed interpolation	
Feedrate override	0～254%
One-digit F code feed	M series only
Jog override	0～655.34%
External deceleration	
Rapid traverse block overlap	
Programmable rapid traverse overlap	
Smart overlap	
In-position check signal	
Program input	
Optional block skip	9
Program file name	
Absolute/incremental programming	G90/G91
Decimal point programming/ pocket calculator type decimal point programming	
Diameter/radius programming	
Rotary axis designation	
Coordinate system setting	
Workpiece coordinate system	G52～G59
Addition of workpiece coordinate system	G54.1, M series only
Workpiece coordinate system preset	
G code system (A/B/C)	T series only
Programmable data input	G10
Programmable parameter input	
Sub program call	
Custom macro	
Custom macro common variables between each path	
G code preventing buffering	
Macro executor	
Macro executor + C language executor	
FANUC PICTURE executor	
FANUC PICTURE function	

Item	Specifications
Auxiliary function	
Auxiliary function	M8 digit
2nd auxiliary function	B8 digit
High-speed M/S/T/B interface	
Waiting function	
Waiting M codes of high-speed type	
Multiple command of auxiliary function	5 commands
Waiting function by specifying start point	
Accuracy compensation function	
Backlash compensation	
Backlash compensation for each rapid traverse and cutting feed	
Stored pitch error compensation	
Editing operation	
Part program editing	
Extended part program editing	
Key and program encryption	
Password function	
Playback	
Background editing	
Memory card program edit & operation	
Multi-path editing function	
Setting and display	
Optional path name display	
Operating monitor screen	
Servo setting screen	
Servo waveform display	
Trouble diagnosis	
Machine alarm diagnosis	
Software operator's panel	
Machine operation menu	
Multi-language display	Machining paths and loader paths are displayed in the same language.
Data protection key	
Protection of data at eight levels	
Warning function against modification of setting	
Graphic display	
Data input/output	
Reader/puncher interface	
External machine zero point shift	
External message	
External data input	
External key input	
External workpiece number search	
External program number search	
Memory card input/output	
USB memory input/output	
One touch macro call	

Signal

Path selection signals HEAD<G0063.0>, HEAD2<G0062.7>

[Classification] Input signal

[Function] These signals select the path the MDI unit is to be for.

[Operation] Operations from the MDI unit will be on the path specified with a combination of HEAD and HEAD2. The relations between path selection signal combinations and selectable paths are as given in the table below.

Path selection signal		Path to be selected
HEAD2<G0062.7>	HEAD<G0063.0>	
"0"	"0"	Path 1
"0"	"1"	Path 2
"1"	"0"	Path 3
"1"	"1"	Path 4

> **NOTE**
> The loader path cannot be selected by path selection signals.

Loader control selection signal LCBS<G0251.1>
Loader control 2 selection signal LCB2<G0251.2>

[Classification] Input signal

[Function] These signals switch the object of screen display or MDI operation between a machining path and a loader path.

[Operation] When LCBS turns to "1", the loader path 1 is subjected to screen display or MDI operation. When LCB2 turns to "1", the loader path 2 is subjected to screen display or MDI operation. When both signals are set to "1", the loader path 1 is selected.
When LCBS or LCB2 is set from "1" to "0", a machining path is switched. Selected path is a machining path which is selected by the path selection signals (HEAD<G0063.0>, HEAD2<G0062.7>).

> **NOTE**
> 1 LCB2 is available when loader path 2 is existed.
> 2 If this signal is set to “0”, a selected path can be switched between the machining path and the loader path by pressing MDI key [⇧ SHIFT] and [HELP] at the same time.

Loader path selection check signal LC1O<F0297.1>
Loader path 2 selection check signal LC2O<F0297.2>

[Classification] Output signal

[Function] These signals indicate that the object of screen display or MDI operation is a loader path.

[Output cond.] These signals are “1” in the following case:
- The object of screen display or MDI operation is the corresponding loader path.

These signals are “0” in the following case:
- The object of screen display or MDI operation is not the corresponding loader path.

LC1O is for the loader path 1, and LC2O for the loader path 2.

No-wait signal NOWT<G0063.1>(for path common signal interface) NMWT<Gn063.7>(for path individual signal interface)

[Classification] Input signal

[Function] Specifies whether to synchronize the paths by the waiting M code.

[Operation] When this signal turns to “1”, the paths are not synchronized by the M code. The M code for waiting specified in a machining program is ignored.

When this signal turns to “0”, the paths are synchronized by the M code. When the M code for waiting is specified for one of paths, wait the corresponding M code is commanded in another path, then starts to execute the next block.

Waiting signal WATO<F0063.6>(for path common signal interface) WATO<Fn063.6>(for path individual signal interface)

[Classification] Output signal

[Function] Indicates that the M code is waiting for a path.

[Output cond.] These signals are “1” as long as:

- One path is waiting for another path. That is, the signal stays “1” for the period from when the M code for waiting is issued to one path to when the corresponding M code is issued to another path.

This signal is “0” as long as:

- Neither of the paths is waiting for the other.

> **NOTE**
> When the path common signal interface (bit 0 (MWT) of parameter No. 8103 = 1) is used, F0063.6="1" results even if path 2 is placed in the wait state.
> So, when the wait state needs to be checked with each path, use the path individual signal interface (bit 0 (MWT) of parameter No. 8103 = 0).

Position switch signals PSW17 to PSW24<Fn330>

[Classification] Output signal

[Function] These signals indicate that the machine coordinates along the controlled axes specified by parameters Nos. 6966 to 6973 are within the ranges specified by parameters Nos. 6974 to 6989.
The position switch signal corresponding to the n-th position switch function is PSWn. (n : 17 to 24)

[Output cond.] These signals are “1” in the following case:

- When the machine coordinates along the controlled axes are within the specified ranges.

These signals are “0” in the following case:

- When the machine coordinates along the controlled axes are not within the specified ranges.

> **NOTE**
> This signal is available only for the loader path.

Signal address

	#7	#6	#5	#4	#3	#2	#1	#0
G0062	HEAD2							
G0063								HEAD
G0251						LCB2	LCBS	
F0297						LC2O	LC1O	
Fn330	PSW24	PSW23	PSW22	PSW21	PSW20	PSW19	PSW18	PSW17

- For path common signal interface (bit0 (MWT) of parameter No.8103 =1)

	#7	#6	#5	#4	#3	#2	#1	#0
G0063							NOWT	
F0063		WATO						

- For path individual signal interface (bit0 (MWT) of parameter No.8103 =0)

Gn063	NMWT							
Fn063		WATO						

Parameter

	#7	#6	#5	#4	#3	#2	#1	#0
0138								MDP

[Input type] Parameter input
[Data type] Bit

#0 MDP To the extensions of input/output files, a path number is:
0: Not added.
1: Added.

NOTE
The extension of the loader path 1 is “PL1” and the loader path 2 is “PL2”.

3131	Subscript of axis name

[Input type] Parameter input
[Data type] Byte axis
[Valid data range] 0 to 9, 65 to 90

In order to distinguish axes under synchronization control, and tandem control, specify a subscript for each axis name.

Setting value	Meaning
0	Each axis is set as an axis other than synchronization axis and tandem control axis.
1 to 9	A set value is used as a subscript.
65 to 90	A set letter (ASCII code) is used as a script.

[Example] When the axis name is X, a subscript is added as indicated below.

Setting value	Axis name displayed on a screen such as the position display screen
0	X
1	X1
77	XM
83	XS

If a multi-path system is used, no extended axis name is used within a path, and no subscript is set for the axis names, then the path number is automatically used as the subscript for the axis names. Note, however, a loader path name is as follows.

- In case that the loader path 2 does not exit: “L”
- In case that the loader path 2 exits: “L1”(loader path 1), “L2”(loader path 2)

To disable the display of axis name subscripts, set a blank (32) of ASCII code in the parameter for specifying an axis name subscript.

NOTE
If even one axis in a path uses an extended axis name when bit 2 (EAS) of parameter No. 11308 is set to 0, subscripts cannot be used for axis names in the path.

3141	Path name (1st character)
3142	Path name (2nd character)
3143	Path name (3rd character)
3144	Path name (4th character)
3145	Path name (5th character)
3146	Path name (6th character)
3147	Path name (7th character)

[Input type] Parameter input
[Data type] Word path
[Valid data range] See the character-code correspondence table.

Specify a path name with code.
Any character string consisting of alphanumeric characters, katakana characters and special characters with a maximum length of seven characters can be displayed as a series name.
When the parameter (No.3141) is set to 0 in a loader path, a path name is as follows.
- In case that the loader path 2 does not exit: “LC”
- In case that the loader path 2 exits: “LC1”(loader path 1), “LC2”(loader path 2)

	#7	#6	#5	#4	#3	#2	#1	#0
3401	GSC	GSB						

[Input type] Parameter input
[Data type] Bit path

#6 GSB The G code system is set.
#7 GSC

GSC	GSB	G code
0	0	G code system A
0	1	G code system B
1	0	G code system C

6036	Number of custom macro variables common to tool path (for #100 to #199)

[Input type] Parameter input
[Data type] Word
[Valid data range] 0 to 100

When the memory common to paths is used, this parameter sets the number of custom macro common variables to be shared (custom macro variables common to paths).
Common variables #100 to #199 may be shared. Ensure that the maximum number of usable macro common variables is not exceeded.

> **NOTE**
> When 0 or a negative value is set, the memory common to paths is not used.

6037	Number of custom macro variables common to tool path (for #500 to #999)

[Input type] Parameter input
[Data type] Word
[Valid data range] 0 to 500

When the memory common to paths is used, this parameter sets the number of custom macro common variables to be shared (custom macro variables common to paths).
Common variables #500 to #999 may be shared. Ensure that the maximum number of usable macro common variables is not exceeded.

> **NOTE**
> When 0 or a negative value is set, the memory common to paths is not used.

6966	Controlled axis for which the 17-th position switch function is performed
to	to
6973	Controlled axis for which the 24-th position switch function is performed

[Input type] Parameter input
[Data type] Byte path
[Valid data range] 0 to Number of controlled axes

Set the controlled axis number corresponding to one of the seventeenth to twenty-fourth position switch functions. When the machine coordinate of the corresponding axis is within a parameter-set range, the corresponding position switch signal is output to the PMC.

> **NOTE**
> 1 The setting of 0 means that the position switch function is not used.
> 2 The 17-th to 24-th position switch function is available only for the loader path.

6974	Maximum value of the operating range of the 17-th position switch
to	to
6981	Maximum value of the operating range of the 24-th position switch

[Input type] Parameter input
[Data type] Real path
[Unit of data] mm, inch, deg (machine unit)
[Min. unit of data] Depend on the increment system of the reference axis
[Valid data range] 9 digit of minimum unit of data (refer to standard parameter setting table (A))
(When the increment system is IS-B, -999999.999 to +999999.999)

Set the maximum value of the operating range of the seventeenth to twenty-fourth position switches.

> **NOTE**
> The 17-th to 24-th position switch function is available only for the loader path.

6982	Minimum value of the operating range of the 17-th position switch
to	To
6989	Minimum value of the operating range of the 24-th position switch

[Input type] Parameter input
[Data type] Real path
[Unit of data] mm, inch, deg (machine unit)
[Min. unit of data] Depend on the increment system of the reference axis
[Valid data range] 9 digit of minimum unit of data (refer to standard parameter setting table (A))
(When the increment system is IS-B, -999999.999 to +999999.999)

Set the minimum value of the operating range of the seventeenth to twenty-fourth position switches.

> **NOTE**
> The 17-th to 24-th position switch function is available only for the loader path.

	#7	#6	#5	#4	#3	#2	#1	#0
8100	NWP						IAL	RST

[Input type] Parameter input
[Data type] Bit machine group

#0 RST Pressing the reset key on the MDI unit is:
0: Valid for two paths.
1: Valid only for the path selected by the path selection signal.

The reset key on the MDI unit is valid for all machine groups. So, in machine groups for which this parameter is set to 0, a reset can be performed for all paths. In machine groups for which this parameter is set to 1, a reset can be performed only for the path that is selected by the path selection signal.

#1 IAL Chose of an option concerning operation continuation when an alarm is issued, and choice of an option concerning the start of automatic operation in alarm state:
0: When an alarm is issued, the operation is stopped with the other path(s) in same group placed in hold state.
When the other path or paths in same group are placed in alarm state, automatic operation cannot be started.
1: Even when an alarm is issued, the operation is continued without stopping the other path(s).
Even when the other path or paths in same group are placed in alarm state, automatic operation can be started.

#7 NWP Servo activation is turned on:
0: Together with other machine groups. (Servo activation is not turned on until other machine groups are ready to turn on servo activation.)
1: Independently of other machine groups. (Each machine group turns on servo activation even if other machine groups are not ready to turn on servo activation.)

	#7	#6	#5	#4	#3	#2	#1	#0
8103							MWP	MWT

[Input type] Parameter input
[Data type] Bit

> **NOTE**
> When at least one of these parameters is set, the power must be turned off before operation is continued.

#0 MWT As the signal interface for the waiting M code:
0: The path individual signal interface is used.
1: The path common signal interface is used.

#1 MWP To specify a P command for the waiting M code:
0: A binary value is used as conventionally done.
1: A path number combination is used.

	#7	#6	#5	#4	#3	#2	#1	#0
8106					SCD			

[Input type] Parameter input
[Data type] Bit

#3 SCD When the function for loader control is valid, path selection by pressing MDI keys SHIFT and HELP at the same time is:
0: Enabled.
1: Disabled.

	#7	#6	#5	#4	#3	#2	#1	#0
11362							LCI	

[Input type] Parameter input
[Data type] Bit path

> **NOTE**
> When this parameter is set, the power must be turned off before operation is continued.

#1 LCI When the function for loader control is valid, a path name at the lower right of the screen is displayed in:
0: Normal display.
1: Reverse display.

> **NOTE**
> This parameter is available only for the loader path.

Alarm and message

Number	Message	Description
PS0010	IMPROPER G-CODE	An unusable G code is specified.

Number	Message	Description
PS0365	TOO MANY MAXIMUM SV/SP AXIS NUMBER PER PATH	The maximum control axis number or maximum control spindle number which could be used within a path was exceeded.
PW0001	X-ADDRESS IS NOT ASSIGNED	The X address of the PMC could not be assigned correctly. This alarm may occur in the following case: - During the setting of parameter No. 3013, the X address could not be assigned correctly for the deceleration dog (*DEC) for a return to the reference position. When there are 4 or more paths or there are 9 or more axes for one path, the signals must be assigned by setting bit 2 (XSG) of parameter No. 3008, parameter No. 3013, and parameter No. 3014.

9 AUXILIARY FUNCTION

9.1 AUXILIARY FUNCTION/2ND AUXILIARY FUNCTION

Overview

- Auxiliary function (M code)

When up to eight digits are specified after M code, a code signal and a strobe signal are sent to the machine. The machine uses these signals to turn on or off its functions.
Usually, only one M code can be specified in one block. In some cases, however, up to five M codes can be specified for some types of machine tools (see "MULTIPLE M COMMANDS IN ONE BLOCK")
Also, parameter No. 3030 can specify the maximum digits and if a specified value exceeds the maximum digits, an alarm may be issued.

- 2nd auxiliary function (B code)

When up to eight digits are specified after address B, a code signal and strobe signal are sent. These signals are used to index the rotation axis of the machine. The code signal is retained until another B code is specified.
In each block, a single B code can be specified. The maximum number of digits that can be specified after address B is specified in parameter No. 3033. If a specified value exceeds the maximum digits, an alarm may be issued.
The address for specifying the 2nd auxiliary function can be changed from B to another address (A, C, U, V, or W) by parameter setting (parameter No. 3460).

Explanation

- Command format of 2nd auxiliary function

Command range

-99999999 to 99999999

Command method

The value specified after the address of the second auxiliary function is output on the code signals B00 to B31. Note the following about a output value.

1. When a command with a decimal point or a negative command is disabled
(When bit 0 (AUP) of parameter No. 3450 is set to 0)

   When the second auxiliary function with no decimal point is specified, the specified value is output on the code signals as is, regardless of the desktop calculator decimal point setting (bit 0 (DPI) of parameter No. 3401).
   Example:

Specified value	Output value
B10	10

   When the second auxiliary function with a decimal point is specified, alarm PS0007 is issued.
   When the second auxiliary function is specified with a negative value, alarm PS0006 is issued.

2. When a command with a decimal point or a negative command is enabled
(When bit 0 (AUP) of parameter No. 3450 is set to 1)

When the desktop calculator decimal point setting is not specified (when bit 0 (DPI) of parameter No. 3401 is set to 0), if the second auxiliary function with no decimal point is specified, the specified value is output on the code signals as is.
Example:

Specified value	Output value
B10	10

When desktop calculator decimal point input is specified (when bit 0 (DPI) of parameter No. 3401 is set to 1), if the second auxiliary function with no decimal point is specified, the specified value multiplied by a magnification is output on the code signals. (Magnifications are shown in Table 9.1 (a).)
Example:

Specified value	Output value
B10	10000 (When metric input is used and the reference axis is IS-B. The magnification is 1000.)

When the second auxiliary function with a decimal point is specified, the specified value multiplied by a magnification is output to the code signals. (Magnifications are shown in Table 9.1 (a).)
Example:

Specified value	Output value
B10.	10000 (When metric input is used and the reference axis is IS-B. The magnification is 1000.)
B0.123	1230 (When inch input is used, the reference axis is IS-B, and parameter AUX is set to 1. The magnification is 10000.)

The magnification is determined as shown below (Table 9.1 (a)) according to the setting unit of the reference axis (specified by parameter No. 1031) and bit 0 (AUX) of parameter No. 3405.

Table 9.1 (a) Magnifications for an output value when the second auxiliary function with a decimal point is specified for desktop calculator decimal point input

Setting unit		Parameter AUX = 0	Parameter AUX = 1
Metric input system	Reference axis: IS-A	100×	100×
	Reference axis: IS-B	1000×	1000×
	Reference axis: IS-C	10000×	10000×
Inch input system	Reference axis: IS-A	100×	1000×
	Reference axis: IS-B	1000×	10000×
	Reference axis: IS-C	10000×	100000×

⚠ **CAUTION**
If a decimal fraction remains after multiplying the specified value with a decimal point by a magnitude in Table 9.1 (a), the fraction is truncated.
Example:

Specified value	Output value
B0.12345	1234 (When inch input is used, the reference axis is IS-B, and parameter AUX is set to 1. The magnification is 10000.)

NOTE

If the number of digits of the specified value exceeds the allowable number of digits (set by parameter No. 3033), alarm PS0003 is issued.
When the specified value is multiplied by a magnitude in Table 9.1 (a), the allowable number of digits must be set for the resultant value.

Basic procedure

The following signals (Table 9.1 (b)) are used with these functions. (For details of the spindle-speed function and tool function, see Chapters “SPINDLE SPEED FUNCTION” and “TOOL FUNCTION”.)

Table 9.1 (b)

Function	Program address	Output signal			Input signal
		Code signal	Strobe signal	Distribution end signal	Completion signal
Auxiliary function	M	M00 to M31	MF	DEN	FIN
Spindle speed function	S	S00 to S31	SF		
Tool function	T	T00 to T31	TF		
2nd auxiliary function	B	B00 to B31	BF		

Each function uses different program addresses and different signals, but they all input and output signals in the same way, as described below. (A sample procedure for the auxiliary function is described below. The procedures for the spindle speed function, tool function, and 2nd auxiliary function, are obtained simply by substituting S, T, or B in place of M.)

<1> Suppose that Mxxx is specified in a program.
For xxx, the number of specifiable digits is specified in parameters Nos. 3030 to 3033 for each function. If a specified value exceeds the maximum digits, an alarm may be issued.

<2> Code signal M00 to M31 is sent to machine interface. After period TMF, specified in parameter No. 3010 (standard value: 16 msec), the strobe signal MF is set to 1. The code signal is the binary representation of the programmed value xxx.(*1) If a move, dwell, spindle, or other function is specified in the same block as the auxiliary function, the execution of the other function is started when the code signal of the auxiliary function is sent.

<3> When the strobe signal is set to 1, read the code signal and perform the corresponding operation on the PMC side.

<4> To execute an operation after the completion of the move, dwell or other function specified in the block, wait until distribution end signal DEN is set to 1.

<5> Upon completion of the operation, set completion signal FIN to 1 on the PMC side. The completion signal is used by the auxiliary function, spindle function, tool function, 2nd auxiliary function, external operation function described later, and other functions. If any of these functions are executed simultaneously, the completion signal must be set to 1 upon completion of all the functions.

<6> If the completion signal remains set to 1 for longer than period TFIN, specified in parameter No. 3011 (standard value: 16 msec), the CNC sets the strobe signal to 0 and reports that the completion signal has been received.

<7> When the strobe signal is set to 0, set the completion signal to 0 in the PMC.

<8> When the completion signal is set to 0, the CNC sets all code signals to 0 and completes all sequences of the auxiliary function.(*2)

<9> Once all other commands in the same block have been completed, the CNC executes the next block.

(*1) When the tool function is executed, the programmed tool number is sent as the code signal (lathe series).

(*2) When the spindle-speed function, tool function, or 2nd auxiliary function is executed, the code signal is maintained until a new code for the corresponding function is specified.

The timing diagram is shown below (Fig. 9.1):

Example 1 Single auxiliary function specified in a block

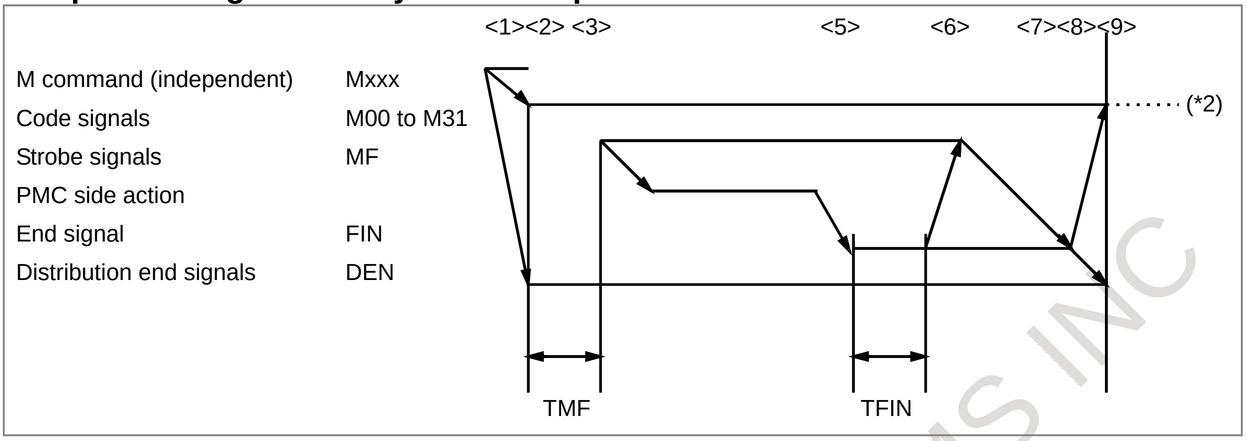

Fig. 9.1

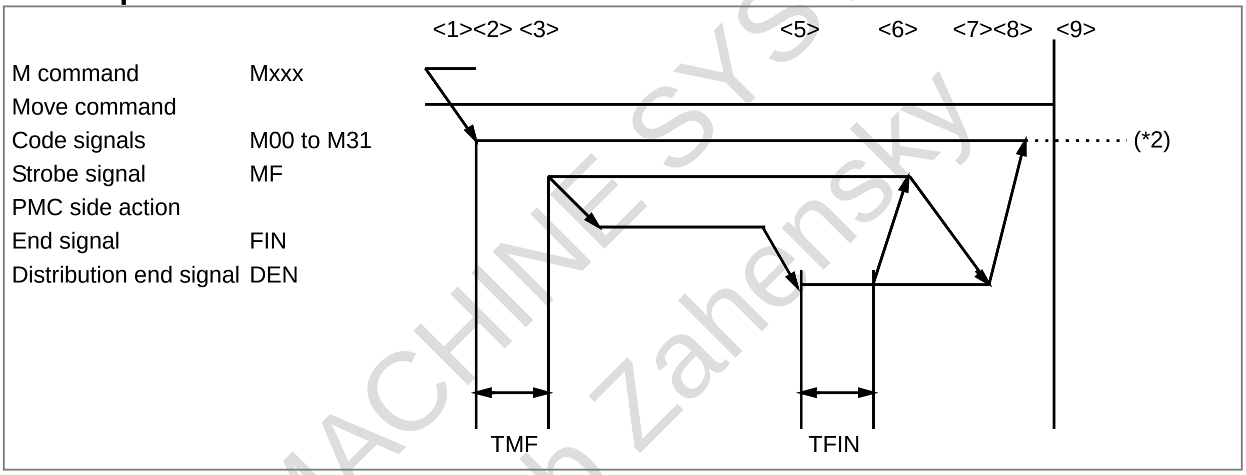
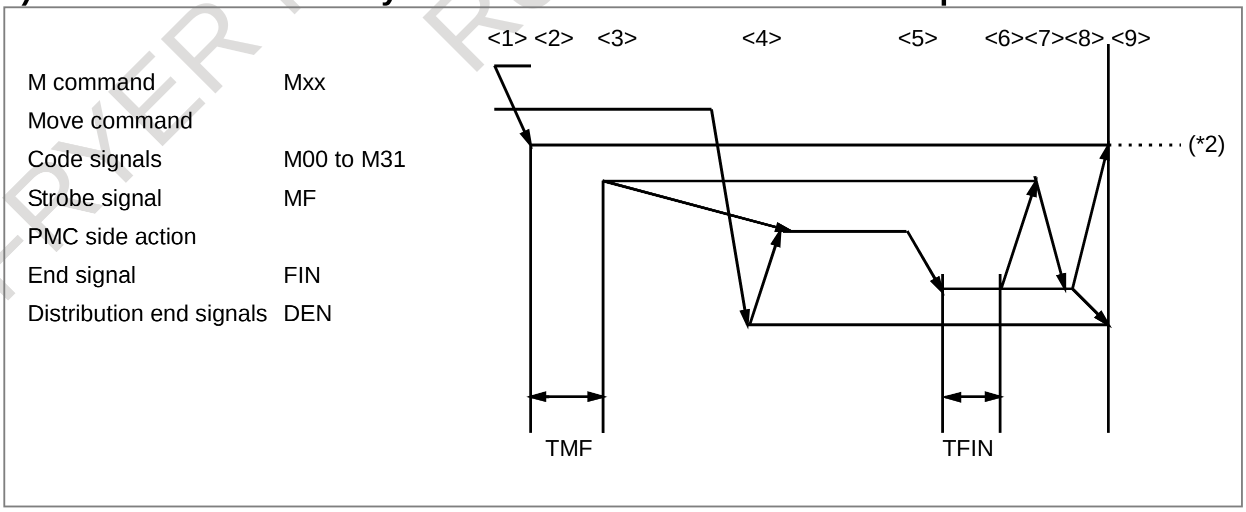
Example 2 Move command and auxiliary function in the same block

a) Execution of a auxiliary function without waiting for move command completion



b) Execution of a auxiliary function after move command completion



Signal

End signal FIN<Gn004.3>

[Classification] Input signal

[Function] This signal reports the completion of a auxiliary function, spindle function, tool function, 2nd auxiliary function, or external operation function.

[Operation] For the control unit operation and procedure when this signal goes “1”, see the description of "Basic procedure" above.
The FIN signal must remain “1” for a certain time (TFIN, which is set by a parameter No. 3011) or longer. The FIN signal driven “1” is ignored if the FIN signal goes “0” before TFIN elapses.

> ⚠ **CAUTION**
> Only one end signal is used for all functions above. The end signal must go “1” after all functions are completed.

2nd auxiliary function end signal BFIN<Gn005.7>

[Classification] Input signal

[Function] This signal reports the completion of a 2nd auxiliary function using the high-speed M/S/T/B interface.

[Operation] For the control unit operation and procedure when this signal goes “1”, see the description of "Basic procedure" above.

Distribution end signal DEN<Fn001.3>

[Classification] Output signal

[Function] These signals report that all commands (such as move commands and dwell) are completed except those auxiliary functions, spindle functions, 2nd auxiliary functions tool functions, and so forth that are contained in the same block and have been sent to the PMC. They also report that the end signal from the PMC is being awaited.

[Output cond.] The DEN signal turns to “1” when:

- Waiting for the completion of auxiliary functions, spindle functions, tool functions, and 2nd auxiliary functions, and all other commands in the same block are completed, and the current position is in the in-position.

The DEN signal turns to “0” when:

- The execution of one block is completed

> **NOTE**
> 1 Bit 5 (NCI) of parameter No. 1601 can specify, whether to only check if an acceleration/deceleration delay is eliminated, or to also check if a servo delay (error) has been reduced to within a certain range.
> 2 When the high-speed MSTB interface is used, the distribution end signal DEN may be set to “0” when the execution of one block is completed. To do this, set bit 2 (CHM) of parameter No. 3002 to 1.

Decode M signals
DM00<Fn009.7>,DM01<Fn009.6>,DM02<Fn009.5>,DM30<Fn009.4>

[Classification] Output signal

[Function] These signals report particular auxiliary functions are specified. The auxiliary functions in a command program correspond to output signals as indicated below.

Command program	Output signal
M00	DM00
M01	DM01
M02	DM02
M30	DM30

[Output cond.] A decode M signal goes “1” when:

- The corresponding auxiliary function is specified, and any move commands and dwell commands specified in the same block are completed. These signals are not output when the end signal of the auxiliary function is returned before completion of such move commands and dwell commands.

A decode M signal goes “0” when:

- The FIN signal goes “1”
- Reset occurs

Auxiliary function code signals M00 to M31<Fn010 to Fn013>
Auxiliary function strobe signal MF<Fn007.0>

[Classification] Output signal

[Function] These signals report the specification of auxiliary functions.

[Output cond.] For the output conditions and procedure, see the description of "Basic procedure" above.

> **NOTE**
> 1 The following auxiliary functions are only processed internally by the control unit; they are not output to the PMC when programmed:
>   - M98, M99, M198
>   - M code that calls a sub program (parameters Nos. 6071 to 6079)
>   - M code that calls a custom macro (parameters Nos. 6080 to 6089)
>
> 2 Decode signals as well as the code signals and strobe signal are output for the auxiliary functions listed below.
> M00, M01, M02, M30

Spindle function code signals S00 to S31<Fn022 to Fn025>
Spindle function strobe signal SF<Fn007.2>

[Classification] Output signal

[Function] These signals report that spindle functions have been specified.

[Output cond.] For the output conditions and procedure, see the description of "Basic procedure" above.

Tool function code signals T00 to T31<Fn026 to Fn029>
Tool function strobe signal TF<Fn007.3>

[Classification] Output signal

[Function] These signals report that tool functions have been specified.

[Output cond.] For the output conditions and procedure, see the description of "Basic procedure" above.

2nd auxiliary function code signals B00 to B31<Fn030 to Fn033>
2nd auxiliary function strobe signal BF<Fn007.7>

[Classification] Output signal
[Function] These signals report that second auxiliary functions have been specified.
[Output cond.] For the output conditions and procedure, see the description of "Basic procedure" above.

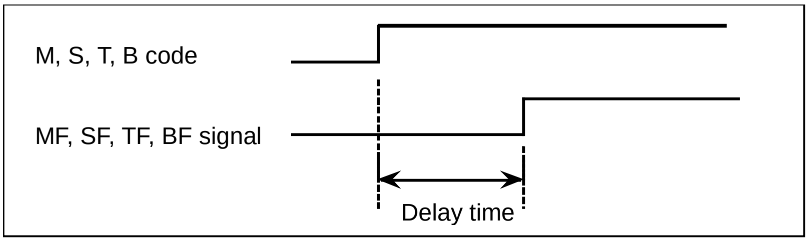
Parameter

3010	Time lag in strobe signals MF, SF, TF, and BF

[Input type] Parameter input
[Data type] Word path
[Unit of data] msec
[Valid data range] 0 to 32767
The time required to send strobe signals MF, SF, TF, and BF after the M, S, T, and B codes are sent, respectively.

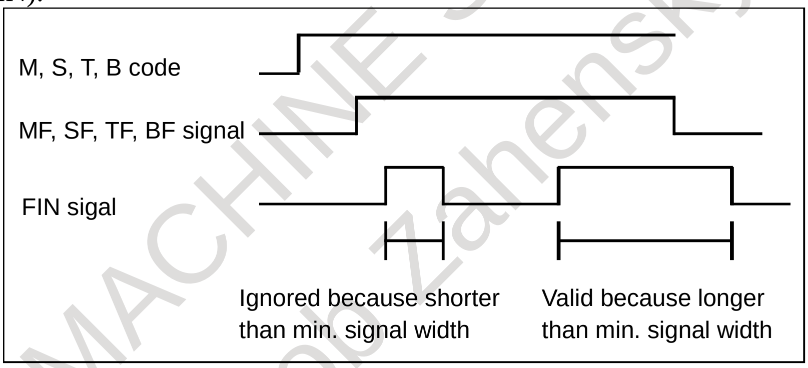


NOTE
The time is counted in units of 8ms. If the set value is not a multiple of eight, it is raised to the next multiple of eight
Example
When 30 is set, 32 ms is assumed.
When 0 is set, 8ms is assumed.

3011	**Acceptable width of M, S, T, and B function completion signal (FIN)**

[Input type] Parameter input
[Data type] Word path
[Unit of data] msec
[Valid data range] 0 to 32767

Set the minimum signal width of the valid M, S, T, and B function completion signal (FIN).



NOTE
The time is counted in units of 8ms. If the set value is not a multiple of eight, it is raised to the next multiple of eight
Example
When 30 is set, 32 ms is assumed.
When 0 is set, 8ms is assumed.

3030	**Allowable number of digits for the M code**
3031	**Allowable number of digits for the S code**
3032	**Allowable number of digits for the T code**

[Input type] Parameter input
[Data type] Byte path
[Valid data range] 1 to 8

Set the allowable numbers of digits for the M, S, and T codes.
When 0 is set, the allowable number of digits is assumed to be 8.

3033	Allowable number of digits for the B code (second auxiliary function)

[Input type] Parameter input
[Data type] Byte path
[Valid data range] 1 to 8

Set the allowable number of digits for the second auxiliary function.
When 0 is set, the allowable number of digits is assumed to be 8.
To enable a decimal point to be specified, bit 0 (AUP) of parameter No. 3450 must be set to 1. In this case, the allowable number of digits set in this parameter includes the number of decimal places.
If a value exceeding the allowable number of digits is specified, the alarm PS0003 is issued.

	#7	#6	#5	#4	#3	#2	#1	#0
3401								DPI

[Input type] Parameter input
[Data type] Bit path

#0 DPI When a decimal point is omitted in an address that can include a decimal point
0: The least input increment is assumed. (Normal decimal point input)
1: The unit of mm, inches, degree, or second is assumed. (Pocket calculator type decimal point input)

	#7	#6	#5	#4	#3	#2	#1	#0
3404			M02	M30				

[Input type] Parameter input
[Data type] Bit path

#4 M30 When M30 is specified in a memory operation:
0: M30 is sent to the machine, and the head of the program is automatically searched for. So, when the ready signal FIN is returned and a reset or reset and rewind operation is not performed, the program is executed, starting from the beginning.
1: M30 is sent to the machine, but the head of the program is not searched for. (The head of the program is searched for by the reset and rewind signal.)

#5 M02 When M02 is specified in memory operation:
0: M02 is sent to the machine, and the head of the program is automatically searched for. So, when the end signal FIN is returned and a reset or reset and rewind operation is not performed, the program is executed, starting from the beginning.
1: M02 is sent to the machine, but the head of the program is not searched for. (The head of the program is searched for by the reset and rewind signal.)

	#7	#6	#5	#4	#3	#2	#1	#0
3405								AUX

[Input type] Parameter input
[Data type] Bit path

#0 AUX When the second auxiliary function is specified in the calculator-type decimal point input format or with a decimal point, the multiplication factor for a value output (onto the code signal) relative to a specified value is such that:

0: The same multiplication factor is used for both of metric input and inch input.
1: A multiplication factor used for inch input is 10 times greater than that used for metric input.

When the second auxiliary function is specified in the calculator-type decimal point input format or with a decimal point, the value output onto the code signal is a specified value multiplied by a value indicated below.

Increment system		Parameter AUX=0	Parameter AUX=1
Metric input system	IS-A for reference axis	100 times	100 times
	IS-B for reference axis	1000 times	1000 times
	IS-C for reference axis	10000 times	10000 times
Inch input system	IS-A for reference axis	100 times	1000 times
	IS-B for reference axis	1000 times	10000 times
	IS-C for reference axis	10000 times	100000 times

3411	M code preventing buffering 1
3412	M code preventing buffering 2
3413	M code preventing buffering 3
to	to
3420	M code preventing buffering 10

[Input type] Parameter input
[Data type] 2-word path
[Valid data range] 3 to 99999999

Set M codes that prevent buffering the following blocks. If processing directed by an M code must be performed by the machine without buffering the following block, specify the M code.
M00, M01, M02, and M30 always prevent buffering even when they are not specified in these parameters.

3421	Range specification 1 of M codes that do not perform buffering (lower limit)
3422	Range specification 1 of M codes that do not perform buffering (upper limit)
3423	Range specification 2 of M codes that do not perform buffering (lower limit)
3424	Range specification 2 of M codes that do not perform buffering (upper limit)
3425	Range specification 3 of M codes that do not perform buffering (lower limit)
3426	Range specification 3 of M codes that do not perform buffering (upper limit)
3427	Range specification 4 of M codes that do not perform buffering (lower limit)
3428	Range specification 4 of M codes that do not perform buffering (upper limit)
3429	Range specification 5 of M codes that do not perform buffering (lower limit)
3430	Range specification 5 of M codes that do not perform buffering (upper limit)
3431	Range specification 6 of M codes that do not perform buffering (lower limit)
3432	Range specification 6 of M codes that do not perform buffering (upper limit)

[Input type] Parameter input
[Data type] 2-word path
[Valid data range] 3 to 99999999

When a specified M code is within the range specified with parameters Nos. 3421 and 3422, 3423 and 3424, 3425 and 3426, 3427 and 3428, 3429 and 3430, or 3431 and 3432, buffering for the next block is not performed until the execution of the block is completed.

NOTE
M00, M01, M02, and M30 are M codes that do not perform buffering, regardless of parameter setting.
M98, M99, M codes for calling subprograms, and M codes for calling custom macros are M codes that performs buffering, regardless of parameter setting.

3436	Range specification 1 of second auxiliary function codes that do not perform buffering (lower limit)
3437	Range specification 1 of second auxiliary function codes that do not perform buffering (upper limit)
3438	Range specification 2 of second auxiliary function codes that do not perform buffering (lower limit)
3439	Range specification 2 of second auxiliary function codes that do not perform buffering (upper limit)

[Input type] Parameter input
[Data type] 2-word path
[Valid data range] 1 to 99999999
Set the upper limit and lower limit of a series of second auxiliary function codes that do not perform buffering.
These parameters are invalid if the setting of an upper limit conflicts with the setting of a lower limit.

	#7	#6	#5	#4	#3	#2	#1	#0
3450	BDX							AUP

[Input type] Parameter input
[Data type] Bit path

#0 AUP The second auxiliary function specified in the calculator-type decimal point input format, with a decimal point, or with a negative value is:
0: Disabled.
1: Enabled.
If the second auxiliary function is specified after setting this bit to 0, the following operation results:
1. When a value is specified without a decimal point
A specified value is output onto the code signal without modification, regardless of the setting of the calculator-type decimal point input format (with bit 0 (DPI) of parameter No. 3401).
2. When a value is specified with a decimal point
The alarm PS0007, “ILLEGAL USE OF DECIMAL POINT” is issued.
3. When a negative value is specified
The alarm PS0006, “ILLEGAL USE OF MINUS SIGN” is issued.

#7 BDX When ASCII code is called using the same address as the address for the second auxiliary function (specified by parameter No. 3460), this parameter prevents the difference between the argument unit used when the second auxiliary function is enabled (bit 2 (BCD) of parameter No.8132 is 1) and the unit when the function is disabled (bit 2 (BCD) of parameter Np.8132 is 0).

0: When bit 0 (AUP) of parameter No. 3450 is set to 1, the argument unit differs, depending on whether the second auxiliary function is enabled or disabled.
1: The same argument unit is used. (The unit applied when the second auxiliary function is enabled is used.)

3460	Second auxiliary function specification address

[Input type] Parameter input
[Data type] Byte path
[Valid data range] 65to67, 85to87

Specify which of A, B, C, U, V, and W is to be used as the address for specifying the second auxiliary function. If an address used as an axis name is specified, the second auxiliary function is disabled.

Name	A	B	C	U	V	W
Setting value	65	66	67	85	86	87

Address B is assumed when a value other than the above is set.
However, the name U, V, or W can be used with the T series only when G code system B or C is used. When a value from 85 to 87 is specified with G code system A, the specification address for the second auxiliary function is B.

11290	M code preventing buffering 11
11291	M code preventing buffering 12
11292	M code preventing buffering 13
to	to
11299	M code preventing buffering 20

[Input type] Parameter input
[Data type] 2-word path
[Valid data range] 0 to 99999999

Set M codes that prevent buffering the following blocks. If processing directed by an M code must be performed by the machine without buffering the following block, specify the M code.
M00, M01, M02, and M30 always prevent buffering even when they are not specified in these parameters.

Note

NOTE

1 When a move command and auxiliary function are specified in the same block, the commands are executed in one of the following two ways:
(1) Simultaneous execution of the move command and auxiliary function commands.
(2) Executing auxiliary function commands upon completion of move command execution.
The selection of either sequence depends on the sequence of PMC.

2 When the 2nd auxiliary function is provided, the address used for specifying the 2nd auxiliary function (B or the address specified with parameter No. 3460) cannot be used as an axis address.

3 The block following M00, M01, M02 and M30, is not read into the input buffer register, if present. Similarly, ten M codes which do not buffer can be set by parameters Nos. 3411 to 3420 and 11290 to 11299.

NOTE

4 For M00 and M01, auxiliary function code signal, auxiliary function strobe signal, and M decode signals are only sent; the control of program stop and optional stop shall be designed on the PMC side.

5 When the automatic operation is stopped by M02 or M30, it is necessary to send the external reset signal from the machine side to the CNC, instead of the FIN signal. When the external reset signal is returned against the M02 or M30, the control returns to the top of the program recently executed, and enters the reset state. When the FIN signal is returned, the control returns to the beginning of the program recently executed, and executes it from the top.

6 In programmable data entry (G10)/programmable parameter entry (G10/G11) command blocks and modes, auxiliary function code (M, S, T, and B) commands are disabled. If a specified code is not in the G10 command format, alarm PS1144, "G10 FORMAT ERROR", is issued.

Alarm and message

Number	Message	Description
PS0003	TOO MANY DIGIT	Data entered with more digits than permitted in the NC instruction word. The number of permissible digits varies according to the function and the word.
PS0006	ILLEGAL USE OF MINUS SIGN	A minus sign (–) was specified at an NC instruction word or system variable where no minus signal may be specified.
PS0007	ILLEGAL USE OF DECIMAL POINT	A decimal point (.) was specified at an address where no decimal point may be specified, or two decimal points were specified.

9.2 AUXILIARY FUNCTION LOCK

Overview

Inhibits execution of a specified M, S, T and B function. That is, code signals and strobe signals are not issued. This function is used to check a program with machine lock.

Signal

Auxiliary function lock signal AFL<Gn005.6>

[Classification] Input signal

[Function] This signal selects auxiliary function lock. That is, this signal disables the execution of specified M, S, T, and B functions.

[Operation] When this signal turns to "1", the control unit functions as described below.

(1) The control unit does not execute M, S, T, and B functions specified for memory operation, DNC operation, or MDI operation. That is, the control unit stops the output of code signals and strobe signals (MF, SF, TF, BF).

(2) If this signal turns to "1" after code signal output, the output operation is executed in the ordinary manner until its completion (that is, until the FIN signal is received, and the strobe signal turns to "0").

(3) Among the auxiliary functions, M00, M01, M02, and M30 are executed even when this signal is “1”. All code signals, strobe signals, decode signals are output in the ordinary manner.
(4) Among the auxiliary functions, even when this signal is “1”, those functions (M98 and M99) that are executed in the control unit without outputting their execution results are executed in the ordinary manner.

> ⚠ **CAUTION**
> Even when this signal is “1”, spindle analog output or spindle serial output is executed.

Auxiliary function lock check signal MAFL<Fn004.4>

[Classification] Output signal
[Function] This signal reports the state of the auxiliary function lock signal AFL.
[Output cond.] This signal turns to “1” when:
- The auxiliary function lock signal AFL is “1”

This signal turns to 0 when:
- The auxiliary function lock signal AFL is “0”

9.3 MULTIPLE M COMMANDS IN A SINGLE BLOCK

Overview

So far, one block has been able to contain only one M code. However, this function allows up to three M codes to be contained in one block, when bit 7(M3B) of parameter No. 3404 is set to 1. And, Up to five M codes can be specified in a block, when bit 5(M5B) of parameter No. 11630 is set to 1.
Up to five M codes specified in a block are simultaneously output to the machine (PMC). This means that compared with the conventional method of a single M command in a single block, a shorter cycle time can be realized in machining.

(Example)

One M command in a single block	Multiple M commands in a single block
M40; M50; M60; M70; M80; G28G91X0Y0Z0; :	M40M50M60 M70M80; G28G91X0Y0Z0; : : : : :

Explanation

Basic procedure

(1) Assume that "MaaMbbMccMddMee;" was commanded by the program.

(2) The 1st M command (Maa) sends the code signals M00 to M31 in a manner similar to the conventional one-block single command. The strobe signal MF is set to “1” after a time TMF set by parameter No. 3010 (Standard setting: 16 msec).
The second M command (Mbb) sends the code signal M200-M231, the third M command (Mcc) sends the code signal M300-M331, the forth M command (Mdd) sends the code signal M400-M431, the fifth M command (Mee) sends the code signal M500-M531, and their respective strobe signals MF2, MF3, MF4 and MF5 are set to “1”.
Furthermore, the three code signals are sent simultaneously.
The strobe signals MF, MF2, MF3, MF4 and MF5 become “1” at the same time.
The code signal is a binary notation of the program command aa, bb and cc.

(3) On the PMC side, read the code signals corresponding to the respective strobe signals when the strobe signals become “1”, and perform the appropriate operations.

(4) When the operation of all M commands ends on the PMC side, the end signal (FIN) is set to “1”.

(5) When the completion signal stays “1” for a time (TFIN) set by parameter No. 3011 (Standard: 16 msec), all strobe signals (MF, MF2, MF3, MF4 and MF5) are set to “0” at the same time and the reception of completion signal is reported.

(6) On the PMC side, when MF, MF2, MF3, MF4 and MF5 are set to “0”, the completion signal is set to “0”.

A time chart for this procedure is shown below (Fig. 9.3):

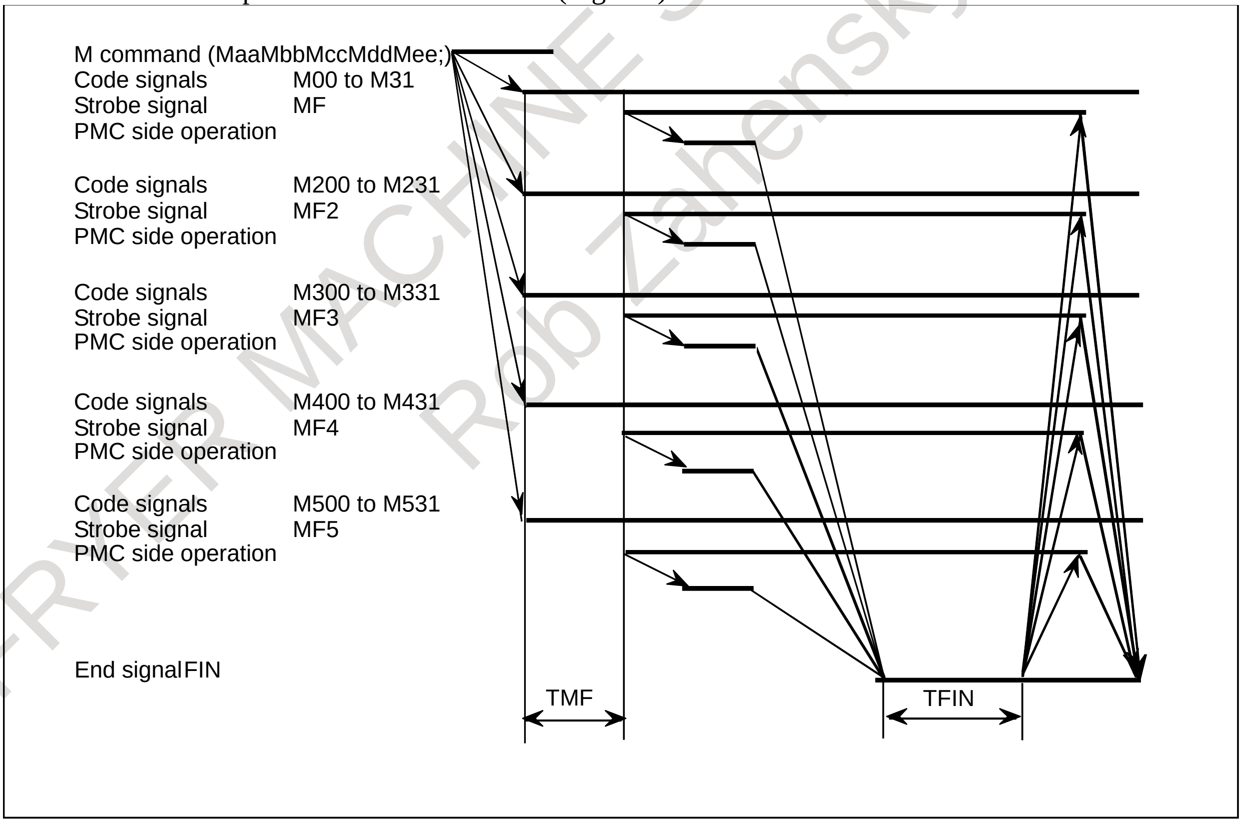

Fig. 9.3

M code preventing buffering

Usually in multiple M commands in a single block, the second M command to the fifth M command cannot be set as M code preventing buffering. By setting bit 0 (MMB) of parameter No. 11658 to 1, the second M command to the fifth M command can be set as M code preventing buffering by any of the following parameters.

- Parameters Nos. 3411 to 3420
- Parameters Nos. 3421 to 3432
- Parameters Nos. 11290 to 11299

Signal

2nd, 3rd, 4th, 5th M function code signals

#7 M3B The number of M codes that can be specified in one block
0: One
1: Up to three

	#7	#6	#5	#4	#3	#2	#1	#0
11630			M5B					

[Input type] Parameter input
[Data type] Bit path

#5 M5B The number of M codes that can be specified in one block
0: One (up to three when bit 7(M3B) of parameter No. 3404 is set to 1)
1: Up to five

	#7	#6	#5	#4	#3	#2	#1	#0
11658								MMB

[Input type] Parameter input
[Data type] Bit path

#0 MMB In multiple M commands in a single block, if any of the second M command to the fifth M command is specified by any of parameters Nos. 3411 to 3420, parameters Nos. 3421 to 3432 or parameters Nos. 11290 to 11299, the M command is:
0: Not recognized as M code preventing buffering
1: Recognized as M code preventing buffering

⚠ **CAUTION**
1 Regardless of setting of bit 0 (MMB) of parameter No. 11658, the first command in multiple commands in a single block can be set as M code preventing buffering.

> ⚠ **CAUTION**
> 2 Though bit 0 (MMB) of parameter No. 11658 is set to 1, M00, M01, M02, M30 or M code preventing buffering specified by any of parameters other than the above must be specified alone in a single block.
> If any of these M codes is specified to any of the second command to the fifth command in multiple M commands in a single block, the M command is not recognized as M code preventing buffering.

Caution

> ⚠ **CAUTION**
> 1 M00, M01, M02, M30, M98, M99, or M198 must not be specified together with another M code.
> 2 Some M codes other than M00, M01, M02, M30, M98, M99, and M198 cannot be specified together with other M codes; each of those M codes must be specified alone in a single block. Such M codes include those that make the CNC perform internal operations in addition to sending the M code signals to the PMC. For example, such M codes are M codes for calling program numbers 9001 to 9009 and M codes for disabling advance reading (buffering) of subsequent blocks.
> The M codes that can be specified in a single block must be those that the CNC only sends the M code signals to the PMC side.
> If bit 0 (MMB) of parameter No. 11658 is set to 1, M code preventing buffering specified by any of parameters Nos. 3411 to 3420, parameters Nos. 3421 to 3432 or parameters Nos. 11290 to 11299 can be specified together with another M code.

Note

> **NOTE**
> 1 CNC allows up to five M codes to be specified in one block. However, some M codes cannot be specified at the same time due to mechanical operation restrictions. For example, M42 can be specified only after the mechanical operation of M41 is completed.
> 2 When bit 7(M3B) of parameter No. 3404 is set to 1, the 1st M code can be up to 8 digits and 2nd, 3rd M codes can be the values up to 65535. When bit 5(M5B) of parameter No. 11630 is set to 1, the 1st to 5th M code can be up to 8 digits.

9.4 HIGH-SPEED M/S/T/B INTERFACE

Overview

To accelerate M/S/T/B function execution, the high-speed M/S/T/B interface has simplified the transfer of the strobe and completion signals of the M/S/T/B functions.
By shortening the execution time of M / S / T / B function, machining time can be reduced.
Whether to use the conventional system or high-speed system for strobe signal and completion signal handling can be specified by bit 7 (MHI) of parameter No. 3001.

The description below uses the auxiliary functions (M code commands) as an example. The same description applies to the spindle function (S code), tool function (T code) and 2nd auxiliary function (B code).

Explanation

- Basic procedure

(1) Assume that the following program is given:
Mxx;
Myy;

(2) In response to an M command, the CNC system sends out the code signals M00 to M31.
The CNC system inverts the logical level of the strobe signal MF, that is, from “0” to “1”, or from “1” to “0”.

(3) The CNC system inverts the strobe signal, then when the logical level of the auxiliary function completion signal MFIN becomes the same as the strobe signal, the CNC assumes the completion of PMC sequence.
With the usual method, the operation is assumed to be completed when a falling edge (“1” to “0”) of the M/S/T/B completion signal FIN is received after a rising edge (“0” to “1”) of the FIN signal is detected. This new system, on the other hand, assumes the operation has been completed upon detection of only one transition of the completion signal.
In addition, the conventional system uses only one completion signal (FIN) common to the M/S/T/B functions. This new system uses a different completion signal for each of the M, S, T, and B functions; the completion signals for the M, S, T, and B functions are MFIN, SFIN, TFIN, and BFIN, respectively.

The Fig. 9.4 (a) below shows the timing chart of these signals with the new system. For comparison, Fig. 9.4 (b) shows the timing chart of the conventional system.

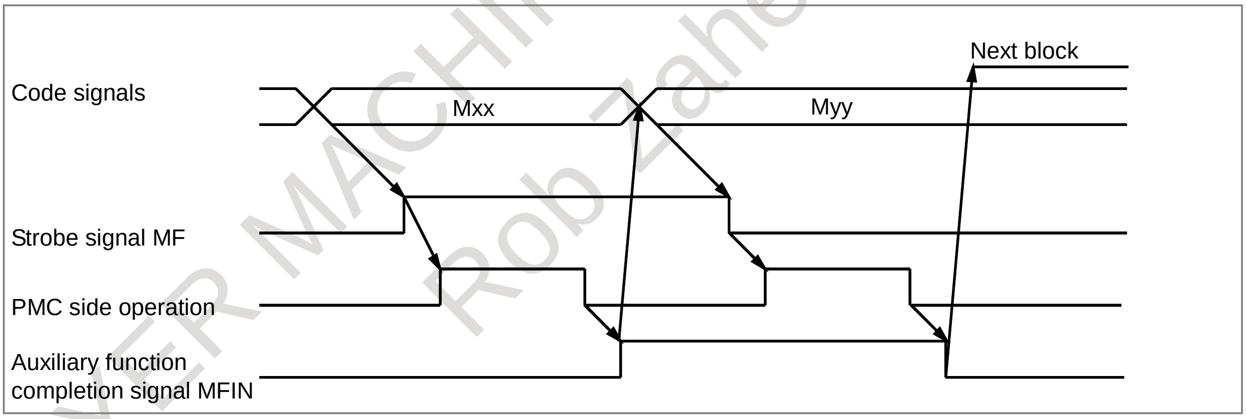

Fig. 9.4 (a) Timing chart of the high-speed system

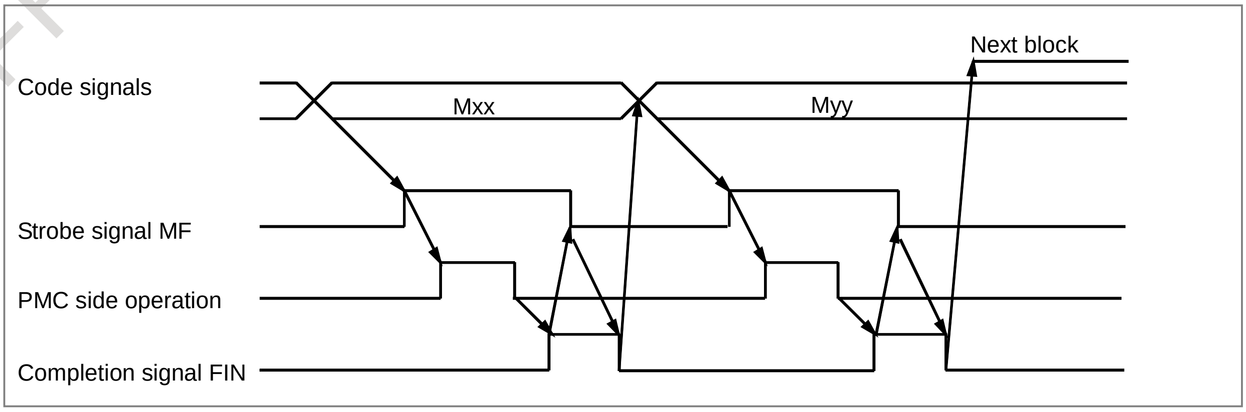

Fig. 9.4 (b) Timing chart of the conventional system

A high-speed interface can also be used for multiple M commands issued for one block. This interface provides separate completion signals for each of the 5 M codes. They are called MFIN (the same name as for the single M command per block function), MFIN2, MFIN3, MFIN4 and MFIN5 respectively. The signal transfer sequence for multiple M codes per block is the same as that for a single M code per block.
The high-speed interface can also be used for the external operation function. In this case, special external operation signal EFD and completion signal EFIN are used.
The procedure for sending and receiving these signals is identical to that for sending and receiving the strobe and completion signals of the auxiliary function (machining center system).

Signal

Auxiliary function completion signal MFIN<Gn005.0>

[Classification] Input signal
[Function] Reports that the execution of a auxiliary function using the high-speed M/S/T/B interface is completed.
[Operation] For the operation and procedure of the control unit when this signal turns to “1” or “0”, see the description of "Basic procedure" above.

Spindle function completion signal SFIN<Gn005.2>

[Classification] Input signal
[Function] Reports that the execution of a spindle speed function using the high-speed M/S/T/B interface is completed.
[Operation] For the operation and procedure of the control unit when this signal turns to “1” or “0”, see the description of "Basic procedure" above.

Tool function completion signal TFIN<Gn005.3>

[Classification] Input signal
[Function] Reports that the execution of a tool function using the high-speed M/S/T/B interface is completed.
[Operation] For the operation and procedure of the control unit when this signal turns to “1” or “0”, see the description of "Basic procedure" above.

2nd auxiliary function completion signal BFIN<Gn005.7>

[Classification] Input signal
[Function] Reports that the execution of a second auxiliary function using the high-speed M/S/T/B interface is completed.
[Operation] For the operation and procedure of the control unit when this signal turns to “1” or “0”, see the description of "Basic procedure" above.

2nd, 3rd, 4th and 5th M function completion signals MFIN2<Gn004.4>,MFIN3<Gn004.5>, MFIN4<Gn004.6>, MFIN5<Gn004.7>

[Classification] Input signal
[Function] Indicate that when the high-speed M/S/T/B interface is used for multiple M commands per block, the 2nd to 5th M functions have been completed.
[Operation] For the operation and procedure of the control unit when this signal turns to “1” or “0”, see the description of "Basic procedure" above.

[Data type] Bit path

#0 CHM For high-speed M/S/T/B, the distribution end signal DEN and an auxiliary function code signal M00 to M31 are:
0: Not turned off even upon completion of the execution of the auxiliary function.
1: Turned off upon completion of the execution of the auxiliary function.

Note

NOTE
1 The strobe signals MF, SF, TF, and BF are "0" when the power is turned on.
2 When the control unit is reset, MF, SF, TF, and BF are set to "0".
3 Using bit 0 (CHM) of parameter No. 3002, select whether to turn the distribution end signal DEN and the auxiliary function code signals M00 to M31 to "0" at the completion of one block.

	External operation function

9.5 M CODE GROUPING FUNCTION

Overview

Classifying up to 500 M codes into up to 127 groups allows the user:
- To receive an alarm if an M code that must be specified alone is included when multiple M codes are specified in a block.
- To receive an alarm if M codes belonging to the same group are specified in the same block when multiple M codes are specified in a block.

Setting an M code group number using the setting screen

- Procedure for displaying the M code group setting screen

You can use the "M code group setting screen" to set a group number for each M code.

Display the "M code group setting screen" using the following procedure:

1 Press function key SYSTEM and the continuous menu key several times. Soft key [M CODE GROUP] appears.
2 Press soft key [M CODE GROUP].

In the “NO.” field, M codes for which an M code group can be set are displayed.
An M code group can be set for the following M codes: M00 to M99, and any 400 M codes selected from M100 and subsequent M codes. For details of how to add the 100th and subsequent M codes, see the explanation of parameters Nos. 3441 to 3444.

In the “DATA” field, the M code group number corresponding to each M code is displayed.

- Setting a group number

To set an M code group number on the “M code group setting screen,” use the following procedure:
1 Select the MDI mode.
2 Set “PARAMETER WRITING” on the setting screen to 1.
3 Display the “M code group setting screen.
4 Move the cursor to the M code to be set using page keys and cursor keys. You can also enter the number of the M code to be set and press soft key [NO.SRH] to move the cursor to the M code.
5 Enter a group number and press soft key [INPUT] or the INPUT key.

The valid range of M code group numbers is from 1 to 127 (127 groups). If a value of 0 is input, it is not registered as an M code group.

- Examples of setting parameters Nos. 3441 to 3444

In the following examples, the number of digits of an M code is 4.
<1> to <4> indicate parameters Nos. 3441 to 3444.

(1) When <1> = 300, <2> = 400, <3> = 500, and <4> = 900 are set

Number
0000 : 0099 } 100 codes
0300 : 0399 } 100 codes
0400 : 0499 } 100 codes
0500 : 0599 } 100 codes
0900 : 0999 } 100 codes

} M code groups can be set for M0000 to M0099, M0300 to M0599, and M0900 to M0999.
M codes M0300 to M0599 and M0900 to M0999 are added to the M code group setting screen.

(2) When <1> = 200, <2> = 0, <3> = 550, and <4> = 800 are set

Number
0000
:
0099
0200
:
0299
0550
:
0649
0800
:
0899

M code groups can be set for M0000 to M0099, M0200 to M0299, M0550 to M0649, and M0800 to M0899.
(The setting of parameter <2> is invalid because it is 0.)
In this case, M codes M0200 to M0299, M0550 to M0649, and M0800 to M0899 are added to the M code group setting screen.

M code group check function

When multiple M commands in a single block (enabled when bit 7 (M3B) of parameter No. 3404 is set to 1) are used, you can check the following items. You can also select whether to check the items using bit 1 (MGC) of parameter No. 3400.

(1) M code to be specified in a single block containing no other M codes
If an M code which must be specified in a single block containing no other M codes is specified together with another M code, an alarm PS5016, ”ILLEGAL COMBINATION OF M CODES” is issued.

(2) M codes in the same group
If multiple M codes in the same group are specified together, an alarm PS5016 is issued.

The valid range of group numbers is from 0 to 127 (128 groups).
Group numbers 0 and 1 have special meaning. Note the following points:

- Each M code with group number 1 is assumed to be an M code to be specified in a single block containing no other M codes.
- For each M code with group number 0, the “same group M code check” is ignored. That is, when multiple M codes with group number 0 are specified in a single block, the alarm is not issued.
- For each M code with group number 0, the “check for an M code to be specified in a single block containing no other M codes” is not ignored. That is, if an M code with group number 1 and an M code with group number 0 are specified in a single block, the alarm is issued.
- For M codes that are not to be output to the machine such as M98, M99, M198, and M codes for subprogram and macro calls (set in parameters Nos. 6071 to 6079 and Nos. 6080 to 6089 and with the macro executor), be sure to set 0 as the group number.
- For M00, M01, M02, M30, and M codes for which buffering is suppressed (set in parameters Nos. 3411 to 3432 and 11290 to 11299), be sure to set 1 as the group number.

Parameter

	#7	#6	#5	#4	#3	#2	#1	#0
3400							MGC	

[Input type] Parameter input
[Data type] Bit path

#1 MGC When a single block specifies multiple M commands, an M code group check is:
0: Made.
1: Not made.

3441	Start number of M codes for which an M code group can be set (1)
3442	Start number of M codes for which an M code group can be set (2)
3443	Start number of M codes for which an M code group can be set (3)
3444	Start number of M codes for which an M code group can be set (4)

[Input type] Parameter input
[Data type] 2-word path
[Valid data range] 0, 100to99999999

Code numbers 0 to 99 on the M code group setting screen correspond to M00 to M99. When adding M codes after the first 100 M codes, specify a start M code number in these parameters. Thus, up to 400 M codes can be added to the M code group setting screen in groups of 100 M codes starting with the set value. When 0 is set, no M codes are added to the M code group setting screen.

When setting these parameters, follow the setting condition described below. If the condition is not satisfied, no M codes are added to the M code group setting screen as in the case where 0 is set.

(Setting condition)

The settings of parameters (1) to (4) (excluding the setting of 0) must satisfy:

99 < (1), (1)+99 < (2), (2)+99 < (3), (3) +99 < (4)

Alarm and message

Number	Message	Description
PS5016	ILLEGAL COMBINATION OF M CODES	M codes which belonged to the same group were specified in a block. Alternatively, an M code which must be specified without other M codes in the block was specified in a block with other M codes.

OPERATOR'S MANUAL (B-64694EN)	M Code Grouping Function

9.6 AUXILIARY FUNCTION OUTPUT IN MOVING AXIS

Overview

By specifying absolute coordinate values and auxiliary functions (M, B) at G50.9 block, the auxiliary functions are output to PMC when absolute coordinate enters the specified area in the next movement block.
G50.9 can be specified up to 2 blocks consecutively. In other words, auxiliary function output points in a movement block can be specified up to two.
Code signals and strobe signals are output to the same signal address as a usual auxiliary function.

Format

G50.9 IP_ Mm11 Mm12 Mm13 Bb11 ;

G50.9 IP_ Mm21 Mm22 Mm23 Bb21 ;

(Movement command block) Mm01 Mm02 Mm03 Bb01 Ss01 Tt01 ;

IP_ : Auxiliary function output start point. (Absolute coordinate value)

M m11 : 1st M auxiliary function (1st block)
M m12 : 2nd M auxiliary function (1st block)
M m13 : 3rd M auxiliary function (1st block)
B b11 : 2nd auxiliary function (1st block)

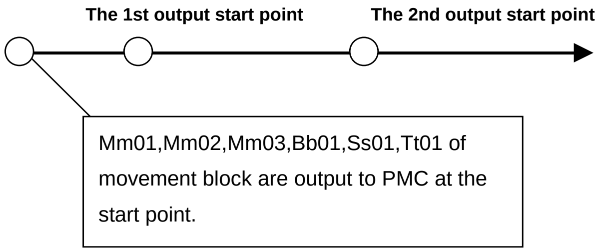
M m21 : 1st M auxiliary function (2nd block)
M m22 : 2nd M auxiliary function (2nd block)
M m23 : 3rd M auxiliary function (2nd block)
B b21 : 2nd auxiliary function (2nd block)

M m01 : 1st M auxiliary function (movement block)
M m02 : 2nd M auxiliary function (movement block)
M m03 : 3rd M auxiliary function (movement block)
B b01 : 2nd auxiliary function (movement block)
S s01 : Spindle speed command
T t01 : T command (Tool compensation)

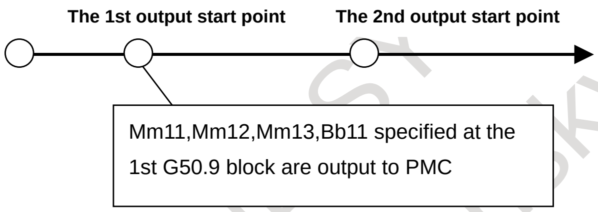
- At least one axis of auxiliary function output start point must be commanded at G50.9 block. The alarm PS5330, " G50.9 FORMAT ERROR" occurs if there is not an axis address at G50.9 block.
- At least one auxiliary function must be commanded at G50.9 block. The alarm PS5330," G50.9 FORMAT ERROR" occurs if an auxiliary function isn't commanded.
- It is possible to command G50.9 block up to 2 blocks consecutively. The alarm PS5330," G50.9 FORMAT ERROR" occurs if more than 3 blocks are commanded.
- Incremental programming cannot be specified in G50.9 block. The alarm PS0009, "IMPROPER NC ADDRESS" occurs. Also, in case of incremental mode (G91) in G code system B/C, incremental programming in G50.9 block is regarded as absolute programming.

Operation

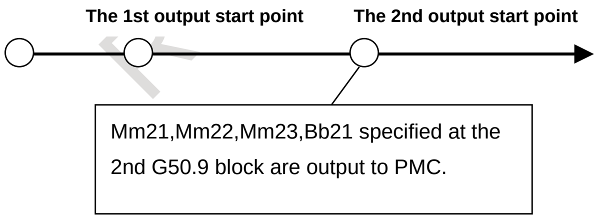
(1) At the start point of movement block, M/S/T/B codes (m01,m02,m03,b01,s01,t01) of movement block are output to PMC, and moving is started.



(2) When moving to the 1st output start point that is specified at the 1st G50.9 block, if FIN processing of
M/S/T/B code which was output to PMC in (1) has completed, M code (m11,m12,m13) and B code (b11) of the 1st G50.9 block are output to PMC.
If FIN processing has not completed, M code (m11,m12,m13) and B code (b11) are not output to PMC at the 1st output start point. They are output immediately after FIN processing completes. Code signals and strobe signals are output to the same signal address as usual auxiliary function.



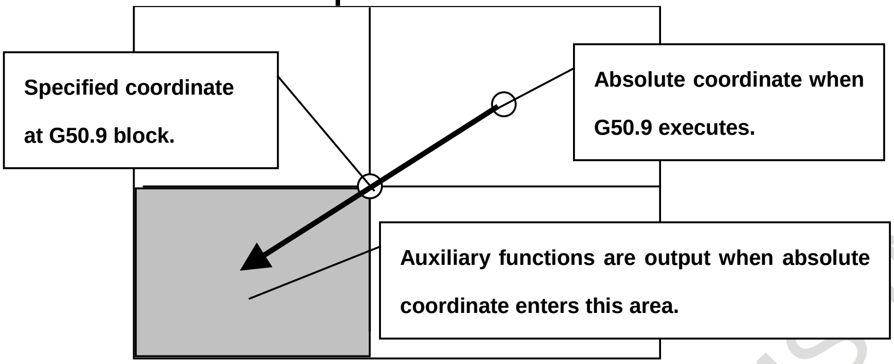
(3) When moving to the 2nd output start point that is specified at the 2nd G50.9 block, if FIN processing of M/S/T/B code which was output to PMC in (2) has completed, M code (m21,m22,m23) and B code (b21) of the 2nd G50.9 block are output to PMC.
If FIN processing has not completed, M code (m21,m22,m23) and B code (b21) are not output to PMC at the 2nd output point. They are output immediately after FIN processing completes.



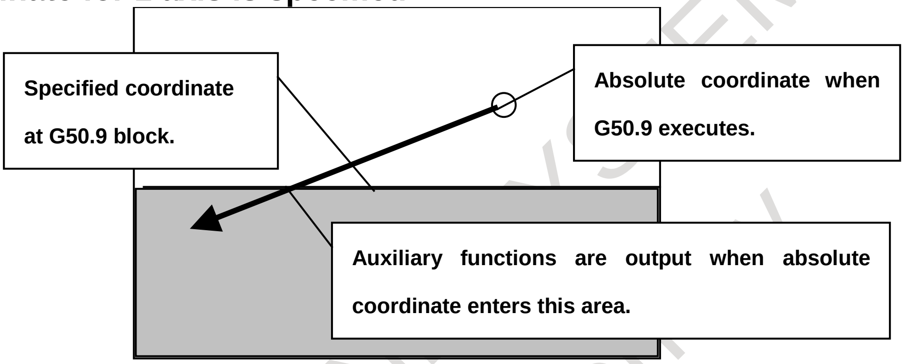
(4) When movement completes, if absolute coordinate has not reached the value that was specified at G50.9 blocks, the alarm PS5331, “ILLEGAL COMMANDED POSITION“ occurs.

Specification of output start point

When coordinates for 2 axes are specified



When coordinate for 1 axis is specified



Priority of auxiliary function output

If absolute coordinate have entered the area that was specified at the 2nd G50.9 block while they have not entered the area that was specified at the 1st G50.9 block, auxiliary function of the 2nd G50.9 block are not output at that time. After absolute coordinate entered the area that was specified at the 1st G50.9 block and FIN processing completed, auxiliary function of the 2nd G50.9 block are output finally.

Alarm at movement completion

When movement completes, if absolute coordinate has not reached the value that was specified at G50.9 blocks, the alarm PS5331, ”ILLEGAL COMMANDED POSITION” occurs.

The alarm PS5331, ”ILLEGAL COMMANDED POSITION” occurs if next block after G50.9 block is no movement command because absolute coordinate does not reach to the value that was specified at G50.9 block.

Example 1) M code

```
G00 X100. ;
G50.9 X200. M128 ;
M01;    ← The alarm PS5331 occurs.
G00 X300. ;
```

Example 2) Empty block

```
G00 X100. ;
G50.9 X200. M128 ;
; (Empty block)        ← The alarm PS5331 occurs.
G00 X300. ;
```

Parameter

	#7	#6	#5	#4	#3	#2	#1	#0
3001	MHI							

[Input type] Parameter input
[Data type] Bit path

#7 MHI Handshake of strobe and completion signals for the M, S, T, and B
0: Normal
1: High-speed

	#7	#6	#5	#4	#3	#2	#1	#0
3104	DAC	DAL						

[Input type] Parameter input
[Data type] Bit path

#6 DAL The displayed absolute position is
0: The actual position that takes tool length offset into account.
1: The programmed position that does not take tool length offset into account.

> **NOTE**
> In lathe systems, whether a tool offset is excluded from displaying absolute position is determined by the setting of bit 1 (DAP) of parameter No.3129.

#7 DAC When an absolute position are displayed:
0: Values not excluding the amount of travel based on cutter compensation and tool nose radius compensation are displayed.
1: Values excluding the amount of travel based on cutter compensation and tool nose radius compensation (programmed positions) are displayed.

> **NOTE**
> When the parameter DAC is set to 1, in the command like circle interpolation where the cutter compensation vector is changed constantly, an absolute position is not correctly displayed during its interpolation except its start point and its end point.

	#7	#6	#5	#4	#3	#2	#1	#0
3129							DAP	

[Input type] Parameter input
[Data type] Bit path

#1 DAP For absolute coordinate display:
0: The actual position including a tool offset (tool movement) is displayed.
1: The programmed position excluding a tool offset (tool movement) is displayed.

> **NOTE**
> In machining center systems, whether the tool length offset is excluded from displaying absolute position is determined according to the setting of bit 6 (DAL) of parameter No.3104.

Signal

Auxiliary function code signals M00 to M31<Fn010 to Fn013>
2nd M function code signals M200 to M215<Fn014 to Fn015>
3rd M function code signals M300 to M315<Fn016 to Fn017>
Auxiliary function strobe signal MF<Fn007.0>
2nd M Function strobe signal MF2<Fn008.4>
3rd M Function strobe signal<Fn008.5>

[Classification] Output signal

[Function] These signals report that M codes have been specified.

[Output cond.] About output condition, procedure etc, please refer to "FANUC Series 0*i*-MODEL F Plus CONNECTION MANUAL (FUNCTION) 10.1 AUXILIARY FUNCTION/2ND AUXILIARY FUNCTION".

2nd auxiliary function code signals B00 to B31<Fn030 to Fn033>
2nd auxiliary function strobe signal BF<Fn007.7>

[Classification] Output signal

[Function] These signals report that second auxiliary functions have been specified.

[Output cond.] About output condition, procedure etc, please refer to "FANUC Series 0*i*-MODEL F Plus CONNECTION MANUAL (FUNCTION) 10.1 AUXILIARY FUNCTION/2ND AUXILIARY FUNCTION".

End signal FIN<Gn004.3>

[Classification] Input signal

[Function] This signal reports the completion of an auxiliary function, a spindle function, a tool function, a 2nd auxiliary function, or an external operation function.

[Operation] About input condition, procedure etc, please refer to "FANUC Series 0*i*-MODEL F Plus CONNECTION MANUAL (FUNCTION) 10.1 AUXILIARY FUNCTION/2ND AUXILIARY FUNCTION".

Auxiliary function completion signal MFIN<Gn005.0>

[Classification] Input signal

[Function] Reports that the execution of an auxiliary function using the high-speed M/S/T/B interface is completed.

[Operation] About input condition, procedure etc, please refer to "FANUC Series 0*i*-MODEL F Plus CONNECTION MANUAL (FUNCTION) 10.1 AUXILIARY FUNCTION/2ND AUXILIARY FUNCTION".

2nd M function completion signal MFIN2<Gn004.4>
3rd M function completion signal MFIN3<Gn004.5>

[Classification] Input signal

[Function] Indicate that when the high-speed M/S/T/B interface is used for multiple M commands per block, the 2nd to 3rd M functions have been completed.

[Operation] About input condition, procedure etc, please refer to "FANUC Series 0*i*-MODEL F Plus CONNECTION MANUAL (FUNCTION) 10.1 AUXILIARY FUNCTION/2ND AUXILIARY FUNCTION".

2nd auxiliary function completion signal BFIN<Gn005.7>

[Classification] Input signal

[Function] Reports that the execution of a second auxiliary function using the high-speed M/S/T/B interface is completed

[Operation] About input condition, procedure etc, please refer to "FANUC Series 0*i*-MODEL F Plus CONNECTION MANUAL (FUNCTION) 10.1 AUXILIARY FUNCTION/2ND AUXILIARY FUNCTION".

Auxiliary function during axis movement output signal MVAF1<Fn316.4>, MVAF2<Fn316.5>

[Classification] Output signal

[Function] Indicates that auxiliary functions specified at G50.9 blocks are outputting.
1st output point : MVAF1
2nd output point : MVAF2

[Output cond.] These signals turn to "1" when

- The absolute coordinate reach the 1st output point and auxiliary function code signals M00 to M31<Fn010 to Fn013> or 2nd auxiliary function code signals B00 to B31<Fn030 to Fn033> are output.
- The absolute coordinate reach the 2nd output point and auxiliary function code signals M00 to M31<Fn010 to Fn013> or 2nd auxiliary function code signals B00 to B31<Fn030 to Fn033> are output.

These signals turn to "0" when

- Each FIN processing has been completed.
- Reset occurs

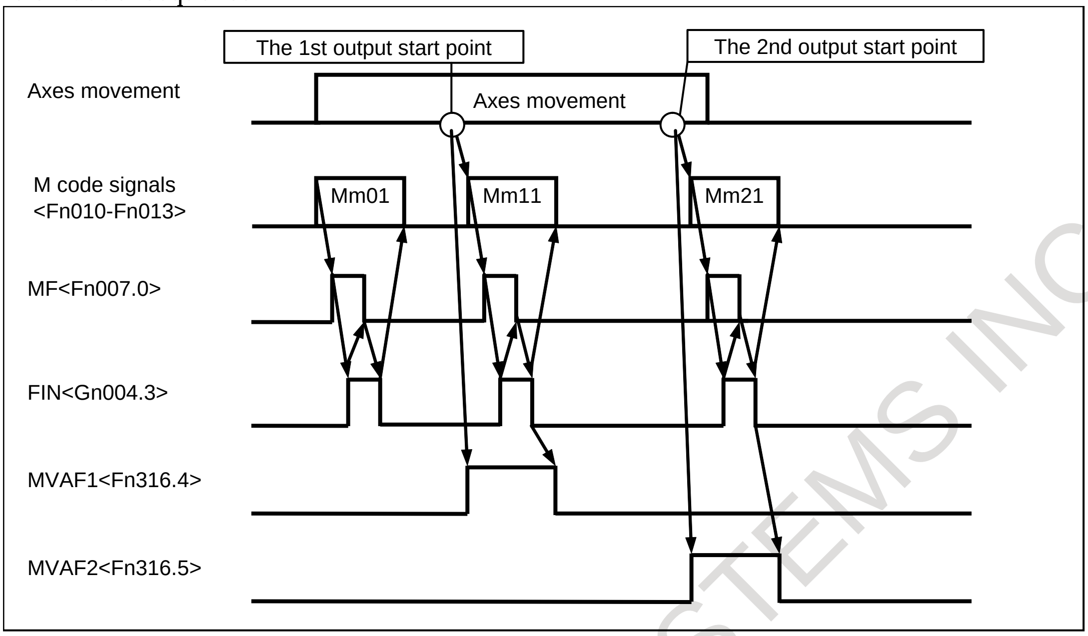
Example of ladder sequence



Alarm and message

Number	Message	Description
PS5330	G50.9 FORMAT ERROR	- There is not coordinates value specification in G50.9 block. - There is not M code, B code command in the G50.9 block. - G50.9 is commanded in canned cycle mode. - 3 blocks of G50.9 block are commanded consecutively.
PS5331	ILLEGAL COMMANDED POSITION	It didn't reach a commanded absolute coordinate value. The movement command or absolute coordinates at G50.9 block are wrong.

Note

Tool nose radius compensation/Cutter compensation C

Because G50.9 block is treated as a block without movement, “Tool nose radius compensation” and “Cutter compensation C” are temporarily canceled when two G50.9 blocks are commanded consecutively.

Tool compensation

When tool compensation amount is changed by T code after the G50.9 block, absolute coordinate value changes according to tool compensation amount. Therefore, absolute coordinate value sometimes enters the area specified by G50.9 block, at the head of the movement block.

Program restart

The histories of M code displayed in the screen of program restart are not in actual output order but in commanded block order.

Multiple M commands in a single block

The parameter M3B (No.3404#7) must be set to 1 in order to command multiple M codes in one block.

M30, M02, M00, M01

Decode signals DM30, DM02, DM01, DM00 are not output while axes are moving if M30, M02, M01, M00 are specified at G50.9 block. These decode signals are output at movement completion, but not output if FIN processing for M30, M02, M01, M00 have already completed.

M98, M198

Subprogram call M code (M98, M198) cannot be commanded at G50.9 block.
The alarm PS0076, "PROGRAM NOT FOUND" occurs.

Macro call M code

Custom macro call M code cannot be commanded at G50.9 block.

Tool life management, Tool management

Even if the M code (M06, etc.) which counts tool life is commanded at G50.9 block, tool life count isn't done.

Waiting M code

Even if a waiting M code is commanded at the G50.9 block, waiting function isn't executed. It is recognized as a usual auxiliary function.

Rigid tapping beginning M code

Even if M code (M29) for beginning rigid tap is commanded at G50.9 block, a mode doesn't switch over to rigid tapping.

M code group check

If plural M codes of one group are commanded at G50.9 block, the alarm PS5016, "ILLEGAL COMBINATION OF MCODES" occurs.

Manual handle retrace

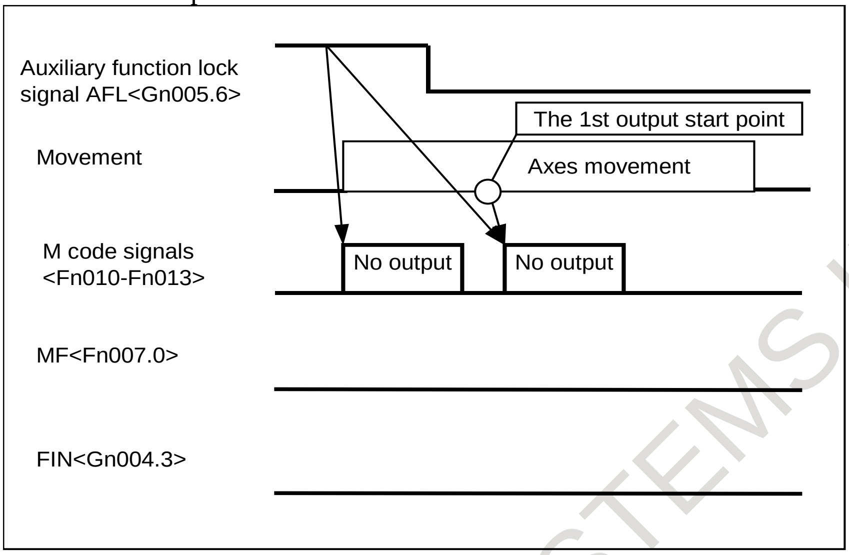
G50.9 block and movement block cannot move backward in manual handle retrace mode.
Only forward movement is possible.

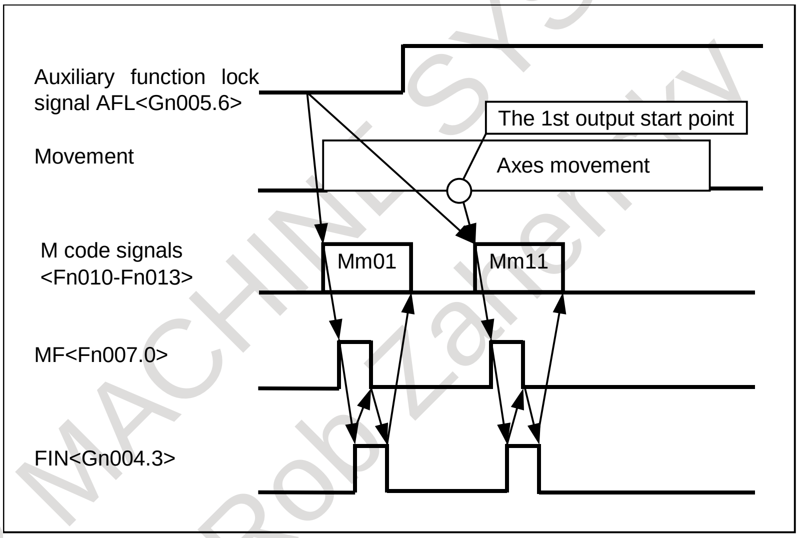
Canned cycle

Canned cycle cannot be specified as movement command block.

Auxiliary function lock

According to the condition of Auxiliary function lock signal AFL <Gn005.6> at beginning of movement block, auxiliary functions are output to PMC.





M code for spindle command (M03/M04/M05)

M code for spindle command (M03/M04/M05) is cannot be specified in G50.9 block.
These M codes are recognized as usual auxiliary functions.

M code that is set by parameter

M code in which specific operation is enabled by parameter setting is cannot be specified in G50.9 block.
This M code is recognized as a usual auxiliary function.

Retrace (M system)

G50.9 block and movement block cannot move backward. Only forward movement is possible.

Dynamic graphic display

Instruction information of M code that is specified in G50.9 block is not displayed in Path Drawing screen/Animation screen

Manual intervention

Do not operate manual intervention in G50.9 block.

Single block

During single block operation, G50.9 block stops.

Incremental programming

Incremental programming cannot be specified in G50.9 block. The alarm PS0009, ”IMPROPER NC ADDRESS” occurs.
Also, in case of incremental mode (G91) in G code system B/C, incremental programming in G50.9 block is treated as absolute programming.

10 SPINDLE SPEED FUNCTION

10.1 SPINDLE SPEED FUNCTION (S CODE OUTPUT)

Overview

When up to five digits are specified after address S, code and strobe signals are sent out and used to control the spindle speed. The code signals are retained until another S code is issued.
One S code is used for each block. Parameter No. 3031 can be used to specify the maximum number of digits. If a number greater than the maximum number is specified, an alarm can be raised.

Signal

Refer to section "Auxiliary Function/Second Auxiliary Function."

Parameter

3031	Allowable number of digits for the S code

[Data type] Byte
[Valid data range] 1 to 5
Set the allowable numbers of digits for the S code.

Note

NOTE
1 When a move command and a spindle-speed function command are specified within the same block, the commands are executed in either of the following two ways:
(1) The move command and spindle-speed function are started at the same time.
(2) After the move command is completed, the spindle-speed function command is started.
Whether (1) or (2) takes place depends on the processing on the PMC side.
2 For S code output when spindle serial output or spindle analog output is used, see Section "SPINDLE SPEED CONTROL".

Reference item

Manual name	Item name
CONNECTION MANUAL (FUNCTION) (this manual)	Auxiliary function/2nd auxiliary function
	Spindle speed control

10.2 SPINDLE SERIAL OUTPUT

Overview

Spindle serial output is a spindle motor control interface.
The spindle serial output can control up to eight serial spindles (up to four serial spindles per path).

Explanation

The terms "logical n-th spindle", "n-th spindle in a path", and "n-th spindle amplifier" in the subsequent descriptions refer to the following:

- Logical n-th spindle:
  The n-th spindle to be controlled in the overall system
- N-th spindle (in a path):
  The n-th spindle to be controlled in a path.
  The first, second, third, and fourth spindles in the descriptions refer to relative spindle numbers within a path. (For a single-path system, the logical n-th spindle equals the n-th spindle.)
- N-th spindle amplifier:
  The n-th spindle amplifier (amplifier No. n) actually connected to the CNC.

For the relationships between them, see "Spindle numbers vs. spindle motors" described later.

For how to set a spindle configuration for each path in multipath control, see the description of spindles in "Multipath Control".
The relationship between the spindles and functions is as shown Table 10.2 (a).

Table 10.2 (a)

Spindle / Function	Serial spindle (*1)			
	First spindle	**Second spindle**	**Third spindle**	**Fourth spindle**
Threading/feed per revolution (synchronous feed)	Available	Available(*3)	Available(*3)	Available(*3)

Spindle output control by the PMC	Available	Available	Available	Available

NOTE
1 Enable spindle serial output (bit 5 (SSN) of parameter No.8133 is 0).
2 The number of controlled spindles must be specified.
3 Enable multi-spindle control (bit 3 (MSP) of parameter No.8133 is 1).
4 These functions belong to the spindle control unit. They cannot be used unless the spindle control unit supports those functions.

- Spindle numbers vs. spindle motors

Logical spindle numbers are associated with spindle motors as follows:

1. Logical spindle numbers and amplifier numbers
   Logical spindle numbers indicate the order of spindles to be controlled (the logical arrangement order). Parameters for the individual spindles are arranged in this order. Logical spindle numbers are assigned sequentially from 1 to the maximum number of spindles. DI/DO signals are allocated for each spindle number within a path, and their signal locations are incremented by 1000 for each path.
   Amplifier numbers indicate the order of spindle amplifiers actually connected to the CNC (the physical arrangement order). They are assigned as shown below (Fig. 10.2 (a)). When a spindle motor is connected to each spindle amplifier, the spindle amplifier numbers and spindle motor numbers match.

2. Setting method

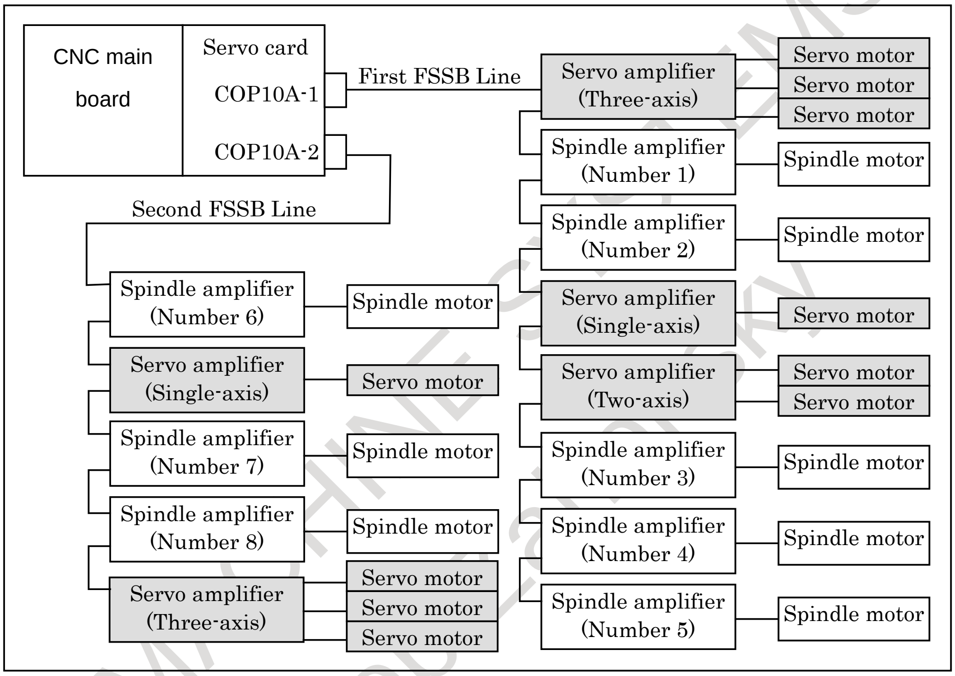

Fig. 10.2 (a) Connection of serial spindles

For each spindle, set the type of the motor in bit 0 (A/S) of parameter No. 3716, and set the amplifier number in parameter No. 3717. For spindles not to be used, set 0 as the amplifier numbers.

Example 1) When using one serial spindle in a single-path system

Parameter	First spindle	Second spindle	Third spindle	Fourth spindle
Bit 0 (A/S) of parameter No. 3716	1	0	0	0
No.3717	1	0	0	0

Example 2) When using four serial spindles in a single-path system

Parameter	First spindle	Second spindle	Third spindle	Fourth spindle
Bit 0 (A/S) of parameter No. 3716	1	1	1	1
No.3717	1	2	3	4

NOTE
In addition, it is necessary to set FSSB. Refer to "1.4.4 FSSB Setting" for details.

Signal

Spindle control unit signals for the serial spindle

<Gn070 - Gn073><Gn304 - Gn307><Fn045 - Fn048><Fn306 - Fn307> : 1st spindle
<Gn074 - Gn077><Gn308 - Gn311><Fn049 - Fn052><Fn308 - Fn309> : 2nd spindle
<Gn204 - Gn207><Gn312 - Gn315><Fn168 - Fn171><Fn310 - Fn311> : 3rd spindle
<Gn266 - Gn269><Gn316 - Gn319><Fn266 - Fn269><Fn312 - Fn313> : 4th spindle

These addresses are assigned to locations on the CNC, but the signals at these addresses are input/output signals of the serial spindle control unit. For details of the signals at these addresses, refer to the following manuals of serial spindles:

FANUC SERVO AMPLIFIER α*i*-B series DESCRIPTIONS (B-65412EN)

FANUC AC SPINDLE MOTOR α*i*-B / β*i*-B series DESCRIPTIONS (B-65452EN)

Serial spindle control unit signals (such as the alarm signals ALMA, ALMB <F045.0, F049.0> etc) are disabled and its operation is not guaranteed after power-on until the parameters have been transferred from the CNC to the spindle amplifier.

After checking the following spindle operation ready signals to see the ready status, use serial spindle control unit signals.

Spindle ready signals

SRSP1R<Fn034.6> : 1st spindle
SRSP2R<Fn034.5> : 2nd spindle
SRSP3R<Fn034.4> : 3rd spindle
SRSP4R<Fn034.3> : 4th spindle

[Classification] Output signal

[Function] These signals post that a corresponding spindle is ready for operation.

[Operation] These signals are set to “1” when:

The corresponding spindle becomes ready for operation (when the following conditions are met).

- The option for the corresponding spindle is provided and is set for use.
- There is no serial communication alarm. (Serial spindle)
- Serial spindle parameters have been transferred. (Serial spindle)
- The spindle control software is ready for operation. (Serial spindle)

These signals are set to “0” when:

The corresponding spindle is not ready for operation.

All-spindle operation ready signal SRSRDY <F0034.7>

[Classification] Output signal

[Function] This signal posts that all spindles used are ready for operation.

[Operation] The signal is set to “1” when:

All spindles used become ready for operation.

The signal is set to “0” when:

Some of the spindles used are not ready for operation.

Spindle warning detail signals SPWRN1 to SPWRN9 <Fn264.0 to Fn265.0>

[Classification] Output signal

[Function] Before an alarm is issued, the occurrence of a warning condition is posted via the warning interface, which is independent of the conventional alarm interface.

Nine signals are output to indicate a decimal code. The relationship between the spindle warning number and signals is expressed as follows:

[Operation] A warning number is output according to the spindle amplifier status as follows:

$$\text{Spindle warning No.} = \sum_{i=1}^{8}\left\{2^{i-1}\times SPWRN_i\right\} + 2^8\times SPWRN_9$$

Warning No.	Description of warning	Spindle operation
56	SPM internal cooling fan stopped	When the stopped state of the internal cooling fan is detected, the warning number is posted from the spindle amplifier to the CNC. The spindle continues operating. About one minute later, an alarm number is posted, and the spindle is placed in the free running state.
88	SPM radiator cooling fan stopped	When the stopped state of the external cooling fan is detected, the warning number is posted from the spindle amplifier to the CNC. The spindle continues operating. If the main circuit overheats because the external cooling fan is stopped, an alarm is posted, and the spindle is placed in the free running state.
58	Overload on converter main circuit	A warning number is output according to the signal received from the PSM In the warning state, the spindle continues operating.
59	Converter internal cooling fan stopped	
113	Converter radiator cooling fan stopped	

The spindle warning detail signals are set to “0” when all alarm factors are eliminated.
When a warning is issued in more than one spindle within the same path, the spindle warning detail signals indicate the warning No. of the spindle having the smallest spindle number.

Parameter

- Settings for spindle motors and spindle numbers

	#7	#6	#5	#4	#3	#2	#1	#0
3716								A/Ss

[Input type] Parameter input
[Data type] Bit spindle

> **NOTE**
> When this parameter is set, the power must be turned off before operation is continued.

#0 A/Ss Spindle motor type is :
0: Analog spindle.
1: Serial spindle.

> **NOTE**
> 1 To use a serial spindle, set 0 to bit 5 (SSN) of parameter No.8133.
> 2 The 1 analog spindle at the maximum can be controlled in a system.
> 3 When using an analog spindle, assign it at the end of the spindle configuration.

3717	Motor number to each spindle

> **NOTE**
> When this parameter is set, the power must be turned off before operation is continued.

[Input type] Parameter input
[Data type] Byte spindle
[Valid data range] 0 to Maximum number of controlled axes

Set a spindle amplifier number to be assigned to each spindle.
0: No spindle amplifier is connected.
1: Spindle motor connected to amplifier number 1 is used.
2: Spindle motor connected to amplifier number 2 is used.
to
n: Spindle motor connected to amplifier number n is used.

NOTE
1 In addition, it is necessary to set FSSB. Refer to "1.4.4 FSSB Setting" for details.
2 If value of this parameter is larger than the maximum value, the alarm SP1996, "ILLEGAL SPINDLE PARAMETER SETTING" occurs.
3 If the spindle motor is treated as hypothetical Cs axis control or spindle control with servo motor, set this parameter to “0”.
4 In the display order of the parameter No.982, the spindle axes since the spindle axis that 0 is set to this parameter become invalid, too. However, the case that the spindle motor is treated as hypothetical Cs axis control or spindle control with servo motor is excepted.
Example) On the following setting, S3 and S4 spindle axes are invalid when the spindle motor of S3 is not treated as hypothetical Cs axis control or spindle control with servo motor.

Display order of No.982	Setting value of No.982	Setting value of No.3717
S1	1	1
S2	2	2
S3	1	0
S4	2	3

3718	Subscript for display of a serial spindle (main spindle) or analog spindle

[Input type] Parameter input
[Data type] Byte spindle
[Valid data range] 0 to 122

Set a subscript to be added to spindle speed display on a screen such as the position display screen.
Used when the spindle switching function is not used, or used for the main spindle when the spindle switching function is used.

NOTE
This parameter is invalid when an extended spindle name is used.

3719	Subscript for display of a serial spindle (sub-spindle)

[Input type] Parameter input
[Data type] Byte spindle
[Valid data range] 0 to 122

Set a subscript to be added to spindle speed display on a screen such as the position display screen.
Used for the sub-spindle when the spindle switching function is used.

NOTE
This parameter is invalid when an extended spindle name is used.

- Connection of serial spindle control unit

	#7	#6	#5	#4	#3	#2	#1	#0
4019	PLD							
4195	PLD							

[Input type] Parameter input
[Data type] Bit spindle

#7 PLD When power is turned on, spindle amplifier parameters for the serial spindle are:
0: Not set automatically.
1: Set automatically.
No. 4019 : (Used when the spindle switching function is not used, or used for the main spindle when the spindle switching function is used)
No. 4195 : (Used for the sub-spindle when the spindle switching function is used)
When this parameter is set to 1 after the spindle motor model code parameter is set, the next power-on operation sets the standard values for the motor model in parameters and sets this parameter to 0.

4133	Spindle motor model code (Used when spindle switching function is not used, or used for main spindle in spindle switching)
4309	Spindle motor model code (For sub-spindle when spindle switching function is provided)

[Input type] Parameter input
[Data type] Word spindle
[Valid data range] 0 to 32767
When setting initial parameters for the serial spindle, specify the spindle motor model code.

- Parameters for the serial spindle control unit

Parameters Nos. 4000 to 4799: For serial spindles
Although the above parameters are stored as CNC parameters, they are actually used by the spindle control unit of serial spindles.
For details of these parameters, refer to the following manuals of serial spindles:
FANUC AC SPINDLE MOTOR αi series PARAMETER MANUAL (B-65280EN)

Alarm and message

Number	Message	Description
SP1220	NO SPINDLE AMP.	Either the cable connected to a serial spindle amplifier is broken, or the serial spindle amplifier is not connected.
SP1227	RECEIVING ERROR (SERIAL SPINDLE)	A receive error occurred in communications between the CNC and the serial spindle amplifier.
SP1228	COMMUNICATION ERROR (SERIAL SPINDLE)	A communications error occurred between the CNC and the serial spindle amplifier.
SP1229	COMMUNICATION ERROR SERIAL SPINDLE AMP.	A communications error occurred between serial spindle amplifiers (amplifiers of even number and odd number).
SP1245 to SP1247	COMMUNICATION DATA ERROR	A communication data error was detected on the CNC. Inquire of FANUC, please.
SP1969 to SP1972	SPINDLE CONTROL ERROR	An error occurred in the spindle control software. Inquire of FANUC, please.

Number	Message	Description
SP1976 to SP1979	SERIAL SPINDLE COMMUNICATION ERROR	An error occurred in the spindle control software. Inquire of FANUC, please.
SP1980 to SP1984	SERIAL SPINDLE AMP. ERROR	Defect on serial spindle amplifier. Inquire of FANUC, please.
SP1985 to SP1987	SERIAL SPINDLE CONTROL ERROR	Defective SIC–LSI on serial spindle amplifier. Inquire of FANUC, please.
SP1988, SP1989	SPINDLE CONTROL ERROR	An error occurred in the spindle control software. Inquire of FANUC, please.
SP1996	ILLEGAL SPINDLE PARAMETER SETTING	The spindle was assigned incorrectly. Check to see the following parameter. (No.3716 or 3717)
SP9000 or later		An alarm is issued from the spindle amplifier unit of the serial spindle. For details, refer to the manual of the serial spindle.

Diagnosis data

- Information about spindle control

	#7	#6	#5	#4	#3	#2	#1	#0
1570	LNK							

[Data type] Bit spindle

LNK 0: The spindle interface does not operate normally.
1: The spindle interface operates normally.

403	Spindle motor temperature information

[Data type] Byte spindle
[Unit of data] °C
[Valid data range] 0 to 255

When the α*i* spindle interface is used, the temperature of the αi spindle motor winding is indicated. The overheat temperature varies depending on the motor.

> **NOTE**
> The overheat temperature has the following error:
> Lower than 160°C: Up to 5°C
> 160 to 180°C: Up to 10°C

- Indication of serial spindle load meter and speed meter

410	Spindle load meter indication (%)

411	Spindle motor speed indication (min^{-1})

[Data type] Word spindle

For correct indication of the load meter and motor speed, the following parameters must be set properly:
Maximum motor speed: Set for each axis in parameters Nos. 4020 (MAIN) and 4196 (SUB).
Load meter indication at maximum output: Set for each axis in parameters Nos. 4127 (MAIN) and 4276 (SUB).

> **NOTE**
> Parameters for (MAIN) and (SUB) must be set when the spindle switching function is used.
> When the spindle switching function is not used, set the parameters for (MAIN).

445	Position data of position coder (pulse)

[Data type] 2-word spindle
[Unit of data] Pulse
[Valid data range] Depend on the bit 0 (ORPUNT) of No.4542 setting (Refer to the table below)

Bit 0 (ORPUNT) of No.4542	Valid data range
0	0 to 4095
1	0 to 32767

> **NOTE**
> Once spindle orientation is performed after power-on, position data can be read. To read position data, set bit 1(SPP) of parameter No. 3117 to 1.
> (Except when maintenance is performed, bit 1(SPP) of parameter No. 3117 must be set to 0.)

449	Position data of position coder (angle)

[Data type] Real spindle
[Unit of data] Refer to the table below
[Valid data range] 0 to 359.999[deg]

Diagnosis data No.449 indicates spindle angle from the one-rotation signal when bit 1 (SPP) of parameter No.3117 is set to 1. Spindle angle displays to three decimal places. It is available for serial spindle. To display spindle angle, spindle orientation must be performed once. Unit of spindle angle data is as follows.

Bit 0 (ORPUNT) of No.4542	Unit of data [deg]
0	0.088
1	0.011

> **NOTE**
> Once spindle orientation is performed after power-on, position data can be read. To read position data, set bit 1(SPP) of parameter No. 3117 to 1.
> (Except when maintenance is performed, bit 1(SPP) of parameter No. 3117 must be set to 0.)

710	Spindle status error No.

[Data type] Byte spindle
The status error number transferred from the spindle amplifier is indicated.

When the spindle is disabled by an error such as a PMC signal input error (for example, when two operation modes are specified at the same time), a status error is recognized while the spindle is disabled. When the signal is input normally, the normal operation is resumed.

For details of spindle error numbers, see the description of alarms (SP alarms) related to serial spindles in the alarm list.

712	Spindle warning No.

[Data type] Byte spindle
The warning number transferred from the spindle amplifier is indicated.

CONNECTION MANUAL (FUNCTION) (This manual)	FSSB Setting

10.3 SPINDLE ANALOG OUTPUT

Overview

Spindle analog output is a spindle motor control interface.
The spindle analog output can control up to 1 analog spindle.

This section assumes that an analog spindle is set for the first spindle (serial spindles are not used with an analog spindle, but only an analog spindle is used). When using both serial and analog spindles, see the next section, "SERIAL/ANALOG SPINDLE CONTROL".

Explanation

The terms "logical n-th spindle", "n-th spindle in a path", and "n-th spindle amplifier" used herein are defined as follows:

- Logical n-th spindle:
  The n-th spindle to be controlled as counted throughout the system
- N-th spindle (in a path):
  The n-th spindle to be controlled as counted within a path
  The terms "first spindle", "second spindle", "third spindle", and "fourth spindle" used herein refer to relative spindle numbers within a path. (In a single-path system, the logical n-th spindle is the n-th spindle.)

For the relationships between them, see "Spindle numbers vs. spindle motors" described later.

For how to set a spindle configuration for each path to be subjected to multi-path control, see the description of spindles in "Multipath Control".

The Table 10.3 (a) lists the relationships between the spindles and functions.

Table 10.3 (a)

Spindle / Function	Analog spindle (*1)
	First spindle
Threading/feed per revolution (synchronous feed)	Available
Constant surface speed control	Available
Spindle speed fluctuation detection (T series)	Available
Actual spindle speed output (T series)	Available
Spindle positioning (T series)	Available

Function \ Spindle	Analog spindle (*1)
	First spindle
Cs contour control	Unavailable
Multi-spindle control	Unavailable
Rigid tapping	Available
Spindle synchronous control	Unavailable
Spindle simple synchronous control	Unavailable
Spindle control unit functions, such as spindle orientation, spindle output switching, and spindle switching (*2)	Available
Polygon machining (T series) (using the servo motor axis and spindle)	Available
Polygon machining with two spindles (T series)	Unavailable
Spindle output control by the PMC	Available

NOTE
1 These functions belong to the spindle control unit. They cannot be used unless the spindle control unit supports them.
2 The number of controlled spindles must be specified.

- Spindle numbers vs. spindle motors

Logical spindle numbers are associated with spindle motors as follows:

1. Logical spindle numbers and amplifier numbers
   Logical spindle numbers indicate the order of spindles to be controlled (the logical arrangement order). Parameters for the individual spindles are arranged in this order. Logical spindle numbers are assigned sequentially from 1 to the maximum number of spindles.
   Amplifier numbers indicate the order of spindle amplifiers actually connected to the CNC (the physical arrangement order). They are assigned as shown below (Fig. 10.3 (a)).
   (Because only one analog spindle can be connected, the spindle amplifier and spindle motor are each assigned with number 1.)

2. Setting method

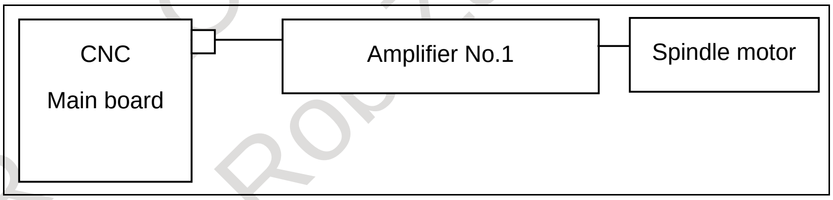

Fig. 10.3 (a) Connection of analog spindle

3. Setting
   For each spindle, the type of the motor used is set in bit 0 (A/S) of parameter No. 3716, and the amplifier number, in parameter No. 3717. For spindles not to be used, the amplifier numbers are 0.

Parameter	First spindle	Second spindle	Third spindle	Fourth spindle
Bit 0 (A/S) of parameter No. 3716	0	0	0	0
No.3717	1	0	0	0

Note

NOTE
1 If a failure occurs in the D/A converter, the following conditions occur.
- Alarm SP1241, “D/A CONVERTER ERROR” is issued.
- The spindle command voltage is set to 0.
- The spindle enable signal is set to “0”.

2 The load meter value (motor load) always becomes 0 no matter what condition occurs.

Parameter

When this parameter is set, the power must be turned off before operation is continued.

#0 A/Ss Spindle motor type is :
0: Analog spindle.
1: Serial spindle.

NOTE
When a serial spindle is used, enable spindle serial output (bit 5 (SSN) of parameter No.8133 is 0).

3717	Motor number to each spindle

NOTE
When this parameter is set, the power must be turned off before operation is continued.

[Input type] Parameter input
[Data type] Byte spindle
[Valid data range] 0 to Maximum number of controlled axes
Set a spindle amplifier number to be assigned to each spindle.
0: No spindle amplifier is connected.
1: Spindle motor connected to amplifier number 1 is used.
2: Spindle motor connected to amplifier number 2 is used.
to
n: Spindle motor connected to amplifier number n is used.

3718	Subscript for display of a serial spindle (main spindle) or analog spindle

[Input type] Parameter input
[Data type] Byte spindle
[Valid data range] 0 to 122
Set a subscript to be added to spindle speed display on a screen such as the position display screen.

Used when the spindle switching function is not used, or used for the main spindle when the spindle switching function is used.

> **NOTE**
> This parameter is invalid when an extended spindle name is used.

	#7	#6	#5	#4	#3	#2	#1	#0
3799							NDPs	

[Input type] Parameter input
[Data type] Bit spindle

#1 NDPs When an analog spindle is used, a position coder disconnection check is:
0: Made.
1: Not made.
(This parameter is valid when bit 0 (NAL) of parameter No. 3799 is set to 0.)
When no position coder is used with an analog spindle, set this parameter to 1.

Alarm and message

Number	Message	Description
SP1241	D/A CONVERTER ERROR	The D/A converter for controlling analog spindles is erroneous.
SP1996	ILLEGAL SPINDLE PARAMETER SETTING	The spindle was assigned incorrectly. Check to see the following parameter. (No.3716 or 3717)

10.4 SERIAL/ANALOG SPINDLE CONTROL

Overview

Serial/analog spindle control allows an analog spindle to be used as one of the controlled spindles in the entire system. Only spindle speed command control and spindle speed command control by the PMC can be used.

> **NOTE**
> 1 When using a serial spindle, set bit 5 (SSN) of parameter No. 8133 to 0.
> 2 The analog spindle must be assigned to the last of the spindle configuration.

Explanation

Serial/analog spindle control allows only one analog spindle to be used as one of the controlled spindles in the entire system. The analog spindle used must be assigned to the last spindle of the spindle configuration.

Spindle functions available in serial/analog spindle control

The table below lists the relationship between the spindles and functions:

Function \ Spindle	Serial spindle (NOTE 1)	Analog spindle
Threading/feed per revolution (synchronous feed)	Available	Unavailable
Constant surface speed control	Available	Unavailable
Spindle speed fluctuation detection	Available	Unavailable
Actual spindle speed output (T series)	Available	Unavailable
Spindle positioning (T series)	Available	Unavailable
Cs contour control	Available	Unavailable

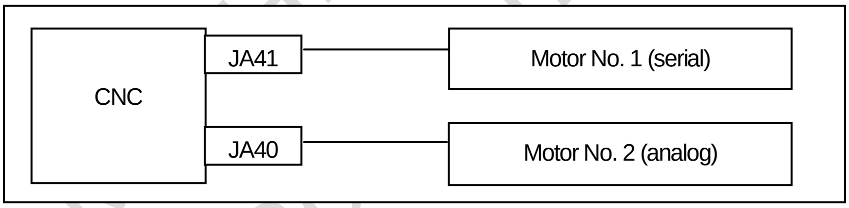
Spindle / Function	Serial spindle (NOTE 1)	Analog spindle
Rigid tapping	Available	Unavailable
Spindle synchronous control	Available	Unavailable
Simple spindle synchronous control	Available	Unavailable
Spindle control unit functions, such as spindle orientation, spindle output switching, and spindle switching (NOTE 2)	Available	Available
Polygon machining (T series) (using the servo motor axis and spindle)	Available	Unavailable
Polygon machining with two spindles (T series) (Spindle and spindle polygon)	Available	Unavailable
Spindle output control by the PMC	Available	Available

NOTE
1 When using a serial spindle, set bit 5 (SSN) of parameter No. 8133 to 0.
2 These functions belong to the spindle control unit. They cannot be used unless the spindle control unit supports these functions.

Connection example

Connect the analog spindle to JA40.
When an analog spindle is used under serial/analog spindle control, a position coder cannot be attached to the analog spindle.
For connection of serial spindles, refer to CONNECTION MANUAL (Hardware) (B-64603EN).

- When connecting one serial spindle and one analog spindle (when the maximum number of controllable spindles is two)



Restrictions

When an analog spindle is used under serial/analog spindle control, there are restrictions as follows:

1 Be sure to assign the analog spindle as the last spindle of the controlled spindles.
Example:
When there are two controlled spindles, and one of these spindles is an analog spindle
The controlled spindle number of the analog spindle is 2.
Set the spindle amplifier number of the analog spindle (parameter No. 3717) to 2.
2 A position coder cannot be installed.
3 Only spindle speed command control and spindle speed command control by the PMC can be used. Other control and spindle functions cannot be used.

Parameter

	#7	#6	#5	#4	#3	#2	#1	#0
3702							EMS	

[Input type] Parameter input
[Data type] Bit path

#1 EMS The multi-spindle control is:
0: Used.
1: Not used.

> **NOTE**
> Make the setting on the side of the path in which multi-spindle control is unnecessary in 2-path control.

	#7	#6	#5	#4	#3	#2	#1	#0
3716								A/Ss

[Input type] Parameter input

> **NOTE**
> When this parameter is set, the power must be turned off before operation is continued.

#0 A/Ss Spindle motor type is :
0: Analog spindle.
1: Serial spindle.

> **NOTE**
> 1 A maximum of one analog spindle can be controlled.
> 2 To use a serial spindle, set bit 5 (SSN) of parameter No. 8133 to 0.
> 3 When using an analog spindle, assign it at the end of the spindle configuration.

3717	Motor number to each spindle

> **NOTE**
> When this parameter is set, the power must be turned off before operation is continued.

[Input type] Parameter input
[Data type] Byte spindle
[Valid data range] 0 to Maximum number of controlled axes

Set a spindle amplifier number to be assigned to each spindle.
0: No spindle amplifier is connected.
1: Spindle motor connected to amplifier number 1 is used.
2: Spindle motor connected to amplifier number 2 is used.
3: Spindle motor connected to amplifier number 3 is used.

> **NOTE**
> When using an analog spindle, assign it at the end of the spindle configuration.
> (Example)
> When there are three spindles in an entire system (two serial spindles and one analog spindle), set the spindle amplifier number (this parameter) of the analog spindle to 3.

3718	Subscript for display of a serial spindle or analog spindle

[Input type] Parameter input
[Data type] Byte spindle
[Valid data range] 0 to 122
Set a subscript to be added to spindle speed display on a screen such as the position display screen.

	#7	#6	#5	#4	#3	#2	#1	#0
3798								ALM

[Input type] Parameter input
[Data type] Bit

#0 ALM The spindle alarm (SP****) for all spindles is:
0: Enabled.
1: Ignored.
When this parameter is set to 1, the spindle-related alarms are ignored. So, be sure to set this parameter to 0 at all times except for special cases such as maintenance.

	#7	#6	#5	#4	#3	#2	#1	#0
3799							NDPs	NALs

[Input type] Parameter input
[Data type] Bit spindle

#0 NALs An alarm detected on the spindle amplifier side is:
0: Displayed.
1: Not displayed.
(This parameter is valid when bit 0 (ALM) of parameter No. 3798 is set to 0.)
When this parameter is set to 1, an alarm detected on the spindle amplifier side is ignored. So, be sure to set this parameter to 0 at all times except for special cases such as maintenance.

#1 NDPs When an analog spindle is used, a position coder disconnection check is:
0: Made.
1: Not made.
(This parameter is valid when bit 0 (NAL) of parameter No. 3799 is set to 0.)
When no position coder is used with an analog spindle, set this parameter to 1.

> **NOTE**
> When an analog spindle is used simultaneously with serial spindle by serial/analog spindle control, a position coder cannot be used as the analog spindle. Be sure to set this parameter to 1.

	#7	#6	#5	#4	#3	#2	#1	#0
8133			SSN					

[Input type] Parameter input
[Data type] Bit

NOTE
When at least one of these parameters is set, the power must be turned off before operation is continued.

#5 SSN Spindle serial output is:
0: Used.
1: Not Used.

Set this parameter as shown below depending on the spindle configuration.

Spindle configuration	Parameter SSN
When all spindles in the entire system are serial spindles	0
When serial spindles and analog spindles are mixed in the entire system	0
When all spindles in the entire system are analog spindles	1

10.5 SPINDLE SPEED CONTROL

Explanation

This section explains the following in relation to spindle speed control:

- Command flow in spindle speed control
- Processing for gear change (M and T type gear selection methods)
- Position coder feedback signal
- Speed arrival signal (SAR)

- Command flow of spindle speed control

The following Fig. 10.5 (a) summarizes spindle speed control.

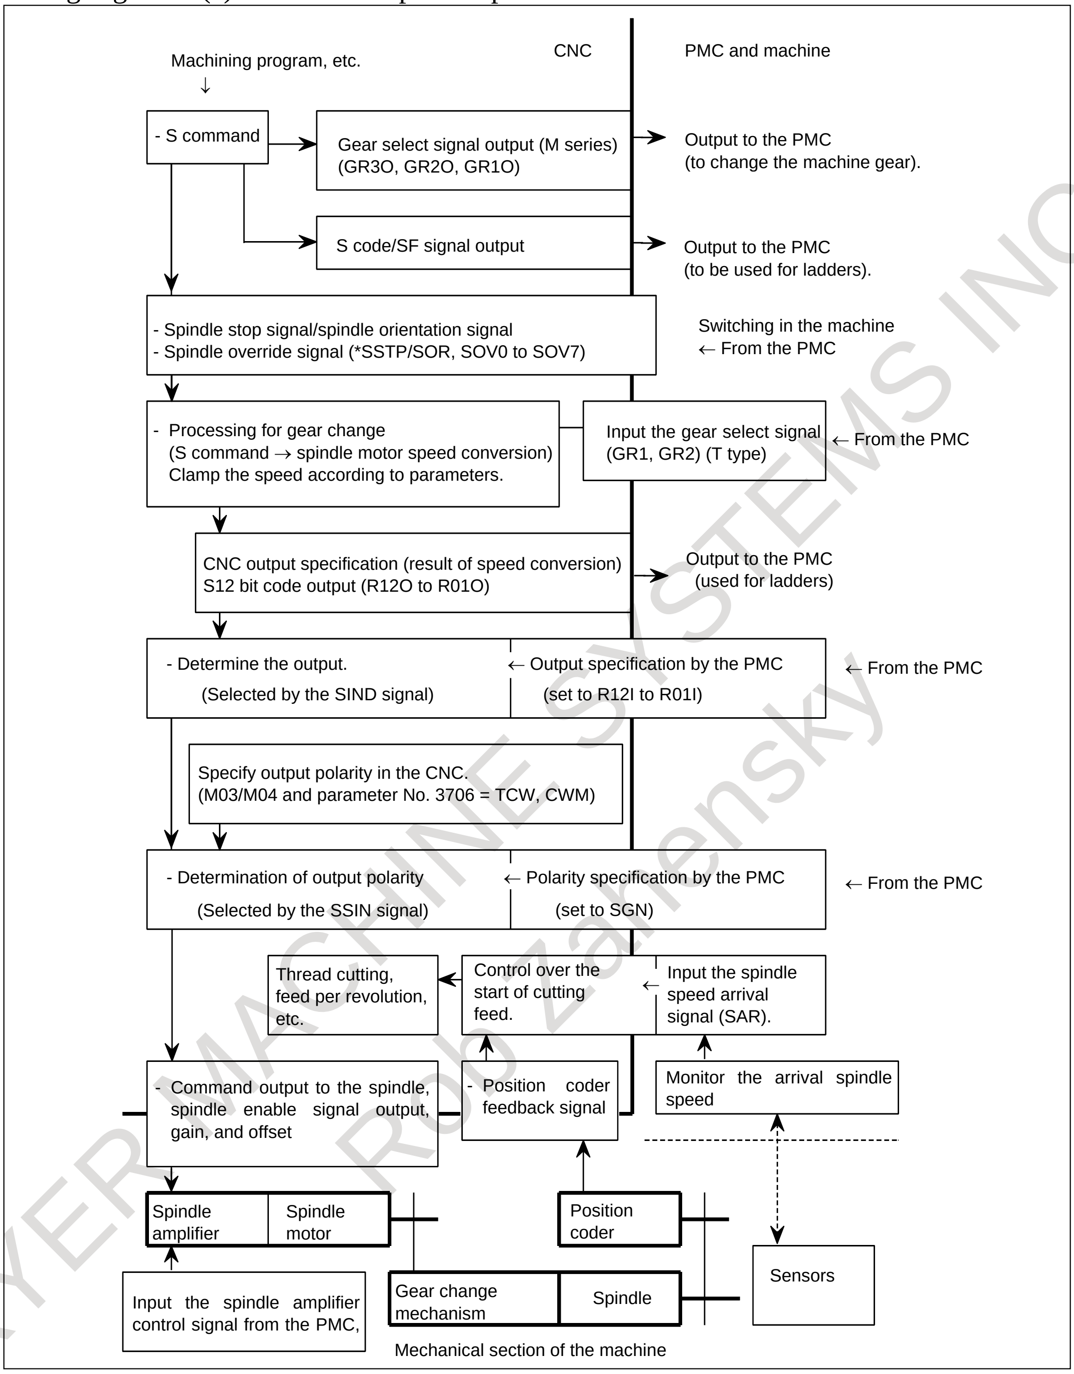

Fig. 10.5 (a)

- S command

The S command specifies the spindle speed entered from machining programs, etc. for the CNC.

For constant surface speed control (during G96 mode), the CNC converts the specified surface speed to the spindle speed.

M

When the M type gear selection method is used (a machining center is used, the constant surface speed control is not provided (bit 0 (SSC) of parameter No. 8133 is 0), and bit 4 (GTT) of parameter No. 3706 is 0), the CNC determines the necessary gear stage for obtaining a certain spindle speed according to the settings in parameters Nos. 3741, 3742, 3743, and so on and the S command value, and posts the gear stage to the PMC.
(GR3O, GR2O, GR1O<Fn034.2, Fn034.1, Fn034.0>)

- S code/SF signal output

With the spindle serial output (bit 5 (SSN) of parameter No. 8133 is 0), the spindle control function in the CNC converts the S command value to the output value for the spindle motor. For correspondence to gear change and constant surface speed control, the S code/SF signals output is different as follows in case of the spindle serial output and spindle analog output are not used.

M

M series → Outputs the S code.
The SF signal is output only when the CNC directs the PMC to change the gear.

T

T series → Outputs neither S code nor SF signal.
(This is because the S code is not always the spindle speed when the constant surface speed control is used.)

If you use the S code and SF signal for processing in the PMC ladder, you must specify parameters related to parameter No. 3705.

- Spindle stop signal (*SSTP)

When the CNC performs spindle speed control, the speed command output to the spindle is set to “0” by this signal. Setting this signal to “0” stops the spindle.
To enable speed commands to be issued to the spindle, set this signal to “1”.

- Spindle orientation signal (SOR)

If the spindle orientation signal is logical 1 and the spindle stop signal is logical 0, the spindle rotates in the direction specified by bit 5 (ORM) of parameter No. 3706 at a constant speed specified by parameter No. 3732.
Because the spindle rotates at a constant speed regardless of the gear stage, this signal can be used to rotate the spindle to drive the stopper or pin during mechanical spindle positioning.

M

For the machining center system, setting bit 1 (GST) of parameter No. 3705 enables the spindle motor to rotate at a constant speed. This function can be used for gear shifting because it maintains a constant speed of the gear change mechanism.

- Spindle speed override signal (SOV00 to SOV07)

This signal specifies an override of 0% to 254% for the specified S value for spindle control.
However, the spindle speed override function is disabled when the CNC is in the following state:
Tapping cycle (M series : G84, G74 T series : G84, G88)
Thread cutting (M series : G33 T series : G32, G92, and G76)
When the spindle speed control is performed but the spindle speed override is not used, set the override value to 100%.

- Processing for gear changing

Although the S command contains the spindle speed, the object that is actually controlled is the spindle motor. Therefore, the CNC must have some provision to detect the gear stage between the speed and spindle motor.
There are two types of gear selection methods:

M type (for the machining center system only)
The CNC selects a gear stage according to the range of speed for each gear stage previously specified in a parameter, as directed by the S command, and informs the PMC of the selected gear stage (one of the three gear stages) using the gear select signal output (GR3O, GR2O, GR1O).
Also, the CNC outputs the spindle speed based on the selected gear stage (output as the gear select signal).

T type
The gear stage to be used is determined on the machine side, and the gear stage is input using the gear selection signals (GR1 and GR2) (one of the four gear stages).
The CNC outputs the appropriate speed command for the selected gear range.

- Selection of gear change system

M

The machining center system can use either M or T type.
M type → Without constant surface speed control, and bit 4 (GTT) of parameter No. 3706 = 0
T type → With constant surface speed control, or bit 4 (GTT) of parameter No. 3706 = 1

NOTE
The M type gear selection method cannot be selected when one of the following functions is used:
- Constant surface speed control
- Multi-spindle control
- Extended spindle name
- Spindle control between paths

T

The lathe system can use only T type.

- M type gear selection method

By specifying from s0 to S99999 in memory or MDI operation, the CNC outputs a command corresponding to the spindle speed. There is a two-speed (GR1O and GR2O) or three-speed range (GR1O, GR2O, GR3O), set by parameters Nos. 3741-3743, and the gear selection signal is output simultaneously.
When the gear selection signal is changed, the SF signal is output at the same time.
By setting bit 6 (SFA) of parameter No. 3705, SF can also be output regardless of gear change.
The meaning of the gear signals is Table 10.5 (a):

Table 10.5 (a)

Gear selection signals	Gear 2-stage	Gear 3-state	Remarks
GR1O	Low	Low	Low : Low Gear Middle : Middle Gear High : High Gear
GR2O	High	Middle	
GR3O		High	

The speed commands output to the spindle motor are as follows:

- For the serial spindle, the speed commands are processed as values 0 to 16383 between the CNC and spindle control unit.
- For the analog spindle, the speed commands are output to the analog voltage signal SVC as analog voltages 0 to 10 V.

The following descriptions exemplify the analog spindle. However, they can be applied to the serial spindle on the assumption that spindle motor speed with analog voltage 10 V corresponds to the maximum spindle motor speed.

(i) M type gear change method A (See Fig. 10.5 (b).)

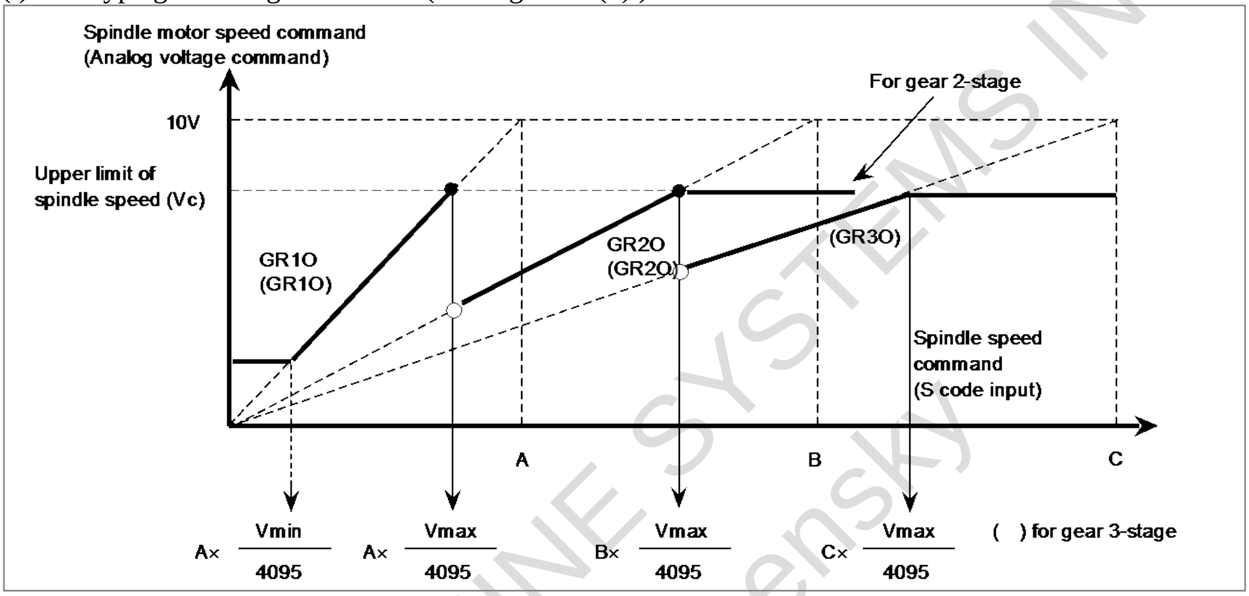

Fig. 10.5 (b) S code input and output voltage

Set the following values as parameters:

- Constant Vmax: for upper limit of spindle speed (parameter No. 3736)

$$\text{Vmax} = 4095 \times \frac{\text{Upper limit of spindle speed}}{\text{Spindle speed at command voltage 10V}}$$

- Constant Vmin; for lower limit of spindle speed (parameter No. 3735)

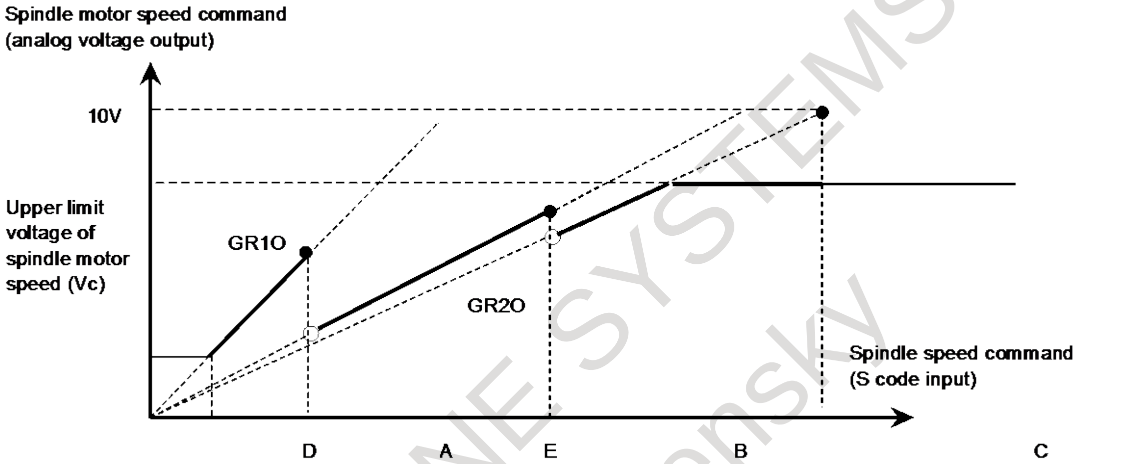
$$\text{Vmin} = 4095 \times \frac{\text{Lower limit of spindle speed}}{\text{Spindle speed at command voltage 10V}}$$

- Spindle speed A (min^{-1}) ; at command voltage 10V and low gear (parameter no. 3741)
- Spindle speed B (min^{-1}) ; at command voltage 10V and high gear (or middle-high gear) (parameter no. 3742)
- Spindle speed C (min^{-1}) ; at command voltage 10V and high gear (parameter no. 3743)(Gear 3-stage)

NOTE

If a specified voltage of 10 V is already higher than the acceptable input voltage for the spindle drive system, calculate hypothetically the spindle speed that corresponds to 10 V using a proportional calculation method and use it instead. Now, in response to the specified S code, the speed command and gear select commands (GR3O, GR2O, GR1O) are output to the spindle motor as shown in Fig. 10.5 (b).

(ii) Gear change point during tapping cycle mode (G84, G74)
In case of G84 (tapping cycle) or G74 (counter tapping cycle) the gear shift speed is changed by bit 3 (SGT) of parameter No. 3705. In this case, gear shift is performed at the speed set by parameters Nos. 3761 and 3762 (Fig. 10.5 (c)).



D : Gear shift point (parameter No. 3761) for low/high speed change (or low/medium speed change) (set by parameter as min^{-1} value) during tapping.
E : Gear shift point (parameter No. 3762) (3-stage gear) for medium/high speed change (set by parameter as min^{-1} value) during tapping.

Fig. 10.5 (c) S code input and output voltage (in tapping)

M

(iii) M type gear change method B (M series) (See Fig. 10.5 (d).)
The speed (min^{-1}) at which the low-speed and the high-speed gears are changed can be set as parameters Nos. 3751 and 3752 by setting bit 2 (SGB) of parameter No. 3705. When a 3-stage gear is used, it is possible to set the speeds (min^{-1}) for switching low-speed and medium-speed gears, and medium-speed and high-speed gears, using parameters Nos. 3751 and 3752.

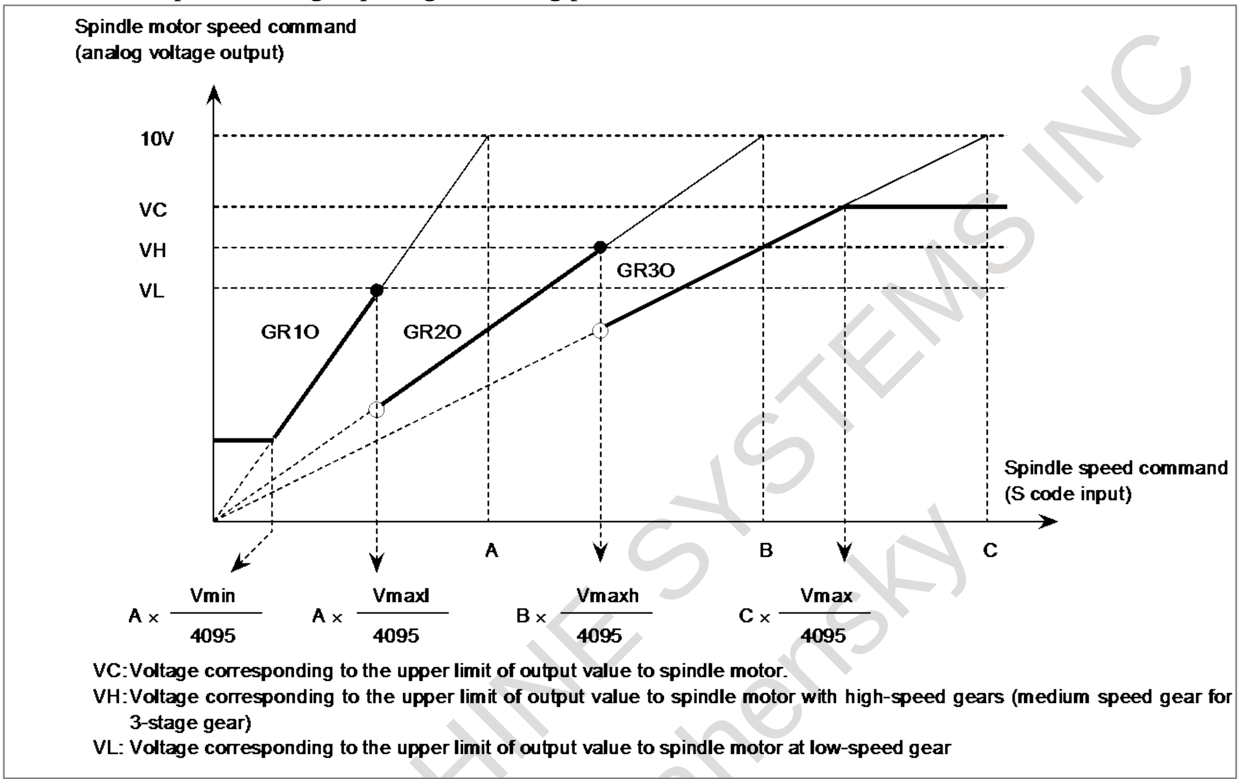


Fig. 10.5 (d) M type gear change B

When using this function, set the following parameters:

- Constant Vmax (Parameter No. 3736) related to the upper limit of spindle motor speed (min^{-1})

$$\text{Vmax} = 4095 \times \frac{\text{Upper limit of spindle motor speed}}{\text{Spindle motor speed when the command voltage is 10V}}$$

- Constant Vmin (Parameter No. 3735) related to the lower limit of spindle motor speed (min^{-1})

$$\text{Vmin} = 4095 \times \frac{\text{Lower limit of spindle motor speed}}{\text{Spindle motor speed when the command voltage is 10V}}$$

- Constant Vmaxl (Parameter No. 3751) related to the upper limit of spindle motor speed (min^{-1}) with low-speed gears

$$\text{Vmaxl} = 4095 \times \frac{\text{Upper limit of spindle motor speed with low-speed gears}}{\text{Spindle motor speed when the command voltage is 10V}}$$

- Constant Vmaxh (Parameter No. 3752) related to the upper limit of spindle motor speed (min^{-1}) with high-speed gears (medium-speed gear for 3-stage gear)

$$\text{Vmaxh} = 4095 \times \frac{\text{Upper limit of spindle motor speed with high-speed gears}}{\text{Spindle motor speed when the command voltage is 10V}}$$

- Spindle speed A (Parameter No. 3741) (min^{-1}) with low-speed gears when the command voltage is 10V
- Spindle speed B (Parameter No. 3742) (min^{-1}) with high-speed gears when the command voltage is 10V (medium-speed gear for 3-stage)
- Spindle speed C (Parameter No. 3743) (min^{-1}) with high-speed gears when the command voltage is 10V (3-stage gear)

Spindle motor speed commands and gear selecting signals (GR1O, GR2O, GR3O) are issued on each S code command as shown in the Fig. 10.5 (d):

> ⚠ **CAUTION**
> 1 In a tapping cycle when bit 3 (SGT) of parameter No. 3705 is set, the gears are changed over at the gear changing point for tapping.
> 2 For this function (bit 2 (SGB) of parameter No. 3705 = 1), when only one-stage gear is used, the voltage corresponding to the upper limit value to the spindle motor is calculated using Vmaxl, and when 2-stage gear is used, it is calculated according to Vmaxh. Therefore, when SGB is 1, set Vmaxl when only one-stage gear is used, Vmaxl and Vmaxh when 2-stage gear is used.

Bit 6 (GMB) of parameter No. 3712 can be used to select the maximum spindle motor speed for each gear.

When the bit 6 (GMB) of parameter No. 3712 is set to 0:

The maximum motor speed when each gear is used is clamped by parameters No. 3741 to 3743 or parameter No. 3736.

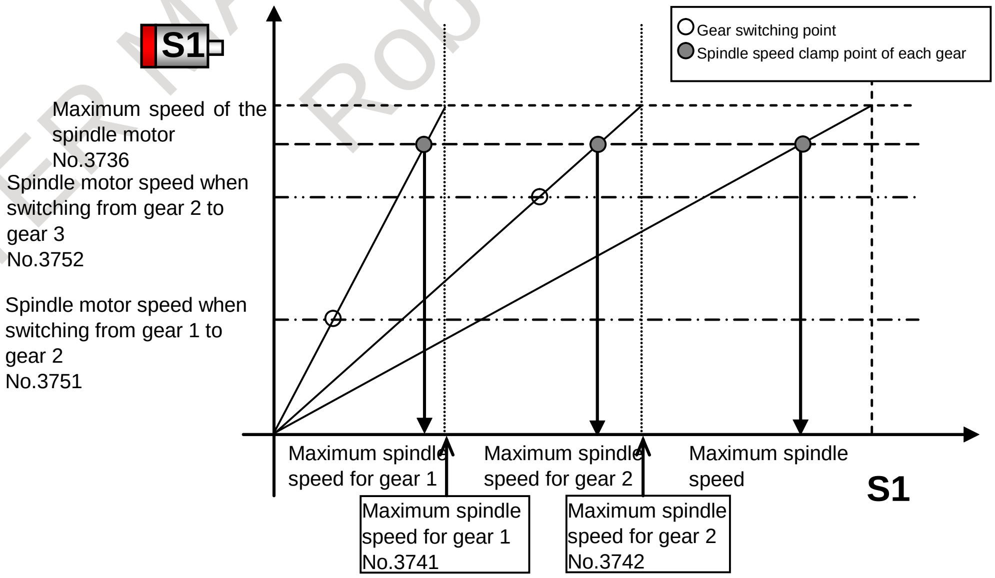

Fig. 10.5 (e) When the bit 6 (GMB) of parameter No. 3712 is set to 0

When the bit 6 (GMB) of parameter No. 3712 is set to 1:

The maximum motor speed of gear 1 is clamped at the motor speed of the switching point from gear 1 to gear 2 and the maximum motor speed of gear 2 is clamped at the motor speed of the switching point from gear 2 to gear 3.

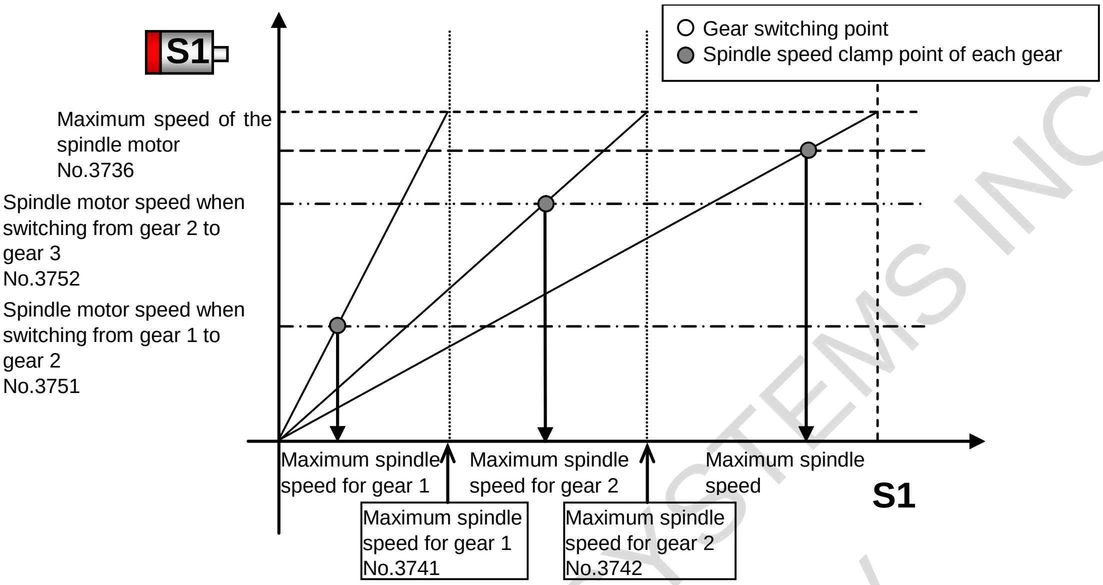

Fig. 10.5 (f) When the bit 6 (GMB) of parameter No. 3712 is set to 1

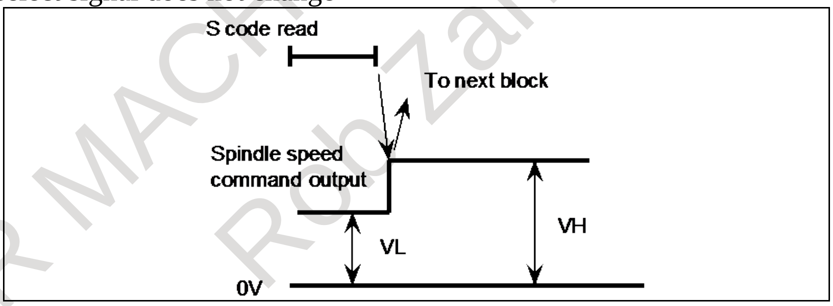
- Time chart

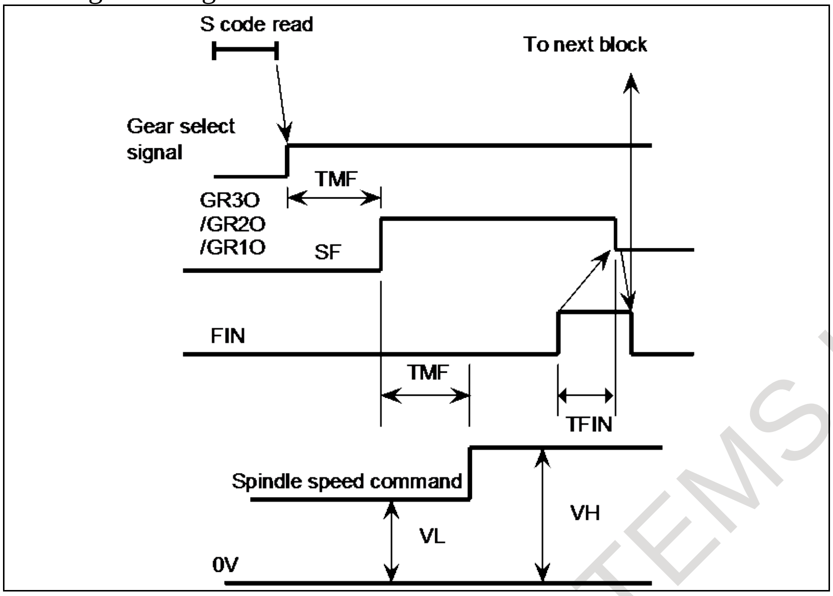
When S code is commanded, the I/O signal time chart is :

(i) When Gear select signal does not change



In this case, the SF signal is not output and the CNC advances to the next block automatically after the next spindle speed command is output.

(ii) When Gear select signal change



In this case, the gear select signal is output; after elapse of the time constant set by parameter (TMF), the SF signal is output. After another TMF elapse, the spindle speed command is output. On the PMC side, change the gears by this SF signal, and return the FIN signal after the end of gear change. The time chart for SF and FIN signals is the same as in S code output. TMF, set by parameter No. 3010, is common to M, S and T functions.
Moreover, specifying bit 6 (SFA) of parameter No. 3705 can specify that the SF signal be output even if no gear change is used.

- Details of T type (Input of GR1, GR2)

To perform the T type gear change, the maximum spindle speed for each gear side must be set in parameters Nos. 3741 to 3744.
The gear select signal is a 2 bit code signal (GR1, GR2). The relationship between the signal and gear number is Table 10.5 (b):

Table 10.5 (b)

Gear select signal		Gear No.	Parameter No. for max. spindle speed
GR1	GR2		
"0"	"0"	1	No. 3741
"1"	"0"	2	No. 3742
"0"	"1"	3	No. 3743
"1"	"1"	4	No. 3744

The following descriptions apply to the analog spindle. Like the descriptions of the M type, they also apply to the serial spindle on the assumption that spindle motor speed with analog voltage 10 V corresponds to the maximum spindle motor speed.
In addition, for the speed command output to the spindle motor, analog voltages 0 to 10 V for analog spindle control correspond to digital data 0 to 16383 for serial spindle control. However, it might be easier if you consider them code signals from 0 to 4095 for convenience sake without distinguishing between serial and analog spindles.
Assume that gear switching is two stage switching. If the spindle speed with the output voltage 10 V is 1000 min^{-1} for the low speed gear (G1) and 2000 min^{-1} for the high speed gear (G2), set these speeds by the parameters Nos. 3741 and 3742. In this case, the analog voltage has the linear relationship shown below (Fig. 10.5 (g)).

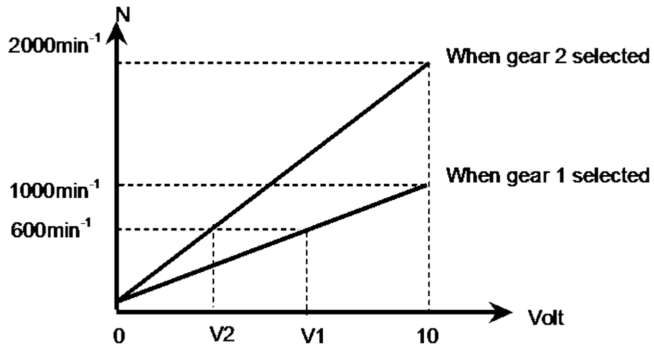


Fig. 10.5 (g)

When spindle speed S=600 is given, V1 (for G1) or V2 (for G2) in the Fig. 10.5 (g) is calculated inside the CNC and output to the machine side.
V1 ; 6 (V)
V2 ; 3 (V)
The value of output voltage V is calculated automatically from the following equations:
V = 10N / R
R : Spindle speed at 10V output voltage
N : Spindle speed given by S command of 5 digits
This is equivalent to the G97 mode for constant surface speed control.
See "CONSTATNT SURFACE SPEED CONTROL" for operations during the constant surface speed control mode (G96).

- Determining spindle speed command output R01O-R12O (Output)

Using the above processing for gear change, the CNC calculates the speed command output to the spindle motor that is necessary to obtain the specified spindle speed with the gear.
The calculation result is output to the PMC through S12-bit code signals indicating a value 0 to 4095. (R12O to R01O<Fn037.3 to Fn036.0>)
Then, according to the selection by the signal used to select the spindle motor speed command SIND <Gn033.7>, the speed command output to the spindle motor is determined.

SIND signal <Gn033.7>	Speed command output to spindle motor
"0"	Speed command output calculated by CNC
"1"	Speed command output set by PMC Also see "SPINDLE OUTPUT CONTROL BY THE PMC".

- Polarity of spindle speed command output

The speed command output to the spindle motor is determined as described above, but the actual output polarity is determined by the CNC as follows (Table 10.5 (c)):

Table 10.5 (c)

Bit 7 (TCW) of parameter No. 3706	Bit 6 (CWM) of parameter No. 3706	Output polarity
0	0	+(M03/M04 command)
0	1	-(M03/M04 command)
1	0	+(M03 command), -(M04 command)
1	1	-(M03 command), +(M04 command)

Then, according to the selection by the signal used to select the polarity of the spindle motor speed command SSIN <Gn033.6>, the output polarity of the speed command output to the spindle motor is determined.

SSIN signal <Gn033.6>	Output polarity of speed command output to spindle motor
"0"	Output polarity determined by CNC
"1"	Output polarity set by PMC Also see "SPINDLE OUTPUT CONTROL BY THE PMC".

NOTE

When bit 7 (TCW) of parameter No. 3706 is 1, and the output polarity is to be determined by the CNC, the CNC cannot determine the output polarity if M03 or M04 has not been specified even once since power-on. As a result, no command is output to the spindle.

- Command output to the spindle control unit

According to the speed command output and the polarity determined so far, the command is sent to the spindle control unit as follows:

- For serial spindle → Digital data 0 to ±16383
- For analog spindle → Analog voltage 0 to ±10 V

- Conditions for stopping spindle speed command output

A command being output to the spindle is set to 0 when *SSTP is set to “0” and when a command that sets the spindle speed command output to 0 such as a S0 command is specified.
With M05, emergency stop, and a reset, the CNC does not set the command output to the spindle to 0.

- Position coder feedback signal

The position coder is necessary for thread cutting or feed per revolution.
The position coder detects the actual spindle speed and the one-rotation signal (used to detect a fixed point on the spindle for threading). Number of pulses output from the position coder is set in parameter No. 3720.
When the gear ratio between the position coder and spindle is to be used, set the gear ratio for the position coder and spindle in parameters Nos. 3721 and 3722, respectively.
However, in the machine to do thread cutting, connect mechanically between the spindle and position coder by the gear ratio=1:1. And these parameters set the No.3721=0, No.3722=0. (It is the setting for the gear ratio 1:1.)
In the general thread cutting, the same thread grooves must be cut several times. To cutting the same thread groove repeatedly, it is necessary to detect the fixed point on the spindle. (One fixed point in the one rotation of the spindle.) One-rotation signal is used for the detection of the one fixed point. Typically, the one-rotation signal is generated on the one fixed point in the one rotation of the position coder.
For these reasons, when doing the thread cutting, the position coder and spindle must be connected by the gear ratio 1:1.
See "RIGID TAPPING" for position coder connection for rigid tapping.

- Speed arrival signal SAR <Gn029.4>

The spindle speed arrival signal SAR is an input signal used as a condition for the CNC to start cutting feed. This signal is used generally when cutting feed should be started after the spindle reaches the specified speed.
In this case, a sensor is used to check the spindle speed. The detected speed is sent to the CNC via the PMC.
When the above operation is performed continuously using the PMC ladder, however, cutting feed may be started based on the SAR signal indicating the previous spindle state (spindle speed before change), if the spindle speed change command and the cutting feed command are issued at the same time.
To avoid the above problem, monitoring the SAR signal can be deferred for a time specified by parameter No. 3740 after the S command or cutting feed command was issued.
When using the SAR signal, set bit 0 (SAR) of parameter No. 3708 to 1.

Item No. 0000 (SPEED ARRIVAL ON) on the diagnosis screen is kept at 1 while this function is keeping the cutting feed block at a halt.

- Reading actual spindle speeds by PMC window

The actual speed of the serial spindles can be read by PMC window (function code 138). Actual spindle speed is calculated by multiplying the ratio of the gear and motor speed. The gear which is in use is distinguished by the following signals.

Table 10.5 (d) Gear selection status

- Analog spindle

Gain and offset

The analog spindle may require gain and offset voltage adjustment depending on the spindle motor speed amplifier being used.
The following parameters are available for such adjustment.

Gain adjustment data: Parameter No. 3730
Offset voltage compensation: Parameter No. 3731

Spindle enable signal ENB<Fn001.4>

Another output related to spindle control is the spindle enable signal ENB.
The ENB signal is logical “1” when a nonzero command output is sent to the spindle. If the command is logical 0, the ENB signal becomes logical “0”.
When the analog spindle is being used, an offset voltage in the spindle motor speed amplifier may cause the spindle motor to rotate at low speed even if the command output (in this case, analog voltage) to the spindle is zero. The ENB signal can be used to stop the motor in such a case.

Electrical specification of analog spindle interface

The ENB1/2 signal on the analog spindle interface is an interface signal that is turned on and off under the same conditions as of the spindle enable signal <Fn001.4>, and it can be used even when a serial spindle is used.
For related signals on the analog spindle interface, refer to the description of the analog spindle interface in the section of the spindle connection in "Connection Manual (Hardware)".

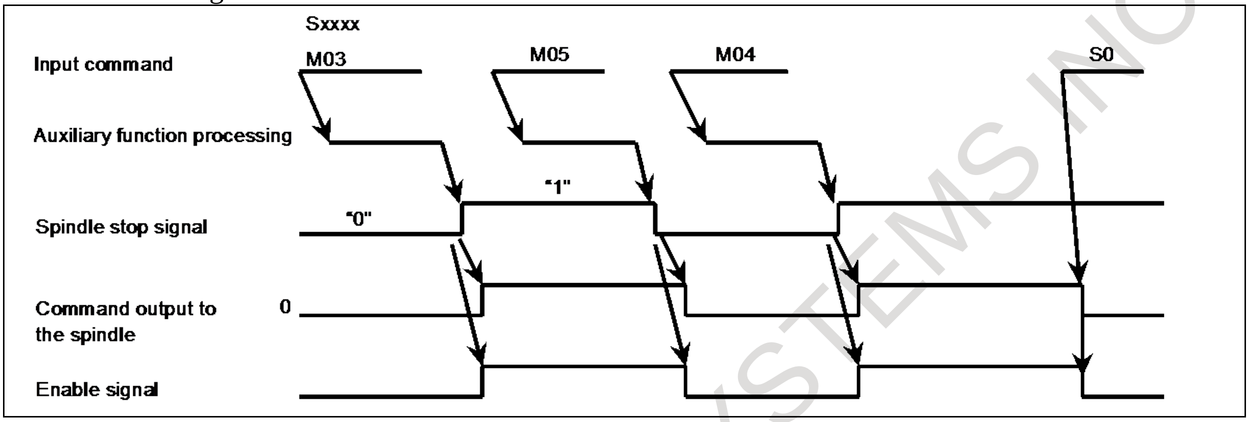
Signal

Spindle stop signal *SSTP<Gn029.6>

[Classification] Input signal

[Function] The command output to the spindle is disabled.

[Operation] When the spindle stop signal turns to “0”, the output voltage becomes 0V and the enable signal ENB turns to “0” (M05 is not output).
When this signal turns to “1”, the analog voltage returns to its original value and the ENB signal turns to “1”.



The above time chart is an example. Actually, the time chart should meet the specification of the spindle control unit.

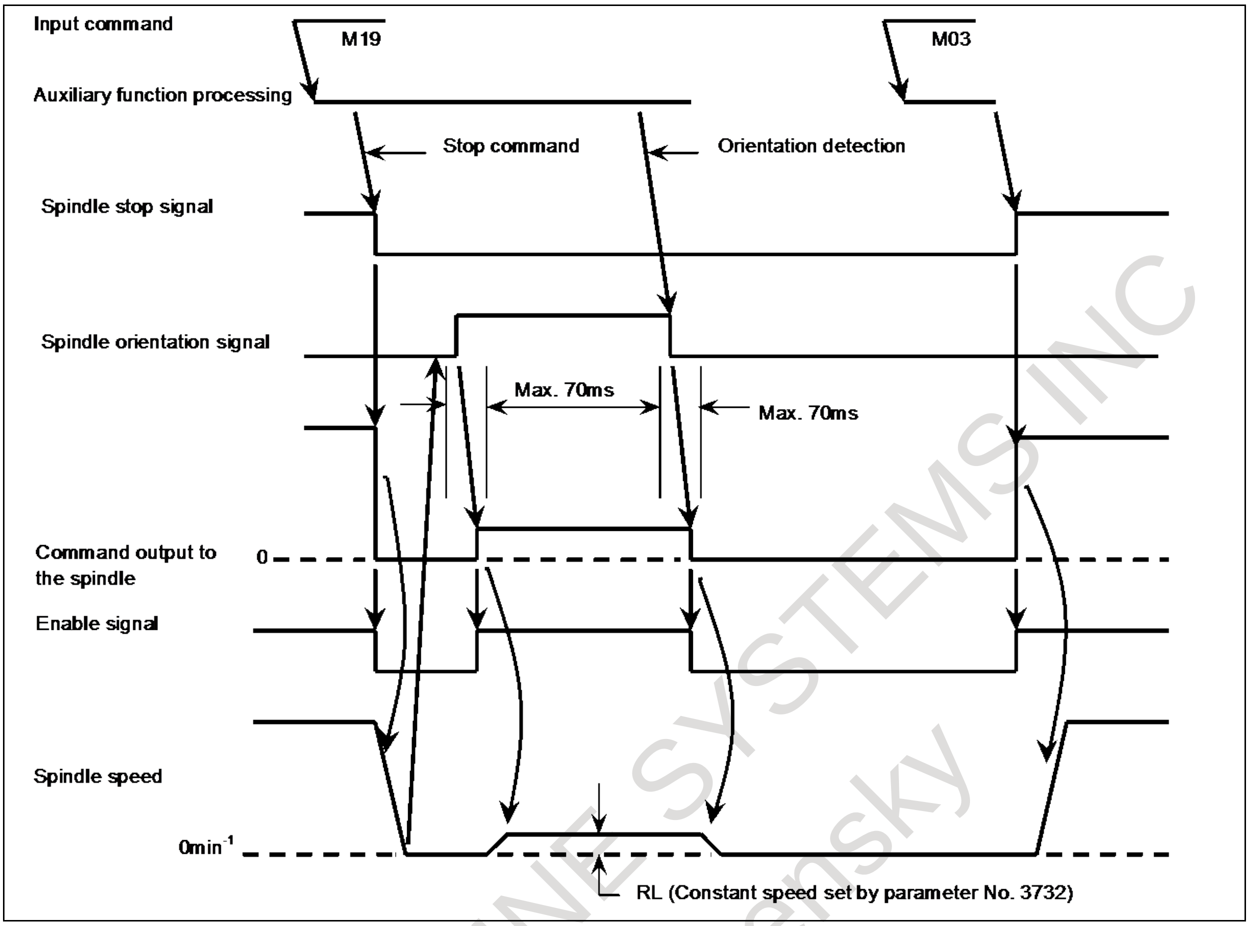
- When this signal is not used, always set the signal to “1”.
- When the M03, M04, or M05 command is issued, the CNC outputs the code signal and strobe signal only.

Spindle orientation signal SOR<Gn029.5>

[Classification] Input signal

[Function] The spindle or the spindle motor is rotated at a constant

[Operation] When the spindle orientation signal turns to “1” and the spindle stop signal *SSTP turns to “0”, a spindle speed command which lets the spindle rotate at the constant speed set by parameter No. 3732 is output. The enable signal ENB also turns to “1”. This signal is disabled when the spindle stop signal is “1”.
In the machining center system, when the spindle speed for orientation is set by bit 1 (GST) of parameter No. 3705 and the SOR signal is input, the CNC outputs the spindle speed command corresponding to the speed set to parameter 3732 with an output polarity set by bit 5 (ORM) of parameter No. 3706, but the gear select signal does not change.
For example, if the SOR signal is turned to 1 with high gear selected, and the speed set to parameter No. 3732 is in the low gear range, the gear select signal does not change and the command output is calculated and output to obtain the set speed at high gear.
When the spindle motor speed is set by bit 1 (GST) of parameter No. 3705=1, the command output is output regardless of gear select signal. When the spindle motor speed is set, it is used for gear shift.
Example of usage is shown below:



Spindle speed override signals SOV0 to SOV7<Gn030>

[Classification] Input signal

[Function] The spindle speed override signal specifies an override from 0% to 254% in 1% units for the S command sent to the CNC.

[Operation] An override value in binary must be set in 8 bits from SOV7 to SOV0.
The spindle speed override function is disabled (an override of 100% is applied) under the following conditions:

- Tapping cycle (M series : G84, G74 T series : G84, G88)
- Thread cutting (M series : G33 T series : G32, G92, G76)

→ When this function is not in use, specify an override of 100%; otherwise, an override of 0% becomes effective, thus disabling the spindle from rotating.

Spindle speed arrival signal SAR<Gn029.4>

[Classification] Input signal

[Function] The SAR signal initiates cutting feed. In other words, if the signal is logical "0", cutting feed will not start.

[Operation] Generally, this signal is used to inform the CNC that the spindle has reached the specified speed.
For this purpose, the signal must be set to "1" only after the actual speed of the spindle has reached the specified speed.
Setting parameter No. 3740 with a wait time before the start of checking the SAR signal inhibits cutting feed from starting under a condition of SAR = "1" specified before the change of the spindle command.
To use the SAR signal, it is necessary to set bit 0 (SAR) of parameter No. 3708 to 1.
The CNC checks the SAR signal under the following conditions:

a. Bit 0 (SAR) of parameter No. 3708 is set to 1.

b. Before starting distribution of the first feed (move command) block after shifting from the rapid traverse mode to the cutting feed mode. This checking is performed after the time set by parameter No. 3740 has elapsed after the feed block is read.

c. Before starting distribution of the first feed command block after an S code is commanded. The wait time for checking is the same as in item b.

d. When an S code and feed are programmed in the same block, the S code (or command output to the spindle) is output, and the SAR signal is checked after a fixed time elapses. If the SAR signal is set to “1”, feed begins.

> ⚠ **CAUTION**
> According to the conditions of item d above, note that if the circuit is so designed that SAR is turned to “0” simultaneously with the output of an S code and the change of spindle speed is initiated by the DEN signal, the operation will stop. That is, the spindle speed does not reach the commanded speed because the CNC is waiting for the DEN signal and distribution is not started because the CNC is waiting for the SAR signal.

Spindle enable signal ENB<Fn001.4>

[Classification] Output signal

[Function] Informs absence or presence of spindle output command.

[Output cond.] The ENB signal becomes logical “0” when the command output to the spindle becomes logical 0. Otherwise, the signal is logical “1”.
During analog spindle control, S0 may not be able to stop the spindle from rotating at low speed because of an offset voltage in the spindle motor speed control amplifier. In such a case, the ENB signal can be used to provide a condition to determine whether to stop the motor.
The analog spindle interface has electric signals (ENB1 and ENB2) similar to the ENB. These signals work under the same conditions as with the ENB signal.
The ENB signal can be used also for serial spindle control.

Gear selection signals GR1O, GR2O, GR3O<Fn034.0 to .2>

[Classification] Output signal

[Function] The gear select signal specifies a gear stage to the PMC.

[Output cond.] For details of this signal, see descriptions on the M type gear selection method in "Overview."

Gear selection signals GR1, GR2<Gn028.1, .2>

[Classification] Input signal

[Function] This signal informs the CNC of the gear stage currently selected.

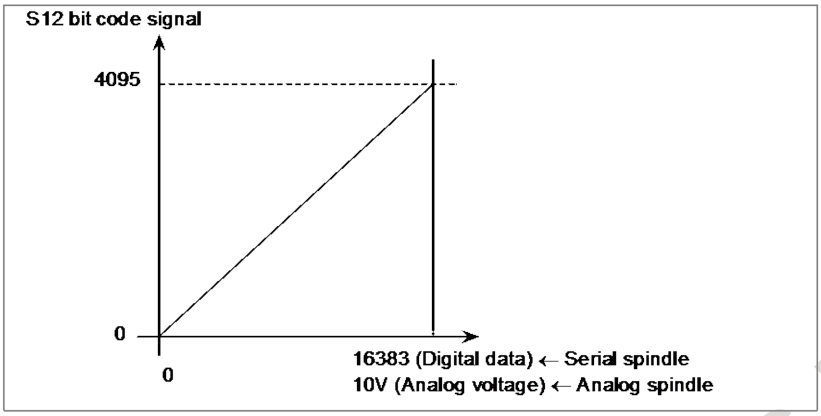
[Operation] For details of this signal, see descriptions on the T type gear selection method in "Overview."

S12-bit code signals R01O to R12O<Fn036.0 to Fn037.3>

[Classification] Output signal

[Function] These signals convert the spindle speed command value calculated by the CNC to code signals 0 to 4095.

[Output cond.] The relationship between the spindle speed command value (calculated by the CNC) and the value output by this signal is as shown below.



These signals convert the spindle speed command value calculated by the spindle control function of the CNC to data from 0 to 4095 (for both serial and analog spindle control) and outputs the result. This does not match the command set by spindle output control of the PMC. (See "SPINDLE OUTPUT CONTROL BY THE PMC".)

- Other signals

Spindle speed function code signals S00 to S31<Fn022 to Fn025> (Output)
Spindle speed function strobe signal SF<Fn007.2> (Output)

See "SPINDLE SPEED FUNCTIONS" and "SPINDLE OUTPUT CONTROL BY THE PMC" for these signals.

Parameter

	#7	#6	#5	#4	#3	#2	#1	#0
3705				EVS				ESF
		SFA	NSF		SGT	SGB	GST	ESF

[Input type] Parameter input
[Data type] Bit path

#0 ESF When the spindle control function (Spindle analog output or Spindle serial output) is used, and the constant surface speed control function is used or bit 4 (GTT) of parameter No. 3706 is set to 1:
- 0: S codes and SF are output for all S commands.
- 1: For the T series:
  S codes and SF are not output for an S command in the constant surface speed control (G96) mode and a command for maximum spindle speed clamping (G92 S_; (G50 for G code system A)).
  For the M series:
  S codes and SF are not output for an S command in the constant surface speed control (G96) mode.

> **NOTE**
> The operation of this parameter varies between the T series and M series.
> For the T series:
> This parameter is valid when bit 4 (EVS) of parameter No. 3705 is set to 1.
> For the M series:
> For an S command for maximum spindle speed clamping (G92 S_;), SF is not output, regardless of the setting of this parameter.

#1 GST The SOR signal is used for:
- 0: Spindle orientation
- 1: Gear shift

#2 SGB Gear switching method is:
- 0: Method A (Parameters Nos. 3741 to 3743 for the maximum spindle speed at each gear are used for gear selection.)
- 1: Method B (When bit 2 (MCH) of parameter No. 3790 is set to 0, parameters Nos. 3751 to 3752 are used for gear selection. When bit 2 (MCH) of parameter No. 3790 is set to 1, parameters Nos. 3753 to 3754 are used for gear selection).

#3 SGT Gear switching method during tapping cycle (G84 and G74) is:
- 0: Method A (Same as the normal gear switching method)
- 1: Method B (Gears are switched during tapping cycle according to the spindle speed set in parameters Nos. 3761 and 3762).

#4 EVS When the spindle control function (Spindle analog output or Spindle serial output) is used, S codes and SF are:
- 0: Not output for an S command.
- 1: Output for an S command.

The output of S codes and SF for an S command in constant surface speed control mode (G96), or for an S command used to specify maximum spindle speed clamping (G92 S_; (G50 for G code system A)) depends on the setting of bit 0 (ESF) of parameter No. 3705.

#5 NSF For the M series, when a T type gear is selected (with bit 4 (GTT) of parameter No. 3706 set to 1 or constant surface speed control is enabled (bit 0 (SSC) of parameter No. 8133 is 1)), and an S code is specified:
- 0: SF is output.
- 1: SF is not output.

> **NOTE**
> This parameter does not affect S code output. For an S command for maximum spindle speed clamping (G92 S_;), SF is not output, regardless of the setting of this parameter.

#6 SFA The SF signal is output:
0: When gears are switched.
1: Irrespective of whether gears are switched.

	#7	#6	#5	#4	#3	#2	#1	#0
3706	TCW	CWM	ORM					
	TCW	CWM	ORM	GTT				

[Input type] Parameter input
[Data type] Bit path

#4 GTT Spindle gear selection method is:
0: Type M.
1: Type T.

> **NOTE**
> 1 M type
> The gear selection signal is not input. The CNC selects a gear based on the speed range of each gear set by a parameter beforehand according to S codes, and the selected gear is posted by outputting the gear selection signal. Moreover, the spindle speed matching the gear selected by the output gear selection signal is output.
> T type
> The gear selection signal is input. The spindle speed matching the gear selected by this signal is output.
> 2 When the constant surface speed control is enabled (bit 0 (SSC) of parameter No. 8133 is 1), type T is selected, regardless of whether this parameter is specified.
> 3 When type T spindle gear switching is selected, the following parameters have no effect:
> No.3705#2(SGB), No.3751, No.3752,
> No.3705#1(GST), No.3705#3(SGT), No.3761, No.3762,
> No.3705#6(SFA), No.3735, No.3736
> On the other hand, parameter No. 3744 becomes usable.

#5 ORM Voltage polarity during spindle orientation
0: Positive
1: Negative

#6 CWM
#7 TCW Voltage polarity when the spindle speed voltage is output

TCW	CWM	Voltage polarity
0	0	Both M03 and M04 positive
0	1	Both M03 and M04 negative
1	0	M03 positive, M04 negative
1	1	M03 negative, M04 positive

	#7	#6	#5	#4	#3	#2	#1	#0
3708		TSO					SAT	SAR
		TSO						SAR

[Input type] Parameter input
[Data type] Bit path

#0 SAR The spindle speed arrival signal SAR is:
0: Not checked
1: Checked

#1 SAT Check of the spindle speed arrival signal SAR at the start of executing the thread cutting block
0: The signal is checked only when bit 0 (SAR) of parameter No. 3708 is set to 1.
1: The signal is always checked irrespective of the setting of SAR.

NOTE
When thread cutting blocks are consecutive, the spindle speed arrival signal is not checked for the second and subsequent thread cutting blocks.

#6 TSO During a threading or tapping cycle, the spindle override is:
0: Disabled (tied to 100%).
1: Enabled.

NOTE
During rigid tapping, the override is tied to 100%, irrespective of the setting of this parameter.

	#7	#6	#5	#4	#3	#2	#1	#0
3709								SAM

[Input type] Parameter input
[Data type] Bit path

#0 SAM The sampling frequency to obtain the average spindle speed
0: 4 (Normally, set to 0.)
1: 1

	#7	#6	#5	#4	#3	#2	#1	#0
3712		GMB						

[Input type] Parameter input
[Data type] Bit

#6 GMB With type-M gear switching method B, the speed of each gear is clamped to:
0 : The maximum rotation speed (No. 3741 to No. 3743) of each gear or the maximum clamping speed (No. 3736) of the spindle motor.
1 : Each gear switching point by parameters Nos. 3751 to 3752 in case of bit 2 (MCH) of parameter No. 3790 is set to 0. Each gear switching point by parameters Nos. 3753 to 3754 in case of bit 2 (MCH) of parameter No. 3790 is set to 1.

	#7	#6	#5	#4	#3	#2	#1	#0
3715								NSAx

[Input type] Parameter input
[Data type] Bit axis

#0 NSAx When a move command is executed for an axis, the spindle speed arrival signal SAR is:
0: Checked.
1: Not checked.
Set an axis for which the spindle speed arrival signal SAR need not be checked when a move command is executed for the axis. When a move command is specified only for an axis with this parameter set to 1, the spindle speed arrival signal SAR is not checked.

	#7	#6	#5	#4	#3	#2	#1	#0
3716								A/Ss

[Input type] Parameter input
[Data type] Bit spindle

NOTE
When this parameter is set, the power must be turned off before operation is continued.

#0 A/Ss Spindle motor type is :
0: Analog spindle.
1: Serial spindle.

NOTE
1 The 1 analog spindle at the maximum can be controlled in a system.
2 To use a serial spindle, set bit 5 (SSN) of parameter No. 8133 to 0.
3 When using an analog spindle, assign it at the end of the spindle configuration.

3717	Spindle amplifier number to each spindle

NOTE
When this parameter is set, the power must be turned off before operation is continued.

[Input type] Parameter input
[Data type] Byte spindle
[Valid data range] 0 to Maximum number of controlled axes
Set a spindle amplifier number to be assigned to each spindle.
0: No spindle amplifier is connected.
1: Spindle motor connected to amplifier number 1 is used.
2: Spindle motor connected to amplifier number 2 is used.
to
n: Spindle motor connected to amplifier number n is used.

3718	Subscript for display of a serial spindle (main spindle) or analog spindle

3719	Subscript for display of a serial spindle (sub-spindle)

[Input type] Parameter input
[Data type] Byte spindle
[Valid data range] 0 to 122

Set a subscript to be added to spindle speed display on a screen such as the position display screen.

3720	Number of position coder pulses

NOTE
When this parameter is set, the power must be turned off before operation is continued.

[Input type] Parameter input
[Data type] 2-word spindle
[Unit of data] Detection unit
[Valid data range] 1 to 32767

Set the number of position coder pulses.

3721	Number of gear teeth on the position coder side

[Input type] Parameter input
[Data type] Word spindle
[Valid data range] 0 to 9999

Set the number of gear teeth on the position coder side in speed control (such as feed per revolution).

3722	Number of gear teeth on the spindle side

[Input type] Parameter input
[Data type] Word spindle
[Valid data range] 0 to 9999

Set the number of gear teeth on the spindle side in speed control (such as feed per revolution).

⚠ CAUTION
1 Parameter No.3721 and No.3722 can not be used for thread cutting. If thread cutting was done by setting the any value on these parameters, the correct screw can't be cut.
In the machine to do thread cutting, connect mechanically between the spindle and position coder by the gear ratio=1:1. And these parameters set the No.3721=0, No.3722=0.
(It is the setting for the gear ratio 1:1.)
2 Parameter No.3721 and No.3722 can not be used for Cs contour control. If Cs contour control was done by setting the any value on these parameters, spindle can’t move as commanded. In the machine to do Cs contour control, connect mechanically between the spindle and position coder by the gear ratio = 1:1. And these parameters set the No.3721=0, No.3722=0. (It is the setting for the gear ratio 1:1.)

3730	Data used for adjusting the gain of the analog output of spindle speed

[Input type] Parameter input
[Data type] Word spindle
[Unit of data] 0.1%
[Valid data range] 700 to 1250

Set data used for adjusting the gain of the analog output of spindle speed.

[Adjustment method]

<1> Assign standard value 1000 to the parameter.
<2> Specify the spindle speed so that the analog output of the spindle speed is the maximum voltage (10 V).
<3> Measure the output voltage.
<4> Assign the value obtained by the following equation to parameter No. 3730.
Setting value = (10 (V) / Measured data (V)) $\times$ 1000
<5> After setting the parameter, specify the spindle speed so that the analog output of the spindle speed is the maximum voltage. Confirm that the output voltage is 10V.

> **NOTE**
> This parameter needs not to be set for serial spindles.

3731	Compensation value for the offset voltage of spindle speed analog output

[Input type] Parameter input
[Data type] Word spindle
[Unit of data] Velo
[Valid data range] -1024 to 1024

Set a compensation value for the offset voltage of spindle speed analog output.
Setting = -8191 $\times$ offset voltage (V)/12.5

[Adjustment method]

<1> Assign standard value 0 to the parameter.
<2> Specify the spindle speed so that the analog output of the spindle speed is 0.
<3> Measure the output voltage.
<4> Assign the value obtained by the following equation to parameter No. 3731.

$$\text{Setting value} = \frac{-8191 \times \text{Offset voltage (V)}}{12.5}$$

<5> After setting the parameter, specify the spindle speed so that the analog output of the spindle speed is 0. Confirm that the output voltage is 0V.

> **NOTE**
> This parameter needs not to be set for serial spindles.

3732	The spindle speed during spindle orientation or the spindle motor speed during spindle gear shift

[Input type] Parameter input
[Data type] 2-word path
[Valid data range] 0 to 20000

Set the spindle speed during spindle orientation or the spindle motor speed during gear shift.

When bit 1 (GST) of parameter No. 3705 is set to 0, set the spindle speed during spindle orientation in min^{-1}.

When bit 1 (GST) of parameter No. 3705 is set to 1, set the spindle motor speed during spindle gear shift calculated from the following formula.

For a serial spindle

$$\text{Setting value} = \frac{\text{Spindle motor speed during spindle gear shift}}{\text{Maximum spindle motor speed}} \times 16383$$

For an analog spindle

$$\text{Setting value} = \frac{\text{Spindle motor speed during spindle gear shift}}{\text{Maximum spindle motor speed}} \times 4095$$

3735	**Minimum clamp speed of the spindle motor**

[Input type] Parameter input
[Data type] Word path
[Valid data range] 0 to 4095

Set the minimum clamp speed of the spindle motor.

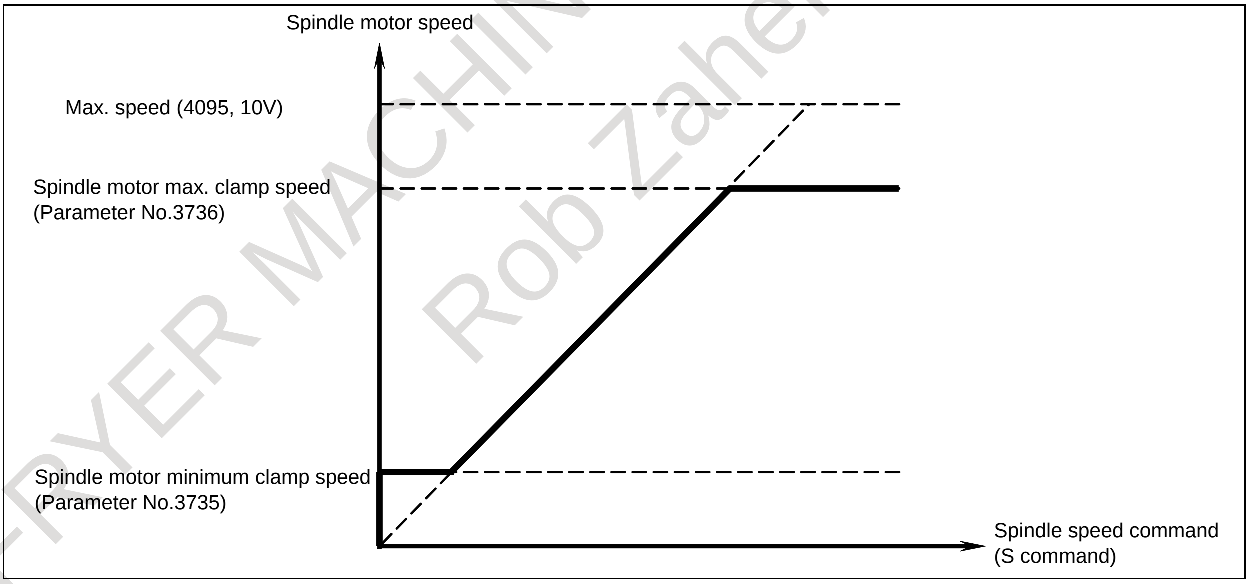
$$\text{Setting value} = \frac{\text{Minimum clamp speed of the spindle motor}}{\text{Maximum spindle motor speed}} \times 4095$$

3736	**Maximum clamp speed of the spindle motor**

[Input type] Parameter input
[Data type] Word path
[Valid data range] 0 to 4095

Set the maximum clamp speed of the spindle motor.

$$\text{Setting value} = \frac{\text{Maximum clamp speed of the spindle motor}}{\text{Maximum spindle motor speed}} \times 4095$$



3740	**Time elapsed prior to checking the spindle speed arrival signal**

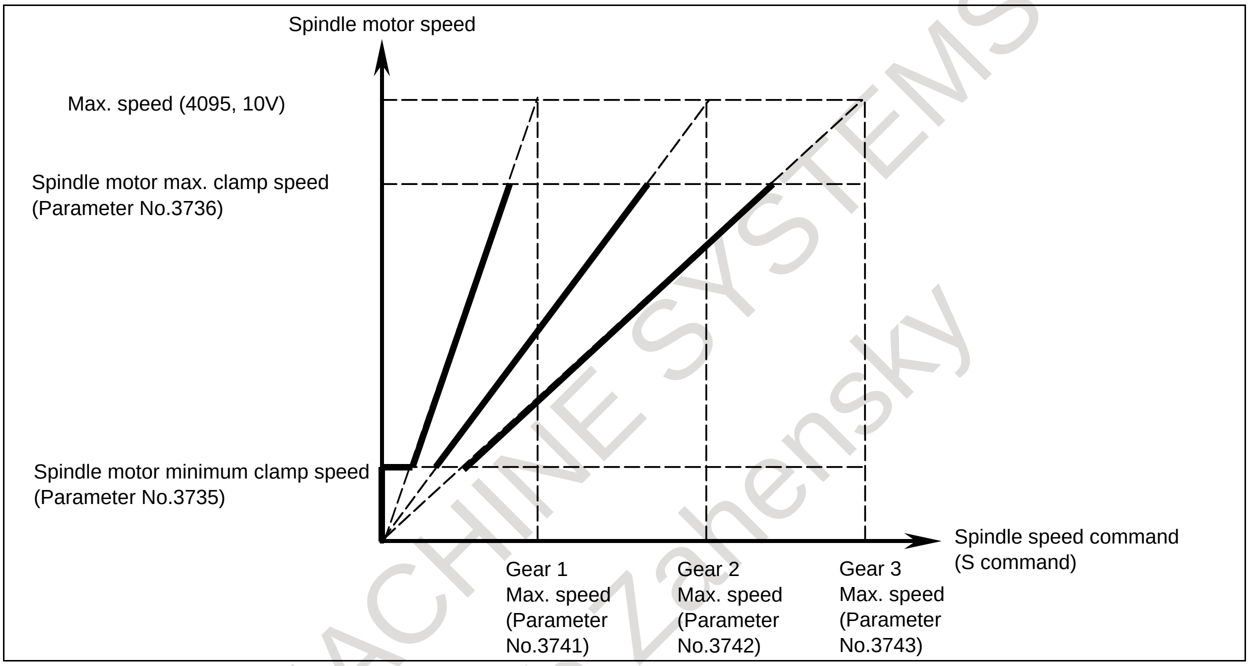
[Input type] Parameter input
[Data type] Word path
[Unit of data] msec
[Valid data range] 0 to 32767

Set the time elapsed from the execution of the S function up to the checking of the spindle speed arrival signal.

3741	**Maximum spindle speed for gear 1**
3742	**Maximum spindle speed for gear 2**
3743	**Maximum spindle speed for gear 3**
3744	**Maximum spindle speed for gear 4**

[Input type] Parameter input
[Data type] 2-word spindle
[Unit of data] min^{-1}
[Valid data range] 0 to 99999999

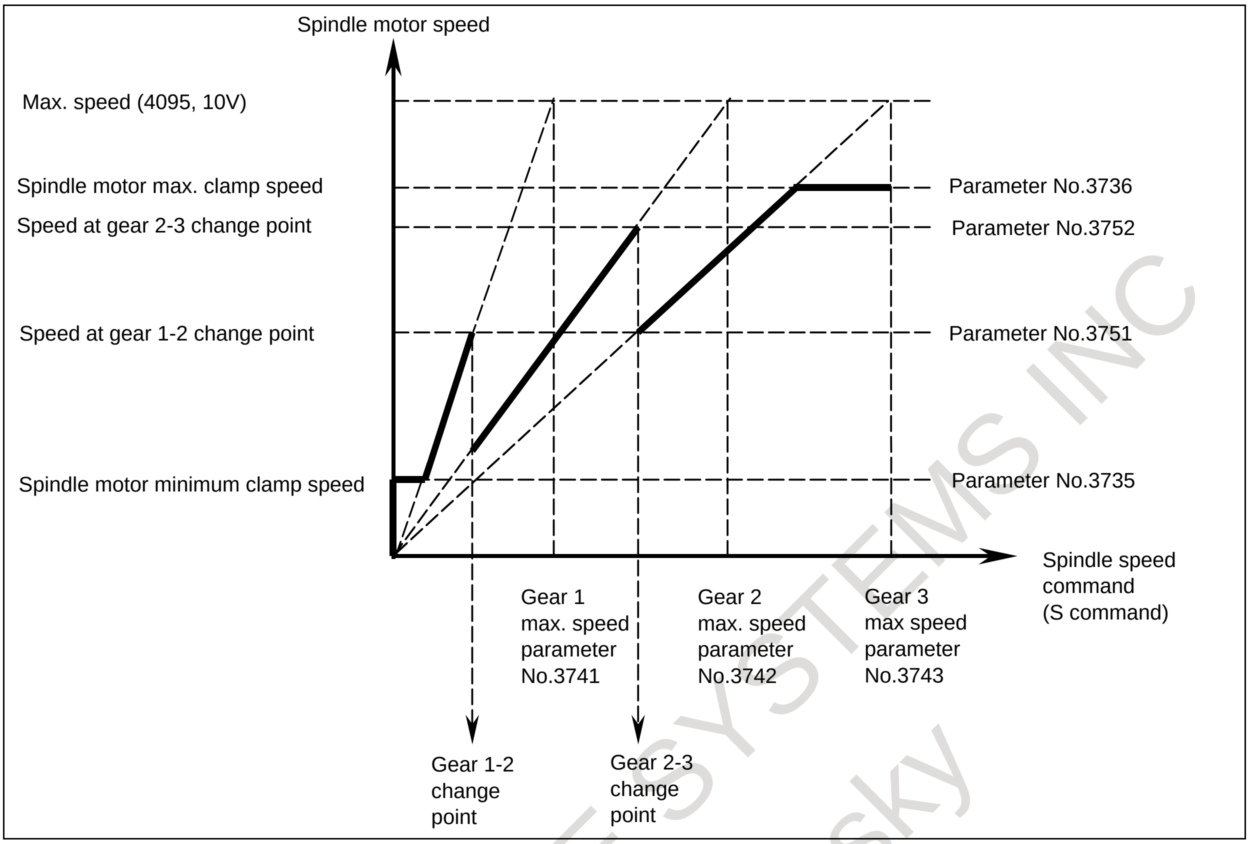
Set the maximum spindle speed corresponding to each gear.



3751	**Spindle motor speed when switching from gear 1 to gear 2**
3752	**Spindle motor speed when switching from gear 2 to gear 3**

[Input type] Parameter input
[Data type] Word path
[Valid data range] 0 to 4095

For gear switching method B, set the spindle motor speed when the gears are switched.
Setting value =
(Spindle motor speed when the gears are switched / Maximum spindle motor speed) × 4095

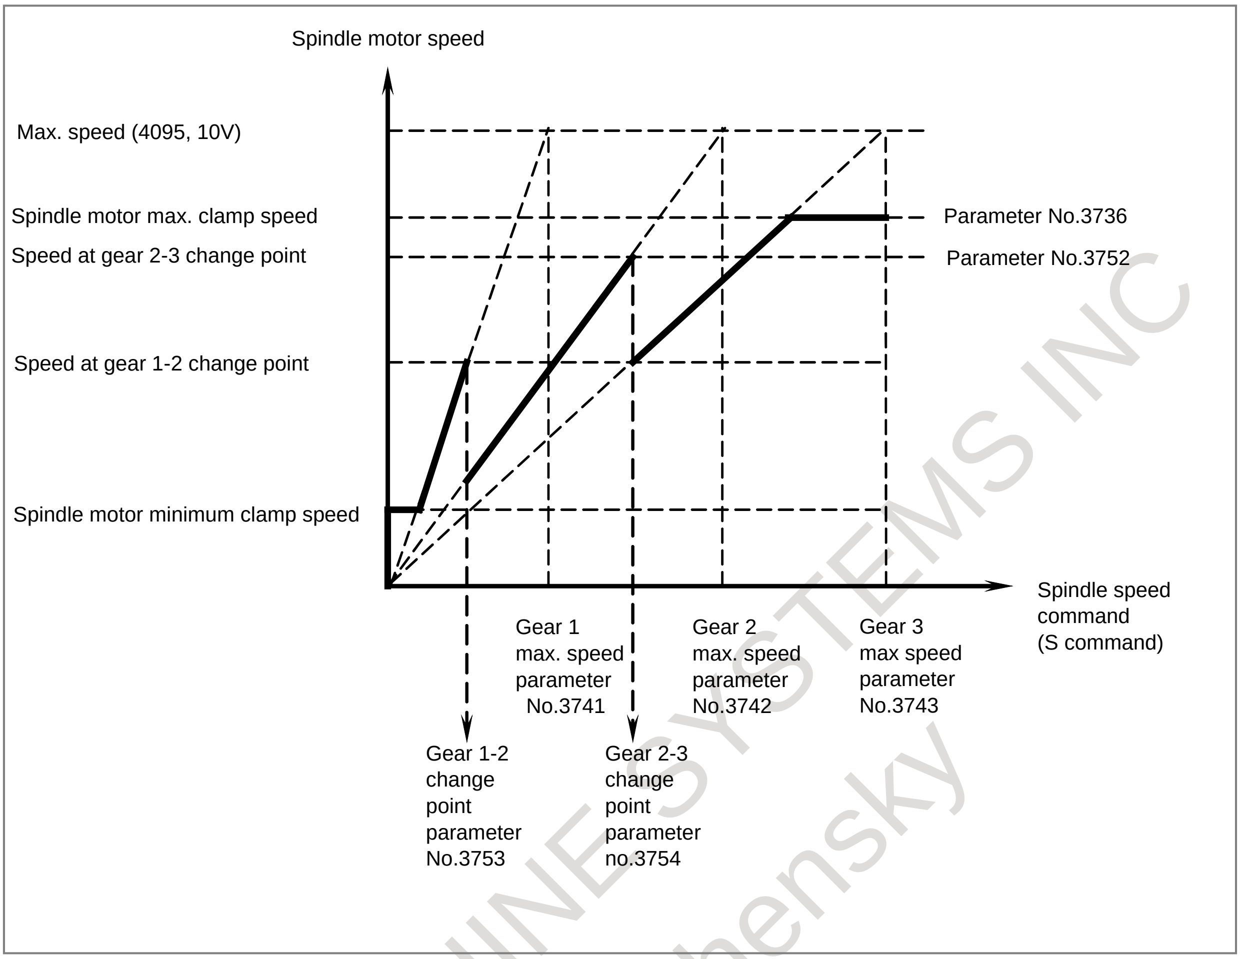


3753	
	Spindle speed when switching from gear 1 to gear 2

3754	
	Spindle speed when switching from gear 2 to gear 3

[Input type] Parameter input
[Data type] 2-word path
[Unit of data] min^{-1}
[Valid data range] 0 to 99999999

When method B is selected as the gear change method (when bit 2 (SGB) of parameter No. 3705 is set to 1) and bit 2 (MCH) of parameter No. 3790 is set to 1, each gear switching point can be set by the spindle speed.

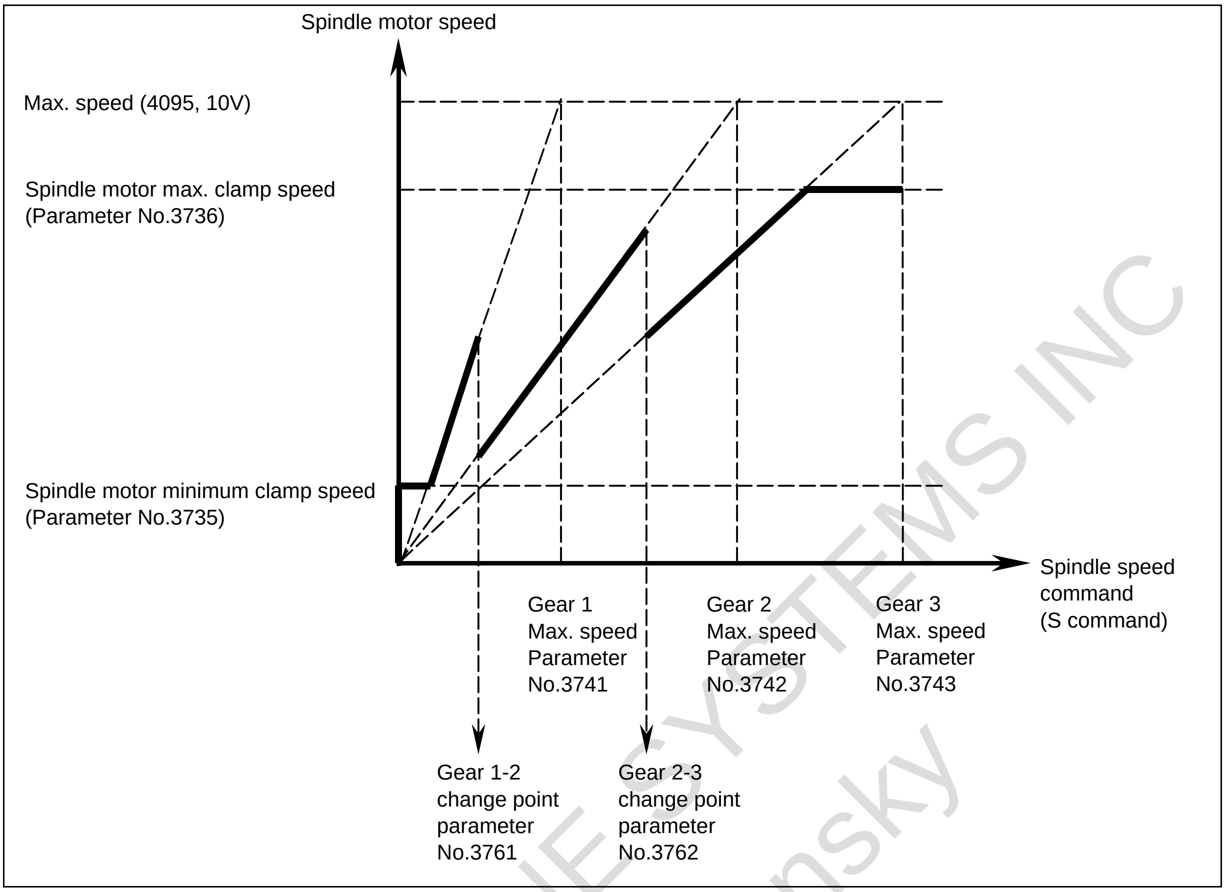


3761	Spindle speed when switching from gear 1 to gear 2 during tapping

3762	Spindle speed when switching from gear 2 to gear 3 during tapping

[Input type] Parameter input
[Data type] 2-word path
[Unit of data] min^{-1}
[Valid data range] 0 to 99999999

When method B is selected as the gear change method in the tapping cycle (when bit 3 (SGT) of parameter No. 3705 is set to 1), set the spindle speed at a change point of each gear.



3772	Maximum spindle speed

[Input type] Parameter input
[Data type] 2-word spindle
[Unit of data] min^{-1}
[Valid data range] 0 to 99999999

This parameter sets the maximum spindle speed.
When a command specifying a speed exceeding the maximum speed of the spindle is specified, or the speed of the spindle exceeds the maximum speed because of the spindle speed override function, the spindle speed is clamped at the maximum speed set in the parameter.

> ⚠ **CAUTION**
> 1 When 0 is set in this parameter, the speed of the spindle is not clamped.
> 2 When spindle speed command control is applied using the PMC, this parameter has no effect, and the spindle speed is not clamped.

> **NOTE**
> 1 For M series, this parameter is valid if the function of constant surface speed control is enabled (bit 0 (SSC) of parameter No.8133 is 1).
> 2 When the constant surface speed control is enabled (bit 0 (SSC) of parameter No. 8133 is 1), the spindle speed is clamped at the maximum speed, regardless of whether the G96 mode or G97 mode is specified.

	#7	#6	#5	#4	#3	#2	#1	#0
3787							SLG	

[Input type] Parameter input
[Data type] Bit spindle

#1 SLG In spindle speed calculation, gear selection status is judged from:
0 : Clutch/gear signals.
1 : Gear selection signals.

> **NOTE**
> 1 Address of clutch/gear signals is as follows.
> CTH1A, CTH2A<Gn070.3, Gn070.2> (First spindle)
> CTH1B, CTH2B<Gn074.3, Gn074.2> (Second spindle)
> CTH1C, CTH2C<Gn204.3, Gn204.2> (Third spindle)
> CTH1D, CTH2D<Gn266.3, Gn266.2> (Fourth spindle)
> 2 Address of gear selection signals is as follows.
> M type gear selection method
> GR1O, GR2O, GR3O<Fn034.0, Fn034.1, Fn034.2>
> T type gear selection method
> GR1, GR2 <Gn028.1, Gn028.2> (First spindle)
> GR21, GR22<Gn029.0, Gn029.1> (Second spindle)
> GR31, GR32<Gn029.2, Gn029.3> (Third spindle)
> GR41, GR42<Gn031.4, Gn031.5> (Fourth spindle)

	#7	#6	#5	#4	#3	#2	#1	#0
3790						MCH		KSA

[Input type] Parameter input
[Data type] Bit path

#0 KSA In the thread cutting (G33(M), G32,G34,G35,G36,G76,G92(T)) and polygon turning (G51.2(T)) using the analog spindle, the value of the speed indication of the spindle until the one rotation signal is detected at the start of thread cutting,
0: It may be temporarily low, possibly 0.
1: It does not change at the speed just before the start.

#2 MCH In spindle gear selection method type M,
0: It can be set from 0 to 4095 by parameter Nos. 3751 to 3752 with the maximum motor speed at the gear switching point as 4095.
1: The switching point of the gear can be set by spindle speed with parameter Nos. 3753 to 3754.

3792	The sampling frequency to obtain the average spindle speed

[Data type] Byte spindle
[Unit of data] No unit
[Valid data range] 0 to 4
The sampling frequency is 2^(parameter data).

NOTE
1. If this parameter is 0 or out of range, the sampling frequency to obtain the average spindle speed obeys SAM (parameter No.3709#0). If you would like to set sampling frequency to 1, set this parameter to 0, and SAM (parameter No.3709#0) to 1.
2. If you change this parameter, operate on the condition that spindle rotation is stop state and the function to use spindle feedback such as feed per revolution is not executed.

	#7	#6	#5	#4	#3	#2	#1	#0
3799		SPC						

[Input type] Parameter input
[Data type] Bit spindle

#6 SPC The position coder pulse to obtain the average spindle speed is:
0 : Sampled without sign data.
1 : Sampled with sign data.

Caution

⚠ **CAUTION**
This section mentioned a spindle speed control that should be prepared on the CNC side. But it is also necessary to design the processing of the signals to the spindle control unit.
Refer to the manual of the spindle control unit used and take necessary actions on the spindle control unit.

10.6 SPINDLE OUTPUT CONTROL BY THE PMC

Overview

The PMC can control the speed and polarity of each spindle motor, connected.
The first to fourth spindles each have their own individual interfaces. By using a PMC ladder program, the user can control the spindles as desired. This section describes how to use the PMC to control spindle rotation and provides example applications.

NOTE
Ladder sequence of the spindle output control by the PMC can be easily incorporated by using PMC function. The FANUC LADDER-III CD, function block that can be incorporated easily spindle output control by the PMC is stored in the form of a library.
For details on library of function block, refer to the documents in the FANUC LADDER-III CD. For details on function block, refer to the PMC Programming Manual (B-64513EN).

Explanation

- Switching control

This function can be used to specify the following:

- Spindle motor speed (number of rotations)
- Output polarity for each spindle motor (direction of rotation)

Usually, the CNC is used to control the speed and polarity of the first spindle motor. If the multi-spindle control is added, the CNC can also control the second to fourth spindle motors.
This function allows the user to select whether the CNC or PMC is used to control the speed and output polarity of the spindle motors.

- Specifying the spindle motor speed

The PMC can be used to specify the spindle motor speed upon executing the following:

- Switching the controller from the CNC to the PMC, by issuing a signal used to select the spindle motor speed command SINDx
- Setting the spindle motor speed data, calculated by the PMC, in spindle control signals R01Ix to R12Ix

When controlled by the PMC, the spindle motor speed is not affected by any signal (for example, the spindle speed override signal) or parameter settings (for example, the maximum speed clamp parameter) related to the spindle speed command of the CNC spindle control function.

→ If the multi-spindle control is added, however, the spindle stop signal *SSTPx <Gn027.3, 4, 5, Gn026.6> can be used to stop a PMC-controlled spindle.

The spindle motor speed data is obtained from the following expression. Its value can range from 0 to 4095:

$$\text{Spindle motor speed data} = \frac{\text{Spindle motor speed}}{\text{Maximum spindle motor speed (parameter No. 4020)}} \times 4095$$

Remark)

Usually, the spindle speed must be controlled. If a gear train is used to connect the spindle to the spindle motor, first obtain the maximum spindle speed at the maximum spindle motor speed.

$$\text{Spindle motor speed data} = \frac{\text{Spindle speed}}{\text{Maximum spindle speed}} \times 4095$$

By using this expression, the spindle motor speed data can easily be obtained.

- Specifying the output polarity for the spindle motor

The PMC can specify the spindle motor output polarity when the following are executed:

- Switching the controller from the CNC to the PMC, by issuing a signal used to select the polarity of the spindle motor speed command SSINx
- Specifying the output polarity to the signal used to specify the polarity of the spindle motor selected by the PMC SGNx

- S-code and SF signals

To control the spindle by the PMC, the PMC may be required to read the S value specified by the CNC.
If the spindle serial output/spindle analog control function is added (if the PMC can control the spindle), the S-code signals <Fn022 to Fn025> and SF signal <Fn007.2> can be output only when several conditions, determined by the CNC spindle control, are satisfied. In some cases, the signals cannot be used under standard conditions.
Specify the related bits of parameter No. 3705 according to the desired application, then use the S-code and SF signals.

- Twelve code signals corresponding to the S value (output)

Twelve code signals corresponding to S value R01O to R12O <Fn036.0 to Fn037.3> are output to the first spindle motor. The output data is calculated from the results of the CNC spindle control. (See Section SPINDLE SPEED CONTROL.)

Even while a spindle is subject to PMC control, an S command that is issued to the CNC is converted to spindle output data and output.
The SIND signal determines whether the speed output command, issued to the spindle motor, is obtained from the twelve code signals corresponding to the S value, or from the R01I to R12I signals calculated and specified by the PMC.
The use of this signal may simplify PMC ladder processing used to enable PMC spindle control.
Using twelve code signals corresponding to S values R01O to R12O <Fn036.0 to Fn037.3>, the input command status of spindle output control by the PMC is not output.

Example

- Sample application 1)

Controlling the first and second spindles of a lathe system

→ Share the gear stages between the first and second spindles.
(If the first spindle uses two gears, for example, specify parameters Nos. 3743 and 3744, thus enabling the use of gears 3 and 4 for the second spindle.)
Perform the necessary setting to enable control of the first and second spindles by the PMC.
To specify a rotation command for the first spindle, enter the gears for the first spindle in GR1 and GR2 and obtain the data of the twelve code signals corresponding to the S value. Specify the data as the speed output command for the first spindle in the PMC control interface for the first spindle.
To specify a rotation command for the second spindle, enter the gears to be used for the second spindle in GR1 and GR2 and obtain the data of the twelve code signals corresponding to the S value. Specify the data as the speed output command for the second spindle in the PMC control interface for the second spindle.

- Sample application 2)

With the stop position of the serial spindle specified externally, specifying the S value as the angle of the stop position for spindle orientation after the spindle positioning mode has been selected

→ Use the gears that are not being used for the first spindle.
(In this application, gear 4 is used to calculate the spindle position. Set parameters Nos. 3744 to 360.)
Specify the M code used to set the spindle to positioning mode and stop the spindle. Enter gear 4 in GR1 and GR2.
Then, specify a spindle positioning angle with the S command.
(To specify the position of 145 degrees, for example, specify S145;.)
Expression 145/360 4095 is calculated and the result is output to the twelve code signals corresponding to the S value (output signal). Enter the data in external stop position commands SHA00 to SHA11 <Gn078.0 to Gn079.3> and perform the orientation.

Signal

PMC spindle control signals

SIND,SSIN,SGN,<Gn033.7,.6,.5>R01I-R12I<Gn032.0-Gn033.3>: for 1st spindle
SIND2,SSIN2,SGN2,<Gn035.7,.6,.5>R01I2-R12I2<Gn034.0-Gn035.3>: for 2nd spindle
SIND3,SSIN3,SGN3,<Gn037.7,.6,.5>R01I3-R12I3<Gn036.0-Gn037.3>: for 3rd spindle
SIND4,SSIN4,SGN4,<Gn273.7,.6,.5>R01I4-R12I4<Gn272.0-Gn273.3>: for 4th spindle

[Classification] Input signal

[Function] The above signals enable the control of a spindle motor by issuing commands from the PMC.
Both the speed and polarity of the spindle motor (direction of rotation) can be controlled.

The speed command and polarity are usually specified by the CNC. The use of these signals allows the user to select whether the speed and polarity are controlled by the CNC or PMC.
Even if the multi-spindle control is not provided, these signals allow the second and third spindles to be controlled.
When the multi-spindle control and type A are being used (if the bit 2 (MSI) of parameter No. 3709 is set to 0), the signals for the second to fourth spindles cannot be used.

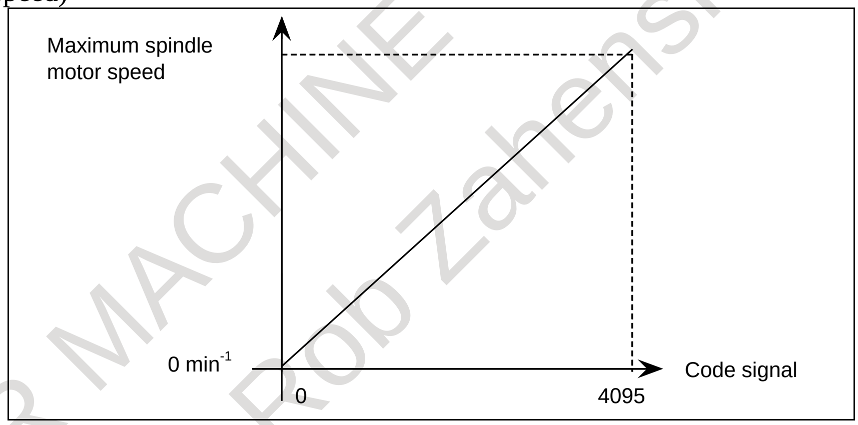
- Details of the signals

- Signal used to select the spindle motor speed command SINDx
  → The above signal is used to select whether the spindle motor speed is controlled by the CNC or PMC.
  "1" : The spindle motor is controlled according to speed commands (R01Ix to R12Ix) issued by the PMC.
  "0" : The spindle motor is controlled according to speed commands issued by the CNC. The spindle speed specified with the S command is output.

- Signals used to input the spindle motor speed command issued by the PMC R01Ix to R12Ix
  → If the PMC is being used to control the spindle motor speed command, specify, in binary format, the value obtained using the following expression.

$$\text{Value to be specified} = \frac{\text{Spindle motor speed}}{\text{Maximum spindle motor speed (parameter No. 4020)}} \times 4095$$

(Spindle motor speed)



- Signal used to select the polarity of the spindle motor speed command, SSINx
  → The above signal selects whether the output polarity of the spindle motor speed command is controlled by the CNC or PMC.
  "1" : The spindle motor is controlled according to the polarity command (SGNx) issued by the PMC.
  "0" : The CNC controls the polarity. The polarity is determined by the bits 7 (TCW) and 6 (CWM) of parameter No. 3706 and the M03 or M04 command.
- Signal used to specify the polarity of the spindle motor selected by the PMC, SGNx
  → If the PMC is used to control the output polarity of the spindle motor speed command, specify the polarity with this signal.
  "1" : The output polarity of the spindle is negative.
  "0" : The output polarity of the spindle is positive.

Twelve code signals corresponding to the S value
R01O to R12O<Fn036.0 to Fn037.3>

[Classification] Output signal

[Function] The S value, specified in the CNC part program, is converted to the speed output of the spindle motor that is required to control the connected spindle. The converted value is sent to the PMC with twelve code signals, in proportional to the spindle motor speed output.
The speed data, the final result of the CNC spindle control, is output to the spindle motor after the spindle gear ratio, spindle speed override, speed clamp, conversion of the surface speed into the spindle speed by the constant surface speed control command, and other data have been considered.

Parameter

	#7	#6	#5	#4	#3	#2	#1	#0
3705				EVS				ESF
		SFA	NSF					ESF

[Input type] Parameter input

[Data type] Bit path

#0 ESF When the spindle control function (Spindle analog output or Spindle serial output) is used, and the constant surface speed control function is used or bit 4 (GTT) of parameter No. 3706 is set to 1:

0: S codes and SF are output for all S commands.

1: For the T series:

S codes and SF are not output for an S command in the constant surface speed control (G96) mode and a command for maximum spindle speed clamping (G92 S_; (G50 for G code system A)).

For the M series:

S codes and SF are not output for an S command in the constant surface speed control (G96) mode.

> **NOTE**
> The operation of this parameter varies between the T series and M series.
> For the T series:
> This parameter is valid when bit 4 (EVS) of parameter No. 3705 is set to 1.
> For the M series:
> For an S command for maximum spindle speed clamping (G92 S_;), SF is not output, regardless of the setting of this parameter.

#4 EVS When the spindle control function (Spindle analog output or Spindle serial output) is used, S codes and SF are:

0: Not output for an S command.

1: Output for an S command.

The output of S codes and SF for an S command in constant surface speed control mode (G96), or for an S command used to specify maximum spindle speed clamping (G92 S_; (G50 for G code system A)) depends on the setting of bit 0 (ESF) of parameter No. 3705.

#5 NSF For the M series, when a T type gear is selected (with bit 4 (GTT) of parameter No. 3706 set to 1 or enable constant surface speed control (bit 0 (SSC) of parameter No.8133 is 0)), and an S code is specified:

0: SF is output.

1: SF is not output.

> **NOTE**
> This parameter does not affect S code output. For an S command for maximum spindle speed clamping (G92 S_;), SF is not output, regardless of the setting of this parameter.

#6 SFA The SF signal is output:

0: When gears are switched.

1: Irrespective of whether gears are switched.

	#7	#6	#5	#4	#3	#2	#1	#0
3709						MSI		

[Input type] Parameter input
[Data type] Bit path

#2 MSI In multi-spindle control, the signal used to select the spindle motor speed command SIND is valid

0: Only when the first spindle is valid (SIND signal for the 2nd, 3rd spindle becomes ineffective) (TYPE-A)

1: For each spindle irrespective of whether the spindle is selected (Each spindle has its own SIND signal). (TYPE-B)

Note

NOTE

1 If the spindle fails to move after the PMC issues the spindle motor speed command, check the following:
Type A is selected (the bit 2 (MSI) of parameter No. 3709 is set to 0) when the multi-spindle control is used.
→ The second to fourth spindles cannot be controlled. The first spindle can be controlled only when the spindle selection signal SWS1 is set to “1”.
The spindle stop signal for each axis is set to “0” when the multi-spindle control is being used.
→ Spindle stop signal for each axis *SSTPx <G027.3, 4, 5, G026.6> stops the spindle.
M03/M04 is not specified when the CNC is being used to control the output polarity.
→ If the bit 7 (TCW) of parameter No. 3706 is set to 1, the M03/M04 command issued to the CNC changes the output polarity for the spindle motor. If no M03/M04 command is specified after the CNC is turned on, the specified speed output is not sent to the spindle motor because the output polarity has not been determined.

2 The SF signal indicates that output of the S code to the PMC has been completed. The signal does not indicate the end of the command for specifying the spindle speed.

3 For an explanation of connecting the second, third or fourth spindle, see Sections "SPINDLE SERIAL OUTPUT" and "MULTI-SPINDLE CONTROL."

4 If the multi-spindle control is not being used, the CNC does not issue any commands to the second to fourth spindles. The output polarity is controlled by the SGNx signal. It is not affected by the SSINx signal.
The speed output to the spindle motor can be controlled only when the SINDx signal is set to “1”.

10.7 EXTENDED SPINDLE NAME

Overview

Extended spindle names can consist of up to three characters beginning with ‘S’, which is the first spindle name character. Use of extended spindle names allows commands to be issued to a particular spindle without specifying a P command.
For details, see the description of extended spindle names in "MULTI SPINDLE CONTROL".

Manual name	Item name
CONNECTION MANUAL (FUNCTION) (This manual)	Multi-spindle control

10.8 CONSTANT SURFACE SPEED CONTROL

Overview

When a surface speed (in m/min or feet/min) is specified with an S code (a numeric value following S), the spindle speed is controlled so that the surface speed is kept constant with respect to the change in tool position.

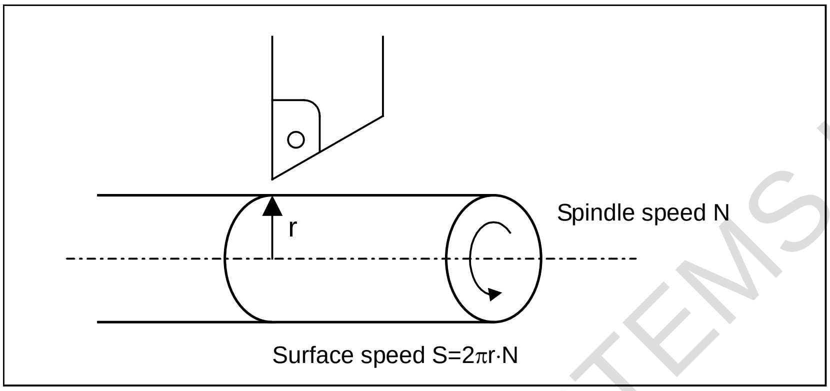

Fig. 10.8 (a) Relationship between surface speed and spindle speed

Explanation

Specify constant surface speed control as follows:

G96 S_ (Surface speed m/min (in metric input) or feet/min (in inch input))

To cancel constant surface speed control, specify the following:

G97 S_ (Spindle speed min^{-1})

To perform constant surface speed control, the maximum spindle speed for each gear select signal issued from the PMC side must be set by parameters Nos. 3741-3744.

The gear select signal is a 2 bit code signal (GR1, GR2). The relationship between the signal and gear number is :

GR1	GR2	Gear number
"0"	"0"	1
"1"	"0"	2
"0"	"1"	3
"1"	"1"	4*

(* :Gear 4 is available only in the lathe specifications.)

- Example of Spindle Analog Output

Assume that gear switching is two stage switching. If the spindle speed with the output 10 V is 1000 min^{-1} for the low speed gear (G1) and 2000 min^{-1} for the high speed gear (G2), set these speeds to the parameters Nos. 3741 and 3742, respectively. In this case, the spindle output has the linear relationship shown below (Fig. 10.8 (b)):

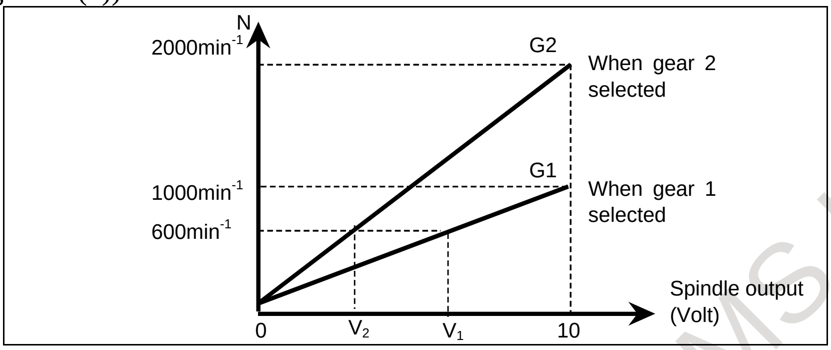

Fig. 10.8 (b)

Here, S = 60 m/min is given as the surface speed; if the position of the present X-axis cutter is 16 mm from the center, the spindle speed N becomes 600 min^{-1} ($S = 2\pi r \cdot N$). Therefore, V_1 (for G1) or V_2 (for G2) is calculated inside the CNC and output to the machine side.

V1 ; 6 (V)
V2 ; 3 (V)

The value of output voltage V is calculated automatically from the following equations:

(i) G96

$V=10S/2\pi rR$

R : Spindle speed (min^{-1}) at 10V output voltage (that is , spindle speed set by parameters Nos. 3741 to 3744)
S : Surface speed (m/min) specified by S command
r : Radius value in the X-axis direction (m)

(ii) G97

$V=10N/R$

R : Spindle speed at 10V output voltage (min^{-1})
N : Spindle speed given by S command (min^{-1})

- Spindle Serial Output

The output to the spindle in spindle serial output is a digital data.
Therefore assume the following relation for calculation:
Spindle analog output (voltage) 10V = Spindle serial output (digital data) 4095.
The above calculation becomes as follows:
The value of Spindle output D:

(i) G96

$D=4095S/2\pi rR$

R : Spindle speed (min^{-1}) at maximum spindle motor speed (that is , spindle speed set by parameters Nos. 3741 to No. 3744)
S : Surface speed (m/min) specified by S
r : Radius value in the X-axis direction (m)

(ii) G97

$D=4095N/R$

R : Spindle speed at maximum spindle motor speed (min^{-1})
N : Spindle speed given by S command (min^{-1})

- Constant surface speed control with no position coder

With a machine having (or using) no position coder, constant surface speed control cannot usually be performed during feed per revolution, but is enabled by setting bit 1 (FPR) of parameter No. 3729 or bit 2 (PCL) of parameter No. 1405 to 1.

NOTE
1 This function is not effective to spindle output control by the PMC.
2 When the setting of bit 1 (FPR) of parameter No.3729 or bit 2 (PCL) of parameter No.1405 is 1, feed per revolution cannot be used to spindle output control by the PMC.

For example, the following program is executed with G code system B and diameters specified.

```
N1   G00 X50.Z10. ;
N2   G96 G95 S12 ;        ←Constant surface speed control and feed per revolution begin.
N3   G01 X20.Z30. F10.;
N4   Z50. ;
N5   G97 S200;            ←Constant surface speed control ends.
N6   G00 Z200.;
N7   M30 ;
```

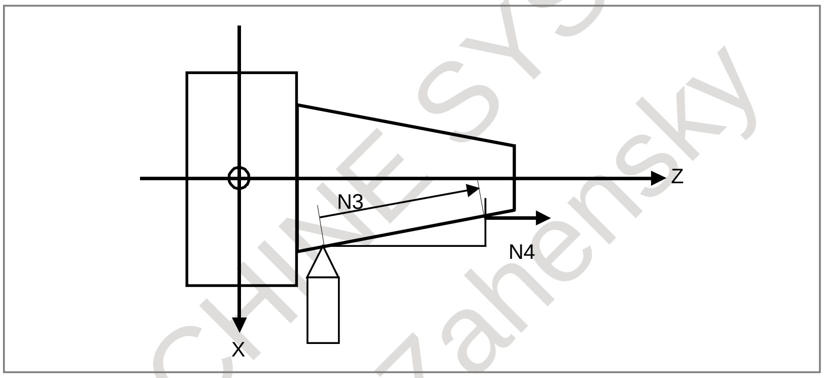

Fig. 10.8 (c) Feed per revolution without position coder

In this program, block N2 issues a constant surface speed control command (G96), a surface speed command (S12 m/min), and a feed-per-revolution command (G95). Block N3 causes the CNC to change the spindle speed specification from 76.4 min^{-1} to 191 min^{-1} so as to maintain a constant surface speed during movement to X = 20.
Meanwhile, the feed-per-revolution speed is changed according to the changed spindle speed specification, and used for movement along the feed axis. However, the specified spindle speed is clamped to the upper limit to the spindle speed specification (for the first spindle, using parameter No. 3772). In the above program, the feed-per-revolution speed command F10 in block N3 corresponds to an actual speed of 764 (mm/min) to 1910 (mm/min).

- Command for maximum spindle speed clamping

When rotation at the maximum spindle speed set by the parameter causes a problem in constant surface speed control, execute a command (M series: G92S_; T series: G50S_;) for maximum spindle speed clamping before starting constant surface speed control in order to prevent the spindle from rotating at a speed equal to or greater than a certain rotation speed.
If bit 4 (CSA) of parameter No. 3712 is set to 1, it is possible to prevent the spindle from rotating at an unintended speed by issuing alarm PS5557, “NO MAX SP SPEED CLAMP COMMAND”, if constant surface speed control is specified when a command for maximum spindle speed clamping has not been executed after power-on due to a program error or an operation error such as execution of a machining program in an incorrect order.

- Spindle speed calculation during the 3-dimensional coordinate system conversion / the tilted working plane indexing

In the constant surface speed control in the 3-dimensional coordinate system conversion / the tilted working plane indexing mode, the coordinate system which is the standard of speed calculation can be changed by the parameter 3CS(No.11221#6).

Table 10.8 (a) The standard coordinate system of spindle speed calculation

Parameter 3CS	Coordinate system of standard
0	Workpiece coordinate
1	Program coordinate (3-dimensional coordinate system conversion) / Feature coordinate (Tilted working plane indexing)

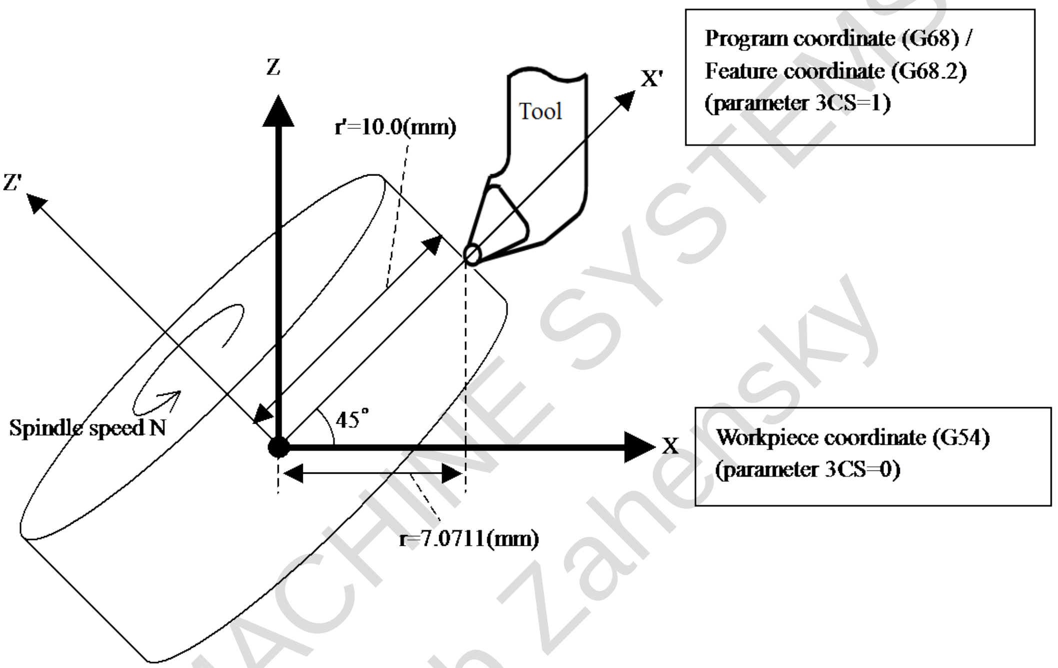

Fig.10.8 (d) Spindle speed calculation during the 3-dimensional coordinate system conversion / the tilted working plane indexing

Example)
When the followings are set by the programming.
- the surface speed S=10(m/min)
- the axis as the calculation reference is X

```
N1 G68 X0 Y0 Z0 I0 J1 K0 R-45.0
N2 G01 G90 X0 Y0 Z0 F100.0
N3 G96 S10 P1
N4 X10.0 Y0 Z0
N5 G97
N6 G69
```

Table 10.8 (b) The spindle speed in N4 (calculation by relation of N=S/2πr)

Parameter 3CS	Radius value r (mm) In the axis (X) as the calculation reference	Spindle speed N(mm^{-1})
0	7.0711	225
1	10.0	159

- Multi-spindle control

Clamp of maximum spindle speed

When bit 0 (CLM) of parameter No.3785 is set to 0, and spindle selection by extended spindle name is enabled, if extended spindle name is commanded at clamp command of maximum spindle speed G92 (G50 in G code system A of T series), alarm PS0539, "MAX SP SPEED CLAMP COMMAND ERROR" is issued. "S" has to be commanded at clamp command of maximum spindle speed.

Example)
Suppose that extended spindle name is set as follows.

Table 10.8 (c)

Spindle number	Extended spindle name
First spindle	S
Second spindle	SB

If "G92 SB30 ;" is commanded, alarm PS0539, "MAX SP SPEED CLAMP COMMAND ERROR" is issued. Clamp of maximum spindle speed has to be commanded "G92 S30 ;". If "S" is set as extended spindle name, alarm PS0539 is not issued.

Selection of axis as the calculation reference in constant surface speed control

When bit 0 (CLM) of parameter No.3785 is set to 0, and spindle selection by address P or extended spindle name of multi-spindle control is enabled, selection of axis as the calculation reference in constant surface speed control "G96 P_ ;" is commanded, alarm PS0190, "ILLEGAL AXIS SELECTED (G96)" is issued. Please change the setting of parameter No.3770 using programmable parameter input (G10) or the like in changing axis as the calculation reference in constant surface speed control.

Example
Suppose that spindle selection by address P is enabled.
- If "G96 P_ ;" is commanded, alarm PS0190 is issued.
- If "G96 S_ P_ ;" is commanded, spindle selected by address P is controlled by constant surface speed control.

Example
Suppose that extended spindle name is set as Table 11.7 (c).
- If "G96 P_ ;" is commanded, alarm PS0190 is issued.
- If "G96 S_ P_ ;" , or "G96 SB_ P_ " is commanded, alarm PS0190 is issued.

When extended spindle name is enabled, address P cannot be commanded at G96 block.

G96 command without surface speed

When bit 1 (G96) of parameter No.3785 is set to 1, and spindle selection by address P or extended spindle name is enabled, if G96 command without surface speed is commanded, alarm PS5355, "S CODE IS NOT COMMANDED AT G96" is issued.

> **NOTE**
> When spindle selection by address P or extended spindle name is enabled, if G96 is commanded without surface speed, surface speed which is commanded at previous G96 command is applied. Axis as the calculation reference in constant surface speed control which is commanded previously regardless of G96/G97 mode is applied. In order to prevent rotation of unexpected spindle by G96 command without surface speed, please command surface speed at G96 command.

- System variable

Clamp value of spindle maximum speed

System variable number	System variable name	Attribute	Description
#100959	[#_CSSSMAX]	R	Spindle maximum speed commanded at clamp command of maximum spindle speed

CNC reads block ahead of the executing block. The value of this system variable can be read after being executed clamp command of maximum spindle speed.

Example 1)

```
O1234 ;
N10 G92 S5000 ;
N20 G96 S60 ;
N30 G01 X200.0 Z-300.0 F2.0 ;
    :
    :
N60 G92 S2500 ;
N70 #1 = #100959 ;
```

Suppose that N30 block is executing. And suppose that CNC has read up to N70 block. Because N60 block has not been executed, maximum spindle speed which can be read at N70 block is 5000[min^{-1}] commanded at N10 block. Therefore, 5000 is substituted for #1. In program of example 1, if 2500 has to be substituted for #1, command block preventing buffering (such as M code preventing buffering) before N70 block.

In the following cases, #100959 is -1.

- Clamp command of maximum spindle speed G92 (G50 in G code system A of T series) has not been executed after turning on the power.

- Rigid tapping

If rigid tapping is commanded during constant surface speed control, alarm PS0200, "ILLEGAL S CODE COMMAND" is issued. Command rigid tapping after canceling constant surface speed control.

Signal

Gear selection signal (Input) GR2, GR1<Gn028.2,.1>

3705				EVS				ESF
			NSF					ESF

[Input type] Parameter input
[Data type] Bit path

#0 ESF When the spindle control function (Spindle analog output or Spindle serial output) is used, and the constant surface speed control function is used or bit 4 (GTT) of parameter No. 3706 is set to 1:

0: S codes and SF are output for all S commands.

1: For the T series:

S codes and SF are not output for an S command in the constant surface speed control (G96) mode and a command for maximum spindle speed clamping (G92 S_; (G50 for G code system A)).

For the M series:

S codes and SF are not output for an S command in the constant surface speed control (G96) mode.

> **NOTE**
> The operation of this parameter varies between the T series and M series.
> For the T series:
> This parameter is valid when bit 4 (EVS) of parameter No. 3705 is set to 1.
> For the M series:
> For an S command for maximum spindle speed clamping (G92 S_;), SF is not output, regardless of the setting of this parameter.

#4 EVS When the spindle control function (Spindle analog output or Spindle serial output) is used, S codes and SF are:

0: Not output for an S command.

1: Output for an S command.

The output of S codes and SF for an S command in constant surface speed control mode (G96), or for an S command used to specify maximum spindle speed clamping (G92 S_; (G50 for G code system A)) depends on the setting of bit 0 (ESF) of parameter No. 3705.

#5 NSF For the M series, when a T type gear is selected (with bit 4 (GTT) of parameter No. 3706 set to 1 or enable constant surface speed control (bit 0 (SSC) of parameter No.8133 is 0)), and an S code is specified:

0: SF is output.

1: SF is not output.

> **NOTE**
> This parameter does not affect S code output. For an S command for maximum spindle speed clamping (G92 S_;), SF is not output, regardless of the setting of this parameter.

	#7	#6	#5	#4	#3	#2	#1	#0
3706								
				GTT				

[Input type] Parameter input
[Data type] Bit path

#4 GTT Spindle gear selection method is:
0: Type M.
1: Type T.

NOTE
1 M type
The gear selection signal is not input. The CNC selects a gear based on the speed range of each gear set by a parameter beforehand according to S codes, and the selected gear is posted by outputting the gear selection signal. Moreover, the spindle speed matching the gear selected by the output gear selection signal is output.
T type
The gear selection signal is input. The spindle speed matching the gear selected by this signal is output.
2 When enable constant surface speed control (bit 0 (SSC) of parameter No.8133 is 0), type T is selected, regardless of whether this parameter is specified.
3 When type T spindle gear switching is selected, the following parameters have no effect:
No.3705#2(SGB), No.3751, No.3752,
No.3705#1(GST), No.3705#3(SGT), No.3761, No.3762,
No.3705#6(SFA), No.3735, No.3736
On the other hand, parameter No. 3744 becomes usable.

	#7	#6	#5	#4	#3	#2	#1	#0
3708			SOC					

[Input type] Parameter input
[Data type] Bit path

#5 SOC During constant surface speed control (G96 mode), the speed clamp by the maximum spindle speed clamp command (G92 S_; (G50 for G code system A of lathe system)) is carried out:
0: Before spindle speed override.
1: After spindle speed override.
If this parameter is set to 0, the spindle speed may exceed the maximum spindle speed (numeric value following S in G92 S_; (G50 for G code system A of lathe system)).
If this parameter is set to 1, the spindle speed is limited to the maximum spindle speed.
The spindle speed is limited to the upper limit of spindle speed specified in parameter No. 3772, irrespective of the setting of this parameter.

	#7	#6	#5	#4	#3	#2	#1	#0
3709							RSC	

[Input type] Parameter input
[Data type] Bit path

#1 RSC In the constant surface speed control mode, the surface speed of a rapid traverse block is calculated:
0: In accordance with the coordinates of the end point.
1: In accordance with the current value, as in cutting feed.

	#7	#6	#5	#4	#3	#2	#1	#0
3712				CSA				

[Input type] Parameter input
[Data type] Bit

#4 CSA When the constant surface speed control command (G96S_) is issued, if no command for maximum spindle speed clamping (G92S_; in system M or G50S_; in system T) has been executed since power turn-on:
0 : No alarm is issued (conventional specification).
1 : Alarm PS5557, “NO MAX SP SPEED CLAMP COMMAND”, is issued.

	#7	#6	#5	#4	#3	#2	#1	#0
3729							FPRs	

[Input type] Parameter input
[Data type] Bit spindle

#1 FPRs Feed per revolution (without a position coder) is:
0: Not used for a spindle.
1: Used for a spindle.
In a machine that does not use a position coder, when bit 1 (FPRs) of parameter No.3729 is set to 1 for each axis, feed per revolution can be performed with a spindle command. A feed per revolution is specified with G95 (G99 for lathe systems) in the same way as for normal operation.
When multi-spindle control is performed, the target spindle for feed per revolution is selected with a position coder select signal (PC2SLC<Gn028.7>, PC3SLC<Gn026.0>, PC4SLC <Gn026.1>).

NOTE
1 The option for constant surface speed control is required.
2 This function is not effective to spindle output control by the PMC.
3 When this parameter is set to 1, feed per revolution cannot be used to spindle output control by the PMC.

3770	Axis as the calculation reference in constant surface speed control

[Input type] Parameter input
[Data type] Byte path
[Valid data range] 0 to Number of controlled axes
Set the axis as the calculation reference in constant surface speed control.

NOTE
When 0 is set to parameter No.3770, constant surface speed control is always applied to the X-axis. In this case, specifying P in a G96 block has no effect on the constant surface speed control.

3771	Minimum spindle speed in constant surface speed control mode (G96)

[Input type] Parameter input
[Data type] 2-word path
[Unit of data] min^{-1}
[Valid data range] 0 to 99999999

Set the minimum spindle speed in the constant surface speed control mode (G96).
When constant surface speed control is performed and the spindle speed is lower than the speed given by this parameter, the spindle speed is clamped to the speed given by this parameter.

3772	Maximum spindle speed

[Input type] Parameter input
[Data type] 2-word spindle
[Unit of data] min^{-1}
[Valid data range] 0 to 99999999

This parameter sets the maximum spindle speed.
When a command specifying a speed exceeding the maximum speed of the spindle is specified, or the speed of the spindle exceeds the maximum speed because of the spindle speed override function, the spindle speed is clamped at the maximum speed set in the parameter.

⚠ **CAUTION**

1 When 0 is set in this parameter, the speed of the spindle is not clamped.
2 When spindle speed command control is applied using the PMC, this parameter has no effect, and the spindle speed is not clamped.

NOTE

1 For M series, this parameter is valid if enable constant surface speed control (bit 0 (SSC) of parameter No.8133 is 0).
2 When enable constant surface speed control (bit 0 (SSC) of parameter No.8133 is 0), the spindle speed is clamped at the maximum speed, regardless of whether the G96 mode or G97 mode is specified.

	#7	#6	#5	#4	#3	#2	#1	#0
3785							G96	CLM

[Input type] Parameter input
[Data type] Bit

#0 CLM When spindle selection by address P or extended spindle name of multi-spindle control is enabled, constant surface speed control command is:

0: The following specifications.
- If extended spindle name is commanded in clamp command of maximum spindle speed, alarm PS0539, “MAX SP SPEED CLAMP COMMAND ERROR” is issued.
- If address P is commanded at selection of axis as the calculation reference in constant surface speed control, alarm PS0190, “ILLEGAL AXIS SELECTED (G96)” is issued.

1: Conventional specifications.

#1 G96 When spindle selection by address P in multi-spindle control, or extended spindle name is enabled, if G96 is commanded without surface speed :
0: Alarm PS5355, " S CODE IS NOT COMMANDED AT G96" is not issued.
1: Alarm PS5355 is issued.

	#7	#6	#5	#4	#3	#2	#1	#0
11221		3CS						

[Input type] Parameter input
[Data type] Bit path

#6 3CS The spindle speed calculation of constant surface speed control during the 3-dimensional coordinate system conversion / the tilted working plane indexing is :
0: Based on the workpiece coordinate system.
1: Based on the program coordinate system (3-dimensional coordinate system conversion) / the feature coordinate system (Tilted working plane indexing).

Alarm and message

Number	Message	Description
PS0190	ILLEGAL AXIS SELECTED (G96)	An illegal value was specified in P in a G96 block or parameter No. 3770. When spindle selection by address P or extended spindle name of multi-spindle control is enabled, selection of axis as the calculation reference in constant surface speed control "G96 P_ ;" cannot be commanded.
PS0539	MAX SP SPEED CLAMP COMMAND ERROR	Clamp of maximum spindle speed is illegal. Extended spindle name cannot be commanded for clamp of maximum spindle speed.
PS5355	S CODE IS NOT COMMANDED AT G96	S code is not commanded at G96. Command S code at G96 block.
PS5557	NO MAX SP SPEED CLAMP COMMAND	No command for maximum spindle speed clamping (M series: G92S_; T series: G50S_;) was executed before the constant surface speed control command (G96S_) was started. Execute a command for maximum spindle speed clamping.

Caution

⚠ **CAUTION**

1 If the spindle speed corresponding to the calculated surface speed exceeds the speed specified in the spindle speed clamp command (G50S_ for T series and G92S_ for M series) during the G96 mode, the actual spindle speed is clamped at the value specified in the spindle speed clamp command.
If the specified spindle speed is lower than the value specified in parameter No. 3771, the actual spindle speed is clamped at the speed specified by No. 3771.

2 If the constant surface speed control function is provided for a machining center system, it affects gear change under normal spindle control. (See "SPINDLE SPEED CONTROL.")

Note

> **NOTE**
> Simultaneous use of multi-spindle control enables constant surface speed control for spindles other than the first spindle. (See "MULTI-SPINDLE CONTROL.")

Reference item

Manual name	Item name
OPERATOR'S MANUAL (B-64694EN)	Constant surface speed control (G96, G97)

10.9 ACTUAL SPINDLE SPEED OUTPUT (T series)

Overview

The PMC can read actual spindle speed.

Signal

Actual spindle speed signals

AR00 to AR15<Fn040, Fn041> : First spindle
AR002 to AR152<Fn202, Fn203> : Second spindle
AR003 to AR153<Fn206, Fn207> : Third spindle
AR004 to AR154<Fn272, Fn273> : Fourth spindle

[Classification] Output signal

[Function] These 16-bit binary code signals output from the CNC to the PMC the actual spindle speed obtained by feedback pulses from the position coder mounted on the spindle.

[Output cond.] These 16-bit binary code signals are always output. The actual spindle speed and the signals have the following relationship:

$$Spindle\ speed = \sum_{i=0}^{15} \left\{ 2^i \times V_i \right\} \mathrm{min}^{-1}$$

where Vi = 0 when ARi is 0 and Vi = 1 when ARi is 1

Signal address

	#7	#6	#5	#4	#3	#2	#1	#0
Fn040	AR07	AR06	AR05	AR04	AR03	AR02	AR01	AR00
Fn041	AR15	AR14	AR13	AR12	AR11	AR10	AR09	AR08

Fn206	AR073	AR063	AR053	AR043	AR033	AR023	AR013	AR003
Fn207	AR153	AR143	AR133	AR123	AR113	AR103	AR093	AR083
Fn272	AR074	AR064	AR054	AR044	AR034	AR024	AR014	AR004
Fn273	AR154	AR144	AR134	AR124	AR114	AR104	AR094	AR084

Note

> **NOTE**
> An absolute error of about 0.5 min^{-1} exists as a measuring error.
> If the speed exceeds 65535min^{-1}, 65535 is assumed and output.

10.10 SPINDLE POSITIONING

Overview

This function positions the spindle using the spindle motor and position coder.
The function has a coarser least command increment compared with the Cs contour control function and has no interpolation capability with other axes. However, it can be installed more easily because the position detector is a position coder.
Generally, the spindle positioning axes are clamped mechanically except when positioning is under way.

Explanation

In the turning process, the workpiece is rotated by the spindle to which it is attached, at the speed specified for the spindle motor. This spindle control state is called the spindle rotation mode.
The workpiece mounted on the spindle can be positioned at a certain angle by moving the spindle attached to the spindle motor by the certain angle. This function is called the spindle positioning function. This spindle control state is called the spindle positioning mode.

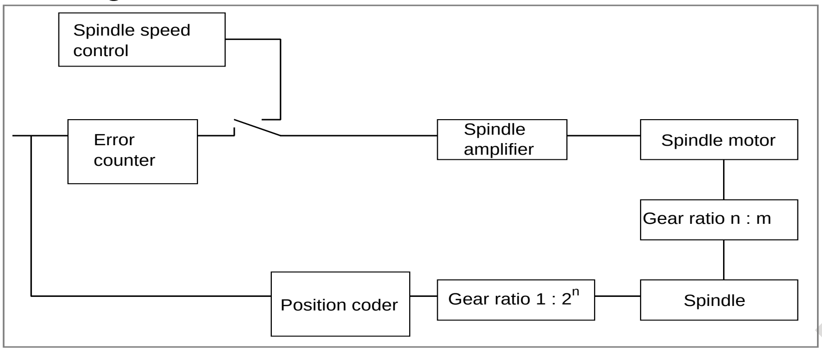
The spindle positioning function can perform the following operations:

- Release the spindle rotation mode and enter the spindle positioning mode
  Specifying a particular M code (set in the relevant parameter) sets a reference position in the spindle positioning mode. (spindle orientation)
- Position the spindle in the spindle positioning mode
  1) Position an optional angle using axis address,
  2) Position a semi-fixed angle using a specific M code (set in the relevant parameter).
- Release the spindle positioning mode and enter the spindle rotation mode
  Specifying a particular M code (set in the relevant parameter) changes the spindle to the spindle rotation mode.

The least command increment, least input increment, and maximum value for the spindle positioning axis are as follows:

- Least command increment
  360/4096 ≒ 0.088 deg (When the gear ratio of the spindle to position coder is 1:1)
- Least input increment
  0.001 deg (IS-B)
- Max. programmable dimension
  ±999999.999 deg

- Control block diagram



The spindle positioning function is enabled only when the number of pulses of the position coder is 4096 pulses (If parameter No.3716#7=1 and serial spindle is used, a number of pluses other than 4096 pluses is possible) and the gear ratio of the spindle to position coder is one of the ratios listed below.

$1 : 2^n$ （n : Integer not smaller than 0）

The least command increment (detection unit) for each gear ratio is as follows (Table 10.10 (a)):

Table 10.10 (a)

Gear ratio of spindle to position coder	Least command increment (detection unit) deg
1 : 1	0.088 (1×360/4096)
1 : 2	0.176 (2×360/4096)
1 : 4	0.352 (4×360/4096)
1 : 8	0.703 (8×360/4096)
⋮	⋮
1 : N	(N×360/4096)

- Selecting a spindle positioning axis

As the target axis for spindle positioning, any axis address can be set in parameter No. 1020.
When setting the servo axis number of a spindle positioning axis (in parameter No. 1023), add a minus sign (-) to the spindle number for which spindle positioning is to be performed.
Spindle positioning axes are assigned after the end of controlled axes.

Setting example 1)
Servo axis : X, Y, Z
Spindle positioning axis : C (first spindle)
Number of spindles : 1

Number of controlled axes	Parameter No. 1020	Parameter No. 1023
1	88 (X)	1
2	89 (Y)	2
3	90 (Z)	3
4	67 (C)	-1

Setting example 2)
Servo axis : X, Z
Spindle positioning axis : C (first spindle), B (second spindle)
Number of spindles : 2

Number of controlled axes	Parameter No. 1020	Parameter No. 1023
1	88 (X)	1
2	90 (Z)	2
3	67 (C)	-1
4	66 (B)	-2

> **NOTE**
> If bit 4 (KSV) of parameter No.11802 is set to 1, spindle positioning will be disabled.

- Switching to spindle positioning mode

Switching to the spindle positioning mode is specified using the M code set in parameter No. 4960.
When the spindle motor is used for the ordinary spindle operation (the spindle rotation mode), switching to the spindle positioning mode must be made before spindle positioning can be performed.

Spindle orientation

After switching to the spindle positioning mode is completed, a spindle orientation is performed. The orientation function stops the spindle at a predetermined position.

The orientation direction is specified by using bit 5 (ZMI) of parameter No. 1006 for analog spindles or bit 4 (RETSV) of parameter No. 4000 for serial spindles.
With the grid shift function, the orientation position can be shifted within ±180 degrees by setting parameter No. 1850 when the spindle is an analog spindle, or can be shifted within the range from 0 to 360 degrees by setting parameter No. 4073 when the spindle is a serial spindle.

Orientation speed

When an analog spindle is used, a movement is made at the rapid traverse rate used for reference position return, which is set in parameter No. 1428, until the orientation enable speed is attained, and after the one-rotation signal is detected, orientation is performed at the FL feedrate set in parameter No. 1425.

* Orientation enable speed

$$1024 \geq \left(\frac{F \times P}{60 \times G \times 0.088} \right) \geq 128\,(pulses)$$

Set the orientation enable speed so that the expression shown is satisfied:
F : Rapid traverse rate for reference position return (deg/min)
G : Position gain (1/sec)
P : Gear ratio of the spindle to position coder

If the above condition is not satisfied, the one-rotation signal cannot be detected, so the spindle continues moving at the rapid traverse rate.
The rapid traverse rate for reference position return cannot be overridden.

* FL speed
Set the FL feedrate so that the following expression is satisfied:

$$1024 \geq \left(\frac{FL \times P}{60 \times G \times 0.088} \right) \geq effective\,area\,of\,spindle\,(pulses)$$

FL : Feedrate (deg/min)
G : Position gain (1/sec)
P : Gear ratio of the spindle to position coder

If the above condition is not satisfied, the accurate stop position cannot be detected, so the orientation is started again from the rapid traverse operation.

When a serial spindle is used, the orientation speed is determined by parameter settings on the spindle side.
When an orientation is performed for a serial spindle, the spindle motor rotates several turns and then the spindle is stopped at the orientation position.

Omitting orientation

When the orientation at the time of switching to the spindle positioning mode is not required (for example, when no start position is specified, and only incremental positioning from the current position is needed), the orientation performed at the time of switching to the spindle positioning mode can be omitted by setting bit 2 (ISZ) of parameter No. 4950. In this case, when the M code for switching to the spindle positioning mode is specified, the spindle control mode is just changed to the spindle positioning mode without orientation. This completes the switching to the spindle positioning mode.

Program origin

The position at which the orientation is completed is regarded as the program origin. The program origin can be changed by coordinate system setting (G92 (T series G code B, C/M series) or G50 (T series G code A)) or automatic coordinate system setting (bit 0 (ZPR) of parameter No. 1201).
When the orientation is omitted, the program origin is not established, so operations by absolute commands in spindle positioning by axis address are not guaranteed.

- Command system

The command system comes in two types: The first positions a semi-fixed angle; the second positions an optional angle.

Semi-fixed angle positioning

Specify a positioning angle with an M code. Six types of M codes Mα to M(α+5) can be specified. The value of α is set in parameter No. 4962 in advance. The positioning angles corresponding to Mα to M(α+5) are listed below, and β is set in parameter No. 4963 in advance.

M code (Example) β=α+5	Indexing angle	(Example) β=30°
Mα	β	30°
M (α+1)	2β	60°
M (α+2)	3β	90°
M (α+3)	4β	120°
M (α+4)	5β	150°
M (α+5)	6β	180°

When the number (γ) of M codes used is specified in parameter No. 4964, M codes Mα to M(α+(γ-1)) can be specified in up to 255 ways (Mα to M(α+(255-1))).

M code (Example) γ = 11	Indexing angle	(Example) β=30°
Mα	β	30°
M (α+1)	2β	60°
M (α+2)	3β	90°
M (α+3)	4β	120°
to	to	to
M (α+11-1)	11β	330°

One of the rotation directions can be set by setting bit 1 (IDM) of parameter No. 4950.

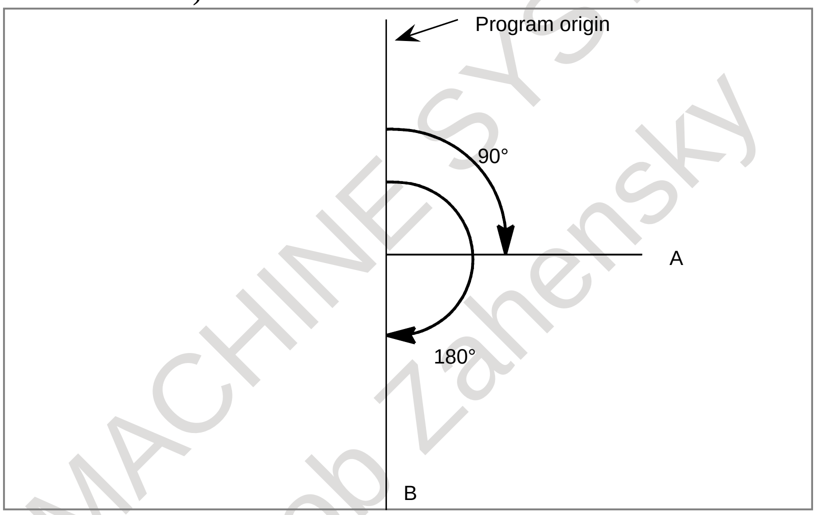
Optional angle positioning

The position at any angle is specified by using an axis address followed by a signed numeric value. The axis address must be specified in the G00 mode.
(In the subsequent explanation, the axis address is assumed to be the C-axis.)
(Example)
C-45000
C180.000
A numeric value with a decimal point can be entered. The position of the decimal point denotes the degree position.
(Example) C36.0 = C36

Absolute and incremental commands

Positioning by specifying a semi-fixed angle (by M code) is always incremental.
One of the rotation directions can be set by setting bit 1 (IDM) of parameter No. 4950.

For positioning at any angle, an absolute command and an incremental command can be specified.
When an absolute command is used for positioning at any angle, short-cut control (by setting bit 1 (RAB) of parameter No. 1008 to 0) is also enabled using the rotation axis rollover function (by setting bit 0 (ROA) of parameter No. 1008 to 1).



Command method		G code system A for T series		G code system B, C for T series M series	
		Address used	Command of A-B on the above Figure	Address used and G-code	Command of A-B on the above Figure
Absolute command	Direct the end point position by the distance from the program origin	C	C180.0 ;	G90, C	G90C180.0 ;
Incremental command	Command by the distance between the start and end points.	H	H90.0 ;	G91, C	G91C90.0 ;

Spindle positioning feedrate

Spindle positioning is done at the rapid traverse rate specified by parameter No. 1420.
Overrides of 100%, 50%, 25% and F0 (parameter No. 1421) are also applied.

- Spindle positioning reset

A specific M code (parameter No. 4961) must be specified when the mode is changed from spindle positioning to normal spindle rotation.

Also in the following cases, the spindle positioning mode is canceled, and the spindle rotation mode is entered:

<1> A reset operation (including emergency stop) is performed when a servo alarm is issued.
<2> A reset operation (including emergency stop) is performed when a spindle alarm is issued.
<3> The orientation operation is stopped in the middle by a reset, alarm, and so on.
<4> A reset operation (including emergency stop) is performed when bit 0 (IOR) of parameter No. 4950 is set to 1.

Diagnosis data

1544	Spindle positioning sequence status

The spindle positioning sequence status is indicated. (For each spindle)

1) Sequence for switching to the spindle positioning mode

Indication	Description
00010003	Wait until spindle stop complete signal SPSTPs is turned on (“0”->”1”)
00010005	Wait for completion of switching to spindle positioning mode
00010006	Wait until spindle unclamp completion signals *SUCPFs is turned on (“1”->”0”)
00010008	Wait for completion of orientation operation
00010009	Wait for completion of preset processing after orientation
0001000A	Wait until spindle clamp completion signals *SCPFs is turned on (“1”->”0”)

2) Spindle positioning sequence

Indication	Description
00020004	Wait until SPSTPs is turned on (“0”->”1”)
	Wait until *SUCPFs is turned on (“1”->”0”)
00020006	Wait for completion of positioning operation
00020007	Wait until *SCPFs is turned on (“1”->”0”)

For spindle positioning sequence B specifications (when bit 7 (IMB) of parameter No. 4950 is set to 1)

00040003	Wait until SPSTPs is turned on (“0”->”1”)
00040005	Wait for completion of switching to spindle positioning mode
00040006	Wait until *SUCPFs is turned on (“1”->”0”)
00040008	Wait for completion of positioning operation
00040009	Wait until *SCPFs is turned on (“1”->”0”)
0004000A	Wait for completion of spindle positioning mode cancellation

3) Spindle positioning mode cancellation sequence

Indication	Description
00030003	Wait until SPSTPs is turned on (“0”->”1”)
	Wait until *SUCPFs is turned on (“1”->”0”)
00030004	Wait for completion of spindle positioning mode cancellation

5207	Clamp/unclamp sequence status

The clamp/unclamp sequence status is indicated. (For each controlled axis)

1) Sequence for switching to the spindle positioning mode

Indication	Description
00030001	Wait until spindle stop complete signal SPSTPs is turned on (“0”->”1”)
00030002	Wait for completion of switching to spindle positioning mode
00030004	Wait until spindle unclamp completion signals *SUCPFs is turned on (“1”->”0”)
00030005	Wait for completion of orientation operation
00030006	Wait until spindle clamp completion signals *SCPFs is turned on (“1”->”0”)

2) Spindle positioning sequence

Indication	Description
00070001	Wait until SPSTPs is turned on (“0”->”1”)
00070002	Wait until *SUCPFs is turned on (“1”->”0”)
00070003	Wait for completion of positioning operation
00070004	Wait until *SCPFs is turned on (“1”->”0”)

For spindle positioning sequence B specifications (when bit 7 (IMB) of parameter No. 4950 is set to 1)

000D0001	Wait until SPSTPs is turned on (“0”->”1”)
000D0002	Wait for completion of switching to spindle positioning mode
000D0004	Wait until *SUCPFs is turned on (“1”->”0”)
000D0005	Wait for completion of positioning operation
000D0006	Wait until *SCPFs is turned on (“1”->”0”)
000D0007	Wait for completion of spindle positioning mode cancellation

3) Spindle positioning mode cancellation sequence

Indication	Description
000B0001	Wait until SPSTPs is turned on (“0”->”1”)
000B0002	Wait until *SUCPFs is turned on (“1”->”0”)
000B0004	Wait for completion of spindle positioning mode cancellation
FFFFFFFF	End of sequence

Spindle tuning screen

In the spindle positioning mode, indications related to the spindle positioning mode appear.
For details, please refer to Spindle tuning screen of MAINTENANCE MANUAL (B-64695EN).

Signal

Spindle unclamp signals

SUCLPA<Fn038.1> : First spindle
SUCLPB<Fn400.1> : Second spindle
SUCLPC<Fn400.2> : Third spindle
SUCLPD<Fn400.3> : Fourth spindle

[Classification] Output signal

[Function] These signals specify that spindle mechanical clamping be released in a spindle positioning sequence.
When this signal turns to “1”, unclamp the spindle on the machine (release the brakes or extract the pin).

[Output cond.] Refer to the sequence (Timing chart) in this section.

Spindle unclamp completion signals
***SUCPFA<Gn028.4> : First spindle**
***SUCPFB<Gn400.1> : Second spindle**
***SUCPFC<Gn400.2> : Third spindle**
***SUCPFD<Gn400.3> : Fourth spindle**

[Classification] Input signal

[Function] These signals indicate that unclamping the spindle is complete in response to the spindle unclamp signal SUCLPs.

Spindle clamp signals
SCLPA<Fn038.0> : First spindle
SCLPB<Fn401.1> : Second spindle
SCLPC<Fn401.2> : Third spindle
SCLPD<Fn401.3> : Fourth spindle

[Classification] Output signal

[Function] These signals specify that the spindle be clamped mechanically in a spindle positioning sequence.
When this signal turns to "1", clamp the spindle on the machine (apply the brakes or insert the pin).

[Output cond.] Refer to the sequence (Timing chart) in this section.

Spindle clamp completion signals
***SCPFA<Gn028.5> : First spindle**
***SCPFB<Gn401.1> : Second spindle**
***SCPFC<Gn401.2> : Third spindle**
***SCPFD<Gn401.3> : Fourth spindle**

[Classification] Input signal

[Function] These signals indicate that clamping the spindle is complete in response to the spindle clamp signal SCLPs.

Spindle positioning mode signals
MSPOSA<Fn039.0> : First spindle
MSPOSB<Fn402.1> : Second spindle
MSPOSC<Fn402.2> : Third spindle
MSPOSD<Fn402.3> : Fourth spindle

[Classification] Output signal

[Function] These signals indicate that the spindle is in the spindle positioning mode.

[Output cond.] Refer to the sequence (Timing chart) in this section.

Spindle stop complete signal
SPSTPA<Gn028.6> : First spindle
SPSTPB<Gn402.1> : Second spindle
SPSTPC<Gn402.2> : Third spindle
SPSTPD<Gn402.3> : Fourth spindle

[Classification] Input signal

[Function] After checking that these signals are set to 1, the CNC performs spindle orientation, spindle positioning, and spindle positioning cancellation.

- Signals related to gear change

Gear selection signals GR1O,GR2O,GR3O<Fn034.0 to 2>

[Classification] Output signal
[Function] These signals inform the PMC of the selected gear stage.
[Output cond.] For information about these signals, see "SPINDLE SPEED CONTROL".

Gear selection signals GR1, GR2<Gn028.1,.2>

[Classification] Input signal
[Function] These signals inform the CNC of the gear stage currently selected.
[Operation] For information about these signals, see "SPINDLE SPEED CONTROL".

Clutch/gear signals (serial spindle)

CTH1A,CTH2A<Gn070.3,Gn070.2> : First spindle
CTH1B,CTH2B<Gn074.3,Gn074.2> : Second spindle
CTH1C,CTH2C<Gn204.3,Gn204.2> : Third spindle
CTH1D,CTH2D<Gn266.3,Gn266.2> : Fourth spindle

See the relevant manual of the serial spindle.

These signals determine the gear parameters (such as the loop gain) to be used.
Although the gear selection signals for a serial spindle are CTH1 and CTH2, also input GR1 and GR2. Avoid changing the states of these signals in the spindle positioning mode.

Relationship between selected gear and spindle gear selection signals

CNC side							Serial spindle side	
Lathe system and machining center system (with constant surface speed control (SSC(No.8133#0)=1))			Machining center system (with constant surface speed control (SSC(No.8133#0)=0))

0	0	1st gear	0	0	0	1st gear	0	0
0	1	2nd gear	0	1	1	2nd gear	0	1
1	0	3rd gear	1	0	0	3rd gear	1	0
1	1	4th gear					1	1

NOTE

1 With a machining system, GR1 and GR2 need not be input if the constant surface speed control is not available (SSC(No.8133#0)=0), and bit 4 (GTT) of parameter No. 3706 is 0. When the CNC outputs gear selection signals GR3O, GR2O, and GR1O to make a gear change on the machine side, CTH1 and CHT2 must also be input.

2 The above combinations of clutch/gear signals (CTH1 and CTH2) are just examples.
Since the serial spindle selects a gear by using CTH1 and CTH2 independent of gear selection on the CNC, the signals must be input as necessary, and serial spindle parameters must be set accordingly.

- Other signals

Reference position return completion signal ZPx<Fn094>

[Classification] Output signal
[Function] This signal indicates that spindle orientation of the spindle positioning axis is completed.
[Output cond.] This signal is set to 1 when spindle orientation is completed, and the signal is set to 0 when spindle positioning or spindle positioning cancellation is performed.

- Sequence (Timimg chart)

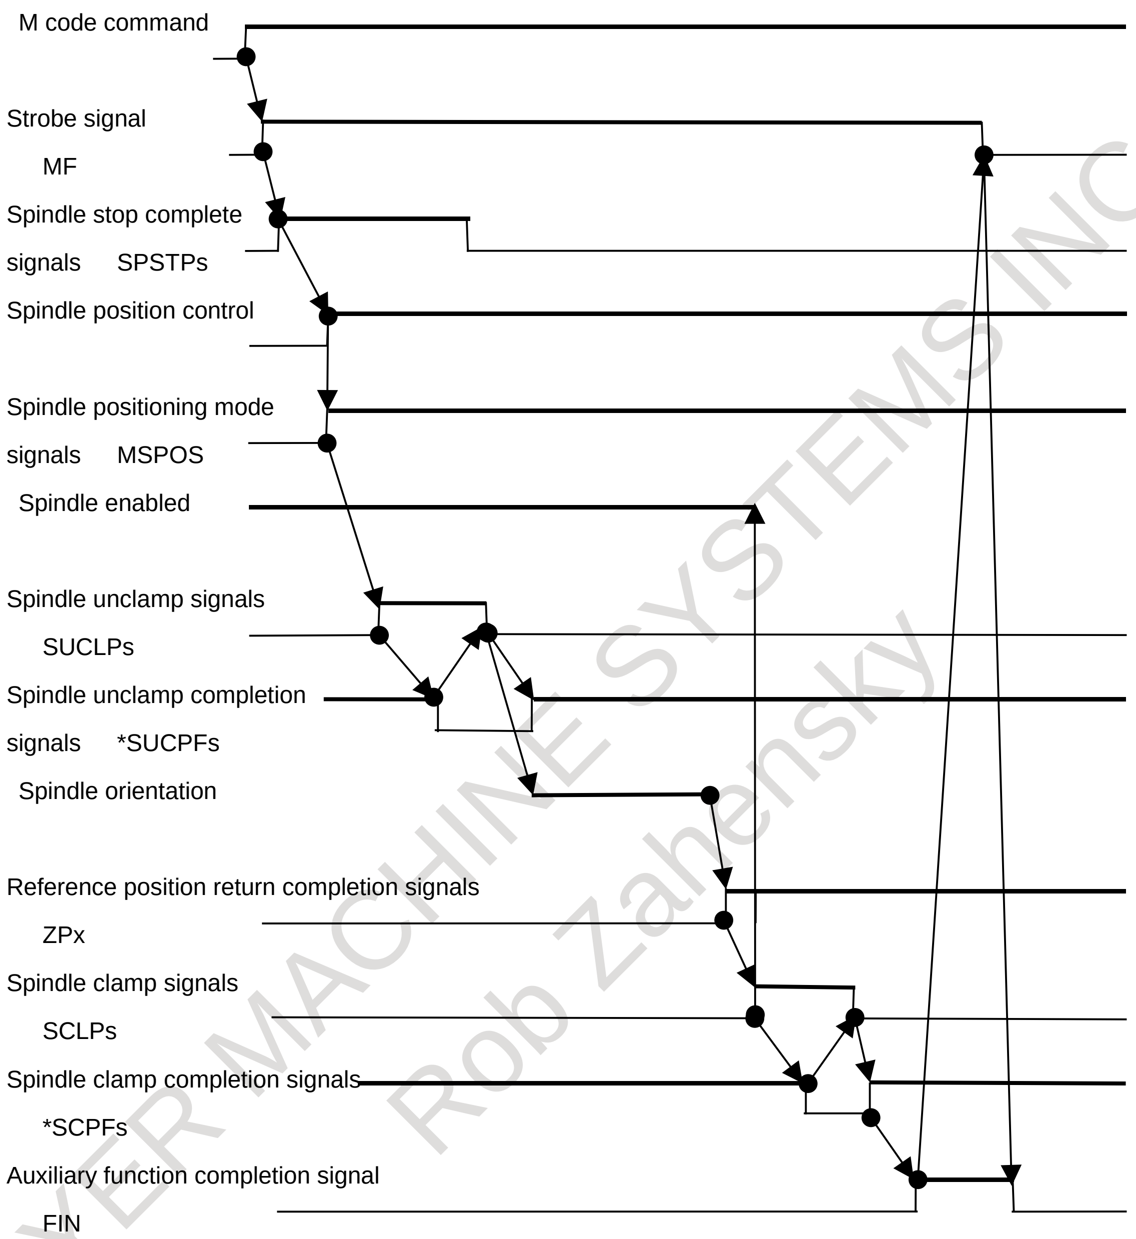
Switching to the spindle positioning mode

The operation of canceling the spindle rotation mode to enter the spindle positioning mode is performed by specifying an M code for switching to the spindle positioning mode.
Set the M code for switching to the spindle positioning mode in parameter No. 4960 in advance.

<1> Suppose that an M code is specified by a program.
<2> Auxiliary function code signal M00 to M31 is sent, and the auxiliary function strobe signal MF is set to 1 at the same time. This sending procedure is the same as for ordinary auxiliary functions.
<3> When strobe signal MF is set to 1, the PMC must read the code signal and perform corresponding processing. After completing the corresponding processing, the PMC sets spindle stop complete signal SPSTPs to 1 when the spindle is stopped.

<4> As soon as setting strobe signal MF to 1, the CNC checks whether spindle stop complete signal SPSTPs is set to 1. When SPSTPs is set to 1, the CNC changes the spindle control mode from the spindle rotation mode to spindle positioning mode, and sets spindle positioning mode signal MSPOSs to 1.
<5> The CNC sets spindle unclamp signal SUCLPs to 1.
<6> When spindle unclamp signal SUCLPs is set to 1, the PMC performs processing to make the spindle usable for positioning. When completing the processing, the PMC sets spindle unclamp completion signal *SUCPFs to 0.
<7> When spindle unclamp completion signal *SUCPFs are set to 0, the CNC sets spindle unclamp signal SUCLPs to 0 to post that the CNC has received the *SUCPFs signal.
<8> When spindle unclamp signal SUCLPs is set to 0, the PMC must set spindle unclamp completion signal *SUCPFs to 1.
<9> The CNC rotates the spindle and stops the spindle at a certain position. (This is generally called spindle orientation.) Then, the CNC sets reference position return completion signal ZPx (x denotes the controlled axis number of the spindle positioning axis) to 1.
<10>The CNC sets spindle clamp signal SCLPs to 1.
<11>When spindle clamp signal SCLPs is set to 1, the PMC clamps the spindle mechanically with a device such as a clutch or shot pin as necessary. After completing the clamping operation, the PMC sets spindle clamp completion signal *SCPFs to 0.
<12>When spindle clamp completion signal *SCPFs is set to 0, the CNC sets spindle clamp signal SCLPs to 0 to post that the CNC has received *SCPFs.
<13>When spindle clamp signal SCLPs is set to 0, the PMC sets spindle clamp completion signal *SCPFs to 1.
<14>Finally, the PMC sets completion signal FIN to 1 for auxiliary function strobe signal MF. In response to this, the CNC sets the MF signal to 0. Then, the PMC sets the FIN signal to 0.

Timing chart for switching to spindle positioning mode



⚠ **CAUTION**

1 Switching between the spindle rotation mode and spindle positioning mode must be performed on the machine side in response to M code commands issued from the CNC.
When the spindle positioning mode is canceled, the spindle becomes ready for accepting speed commands such as an S command. Therefore, a PMC ladder program must be created so that spindle rotation is not performed when the spindle is clamped on the machine side.
Example:
When the spindle is clamped on the machine side, spindle stop signal *SSTP <G029.6> is set to 0.

> ⚠ **CAUTION**
>
> 2 When the spindle is clamped on the machine side (by using a device such as a clutch or shot pin), the spindle must be disabled. Enabling or disabling the spindle means to separately instruct the spindle control unit to enable or disable spindle motor operation by the PMC ladder and so on.
> Example: When a serial spindle is enabled, SFRA <G070.5> is set to 1. When the serial spindle is disabled, SFRA <G070.5> is set to 0.
> Refer to the manual of the spindle control unit to be connected, and add instructions to the ladder program.

Spindle positioning

In the spindle positioning mode, positioning is performed using one of the following two programmed commands:

1) Positioning at a semi-fixed angle by specifying an M code
2) Positioning at any angle by specifying an axis address

The operations performed by using the above two specification methods are the same, except that in positioning at any angle, input/output signals related to auxiliary functions are not exchanged.
The M code used for positioning at a semi-fixed angle is set in parameters Nos. 4962 and 4964 in advance.

When positioning at a semi-fixed angle is performed by specifying the M code, specification A or B can be selected by setting bit 7 (IMB) of parameter No. 4950.

If specification B is selected, specifying an M code that specifies the spindle positioning angle performs operations (1) to (3) below successively.

(1) Canceling the spindle rotation mode and switching to the spindle positioning mode
(2) Positioning the spindle in the spindle positioning mode
(3) Canceling the spindle positioning mode and switching to the spindle rotation mode

If specification A is selected, only the spindle positioning operation is performed in the spindle positioning mode.

[Specification A: Bit 7 (IMB) of parameter No. 4950 = 0]

<1> Suppose that an M code is specified by a program. If an M code is specified in the spindle rotation mode, the CNC issues alarm PS0224, "ZERO RETURN NOT FINISHED".

<2> Auxiliary function code signal M00 to M31 is sent, and the auxiliary function strobe signal MF is set to 1 at the same time. This sending procedure is the same as for ordinary auxiliary functions.

<3> When strobe signal MF is set to 1, the PMC must read the code signal and perform corresponding processing. After completing the corresponding processing, the PMC sets spindle stop complete signal SPSTPs to 1 when the spindle is stopped.

<4> As soon as setting strobe signal MF to 1, the CNC checks whether spindle stop complete signal SPSTPs is set to 1. When SPSTPs is set to 1, the CNC sets the spindle unclamp signal SUCLPs to 1.

<5> When spindle unclamp signal SUCLPs is set to 1, the PMC unclamps the spindle, and when unclamping of the spindle is completed, the PMC sets spindle unclamp completion signal *SUCPFs to 0.

<6> When spindle unclamp completion signal *SUCPFs is set to 0, the CNC sets spindle unclamp signal SUCLPs to 0 to post that the CNC has received the *SUCPFs signal.

<7> When spindle unclamp signal SUCLPs is set to 0, the PMC must set spindle unclamp completion signal *SUCPFs to 1. After setting the SUCLPs signal to 0, the CNC rotates the spindle, makes a movement as specified, then stops the spindle.

<8> The CNC sets spindle clamp signal SCLPs to 1.

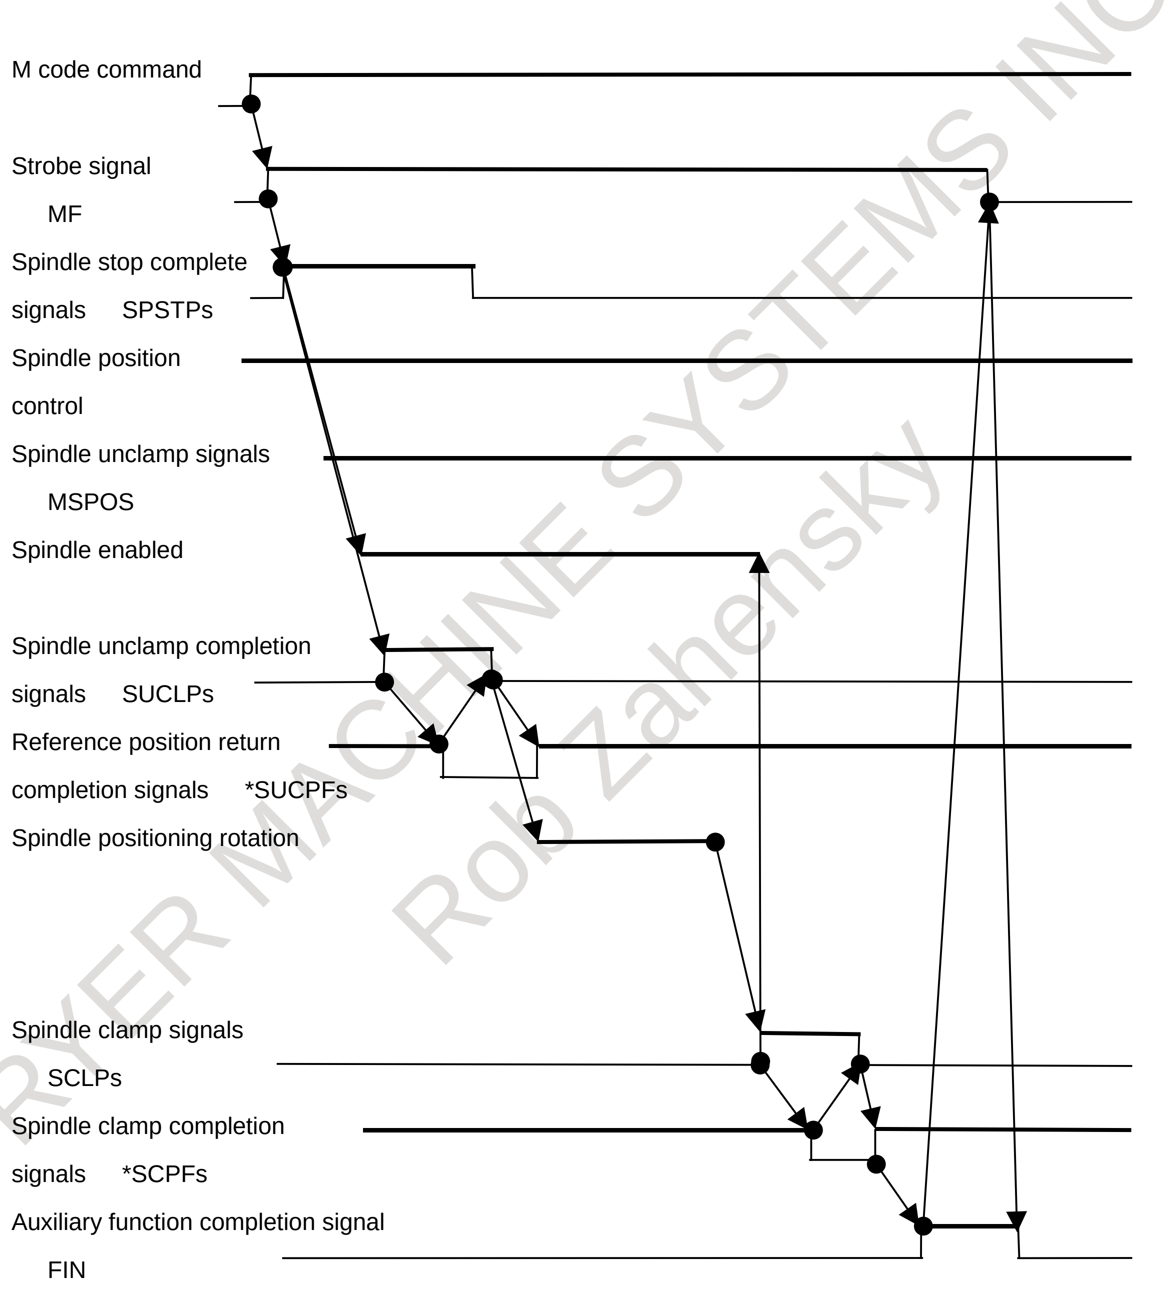
<9> When spindle clamp signal SCLPs is set to 1, the PMC clamps the spindle mechanically with a device such as a clutch or shot pin as necessary. After completing the clamping operation, the PMC sets spindle clamp completion signal *SCLPFs to 0.

<10>When spindle clamp completion signal*SCLPs is set to 0, the CNC sets spindle clamp signal SCLPs to 0 to post that the CNC has received *SCLPFs

<11>When spindle clamp signal SCLPs is set to 0, the PMC sets spindle clamp completion signal *SCLPFs to 1.

<12>Finally, the PMC sets completion signal FIN to 1 for auxiliary function strobe signal MF. In response to this, the CNC sets the MF signal to 0. Then, the PMC sets the FIN signal to 0.

Timing chart for spindle positioning (specification A)



[Specification B: Bit 7 (IMB) of parameter No. 4950 = 1]

<1> Suppose that an M code is specified in a program.

<2> Auxiliary function code signal M00 to M31 is sent, and the auxiliary function strobe signal MF is set to 1 at the same time. This sending procedure is the same as for ordinary auxiliary functions.

<3> When strobe signal MF is set to 1, the PMC must read the code signal and perform corresponding processing. After completing the corresponding processing, the PMC sets spindle stop complete signal SPSTPs to 1 when the spindle is stopped.

<4> As soon as setting strobe signal MF to 1, the CNC checks whether spindle stop complete signal SPSTPs is set to 1. When the SPSTPs signal is set to 1, the CNC switches the spindle control mode from the spindle rotation mode to spindle positioning mode, and sets spindle positioning mode signal MSPOSs to 1.

<5> The CNC sets spindle unclamp signal SUCLPs to 1.

<6> When spindle unclamp signal SUCLPs is set to 1, the PMC unclamps the spindle, and when unclamping of the spindle is completed, the PMC sets spindle unclamp completion signal *SUCPFs to 0.

<7> When spindle unclamp completion signal *SUCPFs is set to 0, the CNC sets spindle unclamp signal SUCLPs to 0 to post that the CNC has received the *SUCPFs signal.

<8> When spindle unclamp signal SUCLPs is set to 0, the PMC sets spindle unclamp completion signal *SUCPFs to 1.

<9> After setting the SUCLPs signal to 0, the CNC rotates the spindle, makes a movement as specified, then stops the spindle.

<10>The CNC sets spindle clamp signal SCLPs to 1.

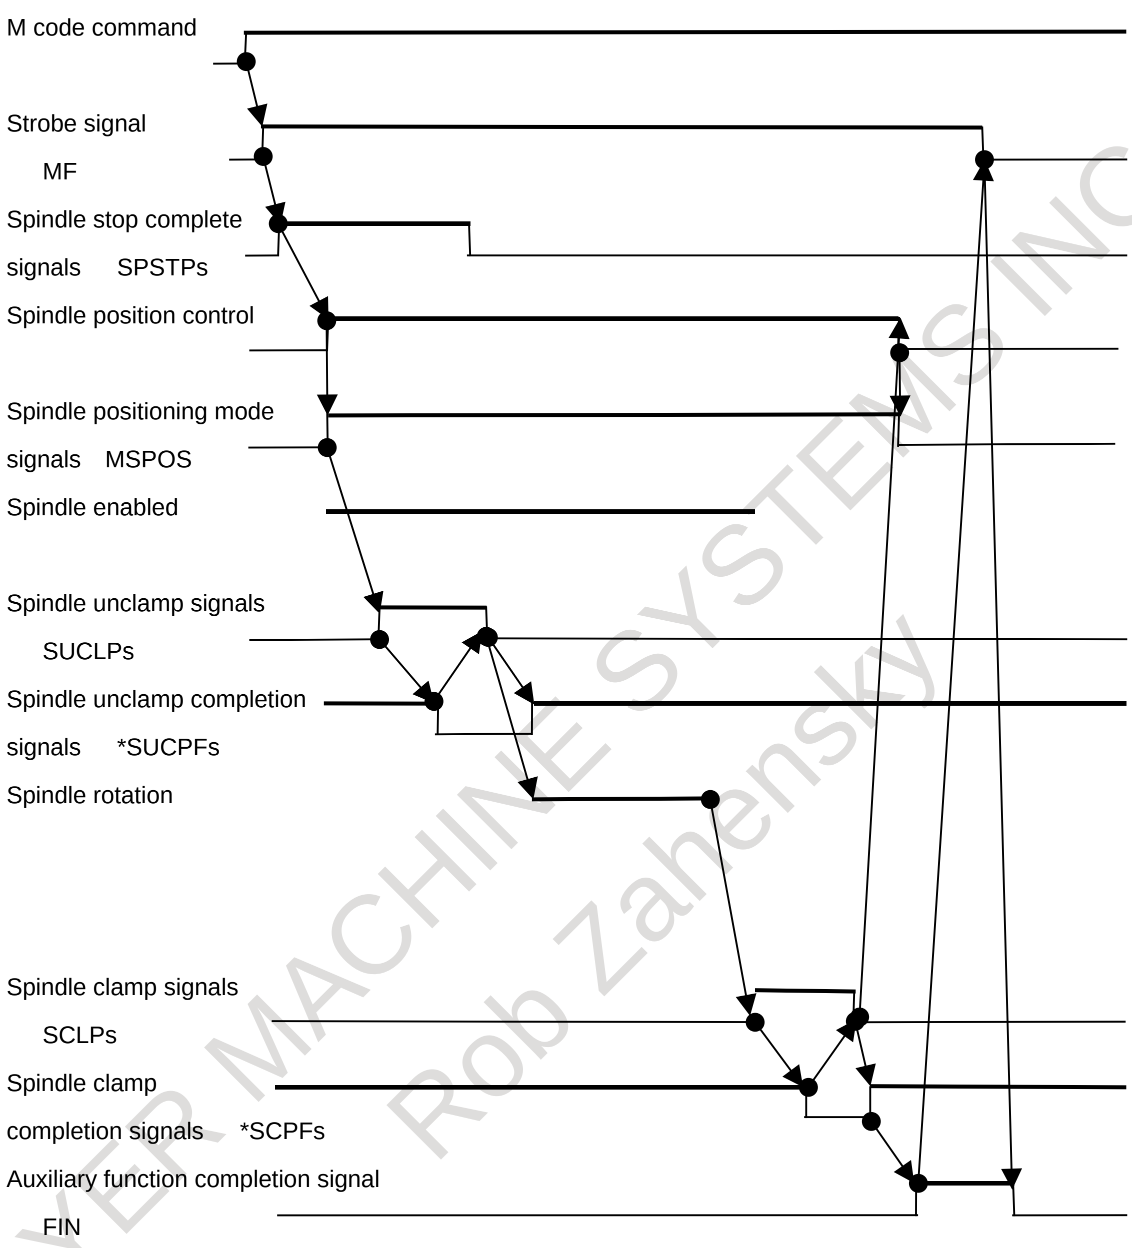
<11>When spindle clamp signal SCLPs is set to 1, the PMC clamps the spindle mechanically with a device such as a clutch or shot pin as necessary. After completing the clamping operation, the PMC sets spindle clamp completion signal *SCLPFs to 0.

<12>When spindle clamp completion signal *SCLPs is set to 0, the CNC sets spindle clamp signal SCLPs to 0 to post that the CNC has received *SCLPFs. The CNC sets the SCLPs signal to 0, and switches the spindle control mode from the spindle positioning mode to spindle rotation mode at the same time. The CNC sets spindle positioning mode signal MSPOSs to 0.

<13>When spindle clamp signal SCLPs is set to 0, the PMC sets spindle clamp completion signal *SCLPFs to 1.

<14>Finally, the PMC sets completion signal FIN to 1 for auxiliary function strobe signal MF. In response to this, the CNC sets the MF signal to 0. Then, the PMC sets the FIN signal to 0.

Timing chart for spindle positioning (specification B)



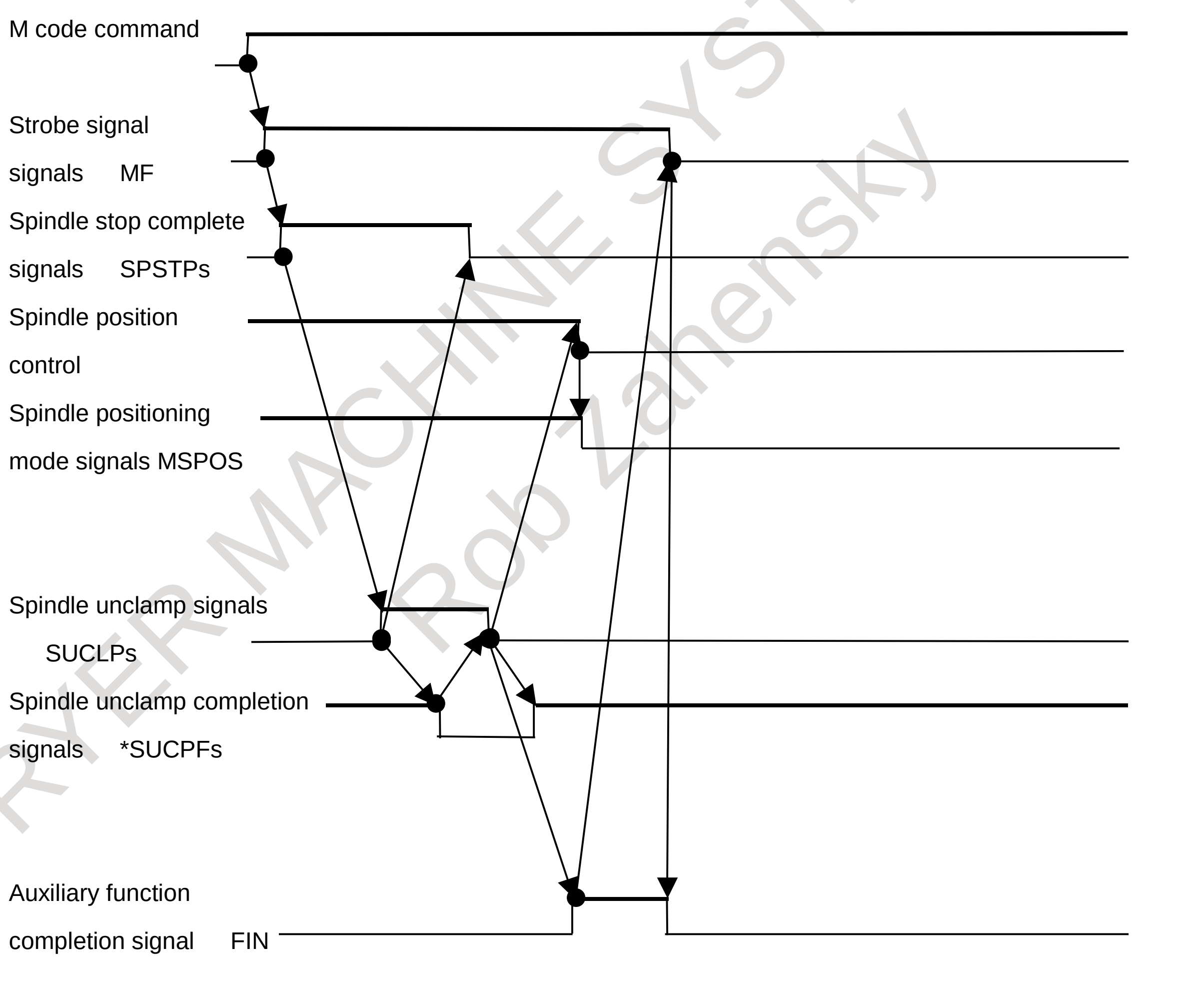
Canceling spindle positioning

To cancel the spindle positioning mode and enter the spindle rotation mode again, use an M code for canceling the spindle positioning mode.
Set the M code in parameter No. 4961 in advance.

<1> Suppose that an M code is specified in a program.
<2> Auxiliary function code signal M00 to M31 is sent, and the auxiliary function strobe signal MF is set to 1 at the same time. This sending procedure is the same as for ordinary auxiliary functions.
<3> When strobe signal MF is set to 1, the PMC must read the code signal and perform corresponding processing. After completing the corresponding processing, the PMC sets spindle stop complete signal SPSTPs to 1 when the spindle is stopped.

<4> As soon as setting strobe signal MF to 1, the CNC checks whether spindle stop complete signal SPSTPs is set to 1. When the SPSTPs signal is set to 1, the CNC sets spindle unclamp signal SUCLPs to 1.
<5> When spindle unclamp signal SUCLPs is set to 1, the PMC unclamps the spindle, and when unclamping of the spindle is completed, the PMC sets spindle unclamp completion signal *SUCPFs to 0.
<6> When spindle unclamp completion signal *SUCPFs is set to 0, the CNC sets spindle unclamp signal SUCLPs to 0 to post that the CNC has received the *SUCPFs signal. As soon as setting the SUCLPs signal to 0, the CNC switches the spindle control mode from the spindle positioning mode to spindle rotation mode. The CNC sets spindle positioning mode signal MSPOSs to 0.
<7> When spindle unclamp signal SUCLPs is set to 0, the PMC sets spindle unclamp completion signal *SUCPFs to 1.
<8> Finally, the PMC sets completion signal FIN to 1 for auxiliary function strobe signal MF. In response to this, the CNC sets the MF signal to 0. Then, the PMC sets the FIN signal to 0.

Timing chart for canceling spindle positioning mode



Parameter

Major related parameters are described below.

	#7	#6	#5	#4	#3	#2	#1	#0
1005								ZRNx

[Input type] Parameter input
[Data type] Bit axis

#0 ZRNx If a move command other than G28 is specified by automatic operation when no reference position return is performed yet after the power is turned on:
0: The alarm PS0224, "ZERO RETURN NOT FINISHED" is issued.
1: Operation is performed without issuing an alarm.

> **NOTE**
> 1 The state in which a reference position has not been established refers to the following state:
> - When an absolute position detector is not used and reference position return has not been performed even once after power-up
> - When an absolute position detector is used and the association of the machine position with the position detected with the absolute position detector has not been completed (See the description of bit 4 (APZx) of parameter No. 1815.)
>
> 2 When the Cs axis coordinates are to be set up, set ZRN to 0.

	#7	#6	#5	#4	#3	#2	#1	#0
1006			ZMIx		DIAx		ROSx	ROTx

[Input type] Parameter input
[Data type] Bit axis

> **NOTE**
> When at least one of these parameters is set, the power must be turned off before operation is continued.

#0 ROTx Setting linear or rotation axis.
#1 ROSx

ROSx	ROTx	Meaning
0	0	Linear axis (1) Inch/metric conversion is done. (2) All coordinate values are linear axis type. (Is not rounded in 0 to 360°) (3) Stored pitch error compensation is linear axis type (Refer to parameter No. 3624)
0	1	Rotary axis (A type) (1) Inch/metric conversion is not done. (2) Machine coordinate values are rounded in 0 to 360°. Absolute coordinate values are rounded or not rounded by bits 0 (ROAx) and 2 (RRLx) of parameter No. 1008. (3) Stored pitch error compensation is the rotation type. (Refer to parameter No. 3624) (4) Automatic reference position return (G28, G30) is done in the reference position return direction and the move amount does not exceed one rotation.

ROSx	ROTx	Meaning
1	1	Rotary axis (B type) (1) Inch/metric conversion is not done. (2) Machine coordinate values, absolute coordinate values and relative coordinate values are linear axis type. (Is not rounded in 0 to 360°). (3) Stored pitch error compensation is linear axis type (Refer to parameter No. 3624) (4) Cannot be used with the rotary axis roll-over function and the index table indexing function (M series)
Except for the above.		Setting is invalid (unused)

#3 DIAx The move command for each axis is based on:
0: Radius specification
1: Diameter specification

#5 ZMIx The direction of manual reference position return is:
0: + direction
1: - direction

	#7	#6	#5	#4	#3	#2	#1	#0
1013							ISCx	ISAx

[Input type] Parameter input
[Data type] Bit axis

> **NOTE**
> When at least one of these parameters is set, the power must be turned off before operation is continued.

#0 ISAx
#1 ISCx Increment system of each axis

Increment system	Bit 1 (ISC)	Bit 0 (ISA)
IS-A	0	1
IS-B	0	0
IS-C	1	0

<u>IS-B is specified for the spindle positioning axis.Therefore, set ISA to ISE to 0.</u>

1022	Setting of each axis in the basic coordinate system

[Input type] Parameter input
[Data type] Byte axis
[Valid data range] 0 to 7

To determine a plane for circular interpolation, cutter compensation, and so forth (G17: Xp-Yp plane, G18: Zp-Xp plane, G19: Yp-Zp plane), specify which of the basic three axes (X, Y, and Z) is used for each control axis, or a parallel axis of which basic axis is used for each control axis.
A basic axis (X, Y, or Z) can be specified only for one control axis.
Two or more control axes can be set as parallel axes for the same basic axis.

Setting	Meaning
0	Rotary axis (Neither the basic three axes nor a parallel axis)
1	X axis of the basic three axes

Setting	Meaning
2	Y axis of the basic three axes
3	Z axis of the basic three axes
5	Axis parallel to the X axis
6	Axis parallel to the Y axis
7	Axis parallel to the Z axis

In general, the increment system and diameter/radius specification of an axis set as a parallel axis are to be set in the same way as for the basic three axes.

1023	Number of the servo axis for each axis

NOTE
When this parameter is set, the power must be turned off before operation is continued.

[Input type] Parameter input
[Data type] Byte axis
[Valid data range] -4 to 80

This parameter associates each control axis with a specific servo axis. Specify values 1+8n, 2+8n, 3+8n, 4+8n, 5+8n, and 6+8n (n = 0, 1, 2, …, 9) like 1, 2, 3, 4, 5, …, 77, and 78.
Set the spindle number targeted for spindle positioning preceded by a minus sign (-1 to –4), as the servo axis number of an axis used as the spindle positioning axis.
Settings
-1 : Spindle positioning by using the first spindle
-2 : Spindle positioning by using the second spindle
-3 : Spindle positioning by using the third spindle
-4 : Spindle positioning by using the fourth spindle

NOTE
One spindle cannot be set as multiple spindle positioning axes.

1260	The shift amount per one rotation of a rotary axis

NOTE
When this parameter is set, the power must be turned off before operation is continued.

[Input type] Parameter input
[Data type] Real axis
[Unit of data] deg
[Min. unit of data] Depend on the increment system of the applied axis
[Valid data range] 0 or positive 9 digit of minimum unit of data (refer to the standard parameter setting table (B))
(When the increment system is IS-B, 0.0 to +999999.999)
Set the shift amount per one rotation of a rotary axis.
For the rotary axis used for cylindrical interpolation, set the standard value.
For the spindle positioning axis, set 360.0.

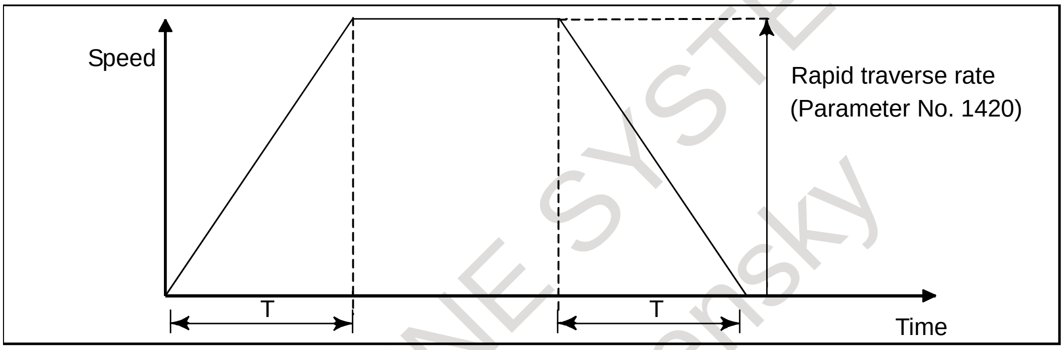
1420	Rapid traverse rate for each axis

[Input type] Parameter input

[Data type] Real axis
[Unit of data] mm/min, inch/min, deg/min (machine unit)
[Min. unit of data] Depend on the increment system of the applied axis
[Valid data range] Refer to the standard parameter setting table (C)
(When the increment system is IS-B, 0.0 to +999000.0)
Set the rapid traverse rate when the rapid traverse override is 100% for each axis.

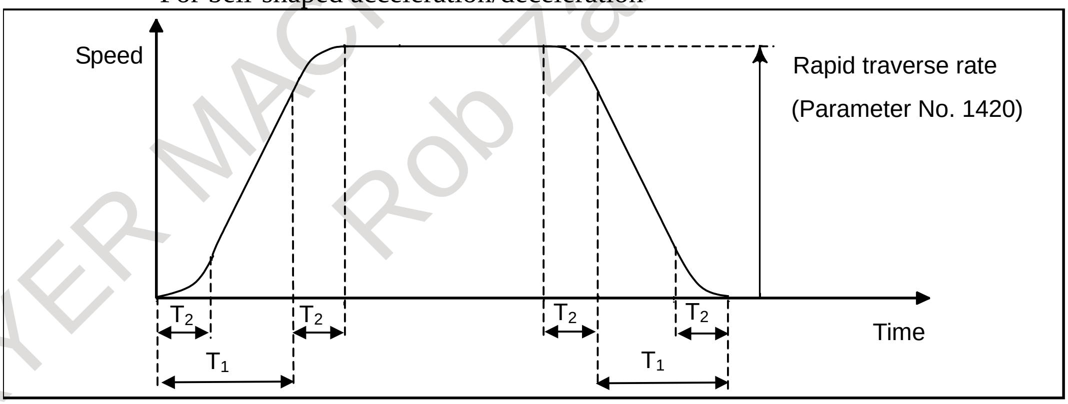
1620	**Time constant T or T1 used for linear acceleration/deceleration or bell-shaped acceleration/deceleration in rapid traverse for each axis**

[Input type] Parameter input
[Data type] Word axis
[Unit of data] msec
[Valid data range] 0 to 4000
Specify a time constant used for acceleration/deceleration in rapid traverse.
[Example]
For linear acceleration/deceleration



T : Setting of parameter No. 1620

For bell-shaped acceleration/deceleration



T_1 : Setting of parameter No. 1620
T_2 : Setting of parameter No. 1621
(However, $T_1 \geq T_2$ must be satisfied.)
Total acceleration (deceleration) time : $T_1 + T_2$
Time for linear portion : $T_1 - T_2$
Time for curve portion : $T_2 \times 2$

1820	Command multiplier for each axis (CMR)

> **NOTE**
> When this parameter is set, the power must be turned off before operation is continued.

[Input type] Parameter input
[Data type] Byte axis
[Valid data range] 1 to 96
Set 2 for spindle positioning axis.

1821	Reference counter size for each axis

> **NOTE**
> When this parameter is set, the power must be turned off before operation is continued.

[Input type] Parameter input
[Data type] 2-word axis
[Unit of data] Detection unit
[Valid data range] 0 to 999999999
Set a reference counter size.
As a reference counter size, specify a grid interval for reference position return based on the grid method.
When a value less than 0 is set, the specification of 10000 is assumed.

1826	In-position width for each axis

[Input type] Parameter input
[Data type] 2-word axis
[Unit of data] Detection unit
[Valid data range] 0 to 99999999
The in-position width is set for each axis.
When the deviation of the machine position from the specified position (the absolute value of the positioning deviation) is smaller than the in-position width, the machine is assumed to have reached the specified position. (The machine is in the in-position state.)

1827	In-position width in cutting feed for each axis

[Input type] Parameter input
[Data type] 2-word axis
[Unit of data] Detection unit
[Valid data range] 0 to 99999999
Set an in-position width for each axis in cutting feed. This parameter is used when bit 4 (CCI) of parameter No. 1801=1.

1828	Positioning deviation limit for each axis in movement

[Input type] Parameter input
[Data type] 2-word axis
[Unit of data] Detection unit
[Valid data range] 0 to 99999999
Set the positioning deviation limit in movement for each axis.

If the positioning deviation exceeds the positioning deviation limit during movement, a servo alarm SV0411, “EXCESS ERROR (MOVING)” is generated, and operation is stopped immediately (as in emergency stop).
Generally, set the positioning deviation for rapid traverse plus some margin in this parameter. Refer to the following set value.

$$\textbf{Setting value} = \frac{\textbf{Rapid traverse rate}^{(\text{Note 1})}}{\textbf{60} \times \textbf{Servo loop gain}^{(\text{Note 2})}} \times \frac{1}{\textbf{Detection unit}} \times 1.2 \textbf{ to } 1.5$$

⚠ CAUTION
If this parameter is not set correctly, machine or workpiece can be damaged.

NOTE
1 Usually, this value is parameter No.1420. When the maximal feedrate of each axis exceeds parameter No.1420 according to the command and override, the value is the maximal feedrate of the each axis.
2 Usually, this value is parameter No.1825. When the servo loop gains other than parameter No.1825 is effective, the value is actual servo loop gains.

1829	Positioning deviation limit for each axis in the stopped state

[Input type] Parameter input
[Data type] 2-word axis
[Unit of data] Detection unit
[Valid data range] 0 to 99999999

Set the positioning deviation limit in the stopped state for each axis.
If, in the stopped state, the positioning deviation exceeds the positioning deviation limit set for stopped state, a servo alarm SV0410, "EXCESS ERROR (STOP)" is generated, and operation is stopped immediately (as in emergency stop).

1850	Grid shift and reference position shift for each axis

NOTE
When this parameter is set, the power must be turned off before operation is continued.

[Input type] Parameter input
[Data type] 2-word axis
[Unit of data] Detection unit
[Valid data range] -99999999 to 99999999

To shift the reference position, the grid can be shifted by the amount set in this parameter.
Up to the maximum value counted by the reference counter can be specified as the grid shift.
In case of bit 4 (SFDx) of parameter No. 1008 is 0: Grid shift
In case of bit 4 (SFDx) of parameter No. 1008 is 1: Reference point shift

NOTE
For setting the reference position without dogs, only the grid shift function can be used.
(The reference position shift function cannot be used.)

1851	Backlash compensating value for each axis

[Input type] Parameter input
[Data type] Word axis
[Unit of data] Detection unit
[Valid data range] -9999 to 9999

Set the backlash compensating value for each axis.
When the machine moves in a direction opposite to the reference position return direction after the power is turned on, the first backlash compensation is performed.

3720	Number of position coder pulses

> **NOTE**
> When this parameter is set, the power must be turned off before operation is continued.

[Input type] Parameter input
[Data type] 2-word spindle
[Unit of data] Number of pulses
[Valid data range] Serial spindle

: 0, 4096 When bit 7 (FBP) of parameter No.3716 is set to 1: 4096×2^{14}

Spindle control with servo motor

: 0, 4096 When bit 7 (FBP) of parameter No.3716 is set to 1: 4096×2^{14}

Analog spindle

: 0, 4096 When bit 7 (FBP) of parameter No.3716 is set to 1: from 0 to 400000

Set the number of position coder pulses.
In analog spindle, 4096 is set to parameter automatically if parameter No.3720 is set to 0 or less.
In serial spindle or spindle control with servo motor, the setting method is changed by setting of the bit 7 (FBP) of parameter No.3716.

- When the bit 7 (FBP) of parameter No.3716 is set to 0:
  4096 is set to parameter automatically if parameter No.3720 is set to 0 or less.
- When the bit 7 (FBP) of parameter No.3716 is set to 1:
  4096×2^{14} is set to parameter automatically.

3721	Number of gear teeth on the position coder side

[Input type] Parameter input
[Data type] Word spindle
[Valid data range] 0 to 9999

Set the number of gear teeth on the position coder side in speed control (such as feed per revolution).

3722	Number of gear teeth on the spindle side

[Input type] Parameter input
[Data type] Word spindle
[Valid data range] 0 to 9999

Set the number of gear teeth on the spindle side in speed control (such as feed per revolution).

⚠ **CAUTION**

1. Parameter No.3721 and No.3722 can not be used for thread cutting.
   If thread cutting was done by setting the any value on these parameters, the correct screw can't be cut.
   In the machine to do thread cutting, connect mechanically between the spindle and position coder by the gear ratio=1:1. And these parameters set the No.3721=0, No.3722=0.
   (It is the setting for the gear ratio 1:1.)
2. Parameter No.3721 and No.3722 can not be used for Cs contour control. If Cs contour control was done by setting the any value on these parameters, spindle can't move as commanded. In the machine to do Cs contour control, connect mechanically between the spindle and position coder by the gear ratio = 1:1. And these parameters set the No.3721=0, No.3722=0. (It is the setting for the gear ratio 1:1.)

	#7	#6	#5	#4	#3	#2	#1	#0
4000				RETSV				

[Input type] Parameter input
[Data type] Bit spindle

#4 RETSV Reference position return direction of spindle on servo mode. (spindle positioning, rigid tapping, etc.)
0 : CCW (Counter clockwise)
1 : CW (Clockwise)

NOTE
The direction for spindle orientation (or reference position return) in spindle positioning using a serial spindle is determined by this parameter.

4056	Gear ratio (HIGH)
4057	Gear ration (MEDIUM HIGH)
4058	Gear ratio (MEDIUM LOW)
4059	Gear ratio (LOW)

[Data type] Word spindle
[Unit of data] Motor speed per spindle rotation × 100
[Valid data range] 0 to 32767
These parameters set the gear ration between the spindle and spindle motor.

NOTE
Set the gear ration between spindle and AC spindle motor when the spindle positioning is performed with serial spindle. For which gear is used, it depends on the clutch/gear signal (serial spindle) CTH1s, CTH1s.

4065	Position gain in servo mode (HIGH)
4066	Position gain in servo mode (MEDIUM HIGH)
4067	Position gain in servo mode (MEDIUM LOW)
4068	Position gain in servo mode (LOW)

[Data type] Word spindle
[Unit of data] 0.01 sec^{-1}
[Valid data range] 0 to 32767

These parameters set a servo loop gain on servo mode. (spindle positioning, rigid tapping, etc.)

NOTE
When the spindle positioning by a serial spindle is performed, set the position control loop gain in place of parameter No. 4970. For which gear is used, it depends on the clutch/gear signal (serial spindle) CTH1s, CTH1s.

4073	Grid shift amount on servo mode

[Input type] Parameter input
[Data type] Word spindle
[Unit of data] Detection unit
[Valid data range] 0to4096

This parameter sets a grid shift amount (distance from the position of a one-rotation signal to the machine zero point) in a servo mode (such as spindle positioning or rigid tapping).

NOTE
The setting of this parameter is used as a grid shift amount for orientation (reference position return) in spindle positioning using a serial spindle.

4074	Reference position return speed on servo mode

[Input type] Parameter input
[Data type] Word spindle
[Unit of data] min^{-1}

The spindle speed set in this parameter is used for spindle orientation in a servo mode (such as spindle positioning or rigid tapping).

NOTE
The setting of this parameter is used as a grid shift amount for orientation (reference position return) in spindle positioning using a serial spindle.

	#7	#6	#5	#4	#3	#2	#1	#0
4950	IMBs	ESIs	TRVs			ISZs	IDMs	IORs

[Input type] Parameter input
[Data type] Bit spindle

#0 IORs Resetting the system in the spindle positioning mode
0: Does not release the mode.
1: Releases the mode

#1 IDMs The direction of spindle positioning (half-fixed angle positioning based on M codes) is:
0: Plus direction.
1: Minus direction.

#2 ISZs When an M code for switching to the spindle positioning mode is specified for spindle positioning:
0: The spindle is switched to the spindle positioning mode, and spindle orientation operation is performed.
1: Only the switching of the spindle to the spindle positioning mode is performed. (Spindle orientation operation is not performed.)

#5 TRVs The rotation direction for spindle positioning is:
0: Same as the specified sign.
1: Opposite to the specified sign.

> **NOTE**
> When a serial spindle is used, this parameter is invalid for the specification of a rotation direction for the orientation command.

#6 ESIs The unit of rapid traverse rate on the spindle positioning axis is:
0: Not increased by a factor of 10.
1: Increased by a factor of 10.

#7 IMBs When the spindle positioning function is used, half-fixed angle positioning based on M codes uses:
0: Specification A
1: Specification B

In the case of half-fixed angle positioning based on M codes, three types of spindle positioning operations can occur:
(1) The spindle rotation mode is cleared, then the mode is switched to the spindle positioning mode. (After switching to the spindle positioning mode, spindle orientation operation is also performed.)
(2) Spindle positioning is performed in the spindle positioning mode.
(3) The spindle positioning mode is cleared, then the mode is switched to the spindle rotation mode.

- In the case of specification A:
  Operations (1) to (3) are specified using separate M codes.
  (1) Specified using an M code for switching to the spindle positioning mode. (See parameter No. 4960)
  (2) Specified using M codes for specifying a spindle positioning angle. (See parameter No. 4962)
  (3) Specified using M codes for clearing spindle positioning operation. (See parameter No. 4961.)

- In the case of specification B:
  When M codes for specifying a spindle positioning angle are specified, operations (1) to (3) are performed successively. (See parameter No. 4962.) (However, spindle orientation operation of (1) is not performed.)

4960	M code specifying the spindle orientation

[Input type] Parameter input
[Data type] 2-word spindle
[Valid data range] 6 to 97
Set an M code for switching to the spindle positioning mode.

NOTE
1 Do not set an M code that duplicates other M codes used for spindle positioning.
2 Do not set an M code used with other functions (such as M00-05, 30, 98, and 99, and M codes for calling subprograms).

4961	M code releasing the spindle positioning mode

[Input type] Parameter input
[Data type] 2-word spindle
[Valid data range] 6 to 97
Set an M code for canceling the spindle positioning mode on the spindle positioning axis.

NOTE
1 Do not set an M code that duplicates other M codes used for spindle positioning.
2 Do not set an M code used with other functions (such as M00-05, 30, 98, and 99, and M codes for calling subprograms).

4962	M code for specifying a spindle positioning angle

[Input type] Parameter input
[Data type] 2-word spindle
[Valid data range] 6 to 9999999
Two methods are available for specifying spindle positioning. One method uses axis address for arbitrary-angle positioning. The other use an M code for half-fixed angle positioning. This parameter sets an M code for the latter method.
In this parameter, set an M code to be used for half-fixed angle positioning based on M codes.
Six M code from Mα to M(α+5) are used for half-fixed angle positioning, when α is the value of this parameter.

- When the number of M codes is set in parameter No. 4964, let α be the value set in parameter No. 4962, and let β be the value set in parameter No. 4964. Then, β M codes from Mα to M(α+β-1) are used as M codes for half-fixed angle positioning based on M codes.

The table below indicates the relationship between the M codes and positioning angles.

M code	Positioning angle	Example: Positioning angle when θ = 30°
Mα	θ	30°
M(α+1)	2θ	60°
M(α+2)	3θ	90°
M(α+3)	4θ	120°
M(α+4)	5θ	150°
M(α+5)	6θ	180°
:	:	:
M(α+β-1)	β×θ	β×30°

β represents the number of M codes set in parameter No. 4964.
(When parameter No. 4964 is set to 0, β = 6.)
θ represents the basic angular displacement set in parameter No. 4963.

NOTE
1. Do not set an M code that duplicates other M codes used for spindle positioning.
2. Do not set an M code used with other functions (such as M00-05, 30, 98, and 99, and M codes for calling subprograms).

4963	Basic angle for half-fixed angle positioning

[Input type] Parameter input
[Data type] Real spindle
[Unit of data] deg
[Min. unit of data] Depend on the increment system of the applied axis
[Valid data range] 0 to 60

This parameter sets a basic angular displacement used for half-fixed angle positioning using M codes.

4964	Number of M codes for specifying a spindle positioning angle

[Input type] Parameter input
[Data type] 2-word spindle
[Valid data range] 0 to 255

This parameter sets the number of M codes used for Half-fixed angle positioning using M codes.
As many M codes as the number specified in this parameter, starting with the M code specified in parameter No. 4962, are used to specify half-fixed angle positioning.
Let α be the value of parameter No. 4962, and let β be the value of parameter No. 4964. That is, M codes from Mα to M(α+β-1) are used for half-fixed angle positioning.
Setting this parameter to 0 has the same effect as setting 6. That is, M code from Mα to M(α+5) are used for half-fixed angle positioning.

NOTE
1. Make sure that M codes from Mα to M (α+β-1) do not duplicate other M codes.
2. Do not set an M code that duplicates other M codes used for spindle positioning.
3. Do not set an M code used with other functions (such as M00-05, 30, 98, and 99, and M codes for calling subprograms).

4970	Position gain

[Input type] Parameter input
[Data type] Word spindle
[Unit of data] 0.01/sec
[Valid data range] 1 to 9999

Set the position gain of the analog spindle in the spindle positioning mode.

4971 to 4974	Position gain multiplier (first stage) to Position gain multiplier (fourth stage)

[Input type] Parameter input
[Data type] Word spindle
[Valid data range] 1 to 32767

Set a position gain multiplier for an analog spindle in spindle positioning.
Position gain multiplier GC is obtained from the following equation:

$$GC = \frac{2048000 \times 360 \times PC \times E}{PLS \times SP \times L}$$

PLS Number of pulses output from the position coder (pulses/rev)
SP Number of gear teeth on the spindle side
PC Number of gear teeth on the position coder side
E Specified voltage (V) for turning the spindle motor at 1000 min^{-1}
L Angular displacement of the spindle (degrees) per spindle motor rotation

[Example] For the spindle motor and gear ratio given below, GC is calculated as follows:

PLS = 4096 pulse/rev
SP = 1
PC = 1
E = 2.2 V
L = 360 deg

$$GC = \frac{2048000 \times 360 \times 1 \times 2.2}{4096 \times 1 \times 360} = 1100$$

> **NOTE**
> On the assumption that the spindle motor used turns at 4500 min^{-1} at 10 V, 2.2 V is required to turn the spindle motor at 1000 min^{-1}

	#7	#6	#5	#4	#3	#2	#1	#0
11802				KSV				

[Input type] Parameter input
[Data type] Bit axis

> **NOTE**
> When at least one of these parameters is set, the power must be turned off before operation is continued.

#4 KSV Servo axis is:
0: Enabled.
1: Disabled.

NOTE
1. This setting is effective regardless of the value of parameter No. 1023.
2. If this setting is made for the axis subject to Cs axis contour/spindle positioning, Cs axis contour/spindle positioning will be disabled.

Alarm and message

Number	Message	Description
PS0136	SPOS AXIS - OTHER AXIS SAME TIME	The spindle positioning axis and another axis are specified in the same block.
PS0137	M-CODE & MOVE CMD IN SAME BLK.	The spindle positioning axis and another axis are specified in the same block.
PS0194	SPINDLE COMMAND IN SYNCHRO-MODE	A Cs contour control mode, spindle positioning command, or rigid tapping mode was specified during the spindle synchronous control mode or spindle command synchronous control mode.
PS0224	ZERO RETURN NOT FINISHED	Reference position return has not been performed before the automatic operation starts. Perform reference position return only when the bit 0 (ZRNx) of parameter No. 1005 is set to 0. Or, spindle positioning command is specified in spindle rotation mode. Switch to spindle positioning mode and specify spindle positioning command.
PS1509	DUPLICATE M-CODE (SPOS AXIS ORIENTATION)	A function to which the same code as this M code is set exists. (spindle positioning, orientation)
PS1510	DUPLICATE M-CODE (SPOS AXIS POSITIONING)	A function to which the same code as this M code is set exists. (spindle positioning, positioning)
PS1511	DUPLICATE M-CODE (SPOS AXIS RELEASE)	A function to which the same code as this M code is set exists. (spindle positioning, mode cancel)
PS1543	ILLEGAL GEAR SETTING	The gear ratio between the spindle and position coder, or the set position coder number of pulses is illegal in the spindle positioning function.
SP0752	SPINDLE MODE CHANGE ERROR	This alarm is generated if the system does not properly terminate a mode change. The modes include the Cs contour control, spindle positioning, rigid tapping, and spindle control modes. The alarm is activated if the spindle control unit does not respond correctly to the mode change command issued by the NC.
SP1224	ILLEGAL SPINDLE-POSITION CODER GEAR RATIO	The spindle–position coder gear ratio was incorrect.
SP1233	POSITION CODER OVERFLOW	The error counter/speed instruction value of the position coder overflowed.
SP1234	GRID SHIFT OVERFLOW	Grid shift overflowed.
SP1240	DISCONNECT POSITION CODER	The analog spindle position coder is broken.
SP1243	ILLEGAL SPINDLE PARAMETER SETTING(GAIN)	The setting for the spindle position gain is incorrect.
SP1244	MOTION VALUE OVERFLOW	The amount of distribution to a spindle is too much
SV0410	EXCESS ERROR (STOP)	The amount of positional deviation during stopping exceeded the parameter No. 1829 setting value.
SV0411	EXCESS ERROR (MOVING)	The amount of positional deviation during traveling became excessive than the parameter setting value.

Number	Message	Description
SV1026	ILLEGAL AXIS ARRANGE	The parameter for servo axis arrange is not set correctly. - Parameter No. 1023 (servo axis number of each axis) is set to a negative value or a duplicate value. - The settings for parameter No. 1023 (servo axis number of each axis) were made with a certain setting skipped among 1 to 6, 9 to 14, or 17 to 22. - A setting of a multiple of 8 or a multiple of 8 minus 1 was made.

Caution

⚠ **CAUTION**

1. While the operations for spindle positioning (canceling the spindle rotation mode to enter the spindle positioning mode, positioning the spindle in the spindle positioning mode, and canceling the spindle positioning mode to enter the spindle rotation mode) are being performed, automatic operation stop signal *SP is invalid. This means that even when the * SP signal is set to 0, automatic operation does not stop until the entire sequence is completed.
2. Dry run and machine lock are not enabled during spindle positioning.
3. For M codes used for the spindle positioning function, auxiliary function lock is not enabled.
4. The spindle positioning function and the serial spindle Cs contour control function cannot be used together. If both functions are available (AXC(No.8133#1)=1 and SCS(No.8133#2)=1), positioning has priority.
5. The spindle positioning axis is treated as one of the controlled axes. Therefore, signals related to controlled axes (such as an overtravel signal) must be set.
6. When analog spindles are used, set exact drift compensation values.
   If an inappropriate drift compensation value is set, the positional deviation amount in the stopped state does not become 0. As a result, the following problems may occur when spindle orientation or spindle positioning is performed:
   - In-position wait state is entered, which results in a stop.
   - The spindle position is deviated. (The spindle does not reach or passes a specified position.)

- Note on using the rigid tapping function together

⚠ **CAUTION**

When using the rigid tapping function together with the spindle positioning function, do not specify rigid tapping in the spindle positioning mode, and contrariwise, do not specify spindle positioning in the rigid tapping mode.

Note

NOTE

1 M code commands related to spindle positioning must each be specified in an independent block. A block for specifying such an M code must not contain any other command. (An M command related to spindle positioning for another spindle must not be contained in the same block, either.)
Even when the function for enabling specification of multiple M codes in a single block is used together, spindle positioning M codes must be specified in an independent block.
2 The axis address for spindle positioning must be specified in an independent block. A block for specifying such an address must not contain any other command. The following commands, however, can be specified together with the axis address in the same block:
G00,G90,G91,G92 (M series, G code system B or C for T series)
G00,G50 (G code system A for T series)
3 M code commands related to spindle positioning are not buffered.
4 Spindle positioning cannot be performed by manual operations (such as a jog feed, manual handle feed, and so forth).
5 Spindle positioning cannot be performed through PMC axis control.
6 Program restart/block restart cannot be performed for spindle positioning. Use MDI for specification.
7 The stored stroke limit check is disabled for the spindle positioning axis.
8 The axis removal function is disabled for the spindle positioning axis.
9 The pitch error compensation function is disabled for the spindle positioning axis.
10 When a setting is made to omit spindle orientation, the reference position return completion signal is not set to 1.
11 In spindle orientation, all-axes interlock/each-axis interlock checks are made only at the start of the block. Even when the signal is input in the middle of block execution, it is ignored.
12 The difference between a move command and the actual movement amount is maintained until the spindle positioning mode is canceled.

FANUC AC SPINDLE MOTOR αi series PARAMETER MANUAL (B-65280EN)

10.11 Cs CONTOUR CONTROL

10.11.1 Cs Contour Control

Overview

The Cs contour control function positions the serial spindle using the spindle motor in conjunction with a dedicated detector mounted on the spindle.
This function can perform more accurate positioning than the spindle positioning function, and has an interpolation capability with other servo axes.

- Increment system

As the least input increment of the Cs contour control axis, IS-B or IS-C must be set.
Selecting IS-C requires the following parameter settings:
Bit 1 (ISC) of parameter No. 1013 = 1
Bit 7 (CSC) of parameter No. 3729 = 1
Bit 0 (CS360M) of parameter No. 4005 = 1

- Command multiplication

Command multiplication for the Cs contour control axis must be set to 2 (1×).

Explanation

In Cs contour control, positioning is possible, as well as interpolation between the Cs contour control axis and a servo axis.

Performing speed control on a serial spindle is referred to as spindle rotation control (the spindle being rotated with a speed command), while performing position control on a spindle is referred to as spindle contour control (the spindle being rotated with a move command). The function for performing such spindle contour control is the Cs contour control function.
Switching between spindle speed control and CS contour control is performed by the DI signal from the PMC.
In the Cs contour control mode, the Cs contour control axis can be operated either manually or automatically, in the same way as normal servo axes.
(For a reference position return, see the relevant description in this section.)

- Setting the Cs contour control axis

If bit 7 (CSS) of parameter No. 3704 is 0:
Cs contour control is enabled for the first spindle in the path.
The axis used for Cs contour control must be set as an axis of the axes controlled by the CNC. Any controlled axis may be set as the Cs contour control axis.

Using parameter No. 1023, assign "-1" in the field corresponding to the chosen servo axis. (For single-path systems)
As the servo axis number (parameter No. 1023) of the axis used as the Cs contour control axis, set the number of the target logical spindle for Cs contour control with a minus sign (-1 to -n). (For multi-path systems)
This setting must be made only once for each control system. The spindle operating as the Cs contour control axis is the first spindle in the path.
If bit 7 (CSS) of parameter No. 3704 is 1:
Cs contour control can be performed for each spindle.
As the servo axis number (parameter No. 1023) of the axis used as the Cs contour control axis, set the number of the target logical spindle for Cs contour control with a minus sign (-1 to -n).
Cs contour control can be performed for more than one spindle at the same time.

The axis used as the Cs contour control axis must be set as a rotation axis (bit 0 (ROTx) of parameter No. 1006, and parameter No. 1022)

> ⚠ **CAUTION**
> Parameter No.3721 and No.3722 can not be used for Cs contour control. If Cs contour control was done by setting the any value on these parameters, spindle can't move as commanded. In the machine to do Cs contour control, connect mechanically between the spindle and position coder by the gear ratio = 1:1. And these parameters set the No.3721=0, No.3722=0. (It is the setting for the gear ratio 1:1.)

> **NOTE**
> If bit 4 (KSV) of parameter No.11802 is set to 1, Cs contour control will be disabled.

- Command Address

The address for the move command in Cs contour control is the axis name specified in parameter No. 1020. This address is arbitrary.

- Switching between spindle speed control and Cs contour control

- Switching from spindle speed control to Cs contour control
  If bit 7 (CSS) of parameter No. 3704 is 0:
    When the Cs contour control change signal CON <Gn027.7> is 1, the first spindle is regarded as the Cs contour control axis.
  If bit 7 (CSS) of parameter No. 3704 is 1:
    When the Cs contour control change signal for each spindle CONS1 to CONS4 <Gn274.0 to 3> is 1, the corresponding spindle is regarded as the Cs contour control axis.

When switching to the CS contour control mode is performed while the spindle is rotating, the spindle stops immediately to perform the change.

- Switching from Cs contour control mode to spindle speed control mode
  If bit 7 (CSS) of parameter No. 3704 is 0:
    When the Cs contour control change signal CON <Gn027.7> is 0, each spindle is placed in the spindle speed control mode.
  If bit 7 (CSS) of parameter No. 3704 is 1:
    When the Cs contour control change signal for each spindle CONS1 to CONS4 <Gn274.0 to 3> is 0, the corresponding spindle is placed in the spindle speed control mode.

Confirm that the move command for the spindle has been completed, then specify the switch. If it is switched while the spindle is moving, the machine enters interlock, or excessive position deviation alarm occurs.

- Setting axes for interpolation with a Cs contour control axis

Up to five servo axes can be used for interpolation with a Cs contour control axis. Any servo axes can be selected for interpolation with the Cs contour control axis by parameter setting. Set parameters as follows:

- When no servo axis is used for interpolation, specify 0 in parameters Nos. 3900, 3910, 3920, 3930, 3940.
- When one or more servo axes are used for interpolation, set the parameter for each as follows :

(1) Assign the axis number (1 to 8) to each of the servo axes used for interpolation in parameters Nos. 39n0 (n=0, 1, 2, 3, or 4).

(2) Set the loop gain for each of the servo axes specified in (1) in parameter nos. 39n1, 39n2, 39n3, 39n4. The loop gain must be the position loop gain for the Cs contour control axis or a desired value. Four parameters are provided to correspond to the four gears of the spindle. Use those parameters according to the inputs of the serial spindle clutch /gear signals (CTH1, CTH2).
(3) When the number of servo axes to be used for interpolation is smaller than five, set 0 in remaining parameter nos. 39n0.

Note on setting bit 7 (CSS) of parameter No. 3704 to 1
Common settings are used whichever spindle is used for Cs contour control. When Cs contour control is performed with more than one spindle, the parameters for the gear specified by the clutch/gear signals (CTH1 and CTH2) of the serial spindle for which the Cs contour mode is specified last are used.

When bit 7 (ALG) of parameter No. 1814 is set to 1, the loop gain can be set automatically at the time of switching between spindle speed control and Cs contour control.

- Automatic setting of the loop gain at the time of switching between spindle speed control and Cs contour control
  1. Switching from spindle speed control to Cs contour control
     The position loop gain of the Cs contour control axis selected by the clutch/gear signals (CTH1 and CTH2) (one of parameters Nos. 4069, 4070, 4071, and 4072) is set automatically for the servo axis for which bit 7 (ALG) of parameter No. 1814 is set to 1.
     When there are multiple Cs contour control axes, the smallest one of the position gain values selected for these axes is set automatically for the other Cs contour control axes and servo axes.
  2. Switching from Cs contour control to spindle speed control
     The original position gain (parameter No. 1825) is set automatically for the servo axis.
     When there are multiple Cs contour control axes, and there are still remaining Cs contour control axes, the smallest one of the position gain values selected for the individual remaining Cs contour control axes is set automatically for the other Cs contour control axes and servo axes.
  3. Switching between spindle speed control and Cs contour control during automatic operation
     Switching is impossible during automatic operation and during axis movement.
     If switching from spindle speed control to Cs contour control or vice versa is made in the middle of a block executed in automatic operation, position gains do not change immediately; they are set automatically after all controlled axes are stopped completely.
  4. Similarly, when switching between spindle speed control and Cs contour control is made in other than automatic operation, automatic setting is performed after the completely stopped states of all controlled axes are confirmed

- Reference Position Return of Cs Contour Control Axis

After the serial spindle is switched from spindle speed control to Cs contour control mode, the current position is undefined. Return the spindle to the reference position.
The reference position return of the Cs contour control axis is as follows:

- In manual mode
  After the serial spindle enters the Cs contour control mode, move the spindle in the direction of the reference position by turning on the feed axis and direction select signal (+Jn <Gn100> or -Jn <Gn102>). The spindle starts the movement to the reference position; when it reaches that position, the reference position return completion signal ZPn <Fn094> turns to 1. Turning any feed axis and direction select signal to 1 moves the tool in the reference position direction.
- In the automatic mode
  (a) G00 command
     If a serial spindle is placed in the Cs contour control mode, then the G00 command is issued without performing reference position return even once when bit 1 (NRF) of parameter No. 3700 is 0, the serial spindle performs a reference position return.
     As G00 is specified, the serial spindle indexes the reference position, then performs positioning at a specified position.

Only when positioning at the reference position is performed, the reference position return completion signal ZPn <Fn094> is set to 1 after completion of the positioning operation.
When a reference position return has been performed at least once, a G00 command performs a normal positioning operation.
When a reference position return is performed manually or by using G28, the spindle is always positioned at the reference position; on the other hand, when a reference position return is performed by using G00, the spindle can be positioned at any specified position.

> **NOTE**
> Set bit 0 (ZRN) of parameter No.1005 to 1.

(b) G28 command
After the serial spindle is put in the Cs contour control mode, issuing the G28 command stops the spindle motor, then moves the spindle to the midpoint. The spindle then returns to the reference position. At this point, the reference position return completion signal ZPn <Fn094> turns to 1.
When the serial spindle has returned to the reference position once while in the Cs contour control mode, the G28 command positions the spindle at the reference position without moving to the midpoint and ZPn comes on.

- Reference position return speed
After the serial spindle is put in the Cs contour control mode, the reference position return speed is the value of reference position return speed in Cs contour control (parameter No.4074). When reference position return speed in Cs contour control (parameter No.4074) is set to 0, the reference position return speed is the value of maximum speed in Cs contour control (parameter No.4021).
- Interruption of reference position return
(a) Manual operation
Return to the reference position can be interrupted by resetting, emergency stop, or turning off the feed axis and direction select signal. When the interrupted return operation is resumed, start from the beginning.
(b) Automatic operation
Return to the reference position can be interrupted by resetting, emergency stop, or feed hold. When the interrupted return operation is resumed, start from the beginning.

- Operation of Cs contour control axis (Manual/Automatic)

If a reference position return is performed on the Cs contour control axis, the axis can be operated in the same way as a normal NC axis.

In the spindle speed control mode, on the other hand, it does not operate as the Cs contour control axis, and alarm PS0197, "C-AXIS COMMANDED IN SPINDLE MODE" occurs during automatic operation.
In the spindle speed mode, inhibit manual operation of the Cs contour control axis using the PMC ladder.

Diagnosis data

- Display of Position Error of Cs Contour Control Axis

418	**Position deviation amount of each spindle**

Position deviation amount of the position loop for the each spindle.
This diagnostic data shows information obtained from the serial spindle control unit. This diagnosis data position error of the CS contour axis during CS contour control.
The position error can also be checked using a servo error display (DGN of No. 300) for an axis under Cs contour control.

300	**Position deviation amount of each servo axis**

Spindle tuning screen

In the Cs contour control mode, indications related to the Cs contour control mode appear.
For details, please refer to Spindle tuning screen of MAINTENANCE MANUAL (B-64695EN).

Signal

Cs contour control change signal CON<Gn027.7>

[Classification] Input signal
[Function] This signal specifies that the first spindle be switched between the spindle speed control and Cs contour control modes.
This signal is valid when bit 7 (CSS) of parameter No. 3704 is 0.

Cs contour control change signals in each axis
CONS1<Gn274.0> : First spindle
CONS2<Gn274.1> : Second spindle
CONS3<Gn274.2> : Third spindle
CONS4<Gn274.3> : Fourth spindle

[Classification] Input signal
[Function] This signal specifies that the first spindle be switched between the spindle speed control and Cs contour control modes.
This signal is valid when bit 7 (CSS) of parameter No. 3704 is 1. In this case, Cs contour control change signal CON <Gn027.7> is invalid.

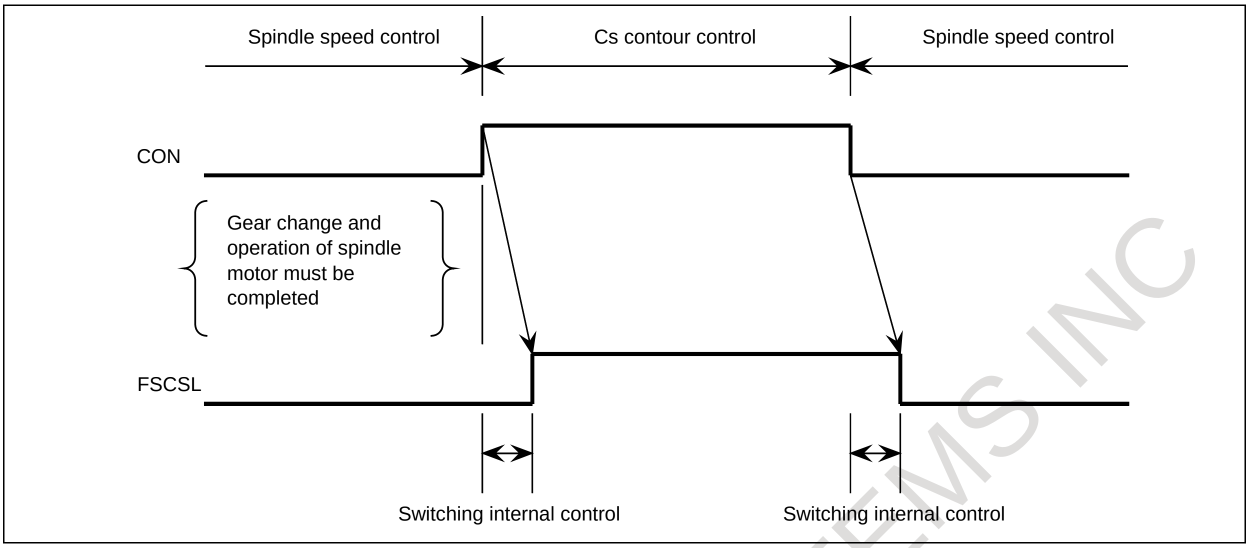
Cs contour control change completion signal FSCSL<Fn044.1>

[Classification] Output signal
[Function] This signal posts that the first spindle has switched to the Cs contour control mode.
[Output cond.] This signal is set to 1 when:
The spindle switches to the Cs contour control mode.
The signal is set to 0 when:
The spindle is not in the Cs contour control mode (is in the spindle speed control mode).
This signal is valid when bit 7 (CSS) of parameter No. 3704 is 0.

Cs contour control change completion signal in each axis
FCSS1<Fn274.0>:First spindle
FCSS2<Fn274.1>:Second spindle
FCSS3<Fn274.2>:Third spindle
FCSS4<Fn274.3>:Fourth spindle

[Classification] Output signal
[Function] This signal posts that the spindle has switched to the Cs contour control mode.
[Output cond.] This signal is set to 1 when:
The spindle switches to the Cs contour control mode.
The signal is set to 0 when:
The spindle is not in the Cs contour control mode (is in the spindle speed control mode).
This signal is valid when bit 7 (CSS) of parameter No. 3704 is 1. In this case, Cs contour control change completion signal FSCSL <Fn044.1> is invalid.

- Time Chart



NOTE
1. Any mechanical gear change needed and inputs for GR1, GR2, CTH1A, and CTH2A must be completed before the CON signal selects Cs contour control mode.
2. A servo excessive error may be generated if the spindle motor is not ready for operation. (Signal SRVA, SFRA <Gn070.4, 5> or other required signals must be appropriately processed on the machine side).
3. In the Cs contouring control mode, do not change the SFR (SRV) signal.

- Other signals

Gear select signals GR1O,GR2O,GR3O<Fn034.0 to 2>

[Classification] Output signal
[Function] This signal is output to the PMC to specify the gear stage.
[Output cond.] For information about this signal, see "SPINDLE SPEED CONTROL".

Gear select signals GR1,GR2<Gn028.1, Gn028.2>

[Classification] Input signal
[Function] This signal informs the CNC of the gear stage currently selected.
[Operation] For information about this signal, see "SPINDLE SPEED CONTROL".

Clutch/Gear signal (Serial spindle)
CTH1A,CTH2A<Gn070.3,Gn070.2> : First spindle
CTH1B,CTH2B<Gn074.3,Gn074.2> : Second spindle
CTH1C,CTH2C<Gn204.3,Gn204.2> : Third spindle
CTH1D,CTH2D<Gn266.3,Gn266.2> : Fourth spindle

Refer to the manual of serial spindle.

These signals determine what parameter (loop gain, etc.) to be used for each gear position.
CTH1 and CTH2 are the gear select signals for the serial spindle, but GR1 and GR2 must also be set. Do not change these signals while in the Cs contour control mode.

Relationship between gears selected and spindle gear select signals

CNC side							Serial spindle	
T/M series with CSSC			M series without CSSC					
GR2	GR1	Gear selection	GR3O	GR2O	GR1O	Gear selection	CTH1	CTH2
0	0	1st stage	0	0	0	1st stage	0	0
0	1	2nd stage	0	1	1	2nd stage	0	1
1	0	3rd stage	1	0	0	3rd stage	1	0
1	1	4th stage					1	1

CSSC: Constant surface speed control

NOTE
1. When the M series does not include the constant surface speed control (bit 0 (SSC) of parameter No. 8133=0), and bit 4 (GTT) of parameter No. 3706=0, GR1 and GR2 do not need to be input. Input CTH1 and CTH2 when gears are changed using GR1O, GR2O and GR3O that output from CNC.
2. The above combination of clutch/gear signals CTH1 and CTH2 is an example. The serial spindle gear is selected by CTH1 and CTH2 independently of gear selection on the CNC side. So, enter necessary signals, and set the corresponding serial spindle parameters.

Cs contour control axis reference position return completion signals ZP1 to ZP8<Fn094>

[Classification] Output signal

[Function] This signal indicates that a reference position return has been made for the Cs contour control axis.

ZPx

x : 1 ..... Reference position return completion signal of 1st spindle
2 ..... Reference position return completion signal of 2nd spindle
3 ..... Reference position return completion signal of 3rd spindle
: :
: :

[Output cond.] If a manual reference position return or automatic reference position return by G28 is performed during the Cs contour control mode, this signal becomes logical 1 when the Cs contour control axis reaches the reference position.

Signals on manual operation

Feed axis and direction select signal +Jn, -Jn <Gn100, Gn102> (Input) Manual handle feed axis select signal HSnA, HSnB, HSnC, HSnD <Gn018, Gn019> (Input) (Refer to respective items in this manual)

The Cs contour control axis can be manually operated in the same way as normal servo axes, except for a manual reference position return.

In the spindle speed control mode, however, manual operations for the Cs contour control axis must be inhibited using the PMC ladder, etc.

Parameter

Major related parameters are described below.
In addition to the parameters described below, axis speed, acceleration, indication, and other parameters can be used. It is not necessary to set the digital servo parameters (parameters Nos. 2000 and up) for the axis used as the Cs contour control axis.

	#7	#6	#5	#4	#3	#2	#1	#0
1005								ZRNx

[Input type] Parameter input
[Data type] Bit axis

#0 ZRNx If a move command other than G28 is specified by automatic operation when no reference position return is performed yet after the power is turned on:
0: The alarm PS0224, "ZERO RETURN NOT FINISHED." is issued.
1: Operation is performed without issuing an alarm.

> **NOTE**
> 1 The state in which a reference position has not been established refers to the following state:
> - When an absolute position detector is not used and reference position return has not been performed even once after power-up
> - When an absolute position detector is used and the association of the machine position with the position detected with the absolute position detector has not been completed (See the description of bit 4 (APZx) of parameter No. 1815.)
>
> 2 When the Cs axis coordinates are to be set up, set this parameter to 0.
> 3 To use a function that establishes the reference point and makes a movement with a command other than G28, such as an axis of Cs contour control, set this parameter to 1.

	#7	#6	#5	#4	#3	#2	#1	#0
1006					DIAx		ROSx	ROTx

[Input type] Parameter input
[Data type] Bit axis

> **NOTE**
> When at least one of these parameters is set, the power must be turned off before operation is continued.

#0 ROTx Setting linear or rotation axis.
#1 ROSx

ROSx	ROTx	Meaning
0	0	Linear axis (1) Inch/metric conversion is done. (2) All coordinate values are linear axis type. (Is not rounded in 0 to 360°) (3) Stored pitch error compensation is linear axis type (Refer to parameter No. 3624)
0	1	Rotary axis (A type) (1) Inch/metric conversion is not done. (2) Machine coordinate values are rounded in 0 to 360°. Absolute coordinate values are rounded or not rounded by bits 0 (ROAx) and 2 (RRLx) of parameter No. 1008. (3) Stored pitch error compensation is the rotation type. (Refer to parameter No. 3624) (4) Automatic reference position return (G28, G30) is done in the reference position return direction and the move amount does not exceed one rotation.

ROSx	ROTx	Meaning
1	1	Rotary axis (B type) (1) Inch/metric conversion is not done. (2) Machine coordinate values, absolute coordinate values and relative coordinate values are linear axis type. (Is not rounded in 0 to 360°). (3) Stored pitch error compensation is linear axis type (Refer to parameter No. 3624) (4) Cannot be used with the rotary axis roll-over function and the index table indexing function (M series)
Except for the above.		Setting is invalid (unused)

Set a Cs contouring control axis as a rotation axis.

> **NOTE**
> 1 Inch/metric conversion is not performed on rotation axes.
> 2 For rotation axes, the machine coordinate system is normalized to the range from 0 to 360 degrees. Automatic reference position return (G28, G30) is done in the direction of manual reference position return and the amount of travel does not exceed one turn.

#3 DIAx The move command for each axis is based on:
0: Radius specification
1: Diameter specification

For a Cs contouring control, set 0.

	#7	#6	#5	#4	#3	#2	#1	#0
1013							ISCx	ISAx

[Input type] Parameter input
[Data type] Bit axis

> **NOTE**
> When at least one of these parameters is set, the power must be turned off before operation is continued.

#0 ISAx
#1 ISCx Increment system of each axis

Increment system	Bit 1 (ISC)	Bit 0 (ISA)
IS-A	0	1
IS-B	0	0
IS-C	1	0

1022	Setting of each axis in the basic coordinate system

[Input type] Parameter input
[Data type] Byte axis
[Valid data range] 0 to 7

To determine a plane for circular interpolation, cutter compensation, and so forth (G17: Xp-Yp plane, G18: Zp-Xp plane, G19: Yp-Zp plane), specify which of the basic three axes (X, Y, and Z) is used for each control axis, or a parallel axis of which basic axis is used for each control axis.
A basic axis (X, Y, or Z) can be specified only for one control axis.
Two or more control axes can be set as parallel axes for the same basic axis.

Setting	Meaning
0	Rotary axis (Neither the basic three axes nor a parallel axis)
1	X axis of the basic three axes
2	Y axis of the basic three axes
3	Z axis of the basic three axes
5	Axis parallel to the X axis
6	Axis parallel to the Y axis
7	Axis parallel to the Z axis

In general, the increment system and diameter/radius specification of an axis set as a parallel axis are to be set in the same way as for the basic three axes.

For a Cs contouring control, set 0.

1023	Number of the servo axis for each axis

NOTE
When this parameter is set, the power must be turned off before operation is continued.

[Input type] Parameter input
[Data type] Byte axis
[Valid data range] 0 to 80
This parameter associates each control axis with a specific servo axis. Specify values 1+8n, 2+8n, 3+8n, 4+8n, 5+8n, and 6+8n (n = 0, 1, 2, …, 9) like 1, 2, 3, 4, 5, …, 77, and 78.
The control axis number is the order number that is used for setting the axis-type parameters or axis-type machine signals
With an axis for which Cs contour control/spindle positioning is to be performed, set -(spindle number) as the servo axis number.
Example)When exercising Cs contour control on the fourth controlled axis by using the first spindle, set -1.

1260	The shift amount per one rotation of a rotary axis

NOTE
When this parameter is set, the power must be turned off before operation is continued.

[Input type] Parameter input
[Data type] Real axis
[Unit of data] deg
[Min. unit of data] Depend on the increment system of the applied axis
[Valid data range] 0 or positive 9 digit of minimum unit of data (refer to the standard parameter setting table (B))
(When the increment system is IS-B, 0.0 to +999999.999)
Set the shift amount per one rotation of a rotary axis.

For the rotary axis used for cylindrical interpolation, set the standard value.

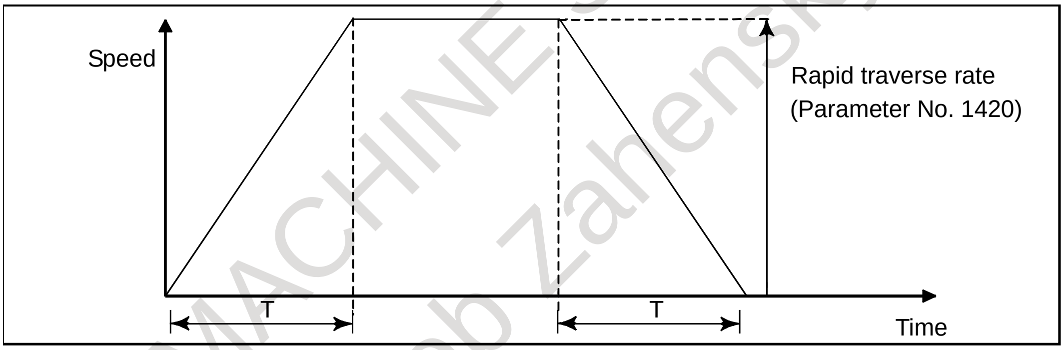
For a Cs contouring control, set 360.0.

1420	Rapid traverse rate for each axis

[Input type] Parameter input
[Data type] Real axis
[Unit of data] mm/min, inch/min, deg/min (machine unit)
[Min. unit of data] Depend on the increment system of the applied axis
[Valid data range] Refer to the standard parameter setting table (C)
(When the increment system is IS-B, 0.0 to +999000.0)
Set the rapid traverse rate when the rapid traverse override is 100% for each axis.

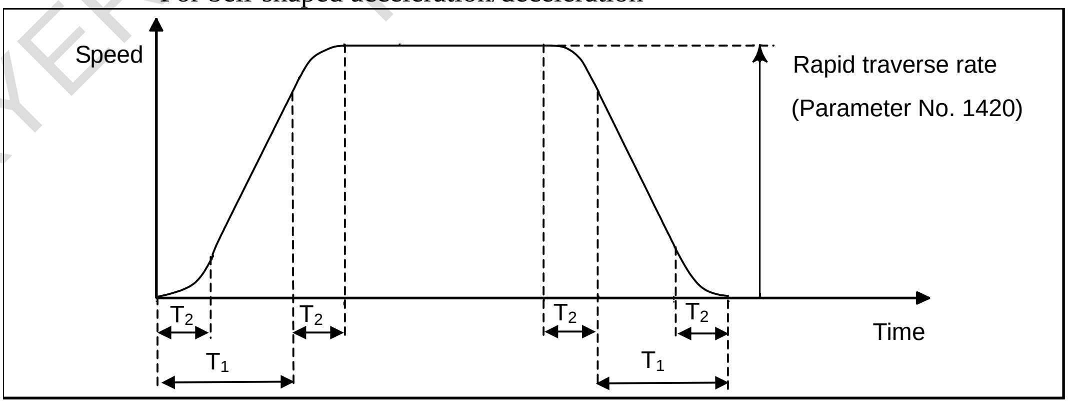
1620	Time constant T or T1 used for linear acceleration/deceleration or bell-shaped acceleration/deceleration in rapid traverse for each axis

[Input type] Parameter input
[Data type] Word axis
[Unit of data] msec
[Valid data range] 0 to 4000
Specify a time constant used for acceleration/deceleration in rapid traverse.
[Example]
For linear acceleration/deceleration



T : Setting of parameter No. 1620

For bell-shaped acceleration/deceleration



T_1 : Setting of parameter No. 1620
T_2 : Setting of parameter No. 1621
(However, $T_1 \geq T_2$ must be satisfied.)
Total acceleration (deceleration) time : $T_1 + T_2$
Time for linear portion : $T_1 - T_2$
Time for curve portion : $T_2 \times 2$

1621	Time constant T_2 used for bell-shaped acceleration/deceleration in rapid traverse for each axis

[Input type] Parameter input
[Data type] Word axis
[Unit of data] msec
[Valid data range] 0 to 512

Specify time constant T_2 used for bell-shaped acceleration/ deceleration in rapid traverse for each axis.

	#7	#6	#5	#4	#3	#2	#1	#0
1814	ALGx							

[Input type] Parameter input
[Data type] Bit axis

#7 ALGx The servo axis loop gain in the Cs contour control mode is:
0: Not matched with the Cs contour control loop gain.
1: Matched with the Cs contour control loop gain.

NOTE
1 For those axes that are used for EGB, spindle positioning, index table indexing, PMC axis control, rigid tapping, and so forth, set this parameter to 0 (Not matched with the Cs contouring control loop gain).
2 When specifying axes subject to interpolation with the Cs contouring control axis by using parameter No. 39n0 (n = 0 to 4), set this parameter to 0.
3 When making a setting so that a position gain is automatically set at the time of Cs contouring control switching by setting bit 7 (ALG) of parameter No. 1814 to 1, set all of parameter No. 39n0 (n = 0 to 4) to 0.

1820	Command multiplier for each axis (CMR)

NOTE
When this parameter is set, the power must be turned off before operation is continued.

[Input type] Parameter input
[Data type] Byte axis
[Unit of data] 0.5 times
[Valid data range] 1 to 96

For a Cs contouring control, set 2.

1825	Servo loop gain for each axis

[Input type] Parameter input
[Data type] Word axis
[Unit of data] 0.01/sec
[Valid data range] 1 to 32767

Set the loop gain for position control for each axis.

> **NOTE**
> If there is a servo axis that is subject to interpolation with the Cs contouring control axis, set parameters Nos. 3900 to 3944 to match the loop gain of the Cs contouring control axis to that of the servo axis in the Cs contour control mode.

1826	In-position width for each axis

[Input type] Parameter input
[Data type] 2-word axis
[Unit of data] Detection unit
[Valid data range] 0 to 99999999

The in-position width is set for each axis.
When the deviation of the machine position from the specified position (the absolute value of the positioning deviation) is smaller than the in-position width, the machine is assumed to have reached the specified position. (The machine is in the in-position state.)

1828	Positioning deviation limit for each axis in movement

[Input type] Parameter input
[Data type] 2-word axis
[Unit of data] Detection unit
[Valid data range] 0 to 99999999

Set the positioning deviation limit in movement for each axis.
If the positioning deviation exceeds the positioning deviation limit during movement, a servo alarm SV0411, "EXCESS ERROR (MOVING)" is generated, and operation is stopped immediately (as in emergency stop).
Generally, set the positioning deviation for rapid traverse plus some margin in this parameter. Refer to the following set value.

$$\textbf{Setting value} = \frac{\textbf{Rapid traverse rate}^{(\textbf{Note 1})}}{\textbf{60} \times \textbf{Servo loop gain}^{(\textbf{Note 2})}} \times \frac{1}{\textbf{Detection unit}} \times 1.2 \textbf{ to } 1.5$$

> ⚠ **CAUTION**
> If this parameter is not set correctly, machine or workpiece can be damaged.

> **NOTE**
> 1 Usually, this value is parameter No.1420. When the maximal feedrate of each axis exceeds parameter No.1420 according to the command and override, the value is the maximal feedrate of the each axis.
> 2 Usually, this value is parameter No.1825. When the servo loop gains other than parameter No.1825 is effective, the value is actual servo loop gains.

1829	Positioning deviation limit for each axis in the stopped state

[Input type] Parameter input
[Data type] 2-word axis
[Unit of data] Detection unit
[Valid data range] 0 to 99999999

Set the positioning deviation limit in the stopped state for each axis.

If, in the stopped state, the positioning deviation exceeds the positioning deviation limit set for stopped state, a servo alarm SV0410, "EXCESS ERROR (STOP)" is generated, and operation is stopped immediately (as in emergency stop).

1830	Axis-by-axis positional deviation limit at servo-off time

[Input type] Parameter input
[Data type] 2-word axis
[Unit of data] Detection unit
[Valid data range] 0 to 99999999

This parameter is used to set a positional deviation limit at servo-off time, on an axis-by-axis basis.
If the value specified with this parameter is exceeded at servo-off time, a servo alarm SV0410, "EXCESS ERROR (STOP)" is issued to cause an immediate stop (same as an emergency stop).
Usually, set the same value as a positional deviation at stop time.

> **NOTE**
> If this parameter is set to 0, the positioning deviation is not checked in servo-off state.

1851	Backlash compensating value for each axis

[Input type] Parameter input
[Data type] Word axis
[Unit of data] Detection unit
[Valid data range] -9999 to 9999

Set the backlash compensating value for each axis.
When the machine moves in a direction opposite to the reference position return direction after the power is turned on, the first backlash compensation is performed.

	#7	#6	#5	#4	#3	#2	#1	#0
3700							NRF	

[Input type] Parameter input
[Data type] Bit path

#1 NRF With the first move command (G00) after switching the serial spindle to Cs contour control mode:
0: A reference position return operation is once performed then positioning is performed.
1: A normal positioning operation is performed.

	#7	#6	#5	#4	#3	#2	#1	#0
3704	CSS							

[Input type] Parameter input
[Data type] Bit path

> **NOTE**
> When this parameter is set, the power must be turned off before operation is continued.

#7 CSS On the each spindle, Cs contour control is:
0: Not performed.
1: Performed.

	#7	#6	#5	#4	#3	#2	#1	#0
3716								A/Ss

[Input type] Parameter input
[Data type] Bit spindle

> **NOTE**
> When this parameter is set, the power must be turned off before operation is continued.

#0 A/Ss Spindle motor type is :
0: Analog spindle.
1: Serial spindle.

> **NOTE**
> When a serial spindle is used, enable the spindle serial output (bit 5 (SSN) of parameter No.8133is 0).

3717	Motor number to each spindle

> **NOTE**
> When this parameter is set, the power must be turned off before operation is continued.

[Input type] Parameter input
[Data type] Byte spindle
[Valid data range] 0 to Maximum number of controlled axes
Set a spindle amplifier number to be assigned to each spindle.
0: No spindle amplifier is connected.
1: Spindle motor connected to amplifier number 1 is used.
2: Spindle motor connected to amplifier number 2 is used.
to
n: Spindle motor connected to amplifier number n is used.

3721	Number of gear teeth on the position coder side

[Input type] Parameter input
[Data type] Word spindle
[Valid data range] 0 to 9999
Set the number of gear teeth on the position coder side in speed control (such as feed per revolution).

3722	Number of gear teeth on the spindle side

[Input type] Parameter input
[Data type] Word spindle
[Valid data range] 0 to 9999

Set the number of gear teeth on the spindle side in speed control (such as feed per revolution).

> ⚠ **CAUTION**
> 1 Parameter No.3721 and No.3722 can not be used for thread cutting. If thread cutting was done by setting the any value on these parameters, the correct screw can't be cut.
> In the machine to do thread cutting, connect mechanically between the spindle and position coder by the gear ratio=1:1. And these parameters set the No.3721=0, No.3722=0.
> (It is the setting for the gear ratio 1:1.)
> 2 Parameter No.3721 and No.3722 can not be used for Cs contour control. If Cs contour control was done by setting the any value on these parameters, spindle can't move as commanded. In the machine to do Cs contour control, connect mechanically between the spindle and position coder by the gear ratio = 1:1. And these parameters set the No.3721=0, No.3722=0. (It is the setting for the gear ratio 1:1.)

	#7	#6	#5	#4	#3	#2	#1	#0
3729	CSCs				NCSs	CSNs		

[Input type] Parameter input
[Data type] Bit spindle

#2 CSNs When the Cs contour control mode is turned off, an in-position check is:
0: Performed.
1: Not performed.

> **NOTE**
> This parameter is Automatic setting parameter. For details, refer to the appendix "Automatic setting / Initial setting parameter" in this manual.

#3 NCSs When the Cs contour control mode is set:
0: Switching to Cs contour control is completed when the spindle activating current is on (the spindle amplifier is ready for operation in the Cs contour control mode).
1: Switching to Cs contour control is completed even when the spindle activating current is off (the spindle amplifier is not ready for operation in the Cs contour control mode).

If this parameter is set to 1, the Cs contour control switch end signal is output without waiting for the spindle to decelerate to a stop.

#7 CSCs The increment system of the Cs contour control axis is:
0: IS-B.
1: IS-C.

3900	Number of servo axis for interpolation with Cs contour control axis

[Input type] Parameter input
[Data type] Byte path
[Valid data range] 0 to number of controlled axes

Set the number of the servo axis to be used for interpolation with the Cs contour control axis. (For group 1)

> **NOTE**
> When there is no servo axis used for interpolation with the Cs contour control axis, set 0.

3901	Loop gain for servo axis for interpolation with Cs contour control axis (HIGH gear)

3902	Loop gain for servo axis for interpolation with Cs contour control axis (MEDIUM HIGH gear)

3903	Loop gain for servo axis for interpolation with Cs contour control axis (MEDIUM LOW gear)

3904	Loop gain for servo axis for interpolation with Cs contour control axis (LOW gear)

[Input type] Parameter input
[Data type] Word path
[Unit of data] 0.01/sec
[Valid data range] 0 to 9999

Set the servo loop gain for each spindle gear of the servo axis used for interpolation with the Cs contour control axis. (For group 1)

3910	Number of servo axis for interpolation with Cs contour control axis

[Input type] Parameter input
[Data type] Byte path
[Valid data range] 0 to number of controlled axes

Set the number of the servo axis to be used for interpolation with the Cs contour control axis. (For group 2)

> **NOTE**
> When there is no servo axis for interpolation with the Cs contour control axis, or when there is not more than one servo axis, set 0.

3911	Loop gain for servo axis for interpolation with Cs contour control axis (HIGH gear)

3912	Loop gain for servo axis for interpolation with Cs contour control axis (MEDIUM HIGH gear)

3913	Loop gain for servo axis for interpolation with Cs contour control axis (MEDIUM LOW gear)

3914	Loop gain for servo axis for interpolation with Cs contour control axis (LOW gear)

[Input type] Parameter input
[Data type] Word path
[Unit of data] 0.01/sec
[Valid data range] 0 to 9999

Set the servo loop gain for each spindle gear of the servo axis used for interpolation with the Cs contour control axis. (For group 2)

3920	Number of servo axis for interpolation with Cs contour control axis

[Input type] Parameter input
[Data type] Byte path
[Valid data range] 0 to number of controlled axes

Set the number of the servo axis to be used for interpolation with the Cs contour control axis. (For group 3)

> **NOTE**
> When there is no servo axis for interpolation with the Cs contour control axis, or when there is not more than two servo axes, set 0.

3921	Loop gain for servo axis for interpolation with Cs contour control axis (HIGH gear)

3922	Loop gain for servo axis for interpolation with Cs contour control axis (MEDIUM HIGH gear)

3923	Loop gain for servo axis for interpolation with Cs contour control axis (MEDIUM LOW gear)

3924	Loop gain for servo axis for interpolation with Cs contour control axis (LOW gear)

[Input type] Parameter input
[Data type] Word path
[Unit of data] 0.01/sec
[Valid data range] 0 to 9999

Set the servo loop gain for each spindle gear of the servo axis used for interpolation with the Cs contour control axis. (For group 3)

3930	Number of servo axis for interpolation with Cs contour control axis

[Input type] Parameter input
[Data type] Byte path
[Valid data range] 0 to number of controlled axes

Set the number of the servo axis to be used for interpolation with the Cs contour control axis. (For group 4)

> **NOTE**
> When there is no servo axis for interpolation with the Cs contour control axis, or when there is not more than three servo axes, set 0.

3931	Loop gain for servo axis for interpolation with Cs contour control axis (HIGH gear)

3932	Loop gain for servo axis for interpolation with Cs contour control axis (MEDIUM HIGH gear)

3933	Loop gain for servo axis for interpolation with Cs contour control axis (MEDIUM LOW gear)

3934	Loop gain for servo axis for interpolation with Cs contour control axis (LOW gear)

[Input type] Parameter input
[Data type] Word path
[Unit of data] 0.01/sec
[Valid data range] 0 to 9999

Set the servo loop gain for each spindle gear of the servo axis used for interpolation with the Cs contour control axis. (For group 4)

3940	Number of servo axis for interpolation with Cs contour control axis

[Input type] Parameter input
[Data type] Byte path
[Valid data range] 0 to number of controlled axes

Set the number of the servo axis to be used for interpolation with the Cs contour control axis. (For group 5)

> **NOTE**
> When there is no servo axis for interpolation with the Cs contour control axis, or when there is not more than four servo axes, set 0.

3941	Loop gain for servo axis for interpolation with Cs contour control axis (HIGH gear)

3942	Loop gain for servo axis for interpolation with Cs contour control axis (MEDIUM HIGH gear)

3943	Loop gain for servo axis for interpolation with Cs contour control axis (MEDIUM LOW gear)

3944	Loop gain for servo axis for interpolation with Cs contour control axis (LOW gear)

[Input type] Parameter input
[Data type] Word path
[Unit of data] 0.01/sec
[Valid data range] 0 to 9999

Set the servo loop gain for each spindle gear of the servo axis used for interpolation with the Cs contour control axis. (For group 5)

	#7	#6	#5	#4	#3	#2	#1	#0
4000					CSO			

[Input type] Parameter input
[Data type] Bit spindle

#3 CSO Direction of reference position return in Cs contour control

0: Reference position return is performed by rotating the spindle counterclockwise (when viewed from the motor output axis).

1: Reference position return is performed by rotating the spindle clockwise (when viewed from the motor output axis).

4021	Maximum speed in Cs contour control

[Input type] Parameter input
[Data type] Word spindle
[Unit of data] min^{-1}

Set the maximum speed of the spindle in Cs contour control.

4056	Gear ratio (HIGH gear)

4057	Gear ratio (MEDIUM HIGH gear)

4058	Gear ratio (MEDIUM LOW gear)

4059	Gear ratio (LOW gear)

[Input type] Parameter input
[Data type] Word spindle
[Unit of data] Motor speed per spindle rotation × 100
[Valid data range] 0 to 32767

Set the gear ratio of the spindle to spindle motor.

> **NOTE**
> When a serial spindle is positioned, set the gear ratio of the spindle to spindle motor.
> The gear ratio to be used for spindle operations is set by clutch/gear signals (serial spindle) CTH1s and CTH2s.

4069	Position gain in Cs contour control (HIGH gear)

4070	Position gain in Cs contour control (MEDIUM HIGH gear)

4071	Position gain in Cs contour control (MEDIUM LOW gear)

4072	Position gain in Cs contour control (LOW gear)

[Input type] Parameter input
[Data type] Word spindle
[Unit of data] 0.01/sec
[Valid data range] 0 to 32767

Set the position gain in Cs contour control.

4074	Reference position return speed in servo mode

[Input type] Parameter input
[Data type] Word spindle
[Unit of data] min^{-1}

As the spindle orientation speed in a servo mode (spindle positioning, rigid tapping, and so on), the spindle speed set in this parameter is used.

> **NOTE**
> When a serial spindle is positioned, the orientation (reference position return) speed depends on this parameter.

4135	Grid shift amount in Cs contour control

[Input type] Parameter input
[Data type] 2-word spindle
[Unit of data] Detection unit
[Valid data range] Within ±1 rotation (For 1-micron detection, for example, -360000 to 360000)

Set the grid shift amount (the distance from the one-rotation signal position to machine zero point) in Cs contour control.

	#7	#6	#5	#4	#3	#2	#1	#0
11802				KSV				

[Input type] Parameter input

[Data type] Bit axis

> **NOTE**
> When at least one of these parameters is set, the power must be turned off before operation is continued.

#4 KSV Servo axis is:
0: Enabled.
1: Disabled.

> **NOTE**
> 1 This setting is effective regardless of the value of parameter No. 1023.
> 2 If this setting is made for the axis subject to Cs axis contour/spindle positioning, Cs axis contour/spindle positioning will be disabled.

Alarm and message

Number	Message	Description
PS0194	SPINDLE COMMAND IN SYNCHRO-MODE	A Cs contour control mode, spindle positioning command, or rigid tapping mode was specified during the spindle synchronous control mode or spindle command synchronous control mode.
PS0197	C-AXIS COMMANDED IN SPINDLE MODE	The program specified a movement along the Cs-axis when the Cs contour control switching signal was off.
SP0752	SPINDLE MODE CHANGE ERROR	This alarm is generated if the system does not properly terminate a mode change. The modes include the Cs contour control, spindle positioning, rigid tapping, and spindle control modes. The alarm is activated if the spindle control unit does not respond correctly to the mode change command issued by the NC.

Caution

> ⚠ **CAUTION**
> 1 The M codes to specify Cs contour control mode switching must be assigned to M codes not buffered. (Parameters Nos. 3411 to 3420 and 11290 to 11299)
> 2 Avoid changing spindle gears in Cs contour control mode. When a gear change is required, be sure to perform the gear change in spindle speed control mode.
> 3 The following error compensation functions are enabled for the Cs contour control axis:
> Pitch error compensation, both-direction pitch error compensation, backlash compensation

⚠ CAUTION

4 For the axis under Cs contour control, the following functions cannot be used:
- Index table indexing
- Axis synchronous control
- Axis switching
- PMC axis control (However, it is possible to use under Cs contour control when Rapid traverse (00h), Cutting feed (01h), Continuous feed (06h), Machine coordinate system selection (20h), Speed command (10h) and position control is selected.
(when bit 2(VCP) of parameter No.8007 is set to 1 and bit 1 (EVP) of No.8005is set to 1))
- Polar coordinate command
- Removal of controlled axis

5 In the Cs contour control mode, when an axis control parameter for the Cs contour control axis such as the acceleration/deceleration time constant is changed, the new parameter value does not become valid immediately. The new parameter value becomes valid after the Cs contour control mode is canceled then entered again.

6 When the position gain is automatically set at Cs contour control switching (when bit 7 (ALG) of parameter No. 1814 is set to 1), changing the setting in parameters Nos. 4069 to 4072 of the loop gain corresponding to the selected spindle gear does not make the new setting valid immediately.
To make the new setting valid, cancel the Cs contour control mode, then set the Cs contour control mode again. If more than one Cs contour control axis is present, however, the newly set value is included in the position gain values selected for these axes among which the smallest value is to be selected.

7 When the axis under Cs contour control is turned by speed command (10h) of PMC axis control, it is necessary to set parameter No.2023 (Number of velocity pulses(PULCO)).

Reference item

For details of the parameters (parameters Nos. 4000 to 4539), signals, and alarms for the serial spindle control unit, refer to the following manuals of serial spindles:
FANUC AC SPINDLE MOTOR α*i* series PARAMETER MANUAL (B-65280EN)

10.11.2 Cs Contour Control Torque Limit Skip

Overview

This function enables a torque limit skip for the Cs contour control axis.

Explanation

Torque limit command signal TLMH and load detection signal LDT1 for serial spindles are used to make a torque limit skip for the Cs contour control axis.
With this function, if load detection signal LDT1 of a serial spindle operated under Cs contour control is set to 1 when a torque limit skip is specified (G31 P98/P99), skip processing is performed.

To use this function, make the following settings:
(1) Set bit 0 (CST) of parameter No. 6215 for the corresponding Cs contour control axis to 1.
(2) Set a torque limit in parameter No. 4025. (Unit: %, maximum torque ratio)

(3) Set torque limit command signal TLMH to 1. In this signal state, the output torque is limited to the value set in parameter No. 4025.
(4) Set the load detection level in parameter No. 4026. This setting must be slightly smaller than the torque limit set in step (2) above.

When this load detection level is reached, load detection signal LDT1 is output, enabling skip processing if a torque limit skip is specified (G31 P98/P99).

The other specifications are the same as for normal torque limit skip. For details of the torque limit skip, refer to the description of torque limit skip in "Connection Manual (Function)" and the description of torque limit skip in "Operator’s Manual".
For torque limit command signal TLMH and load detection signal LDT1 for serial spindles, refer to relevant manuals such as "FANUC Spindle Motor αi series PARAMETER MANUAL" (B-65280EN).

NOTE

The torque limit override function by address Q (when bit 0 (TQO) of parameter No. 6286 is set to 1) is disabled for Cs contour control axes. PMC sequence programs must be created so that Cs contour control axes are always placed in the torque limit state before the G31 P99/P98 is specified.

(Sample program)

```
O0012
:
Mxx (Specify torque limit from PMC)
:
G31 P99 C200.F100. (Torque limit skip command)
:
Mxx (Cancel torque limit from PMC)
:
M30
```

Signal

Torque limit command signal (serial spindle)

TLMHA<Gn070.1> : First spindle
TLMHB<Gn074.1> : Second spindle
TLMHC<Gn204.1> : Third spindle
TLMHD<Gn266.1> : Fourth spindle

[Classification] Input signal
[Function] These signals limit the output torque of the corresponding serial spindle to the value set in parameter No. 4025. To cause a torque limit skip for a Cs contour control axis, set this signal to 1. For details, refer to the relevant manual of the serial spindle.

Load detection signal (serial spindle)

LDT1A <Fn045.4> : First spindle
LDT1B <Fn049.4> : Second spindle
LDT1C <Fn168.4> : Third spindle
LDT1D <Fn266.4> : Fourth spindle

[Classification] Output signal
[Function] These signals are output when the load on the corresponding serial spindle has reached the value set in parameter No. 4026.
For details, refer to the relevant manual of the serial spindle.

Torque limit state signal (serial spindle)
TLMA <Fn045.6> : First spindle
TLMB <Fn049.6> : Second spindle
TLMC <Fn168.6> : Third spindle
TLMD <Fn266.6> : Fourth spindle

[Classification] Output signal

[Function] These signals are output when the torque is being limited by the corresponding torque limit command signal.
For details, refer to the relevant manual on the serial spindle.

Signal address

- For first serial spindle

	#7	#6	#5	#4	#3	#2	#1	#0
Gn070							TLMHA	
Fn045		TLMA		LDT1A				

- For second serial spindle

	#7	#6	#5	#4	#3	#2	#1	#0
Gn074							TLMHB	
Fn049		TLMB		LDT1B				

- For third serial spindle

	#7	#6	#5	#4	#3	#2	#1	#0
Gn204							TLMHC	
Fn168		TLMC		LDT1C				

- For fourth serial spindle

	#7	#6	#5	#4	#3	#2	#1	#0
Gn266							TLMHD	
Fn266		TLMD		LDT1D				

Parameter

	#7	#6	#5	#4	#3	#2	#1	#0
6215								CSTx

[Input type] Parameter input
[Data type] Bit axis

#0 CSTx On a Cs contour control axis, torque limit skip operation is:
0: Not performed.
1: Performed.
Torque limit skip operation is performed using the torque limit command signal TLMH and the load detection signal LDT1 of the serial spindle.

	#7	#6	#5	#4	#3	#2	#1	#0
4009				LDTOUT				

[Input type] Parameter input
[Data type] Bit spindle

#4 LDTOUT Whether to output the load detection signals (LDT1 and LDT2) during acceleration/deceleration:
0: Not output during acceleration/deceleration. (standard setting value)
1: Output (at all times) during acceleration/deceleration if the parameter-set level is exceeded.

4025	Torque limit value

[Input type] Parameter input
[Data type] Word spindle
[Unit of data] 1%
[Valid data range] 0to100

Set a torque limit value applicable when a torque limit command (TLMH) is specified. Specify limit value data, assuming that the maximum torque represents 100%.

4026	Load detection level 1

[Input type] Parameter input
[Data type] Word spindle
[Unit of data] 1%
[Valid data range] 0 to 100

Set the detection range of the load detection signal (LDT1).
When the motor output exceeds (setting data)% of the maximum output, the load detection signal LDT1 is set to 1.

NOTE
1 If torque limit skip is specified (with bit 0 of parameter No. 6215 set to 1) for a Cs contouring control axis, an excessive error check during a stop is not made for the axis when the load detection state (LDT1 = 1) is set while the torque limit command is specified (TLMH = 1) in the Cs contouring control mode.
2 If torque limit skip is specified (with bit 0 of parameter No. 6215 set to 1) for a Cs contouring control axis, an in-position check is not made for the axis when the load detection state (LDT1 = 1) is set in the Cs contouring control mode.

10.11.3 Cs Contour Control Arbitrary Reference Position Setting Function

Overview

When bit 0 (CRF) of parameter No. 3700 is set to 1, any position can be set as the reference position by the first reference position return command (G28 or a manual reference position return) issued after the serial spindle enters the Cs contour control mode.

Explanation

When the first reference position return command (G28 or a manual reference position return) is executed after the serial spindle enters the Cs contour control mode, a reference position return is performed with the current position assumed to be the reference position. Therefore, a spindle movement for positioning at the reference position is not made.
Since the reference position return operation does not involve positioning to a spindle position specific to the spindle, the cycle time can be reduced.

NOTE

1 The spindle position at a reference position set by a reference position return operation by using this function is not guaranteed to match the spindle position at a reference position set by a reference position return operation performed again after the Cs contour control mode is turned off then back on.
2 When an intermediate point is specified in G28, a movement to the intermediate point is made, then that position is set as the reference position.
3 When this function is used, and a G00 command is issued for a Cs contour control axis without performing a reference position return even once after the serial spindle is placed in the Cs contour control mode, alarm PS0303, "REFERENCE POSITION RETURN IS NOT PERFORMED" is issued even if bit 1 (NRF) of parameter No. 3700 is set to 0. A reference position return must always be performed using the G28 command.
4 When this function is used, grid shift at the time of reference position return (parameter No. 4135) is invalid.
5 In automatic phase matching of the spindle EGB, if the master axis is a Cs contour control axis, this function cannot be used.

Parameter

	#7	#6	#5	#4	#3	#2	#1	#0
3700							NRF	CRF

[Input type] Parameter input
[Data type] Bit path

#0 CRF Reference position setting at an arbitrary position under Cs contour control is:
0: Not used.
1: Used.

#1 NRF With the first move command (G00) after switching the serial spindle to Cs contour control mode:
0: A reference position return operation is once performed then positioning is performed.
1: A normal positioning operation is performed.

NOTE
When this function is used, an attempt to specify G00 for a Cs contour control axis without performing a reference position return operation even once after switching the serial spindle to the Cs contour control mode results in the alarm PS0303, "REFERENCE POSITION RETURN IS NOT PERFORMED" even if bit 1 (NRF) of parameter No. 3700 is set to 0. Be sure to perform a reference position return operation by specifying G28.

4135	Grid shift amount on Cs contouring control

[Input type] Parameter input
[Data type] 2-word spindle
[Unit of data] 1 pulse unit (=0.001°) (0.0001° when bit 0 (CS360M) of parameter No. 4005 is set to 1)
[Valid data range] -360000 to +360000
(-3,600,000 to +3,600,000 when bit 0 (CS360M) of parameter No. 4005 is set to 1)
Use this parameter to shift the machine reference position on Cs contouring control.

The machine reference position of the spindle shifts by the set number of pulses in the CCW direction.

Alarm and message

Number	Message	Description
PS0303	REFERENCE POSITION RETURN IS NOT PERFORMED	When the setting of a reference position at any position was possible in Cs contour control (bit 0 (CRF) of parameter No. 3700 = 1), a G00 command was issued for the Cs contour axis without a return to the reference position after the serial spindle was switched to Cs contour control mode. Perform a reference position return with a G28 command before issuing a G00 command.

Reference item

Manual name	Item name
CONNECTION MANUAL (FUNCTION) (This manual)	Cs contour control

10.11.4 Cs Contour Control Axis Coordinate Establishment

Overview

Shifting a serial spindle from spindle rotation control to Cs contour control results in its current position being lost.
This function is intended to establish the current position without making a reference position return. This is done by setting the Cs axis coordinate establishment request signal CSFIx<Gn274.4 to 7> to 1.

NOTE

Once the power has been turned on, this function remains enabled until the power is turned off after the return of the Cs contour axis to the reference position.
However, when you use αiCZ sensor (serial type) as a spindle sensor and the Z-phase signal is detected one or more times after power on, this function is available without reference position return.
Moreover, when you use a distance coded sensor and the Z-phase signal is detected three or more times after power on, this function is available without reference position return.
Moreover, when you use the serial type sensor (RCN2390F (made by HEIDENHAIN) etc.), which recognizes the position within one revolution just after power on, as a spindle sensor, this function is available without reference position return.

Explanation

- Setting

This function is enabled by setting bit 2 (CSF) of parameter No. 3712 and bit 5 (CSPTRE) of parameter No. 4353 to 1.
(Using this function requires resetting bit 7 (RFCHK3) of parameter No. 4016 to 0.)

Inhibit buffering with the M code (parameters Nos. 3411 to 3432 and 11290 to 11299) used to set the Cs axis coordinate establishment request signal CSFIx<Gn274.4 to 7> to 1.

- Cs axis coordinate establishment procedure

(1) Turn the Cs contour control mode ON, using the M code as a trigger, and set the Cs axis coordinate establishment request signal CSFIx<Gn274.4 to 7> to 1.
(2) The absolute, relative, and machine coordinate systems for the Cs axis are established if the Cs axis origin established state signal CSPENx is 1.
(Establishing the relative coordinate system requires setting bit 3 (PPD) of parameter No. 3104 to 1.)
(3) Once the coordinate systems are established, the reference position established signal ZRFx<Fn120.0 to 7> becomes 1. So, reset the Cs axis coordinate establishment request signal CSFIx<Gn274.4 to 7> to 0.
(4) Perform the FIN processing for the M code.

NOTE
1 When inputting the MRDY, SFR, and SRV signals from the PMC to serial spindles via the CNC, ensure they are input normally.
2 In an emergency stop or servo alarm condition, no Cs axis coordinate system can be established.
3 Do not shift the Cs contour axis when Cs axis coordinate establishment is under way.
4 Generally, when Cs contouring axis performs reference position return after power on, CSPENx becomes 1. However, CSPENx becomes 1 even without reference position return when the following sensors are used as spindle sensors.
- αiCZ sensor (serial type)
  When Z-phase signal is detected one or more times after power on, CSPENx becomes 1.
- Distance coded sensor
  When Z-phase signal is detected three or more time after power on, CSPENx becomes 1.
- The serial type sensor (RCN2390F (made by HEIDENHAIN) etc) which recognizes the position within one revolution just after power on, CSPENx becomes 1.

- Case in which no Cs axis coordinate establishment can be performed

If Cs axis coordinate establishment cannot be performed, alarm PS5346 is issued for the path where the absolute coordinates (workpiece coordinates) are is to be established.

The following conditions prevent Cs axis coordinate establishment.
- The Cs axis origin established state signal CSPENx is 0.
- An attempt to transfer positional information from the spindle amplifier has failed.
- The servo section is off when an attempt is made to start Cs axis coordinate establishment.
- The Cs axis is under synchronous control or superimposed control.
- An emergency stop condition has occurred during coordinate establishment.
- The Cs axis has exited composite control during coordinate establishment.
- An attempt has been made to start synchronous, composite, or superimposed control for the Cs axis during coordinate establishment.

The Cs axis coordinate establishment alarm signal CSFOx<Fn274.4 to 7> becomes 1 in the path to which the spindle is connected. So, reset the Cs axis coordinate establishment request signal CSFIx<Gn274.4 to 7> to 0.
Resetting the Cs axis coordinate establishment request signal CSFIx<Gn274.4 to 7> to 0 causes the Cs axis coordinate establishment alarm signal CSFOx<Fn274.4 to 7> to be reset to 0.

- Clearing alarm PS5346

Alarm PS5346 cannot be cleared before the Cs axis reference return position is established.
In the path where alarm PS5346 occurred, make a manual reference position return for the Cs axis.
Once the reference position has been established, a reset can clear alarm PS5346.

Performing a reset after the Cs contour control mode is exited enables alarm PS5346 to be cleared.

- Serial type sensor which recognizes the position within one revolution just after power on

When you use the serial type sensor which recognizes the position within one revolution just after power on, CSPENx becomes 1 without reference position return, and Cs Contour Control Axis Coordinate Establishment is available.

The example of applicable sensor is listed below.

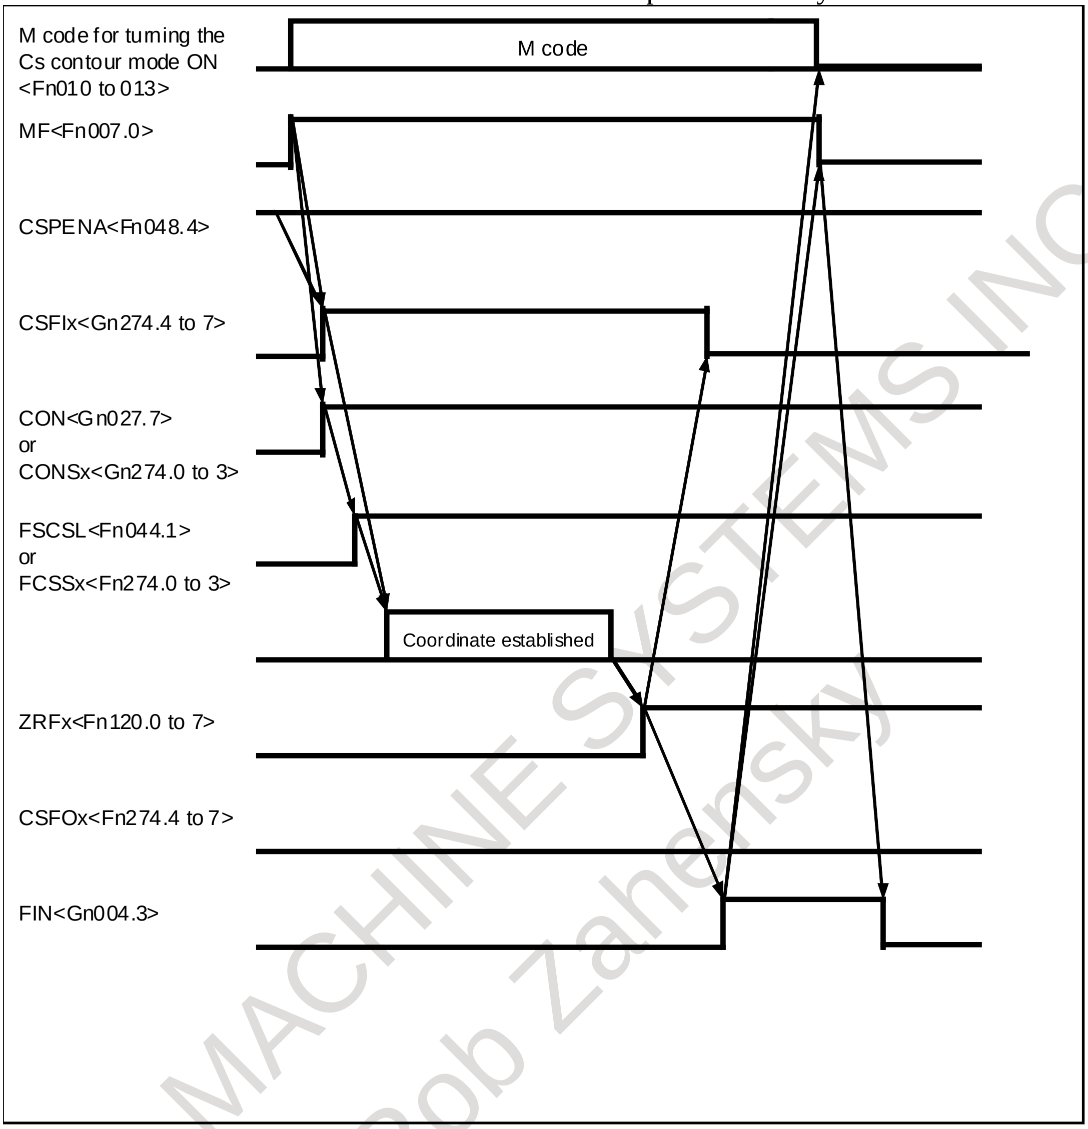
- HEIDENHAIN
  RCN2390F
  RCN2590F
  RCN5390F
  RCN5590F
  RCN8390F
  RCN8590F

NOTE

1 To use the above sensor, the corresponding spindle software is required.
2 To use the above sensor as a spindle sensor, the following parameters should be set.
   - No.4002(#3,#2,#1,#0)=(0, 1, 1, 0)
   - No.4361=8192
   - No.4548#0=1

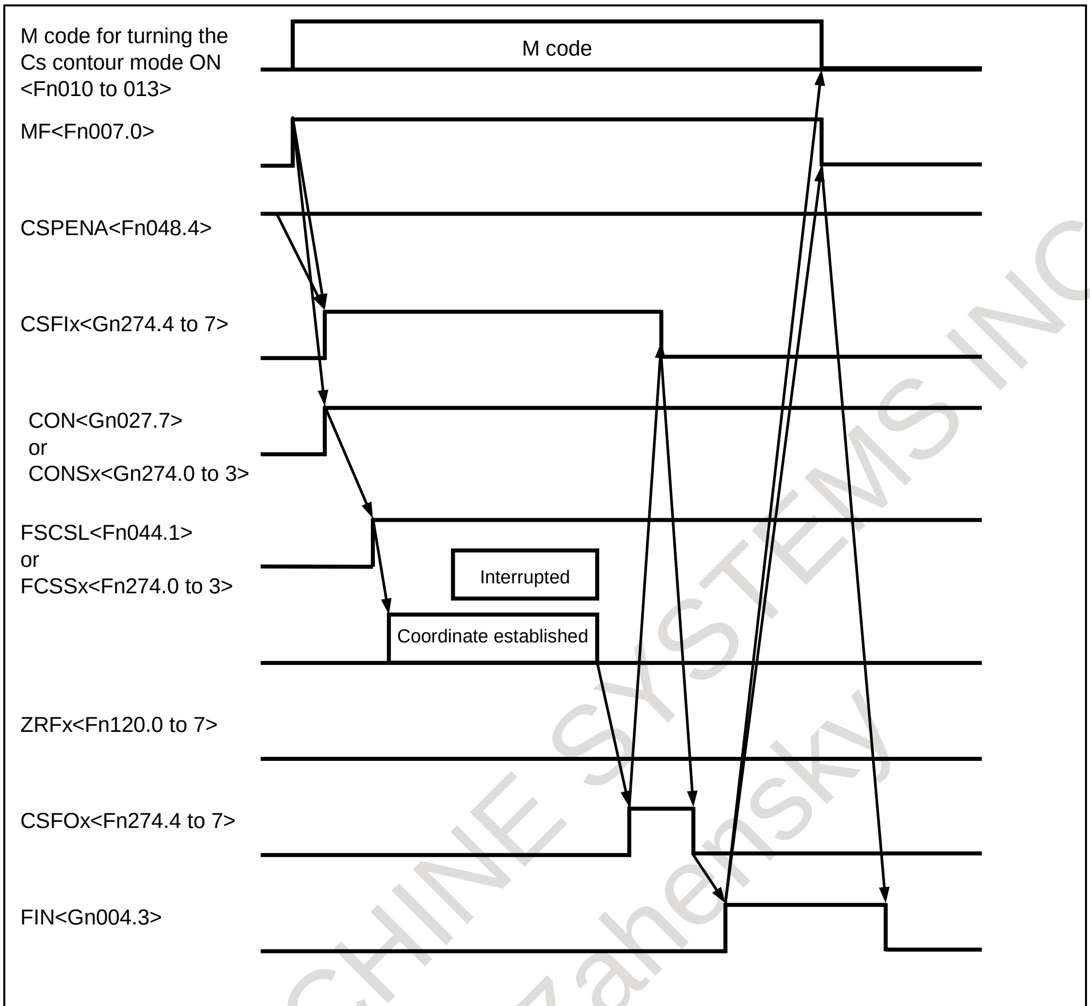
- Sequence (timing chart)

Case in which Cs axis coordinate establishment has been completed normally



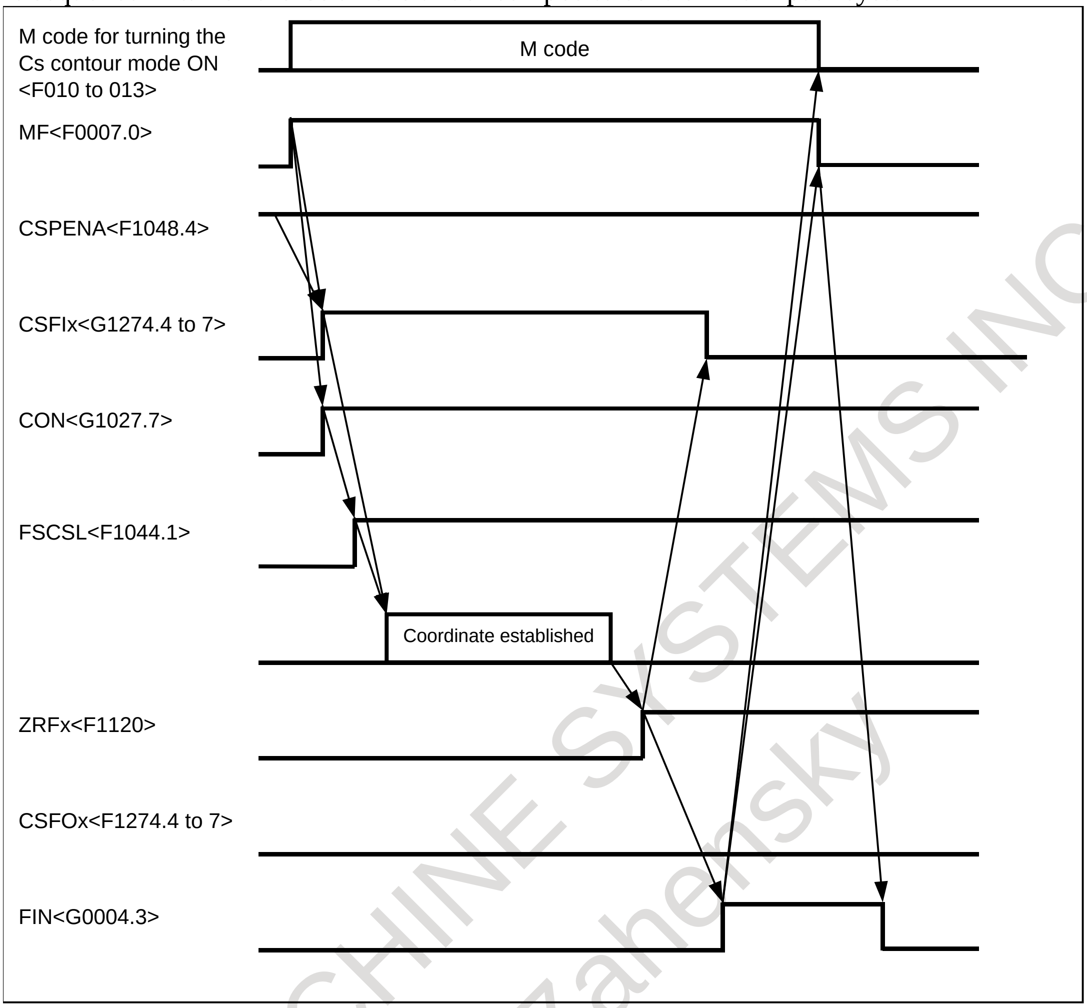
Cs axis coordinate establishment remains enabled in the Cs contour mode.
In any mode other than the Cs contour mode, setting the Cs axis coordinate establishment request signal CSFIx<Gn274.4 to 7> to 1 causes Cs axis coordinate establishment to be ignored.

Case in which Cs axis coordinate establishment cannot be achieved



A failure in coordinate establishment prevents the ZRFx signal <Fn120.0 to 7> from being set to "1".

Example sequence in which the Cs axis is under composite control in a 2-path system



(1) In path 1, issuing an M code causes the MF signal <F0007.0> to be set to 1.
(2) Make sure that the Cs origin established state signal CSPENA <F1048.4> in path 2 is 1, and set the Cs axis coordinate establishment request signal CSFI1<G1274.4> and Cs axis contour control switching signal CON<G1027.7> in path 2 to 1.
(3) The absolute and relative coordinates in path 1 and the machine coordinates in path 2 are established.
(4) Upon completion of count-up, the reference position establishment signal ZRFx<F0120.0 to 7> in path 2 becomes 1. So, reset the Cs axis coordinate establishment request signal CSFI1<G1274.4> in path 2 to 0.
(5) Perform FIN processing for the M code in path 1.

Note

- CMR

Set the command multiplier CMR (parameter No. 1820) for the Cs axis to be subjected to composite control to the same value. If it is set to a different value, coordinate establishment does not end normally.

- Axis synchronous control

Feed axis synchronization control cannot be used for the Cs contour control axis.

- Synchronous control

Setting the Cs axis establishment request signal CSFIx <Gn274.4 to 7> to 1 during synchronization control results in alarm PS5346.
After disabling synchronization control, perform Cs coordinate establishment, and then start synchronization control again.

- Composite control

Disabling or enabling composite control during Cs axis coordinate establishment results in alarm PS5346.

- Superimposed Control

Setting the Cs axis coordinate establishment request signal CSFIx <Gn274.4 to 7> to 1 during superimposed control results in alarm PS5346.
After disabling superimposed control, perform Cs coordinate establishment, and then start superimposed control again.

- Spindle command synchronous control

If the master axis is parked, coordinate establishment is performed according to the slave axis machine position.
Set the Cs axis coordinate establishment request signal CSFIx <Gn274.4 to 7> for the master axis to 1.
The Cs axis coordinate establishment alarm signal CSFOx <Fn274.4 to 7> that is output corresponds to the master axis.

- External machine coordinate system shift

Do not shift external machine coordinate systems during Cs axis coordinate establishment.

Signal

Cs axis coordinate establishment request signals CSFI1 to CSFI4<Gn274.4 to 7>

[Classification] Input signal

[Function] These signals perform the Cs axis coordinate establishment (Cs contour control function).

[Operation] When the signals become 1, the control unit behaves as follows:
- If the signals are 1 in the Cs contour control mode, the absolute and machine coordinates are established according to the Cs axis machine position.
- When the signals become 0, the control unit behaves as follows:
The Cs axis coordinate establishment alarm signal CSFOx<Fn274.4 to 7> becomes 0.

Cs axis coordinate establishment alarm signals CSFO1 to CSFO4<Fn274.4 to 7>

[Classification] Output signal

[Function] These signals indicate that Cs axis coordinate establishment has not been completed normally.

[Output cond.] These signal is 1 in the following case :
- Cs axis coordinate establishment has not been completed normally.

These signal is 0 in the following case :
- The Cs contour control mode is exited, or
- The corresponding Cs axis coordinate establishment request signal CSFIx<Gn274.4 to 7> becomes 0.

Cs axis origin established state signals
First spindle: CSPENA<Fn048.4>, Second spindle: CSPENB<Fn052.4>, Third spindle: CSPENC<Fn171.4>, Fourth spindle: CSPEND<Fn269.4>

[Classification] Output signal

[Function] These signals indicate that Cs coordinate establishment processing is available.

[Output cond.] These signal is 1 in the following case :

- A reference position return is completed normally in the Cs contour control mode.

These signal is 0 in the following case :

- A spindle alarm is detected or the spindle motor rotation speed exceeds the maximum allowable rotation speed (specified in parameter No. 4020).

CONNECTION MANUAL (FUNCTION) (This manual)	Cs contour control

10.11.5 Cs Contour Control Manual High-Speed Reference Position Return

Overview

This function makes it possible to perform high-speed type reference position return as manual reference position return after the reference position for the Cs contour control axis is established (ZRF <Fn120> = 1).

Explanation

As manual reference position return after the reference position for the Cs contour control axis is established,

- When the bit 6 (CHM) of parameter No. 3729 is set to 0:
  Spindle orientation is performed.
- When the bit 6 (CHM) of parameter No. 3729 is set to 1:
  High-speed type reference position return is performed.

Parameter

	#7	#6	#5	#4	#3	#2	#1	#0
3729		CHMs						

[Input type] Parameter input
[Data type] Bit spindle

#6 CHMs Manual reference position return after the reference position for the Cs contour control axis is established is performed as:
0: Spindle orientation operation.
1: High-speed type of reference position return operation.

Limitation

- Manual reference position return before the reference position is established

If manual reference position return is performed on the Cs contour control axis before the reference position is established, the return is performed as spindle orientation even if bit 6 (CHM) of parameter No. 3729 is set to 1.

10.12 MULTI-SPINDLE CONTROL

Overview

In addition to the first spindle, the second to fourth spindles can be controlled using an S command from the CNC.
Spindle commands are specified using a single S command as conventionally done. A spindle is selected depending on the signal from the PMC or the address P command.
Gear change between two stages can be made for the second, third, and fourth spindles in the same manner as for the first spindle.
A maximum speed can be set for each spindle, and the speed of each spindle can be clamped to the corresponding maximum speed (according to the setting in parameter No. 3772).
The position coder interfaces for the second to fourth spindles can be selected and added.
The first to fourth position coders are selected by signals from the PMC.

> **NOTE**
> Multi-spindle control can be used by setting bit 3(MSP) of parameter No.8133 to 1 and bit 1(EMS) of parameter No.3702 to 0.

Explanation

- Multi-spindle control in machining center

M

- Only when the T-type gear change is selected (when the constant surface speed control function is enabled(bit 0(SCC) of parameter No.8133 is 1)or when bit 4 (GTT) of parameter No. 3706 is set to 1), multi-spindle control is enabled.
- For information about rigid tapping, see "RIGID TAPPING".

- Control methods

There are three types of multi-spindle control methods: a method that can use the SIND (spindle motor speed control by the PMC) function only for the first spindle (TYPE-A), a method that can use the SIND function for the four spindles independently (TYPE-B), and a method that is equivalent to TYPE-B and can use address P to select the spindle to be controlled by the S command.

Basic control 1 (Common to TYPE-A and TYPE-B)

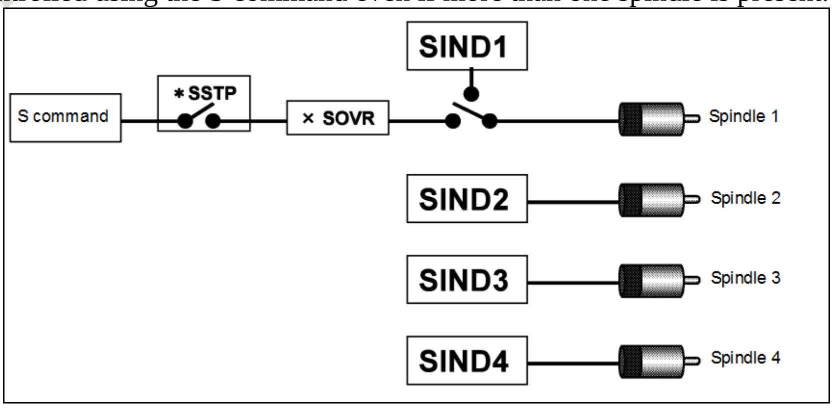
An S command is sent as a speed command to each spindle selected, using a spindle selection signal (SWS1 to SWS4 <Gn027.0-2>, <Gn026.3>). Each spindle rotates at the specified speed. If a spindle is not sent a spindle selection signal, it continues to rotate at its previous speed. This allows the spindles to rotate at different speeds at the same time.

Basic control 2 (Common to TYPE-A, TYPE-B, and the method of making spindle selection by address P)

Each spindle also has a spindle stop signal (*SSTP1 to *SSTP4 <Gn027.3-5>, <Gn026.6>) to stop its rotation; an unused spindle can still be stopped.
There is a spindle enable signal to control each spindle; ENB <Fn001.4> controls the first spindle, while ENB2 to ENB4 <Fn038.2, 3>, <Fn039.1> control the second and third spindles, respectively.
The selection of the position coder by the position coder select signals PC2SLC, PC3SLC, and PC4SLC <Gn028.7>, <Gn026.0>, <Gn026.1> is used to select between the first to fourth position coders.

When multi-spindle control is disabled

When bit 1 (EMS) of parameter No. 3702 is 1, multi-spindle control is disabled. In this case, only the first spindle can be controlled using the S command even if more than one spindle is present.



Multi-spindle control (TYPE-A)

When bit 2 (MSI) of parameter No. 3709=0, TYPE-A is used.
When the first spindle is selected with the SWS1 signal, the SIND signal <Gn033.7> is used to determine whether the spindle analog voltage is controlled by the PMC or CNC; then signals R01I to R12I

<Gn032.0 to Gn033.3> are used to set that spindle's analog voltage. These signals do not affect the second to fourth spindles.
The PMC-based polarity (rotation direction) control signals SGN<Gn033.5> and SSIN <Gn033.6> will function for any spindle selected by SWS1 to SWS4.
The concept of Type A multi-spindle control is outlined below (Fig. 10.12 (a)).

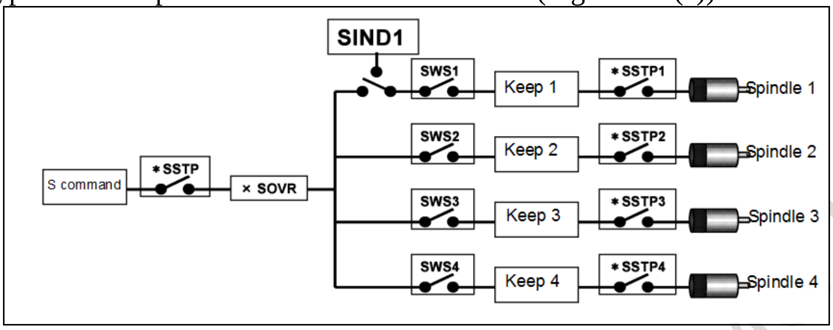


Fig. 10.12 (a)

Multi-spindle control (TYPE-B)

Select Type B control by setting bit 2 (MSI) of parameter No. 3709 to 1.
Each spindle has its own SIND, SSIN and SGN signals.
Each of these signals functions regardless of selection state of the spindle selection signals (SWS1 to SWS4).
When either the spindle selection signals (SWS1 to SWS4) or the SIND signal for the first, second, third, or fourth spindle is set to 1, the polarity control signals SSIN, SGN will function.
The concept of Type B multi-spindle control outlined below (Fig. 10.12 (b)).

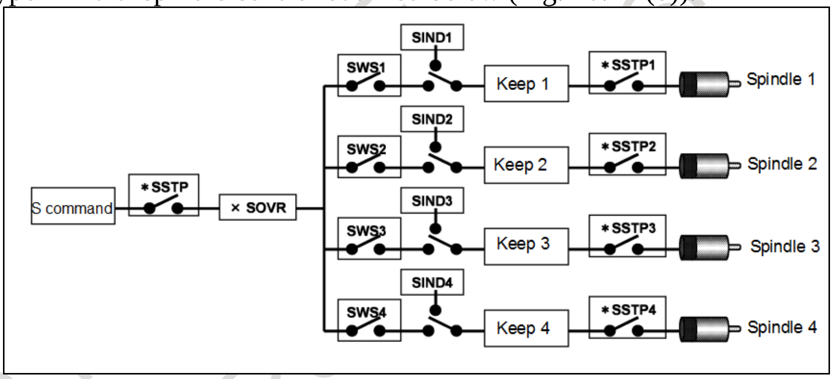

Fig. 10.12 (b)

Multi-spindle control: when a spindle is selected by address P

If bit 3 (MPP) of parameter No. 3703 is set to 1, a spindle is selected by address P. This control method is basically the same as TYPE-B. The first, second, third, and fourth spindles each have their own SIND, SSIN, and SGN signals. A spindle is selected by the P command instead of the spindle selection signals (SWS1 to SWS4). The relationship between the P code and the selected spindle is set in parameter No. 3781.
Polarity (rotation direction) control signals SSIN and SGN for each spindle are valid only for the spindle selected by the P command or for the spindle of which SIND signal is 1.
The concept of multi-spindle control (spindle selection by address P) is outlined below (Fig. 10.12 (c)).

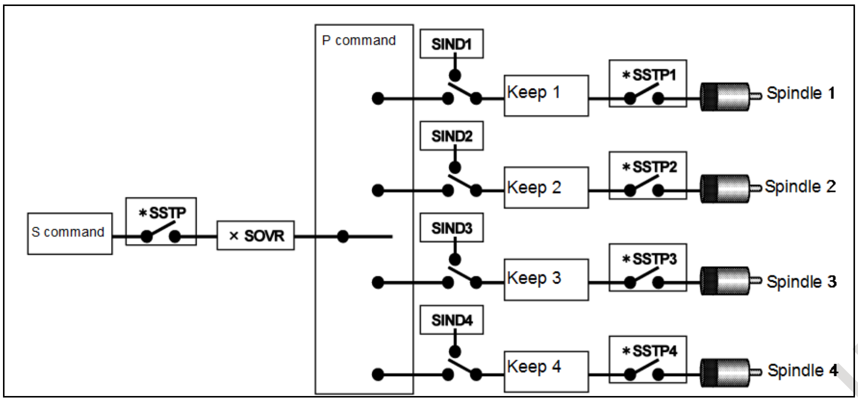

Fig. 10.12 (c)

In case of multi-path control, the P code becomes valid in all paths. For example, suppose that the P code to select the first spindle of path 2 is set to 21. When the following is specified in path 1:

S1000 P21;

Then, 1000 is specified for the first spindle in path 2. Therefore, the same P code cannot be used even in different paths.

- A spindle is selected by address P

Restrictions

The command for spindle selection by address P and the G code or M code including address P cannot be commanded on the same block. If you use the same address, it may result in the machine behaving unexpectedly. Command on separate block. About the function including address P, refer to the appendix “LIST OF FUNCTIONS INCLUDE ADDRESS P IN THE PROGRAM COMMAND”.

- Extended spindle name

Usually, S is used as commands for spindles. If the conditions listed below are all satisfied, extended spindle names can be used. Extended spindle names can consist of up to three characters beginning with S as the first spindle name character, and use of an extended spindle name allows a command to be executed for a specific spindle.

- The serial (analog) spindle function is enabled.
- The multi-spindle control is enabled.
- Bit 0 (EEA) of parameter No. 1000 is 1.
- Bit 3 (MPP) of parameter No. 3703 is 1.
- Bit 1 (ESN) of parameter No. 3798 is 1.
- Bit 4 (GTT) of parameter No. 3706 is 1. (for machining center system only)

As the second and third characters of spindle names, any characters from 0 to 9 and from A to Z may be set in ASCII code. In spindles, the third spindle name character is not valid unless the second spindle name character is set. If a character 0 to 9 is set as the second spindle name character, a character A to Z must not be set as the third spindle name character.

If a spindle name ends with a numeric character, ‘=‘ is required between the spindle name and a specified value.

	Spindle name 1st character (fixed)	Spindle name 2nd character (No.3738)	Spindle name 3rd character (No.3739)
Setting value	‘S’	‘0’ to ‘9’	‘0’ to ‘9’
		‘A’ to ‘Z’	‘0’ to ‘9’ ‘A’ to ‘Z’
Correct example <1>	‘S’	1	1
Correct example <2>		A	1
Correct example <3>		A	B
Incorrect example		1	A

In case of multi-path control, extended spindle names become valid in all paths. For example, suppose that the first spindle of path 2 is named SA. When the following is specified in path 1:

SA1000;

Then, 1000 is specified for the first spindle in path 2. Therefore, the same extended spindle name cannot be used even in different paths.

Restrictions

More than one extended spindle name cannot be specified within the same block. Also, ‘S’ and an extended spindle name cannot be specified together within the same block. If they are specified together, P/S alarm No. 333 is issued.
When extended spindle names are used, subscripts (MAIN (in parameter No. 3718), SUB (in parameter No. 3719) cannot be used.
When the custom macro function is enabled, the same extended spindle names as reserved words cannot be used. They are regarded as reserved words.
The target spindle for rigid tapping cannot be selected by specifying an extended spindle name.

Multi-spindle address P signal

When extended spindle names are used, the value in parameter No. 3781 corresponding to the spindle number of the spindle name specified last is output to MSP00 to MSP15 <Fn160.0 to Fn161.7>. If a command for a spindle has not been specified even once, the value set in parameter No. 3775 is output.

Supplement

When extended spindle names are used, the value of the spindle command specified last is indicated as the modal indication of S.
When the serial (analog) spindle function and multi-spindle control are enabled, the method for selecting the target spindle is determined according to the settings of bit 3(MPP) of parameter No. 3703 and bit 1 (ESN) of parameter No. 3798 as follows:

Bit 3 (MPP) of parameter No. 3703	Bit 1 (ESN) of parameter No. 3798	Method for selecting target
0	0	Signal selection
0	1	Signal selection
1	0	P command (S_ P_)
1	1	Specification of extended spindle name or P command (S_ P_)

If MPP and ESN are both set to 1, both the S_P_ command and extended spindle names can be used.

NOTE

Address S indicates a command for all spindles. When multiple spindles are used, and bit 3 (MPP) of parameter No. 3703 is 1, a particular spindle must be specified by using address P and so on. If spindle name S is set when extended spindle names are used, S indicates a particular spindle (except the command for clamping at the maximum spindle speed in constant surface control (G50(G92)S_)).

This means that if spindle name S is set when extended spindle names are used, a command specifying S only is a command for the spindle named S. (Even when P is specified in the same block, it is ignored.) When S is not set in a spindle name, a command specifying S only is regarded as a command for the spindle for which a command has been issued last. (This is the same as the operation of a command specifying only S when multiple spindles are used, extended spindle names are not used, and bit 2 (MPA) of parameter No. 3706 is set to 1.)

Example: When extended spindle names are used, and commands with extended spindle names and S_P_ commands are used together

1. When the first spindle is SA, the second spindle is SB, and 1 is set for the first spindle and 2 is set for the second spindle in parameter No. 3781

<u>If bit 2 (MPA) of parameter No. 3706 is 0</u>

N10 M03;
N20 SA100; → 100 is specified for 1st spindle.
N30 SB200; → 200 is specified for 2nd spindle.
N40 S200P1; → 200 is specified for 1st spindle.
N50 S300; → P/S alarm No. 5305 is issued.
N60 S200P2;
N70 S300;
N80 SA400;
N90 S500;
N100 SB400;
N110 S500;

<u>If bit 2 (MPA) of parameter No. 3706 is 1</u>

N10 M03;
N20 SA100; → 100 is specified for 1st spindle.
N30 SB200; → 200 is specified for 2nd spindle.
N40 S200P1; → 200 is specified for 1st spindle.
N50 S300; → 300 is specified for 1st spindle.
N60 S200P2; → 200 is specified for 2nd spindle.
N70 S300; → 300 is specified for 2nd spindle.
N80 SA400; → 400 is specified for 1st spindle.
N90 S500; → 500 is specified for 1st spindle.
N100 SB400; → 400 is specified for 2nd spindle.
N110 S500; → 500 is specified for 2nd spindle.

NOTE

2. When the first spindle is SA, the second spindle is S, and 1 is set for the first spindle and 2 is set for the second spindle in parameter No. 3781

   If bit 2 (MPA) of parameter No. 3706 is 0

   N10 M03;
   N20 SA100; → 100 is specified for 1st spindle.
   N30 S200P1; → 200 is specified for 2nd spindle.
   N40 S300; → 300 is specified for 2nd spindle.
   N50 S200P2; → 200 is specified for 2nd spindle.
   N60 S300; → 300 is specified for 2nd spindle.
   N70 SA400; → 400 is specified for 1st spindle.
   N80 S500; → 500 is specified for 2nd spindle.

   If bit 2 (MPA) of parameter No. 3706 is 1

   N10 M03;
   N20 SA100; → 100 is specified for 1st spindle.
   N30 S200P1; → 200 is specified for 2nd spindle.
   N40 S300; → 300 is specified for 2nd spindle.
   N50 S200P2; → 200 is specified for 2nd spindle.
   N60 S300; → 300 is specified for 2nd spindle.
   N70 SA400; → 400 is specified for 1st spindle.
   N80 S500; → 500 is specified for 2nd spindle.

Example

- Example of setting spindle names when extended spindle names are used
  No.3738=0,No.3739=0 → 'S'
  No.3738=65,No.3739=0 → 'SA'
  No.3738=66,No.3739=65 → 'SBA'
  No.3738=49,No.3739=0 → 'S1'
  No.3738=49,No.3739=48 → 'S10'
  No.3738=0,No.3739=65 → 'S'

- Specifying spindle names that end with a numeric character
  S1=100
  S11=200

- Specifying spindle names that end with an alphabetical character
  S100 or S=100
  SB200 or SB=200
  SBB300 or SBB=300

Override for individual spindles

Different override values can be applied to individual axes separately at a time. The override values can be selected from between 0% and 254%. This function is made usable by setting bit 3 (MSC) of parameter No. 3713 to 1 for multi-spindle control.

- Specification

When each spindle speed override function (bit 4 (EOV) of parameter No. 3713 =1) is effective, the specifications is as following.

- Override signals for each spindle are following.
  SOV0 to 7: Override signal for the first spindle
  SOV20 to 27: Override signal for the second spindle
  SOV30 to 37: Override signal for the third spindle
  SOV40 to 47: Override signal for the fourth spindle
- Because override is applied to individual axes separately, it is possible to use different values for each axis simultaneously.

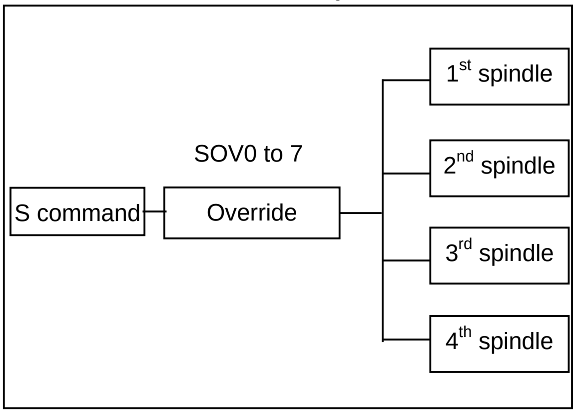

Fig. 10.12 (d) Bit 4 (EOV) of parameter No. 3713 = 0

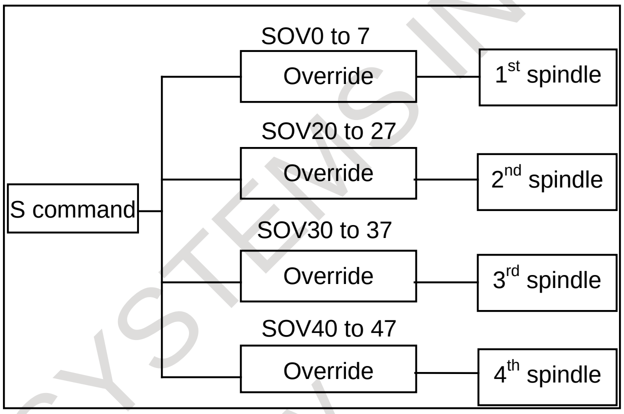

Fig. 10.12 (e) Bit 4 (EOV) of parameter No. 3713 = 1

Also for spindle control in a multi-path system, this function can be used to apply override to individual axes separately. Fig. 10.12 (f), “Bit 4 (EOV) of parameter No. 3713 = 0 (2-path system)” and Fig. 10.12 (g), “Bit 4 (EOV) of parameter No. 3713 = 1 (2-path system)” are examples of using this function for a 2-path system. In these examples, both path 1 and path 2 spindles are controlled by the spindle commands in path 2.

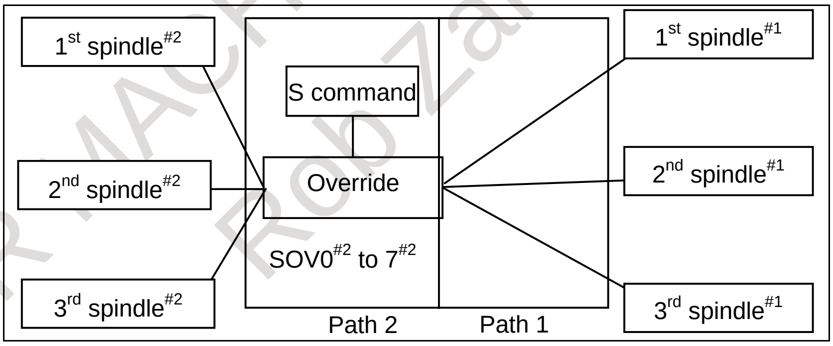

Fig. 10.12 (f) Bit 4 (EOV) of parameter No. 3713 = 0 (2-path system)

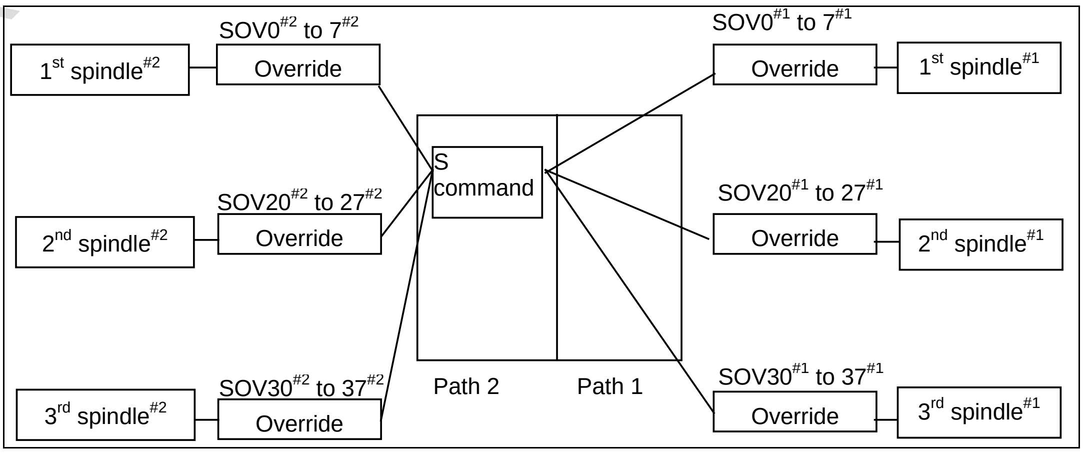

Fig. 10.12 (g) Bit 4 (EOV) of parameter No. 3713 = 1 (2-path system)

- Note

- Setting bit 5 (SOV) of parameter No. 3106 (spindle override value display) causes the override value for the first spindle to be displayed.
- When constant surface speed control is used, override is applied after the spindle rotation speed is clamped to the clamp speed specified by the spindle rotation speed clamp command (for the T series, G50S_, or for the M series, G92S_). Note, therefore, that if an override of 100% or higher is applied, the spindle may rotate faster than the specified clamp speed.
  Bit 5 (SOC) of parameter No. 3708 (for specifying to clamp the spindle rotation speed for constant surface speed control after spindle speed override is put into effect) is invalid. The note given above still applies even if this parameter is set. The spindle rotation speed can be clamped to the clamp speed specified as the spindle rotation speed upper limit (parameter No. 3772).
- When this function is in use, a spindle override of 100% is applied during tapping cycle mode operation (for the M series, G84 and G74 or, for the T series, G84 and G88) or threading operation (for the M series, G33 or, for the T series, G32, G92, and G76). Setting bit 6 (TSO) of parameter No. 3708 to 1 enables spindle override.
- For spindles not subjected to override, keep their spindle override signals set to 100%.
- No spindle override is applied to spindles which are under spindle rotation speed control directed by the PMC.

Position coder selection by address P (bit 6 (MPC) of parameter No. 3713=1)

When the spindle is selected by address P in multi-spindle control (bit 3 (MPP) of parameter No. 3703=1), position coder feedback is automatically selected by address P for feed per revolution, thread cutting, and so on.

- Explanation

When the spindle is selected by address P in multi-spindle control (bit 3 (MPP) of parameter No. 3703=1), the program of spindle selection by address P is as follows.

S_ P_ ;

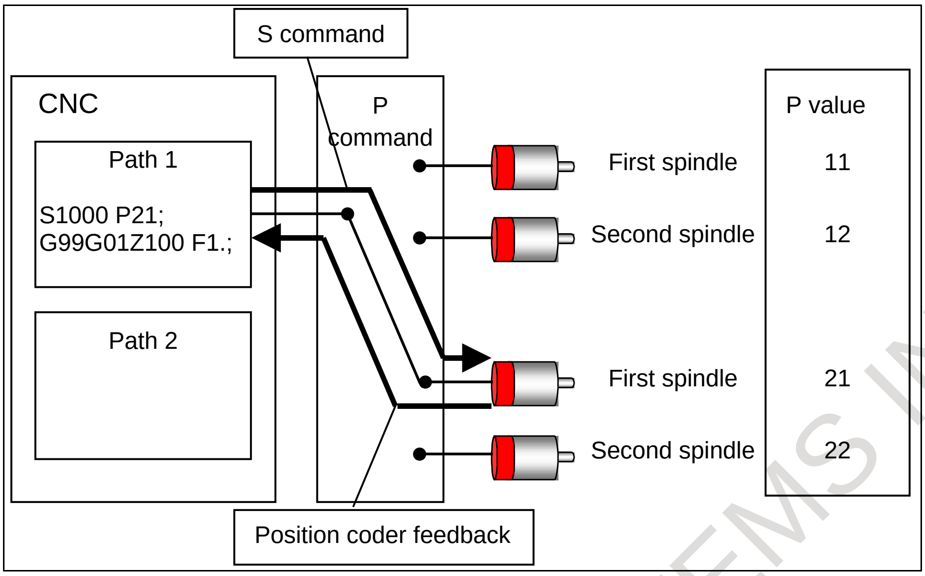
When the bit 6 (MPC) of parameter No. 3713 is set to 1, this command causes the position coder to be automatically selected according to the selected spindle. This condition is the same as the selection of the position coder by the position coder select signals PC2SLC<Gn028.7>, PC3SLC<Gn026.0> and PC4SLC<Gn026.1> and inter-path spindle feed-back signals SLPCA<Gn064.2>, SLPCB<Gn064.3>, SLPCC<Gn403.4>, and SLPCD<Gn403.5>. (These signals are ignored even if they are set from the PMC ladder.)

- Example

In the following program:

```
S1000 P21 ;
G99 G01 Z100. F1. ;
```

(1) The first spindle in path 2 is specified by S1000.
(2) Position coder feed-back for the first spindle in path 2 is selected automatically.
    (Used in feed per revolution)



- Relationship with other functions

Constant surface speed control

The control function for keeping the surface speed constant can be used with any of the four spindles, if the spindle speed is within the range allowable for this function. (If position coders are required, this function is enabled for serial spindles.) The spindle selection signal (SWS1 to SWS4) for the spindle must stay set at 1 during machining using this function.

Spindle speed fluctuation detection

When this function is used with multi-spindle control, multiple position coders can be used. So, when a spindle speed fluctuation is detected, attention must be paid to the states of the position coder selection signals (PC2SLC, PC3SLC, and PC4LC) and spindle selection signals (SWS1 to SWS4)

Actual spindle speed output

The actual spindle speed output function conveys speed information obtained from the position coder specified by the position coder selection signals (PC2SLC, PC3SLC, and PC4SLC) to the PMC.

Polygon turning

Polygon turning rotates a tool axis in phase with the spindle. To perform polygon turning when multi-spindle control issued, select the spindle and the position coder associated with the spindle.

Spindle synchronization, polygon turning between spindles, simplified synchronization control

During spindle synchronization, polygon turning between spindles or simplified synchronization control, the slave spindle operates in phase with the master spindle. Multi-spindle control for the master spindle can be used during synchronization control, but multi-spindle control for the slave spindle is disabled.

Rigid tapping

One of the first to fourth spindles can be selected as the rigid tapping axis according to the states of the spindle selection signals (SWS1 to SWS4) to perform rigid tapping. However, the following restrictions are imposed:

- Set the SWS1 to SWS4 signals before directing rigid tapping;
- Do not switch the SWS1 to SWS4 signals during rigid tapping; and
- Use the appropriate ENB signal (either ENB or ENB2) for the selected spindle as the ENB signal for the rigid tapping PMC sequence.

The spindles not used for rigid tapping can be rotated at a speed specified before rigid tapping starts, or can be stopped.

Ladder sequence (signal operation)

Outline of the CNC processing and the relation with the ladder

On multi-spindle control TYPE-A and TYPE-B, CNC considers S command (program command), signals related to S command (ex. Spindle override) and G-code (ex. G96/G97), and converts to the actual spindle rotation speed. Then CNC sends this value only to the spindle that is selected by spindle selection signals SWS1 to SWS4 <Gn027.0 to Gn027.2 and Gn026.3>. On this document, a series of this processing is called "S renewal processing". S renewal processing is asynchronously executed with the changing of the select/non-select condition of the spindle by ladder sequence. Therefore, the order of the changing of the select/non-select condition of each spindle and S command must be considered by the ladder sequence or the program command according to the necessity.

S command

Ladder can confirm the S command by SF signal. In case of waiting the completion of S renewal processing after the S command, please take time by using the timer of ladder and so on.
A necessary processing time to complete S renewal processing from the S command is 16msec. As for the output condition of SF signal, please refer to parameter No.3705. On T series system, please set EVS (Parameter No.3705#4) to "1" to output SF signal.

Time chart

The example of the time chart when executing the following program is shown.

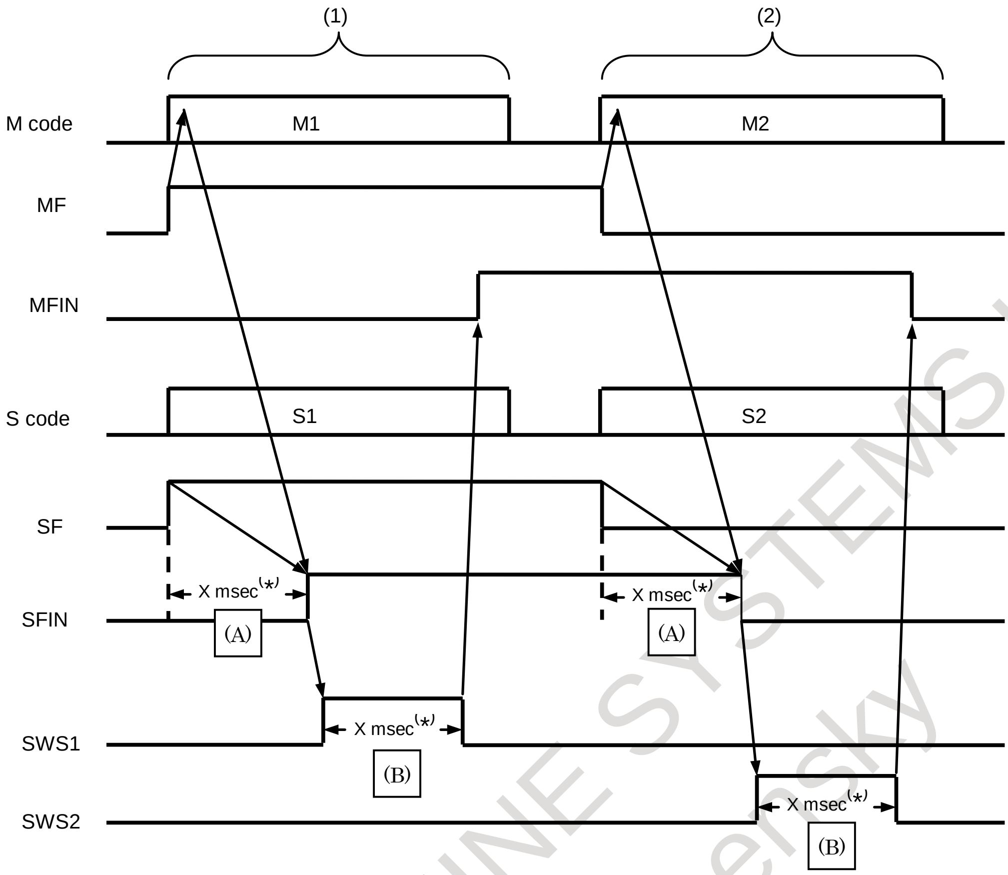
M1_ S1_ ; ………… (1)

M2_ S2_ ; ………… (2)

(1): The program to execute S command of S1_ to the 1st spindle.

(2): The program to execute S command of S2_ to the 2nd spindle. And at this time, the 1st spindle must keep S1_, which was commanded in (1).

The following time chart shows example in case of high-speed M/S/T/B. (bit 7 (MHI) of parameter No.3001)



(*) As for the value of "X msec", refer to the following Appendix 1.

In the time chart, it takes time to start S renewal processing of CNC in (A).
At this time, both SWS1 and SWS2 signals are "0". Therefore, S command is not forwarded to any spindle even when S renewal processing is completed.

It takes time to execute S renewal processing with selecting the objective spindle (SWSx=1) in (B).
At this time, the 1st spindle (or the 2nd spindle) is selected, the renewal S command is forwarded to the objective spindle after completing S renewal processing.

If (B) ends, please return all spindles to non-selected condition (SWSx=0).

(Supplement 1) The (A) part and the (B) part are timer of ladder sequence. As for X msec, please apply the value which suits the condition “X msec > 16 msec ”.

(Supplement 2) While machining by the constant surface control, the spindle must be always selected condition. Please refer to "Relationship with other functions" previously described.

Signal

Spindle selection signals SWS1,SWS2,SWS3,SWS4<Gn027.0,.1,.2>,<Gn026.3>

[Classification] Input signal

[Function] Controls whether S command specified to the NC is output to the spindle or not in multi-spindle control.

SWS1 1 : Outputs a speed command to the first spindle.
0 : Outputs no speed command to the first spindle.

SWS2 1 : Outputs a speed command to the second spindle.
0 : Outputs no speed command to the second spindle.

SWS3 1 : Outputs a speed command to the third spindle.
0 : Outputs no speed command to the third spindle.

SWS4 1 : Outputs a speed command to the fourth spindle.
0 : Outputs no speed command to the fourth spindle.

Individual spindle stop signals *SSTP1,*SSTP2,*SSTP3,*SSTP4<Gn027.3,.4,.5>,<Gn026.6>

[Classification] Input signal

[Function] Effective only to multi-spindle control, each spindle can be stopped by this signal.

*SSTP1 1 : Does not set 0 min^{-1} for output to the first spindle.
0 : Sets 0 min^{-1} for output to the first spindle.

*SSTP2 1 : Does not set 0 min^{-1} for output to the second spindle.
0 : Sets 0 min^{-1} for output to the second spindle.

*SSTP3 1 : Does not set 0 min^{-1} for output to the third spindle.
0 : Sets 0 min^{-1} for output to the third spindle.

*SSTP4 1 : Does not set 0 min^{-1} for output to the fourth spindle.
0 : Sets 0 min^{-1} for output to the fourth spindle.

Gear select signals GR11<Gn028.1>,GR12<Gn028.2>,GR21<Gn029.0>,GR22<Gn029.1>, GR31<Gn029.2>,GR32<Gn029.3>,GR41<Gn031.4>,GR42<Gn031.5>

[Classification] Input signal

[Function] Gear selection signals when multi-spindle control is equipped. These signals post the gear stage currently selected (4 stages).

Gear	GRs1	GRs2
Gear 1	0	0
Gear 2	1	0
Gear 3	0	1
Gear 4	1	1

(s is 1, 2, 3, or 4.)

Position coder selection signals PC2SLC<Gn028.7>,PC3SLC<Gn026.0>,PC4SLC<Gn026.1>

[Classification] Input signal

[Function] These signals select the position coder of the serial spindle used for multi-spindle control.

Position coder to be selected	PC2SLC	PC3SLC	PC4SLC
First position coder	0	0	0
Second position coder	1	0	0
Third position coder	0	1	0
Fourth position coder	0	0	1

If PC2SLC, PC3SLC, and PC4SLC are set to 1, the position coder of a lower number is selected.

When the second, third, or fourth position coder is not installed, do not switch this signal.

Always set 0 for first position coder.

Spindle enable signals
ENB<Fn001.4>,ENB2<Fn038.2>,ENB3<Fn038.3>,ENB4<Fn039.1>

[Classification] Output signal

[Function] These signals inform PMC of whether or not to perform output to the second to fourth spindles in multi-spindle control. The signals are used as a condition to stop the analog spindle, and are also used for a PMC ladder sequence that is associated with rigid tapping. (See "RIGID TAPPING.")

[Output cond.]

ENB	Enables output of command other than 0 to the first spindle control unit. Outputs 0 to the first spindle control unit.
ENB2	Enables output of command other than 0 to the second spindle control unit. Outputs 0 to the second spindle control unit.
ENB3	Enables output of command other than 0 to the third spindle control unit. Outputs 0 to the third spindle control unit.
ENB4	Enables output of command other than 0 to the fourth spindle control unit. Outputs 0 to the fourth spindle control unit.

Spindles control signal by PMC
For 1st spindle SIND,SSIN,SGN<Gn033.7,.6,.5>,R01I-R12I<Gn032.0-Gn033.3>
For 2nd spindle SIND2,SSIN2,SGN2<Gn035.7,.6,.5>,R01I2-R12I2<Gn034.0-Gn035.3>
For 3rd spindle SIND3,SSIN3,SGN3<Gn037.7,.6,.5>,R01I3-R12I3<Gn036.0-Gn037.3>
For 4th spindle SIND4,SSIN4,SGN4<Gn273.7,.6,.5>,R01I4-R12I4<Gn272.0-Gn273.3>

[Classification] Input signal

[Function] The spindle motor of each spindle can be controlled by issuing commands from the PMC. The speed command and polarity (rotation direction) of the spindle motor can be controlled. Usually, CNC commands are used to specify a speed and polarity. By using these signals, whether commands issued from the CNC or PMC are to be used for this control can be selected.

Even when multi-spindle control is not being used, the signals can be used to control the second to fourth spindles.

When multi-spindle control is being used, and TYPE-A is selected (bit 2 (MSI) of parameter No. 3709 is set to 0), the signals for the second to fourth spindles cannot be used.

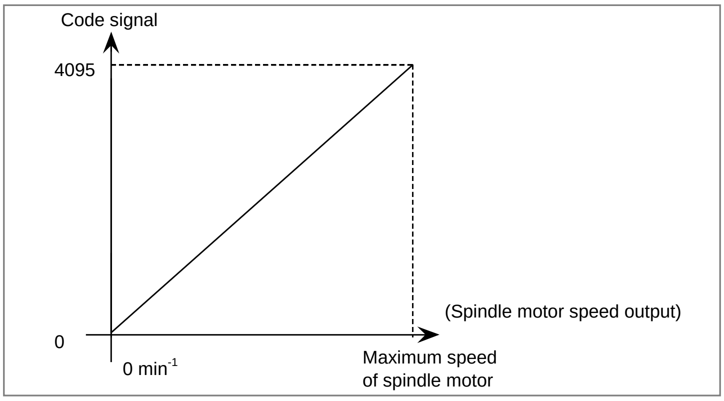
For details of each signal, see "SPINDLE OUTPUT CONTROL BY THE PMC."

S12-bit code signals
R01O to R12O<Fn036.0 to Fn037.3>,
R01O2 to R12O2<Fn200.0 to Fn201.3>,
R01O3 to R12O3<Fn204.0 to Fn205.3>,
R01O4 to R12O4<Fn270.0 to Fn271.3>,

[Classification] Output signal

[Function] If bit 3 (MRS) of parameter No. 3709 is 1, the spindle speed command value calculated by the CNC is converted to a code signal from 0 to 4095, and the conversion result is output to a spindle. If MRS is set to 0, the data of the currently selected spindle (when more than one spindle is selected, the spindle with the smallest number) is output only to R01O to R12O for the first spindle.

[Output cond.] The relationship between the spindle speed command output value (the value calculated by the CNC) and the value output to these signals is plotted in the graph shown below. Note that for either a serial or analog spindle, the output value on these signals is a value 0 to 4095 as a result of conversion from the spindle speed command output value calculated by the spindle control function of the CNC; the output value on these signals is not the actual output value.



Address P signals MSP00 to MSP15<Fn160.0 to Fn161.7>

[Classification] Output signal

[Function] The P value specified last by the S_P_; command is output.
When extended spindle names are used, the value in parameter No. 3781 corresponding to the spindle number of the spindle name specified last is output.

[Output cond.] When multi-spindle control by using address P is enabled (bit 3 (MPP) of parameter No. 3703 is 1), the P value specified in the S_P_; command is output. When no S_P_; command has been specified even once since power-up, the initial P value set in parameter No. 3775 is output.
When extended spindle names are used, the value in parameter No. 3781 corresponding to the spindle number of the spindle name specified last is output. When no spindle name has been specified even once, the value set in parameter No. 3775 is output.

1st spindle speed override signal SOV0 to SOV7<Gn030>
2nd spindle speed override signal SOV20 to SOV27<Gn376>
3rd spindle speed override signal SOV30 to SOV37<Gn377>
4th spindle speed override signal SOV40 to SOV47<Gn378>

[Classification] Input signal

[Function] If bit 4 (EOV) of parameter No. 3713 = 1, an override of 0% to 254% of the rotation speed specified by the CNC can be applied to individual spindles separately.

[Operation] Specify an override value, using an 8-bit binary number.
If all bits are 1, however, an override of 0% is assumed.

> **NOTE**
> If bit 4 (EOV) of parameter No. 3713 = 0, the override signals SOV0 to SOV7 are applied to all spindles that receive speed commands.
> The signals SOV20 to SOV27, SOV30 to SOV37, and SOV40 to SOV47 are invalid.

Spindle command path specification signal SPSP<Gn536.7>

[Classification] Input signal

[Function] Turns spindle command path specification ON or OFF.

[Operation] If a command based on address P (bit 3 (MPP) of parameter No. 3703 = 1 and bit 1 (ESN) of parameter No. 3798 = 0) or a command based on an extended spindle name (bit 3 (MPP) of parameter No. 3703 = 1, bit 0 (EEA) of parameter No. 1000 = 1, and bit 1 (ESN) of parameter No. 3798 = 1) is used in multi-spindle control:

- Setting this signal to 1 enables path specification for spindle commands.
  Spindle commands can be issued from the path specified by parameter No. 11090.
  If a spindle command is issued from a path other than the path, PS5305 alarm is issued.
- Setting this signal to 0 disables path specification for spindle commands.
  Spindle commands can be issued from individual paths no matter what the setting of parameter No. 11090.

Parameter

Parameters related to the first spindle and first position coder are the same as those used conventionally. The following explains the parameters added in connection with this function and related parameters:

	#7	#6	#5	#4	#3	#2	#1	#0
1000								EEA

[Input type] Parameter input
[Data type] Bit

#0 EEA An extended axis name and extended spindle name are:
0: Invalid
1: Valid

	#7	#6	#5	#4	#3	#2	#1	#0
3106			SOV					

[Input type] Setting input
[Data type] Bit

#5 SOV A spindle override value is:
0: Not displayed.
1: Displayed.

NOTE
This parameter is valid only when bit 2 (DPS) of parameter No. 3105 is set to 1.

	#7	#6	#5	#4	#3	#2	#1	#0
3702							EMS	

[Input type] Parameter input
[Data type] Bit path

#1 EMS The multi-spindle control is:
0: Used.
1: Not used.

	#7	#6	#5	#4	#3	#2	#1	#0
3703					MPP			

[Input type] Parameter input
[Data type] Bit

> **NOTE**
> When this parameter is set, the power must be turned off before operation is continued.

#3 MPP In multi-spindle control, a spindle selection using a programmed command instead of using the signals (SWS1 to SWS4<Gn027.0 to Gn027.2, Gn026.3>) is:

0: Not made.
1: Made.

> **NOTE**
> When this parameter is set to 1, set parameter No. 3781 at the same time.

	#7	#6	#5	#4	#3	#2	#1	#0
3706						MPA		
				GTT		MPA		

[Input type] Parameter input
[Data type] Bit path

#2 MPA If a spindle is to be selected using a P command (with bit 3 (MPP) of parameter No. 3703 set to 1) in multi-spindle control, and a P command is not specified together with an S command:

0: The alarm PS5305, “ILLEGAL SPINDLE NUMBER” is issued.
1: The last P specified by S_ P_; (by S_ P_; specified for the path in case of a multi-path system) is used. If P is not specified even once after power-up, the value of parameter No. 3775 is used.

> **NOTE**
> This parameter is valid only when bit 3 (MPP) of parameter No. 3703 is set to 1.

#4 GTT Spindle gear selection method is:

0: Type M.
1: Type T.

> **NOTE**
> 1 This parameter is effected for M system.
> 2 M type
> The gear selection signal is not input. The CNC selects a gear based on the speed range of each gear set by a parameter beforehand according to S codes, and the selected gear is posted by outputting the gear selection signal. Moreover, the spindle speed matching the gear selected by the output gear selection signal is output.
> T type
> The gear selection signal is input. The spindle speed matching the gear selected by this signal is output.
> 3 When the constant surface speed control is enabled(bit 0(SSC) of parameter No.8133 is 1), type T is selected, regardless of whether this parameter is specified.

NOTE

4 When type T spindle gear switching is selected, the following parameters have no effect:
No.3705#2(SGB), No.3751, No.3752,
No.3705#1(GST), No.3705#3(SGT), No.3761, No.3762,
No.3705#6(SFA), No.3735, No.3736
On the other hand, parameter No. 3744 becomes usable.

5 When multi spindle control is used, select to T type.

	#7	#6	#5	#4	#3	#2	#1	#0
3708		TSO	SOC					

[Input type] Parameter input
[Data type] Bit path

#5 SOC During constant surface speed control (G96 mode), the speed clamp by the maximum spindle speed clamp command (G92 S_; (G50 for G code system A of lathe system)) is carried out:
0: Before spindle speed override.
1: After spindle speed override.
If this parameter is set to 0, the spindle speed may exceed the maximum spindle speed (numeric value following S in G92 S_; (G50 for G code system A of lathe system)).
If this parameter is set to 1, the spindle speed is limited to the maximum spindle speed.
The spindle speed is limited to the upper limit of spindle speed specified in parameter No. 3772, irrespective of the setting of this parameter.

#6 TSO During a threading or tapping cycle, the spindle override is:
0: Disabled (tied to 100%).
1: Enabled.

NOTE

During rigid tapping, the override is tied to 100%, irrespective of the setting of this parameter.

	#7	#6	#5	#4	#3	#2	#1	#0
3709					MRS	MSI		

[Input type] Parameter input
[Data type] Bit path

#2 MSI In multi-spindle control, the SIND signal is valid
0: Only when the first spindle is valid (SIND signal for the 2nd, 3rd spindle becomes ineffective) (TYPE-A)
1: For each spindle irrespective of whether the spindle is selected (Each spindle has its own SIND signal). (TYPE-B)

#3 MRS When the actual spindle speed signals and S 12-bit code signals are output in multi-spindle control:
0: The signals common to the first spindle and second spindle are used, and the signals for the spindle selected by the spindle selection signal are output.
1: The signals for the first spindle and the signals for the second spindle are output separately.

	#7	#6	#5	#4	#3	#2	#1	#0
3713		MPC		EOV	MSC			

[Input type] Parameter input
[Data type] Bit

> **NOTE**
> When at least one of these parameters is set, the power must be turned off before operation is continued.

#3 MSC Multi-spindle control TYPE-C is:
0: Not used.
1: Used.

> **NOTE**
> If parameter MSC and bit 2 (MSI) of parameter No. 3709 for multi-spindle control TYPE-B) are set to 1 at the same time, multi-spindle control TYPE-C is enabled.

#4 EOV Each spindle speed override is:
0: Not used.
1: Used.

> **NOTE**
> Multi-spindle control TYPE-C (bit 3 (MSC) of parameter No. 3713=1) is necessary to use this function.

#6 MPC When a spindle is selected with address P in a program during multi-spindle control (bit 3 (MPP) of parameter No. 3703 is set to 1), position coder feedback used for thread cutting, feed per revolution, and so forth is:
0: Not changed automatically according to the selected spindle.
1: Changed automatically according to the selected spindle.

> **NOTE**
> Setting this parameter produces the same effects as when position coder select signals PC2SLC<Gn028.7>, PC3SLC<Gn026.0>, and PC4SLC<Gn026.1>, inter-path spindle feedback signals SLPCA<Gn064.2>, SLPCB<Gn064.3>, SLPCC<Gn403.4>, and SLPCD<Gn403.5> are set.
> At this time, even when an attempt to set these signals is made by a PMC ladder, these signal operations are ignored.

3718	Subscript for display of a serial spindle (main spindle) or analog spindle

[Input type] Parameter input
[Data type] Byte spindle
[Valid data range] 0 to 122

Set a subscript to be added to spindle speed display on a screen such as the position display screen.
Used when the spindle switching function is not used, or used for the main spindle when the spindle switching function is used.

NOTE
This parameter is invalid when an extended spindle name is used.

3719	Subscript for display of a serial spindle (sub-spindle)

[Input type] Parameter input
[Data type] Byte spindle
[Valid data range] 0 to 122

Set a subscript to be added to spindle speed display on a screen such as the position display screen.
Used for the sub-spindle when the spindle switching function is used.

NOTE
This parameter is invalid when an extended spindle name is used.

3720	Number of position coder pulses

NOTE
When this parameter is set, the power must be turned off before operation is continued.

[Input type] Parameter input
[Data type] 2-word spindle
[Unit of data] Number of pulses
[Valid data range] Serial spindle
: 0, 4096 When bit 7 (FBP) of parameter No.3716 is set to 1: $4096\times2^{\wedge14}$
Spindle control with servo motor
: 0, 4096 When bit 7 (FBP) of parameter No.3716 is set to 1: $4096\times2^{\wedge14}$
Analog spindle
: 0, 4096 When bit 7 (FBP) of parameter No.3716 is set to 1: from 0 to 400000

Set the number of position coder pulses.
In analog spindle, 4096 is set to parameter automatically if parameter No.3720 is set to 0 or less.
In serial spindle or spindle control with servo motor, the setting method is changed by setting of the bit 7 (FBP) of parameter No.3716.

- When the bit 7 (FBP) of parameter No.3716 is set to 0:
  4096 is set to parameter automatically if parameter No.3720 is set to 0 or less.
- When the bit 7 (FBP) of parameter No.3716 is set to 1:
  $4096\times2^{\wedge14}$ is set to parameter automatically.

3721	Number of gear teeth on the position coder side

[Input type] Parameter input
[Data type] Word spindle
[Valid data range] 0 to 9999

Set the number of gear teeth on the position coder side in speed control (such as feed per revolution).

3722	Number of gear teeth on the spindle side

[Input type] Parameter input
[Data type] Word spindle

[Valid data range] 0 to 9999

Set the number of gear teeth on the spindle side in speed control (such as feed per revolution).

> ⚠ **CAUTION**
> 1 Parameter No.3721 and No.3722 can not be used for thread cutting.
> If thread cutting was done by setting the any value on these parameters, the correct screw can't be cut.
> In the machine to do thread cutting, connect mechanically between the spindle and position coder by the gear ratio=1:1. And these parameters set the No.3721=0, No.3722=0.
> (It is the setting for the gear ratio 1:1.)
> 2 Parameter No.3721 and No.3722 can not be used for Cs contour control. If Cs contour control was done by setting the any value on these parameters, spindle can’t move as commanded. In the machine to do Cs contour control, connect mechanically between the spindle and position coder by the gear ratio = 1:1. And these parameters set the No.3721=0, No.3722=0. (It is the setting for the gear ratio 1:1.)

3738	Spindle name 2 of each spindle
3739	Spindle name 3 of each spindle

[Input type] Parameter input
[Data type] Byte spindle
[Valid data range] 48 to 57, 65 to 90

The command for a spindle is basically "S".
When all conditions below are satisfied, however, an extended spindle name can be used. An extended spindle name consists of up to three characters starting with "S" as the first spindle name. Thus, a command for a spindle can be specified.

- The serial (analog) spindle function is enabled.
- The multi-spindle control is enabled.
- Bit 0 (EEA) of parameter No. 1000 is set to 1.
- Bit 3 (MPP) of parameter No. 3703 is set to 1.
- Bit 1 (ESN) of parameter No. 3798 is set to 1.
- Bit 4 (GTT) of parameter No. 3706 is set to 1. (M series only)

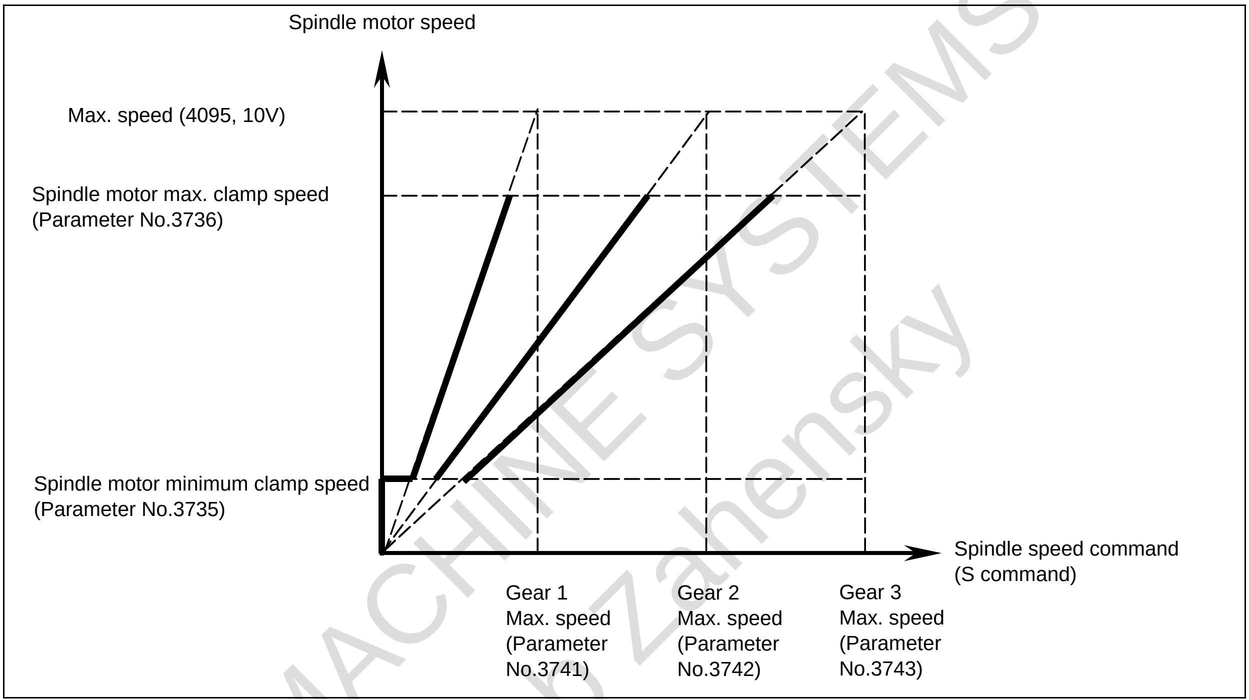
As spindle name 2 (parameter No. 3738) and spindle name 3 (parameter No. 3739), ASCII codes from 0 to 9 and A to Z can be arbitrary set. However, before spindle name 3 for a spindle can be valid, spindle name 2 must be set for the spindle. Moreover, when a character from 0 to 9 is set as spindle name 2, do not set a character from A to Z as spindle name 3.

> **NOTE**
> 1 When an extended spindle name is used, a subscript (for a main spindle (parameter No. 3718)) and a subscript (for a sub-spindle (parameter No. 3719)) are unusable.
> 2 When the custom macro function is enabled, the same extended spindle name as a reserved word must not be used. Such an extended spindle name is regarded as a reserved word.

3741	Maximum spindle speed for gear 1
3742	Maximum spindle speed for gear 2
3743	Maximum spindle speed for gear 3
3744	Maximum spindle speed for gear 4

[Input type] Parameter input
[Data type] 2-word spindle
[Unit of data] min^{-1}
[Valid data range] 0 to 99999999

Set the maximum spindle speed corresponding to each gear.



3772	Maximum spindle speed

[Input type] Parameter input
[Data type] 2-word spindle
[Unit of data] min^{-1}
[Valid data range] 0 to 99999999

This parameter sets the maximum spindle speed.
When a command specifying a speed exceeding the maximum speed of the spindle is specified , or the speed of the spindle exceeds the maximum speed because of the spindle speed override function, the spindle speed is clamped at the maximum speed set in the parameter.

> ⚠ **CAUTION**
> 1 When 0 is set in this parameter, the speed of the spindle is not clamped.
> 2 When spindle speed command control is applied using the PMC, this parameter has no effect, and the spindle speed is not clamped.

> **NOTE**
> 1 For M series, this parameter is valid if the function of constant surface speed control is enabled(bit 0(SSC) of parameter No.8133 is 1).
> 2 When the constant surface speed control is enabled, the spindle speed is clamped at the maximum speed, regardless of whether the G96 mode or G97 mode is specified.

3775	Default P command value for spindle selection in multi-spindle control

> **NOTE**
> When this parameter is set, the power must be turned off before operation is continued.

[Input type] Parameter input
[Data type] Word path
[Valid data range] 0 to 32767

When bit 3 (MPP) of parameter No. 3703 is set to 1 and bit 2 (MPA) of parameter No. 3706 is set to 1 in multi-spindle control, set a default P command value applicable if S_P_ is not specified even once after power-up.

3781	P code for selecting the spindle in multi-spindle control

[Input type] Parameter input
[Data type] Word spindle
[Valid data range] 0 to 32767

If bit 3 (MPP) of parameter No. 3703 is set to 1, set the P code to select each spindle under multi-spindle control. Specify the P code in a block containing the S command.

[Example] If the P code value for selecting the second spindle is set to 2,
S1000 P2;
causes the second spindle to rotate at S1000.

> **NOTE**
> 1 This parameter is valid if bit 3 (MPP) of parameter No. 3703 is set to 1.
> 2 If this parameter is set to 0, the corresponding spindle cannot be selected by a P code.
> 3 Under multi-path control, the P code specified here is valid for each path.
> For instance, if the P code to select the first spindle of path 2 is set to 21, specifying S1000 P21; in path 1 causes the first spindle of path 2 to be rotated at S1000.
> 4 Identical P code values cannot be used for different spindles. (Identical P code values cannot be used even if the paths are different.)
> 5 When this parameter is used (when bit 3 (MPP) of parameter No. 3703 is set to 1), the spindle command selection signal is invalid.
> 6 To use this parameter, enable the multi-spindle control function(bit 1(MSP) of parameter No.8133 is 1).

	#7	#6	#5	#4	#3	#2	#1	#0
3786						MPF		

[Input type] Parameter input
[Data type] Bit

> **NOTE**
> When this parameter is set, the power must be turned off before operation is continued.

#2 MPF When M03/M04/M05 is commanded by "M_P_" format in multi-spindle control, multi-spindle address P signal <Fn160-Fn161> is:
0: Not output.
1: Output.

> **NOTE**
> This parameter is valid when bit 3 (MPP) of parameter No.3703 is set to 1.

	#7	#6	#5	#4	#3	#2	#1	#0
3798							ESN	

[Input type] Parameter input
[Data type] Bit

#1 ESN When the multi-spindle control is enabled and bit 3 (MPP) of parameter No. 3703 is set to 1, a spindle is specified in a program by using:
0: P command.
1: Extended spindle name.

A spindle to be specified is selected as follows:

Bit 1 (ESN) of parameter No. 3798	Bit 3 (MPP) of parameter No. 3703	Selection method
0	0	Signal selection
0	1	P command (S_P_)
1	0	Signal selection
1	1	Extended spindle name or P command (S_P_)

> **NOTE**
> This parameter is valid when bit 0 (EEA) of parameter No. 1000 is set to 1.
> When setting this parameter to 1, set also parameter No. 3738 and No. 3739 properly.

11090	Path number with which the rotation of each spindle is specified

[Input type] Parameter input
[Data type] Byte spindle
[Valid data range] 0 to 10

When a path is specified for spindle commands, this parameter sets a path number with which the rotation of a spindle can be specified.
0: Spindle commands can be issued from all paths.

1 to 10: Spindle commands can be issued from a set path.

NOTE

1. This parameter is valid when spindle command path specification signal SPSP<Gn536.7> is set to "1".
2. If the setting is illegal, an alarm PS5305, “ILLEGAL SPINDLE NUMBER” is issued when a spindle command is issued from any one of the paths.
3. This setting does not apply to spindle commands using the spindle select signals SWS1 to SWS4<Gn027.0 to Gn027.2, Gn026.3>.

Caution

⚠ **CAUTION**

1. If the primary spindle stop signal *SSTP<Gn029.6> for stopping all selected (SWS1 to SWS4) spindles’ rotation is cleared, the speed command is restored. A spindle not selected by SWS1 to SWS4 and rotating at its previous speed, which is stopped using its respective command *SSTP1 to *SSTP4, cannot be restored to that speed when the signal is cleared.
2. While a function using a position coder feedback such as feed per revolution and a threading command is being executed, avoid changing the selection of a position coder by using position coder selection signals PC2SLC<Gn028.7> , PC3SLC<Gn026.0> , and PC4SLC<Gn026.1> .
3. Type A multi-spindle control differs from Type B in the relationship between the SWS1 and SIND signals for the first spindle. In Type A, SIND functions only when SWS1 is set to "1". In Type B, SIND functions whether SWS1 is "1" or "0"; each spindle is selected by either of its respective SWS1 or SIND signals being set to "1".

Note

NOTE

1. The spindle orientation signal SOR<Gn029.5>, spindle speed override signals SOV0 to SOV7<Gn030>, and spindle stop signal *SSTP <Gn029.6> only function for the selected spindle.
2. The multi-spindle control allows multiple position coder interfaces to be used. But the number of actual speed indications on the CNC screen does not change. The speed based on the feedback information of the selected position coder is displayed.
3. An SOR command has priority over S commands and SIND-based rotation control from the PMC, and will cause all selected spindles to perform orientation rotation.

Alarm and message

Number	Message	Description
PS0333	TOO MANY SPINDLE COMMANDS	Multiple spindle commands could be found in the same block in using an expansion spindle name. Only one spindle could be commanded in the same block.

Number	Message	Description
PS5305	ILLEGAL SPINDLE NUMBER	In a spindle select function by address P for a multiple spindle control, 1 Address P is not specified. 2 Parameter No. 3781 is not specified to the spindle to be selected. 3 An illegal G code which cannot be commanded with an S_P_; command is specified. 4 The multi-spindle control cannot be used because the bit 1 (EMS) of parameter No. 3702 is 1. 5 The spindle amplifier number of each spindle is not set in parameter No. 3717. 6 A prohibited command for a spindle was issued (parameter No. 11090). 7 An invalid value is set in parameter No. 11090.
SP1202	SPINDLE SELECT ERROR	In the multi-spindle control, the spindle number other than the valid spindle number was selected by a position coder select signal. An attempt was made to select the spindle number of the system having no valid spindle.

10.13 RIGID TAPPING

Overview

In a tapping cycle (Machining center system: G84/G74, Lathe system: G84/G88), synchronous control is applied to the tapping operation of a tapping axis and the operation of the spindle.
This capability eliminates the need to use a tool such as a float tapper, thus enabling higher-speed, higher-precision tapping.
Whether a tapping cycle is an ordinary tapping cycle or rigid tapping cycle is determined by the miscellaneous function code for rigid tapping M29. (A different M code can be used by setting the parameters accordingly, but M29 is used in the description given here.)
By setting the parameters, G codes for tapping cycles can be changed to G codes for rigid tapping only. In this case, the CNC specifies M29 internally.
To perform rigid tapping, the following must be added to the ordinary connections:

- Connection of a position coder to the spindles
- Addition of a sequence to the PMC
- Setting of related parameters

To avoid duplicate descriptions, assume the following unless noted otherwise:

G code for a tapping cycle	
Machining center system	**Lathe system**
G84/G74	G84/G88

Gear selection method	
Machining center system	**Lathe system**
M-type or T-type gear selection method	T-type gear selection method only

Parameters used according to the number of gear stages
No.5221 to No.5224, No.5231 to No.5234, No.5241 to No.5244, No.5261 to No.5264, No.5271 to No.5274, No.5281 to No.5284, No.5291 to No.5294, No.5321 to No.5324,etc.

> ⚠ **CAUTION**
> 1 In the text of this section, a description of up to four-step gears is provided. Gears of four steps are used with the lathe system, but gears of up to only three steps are used with the machining center system.
> 2 When M-type gear selection is used for the machining center system, the maximum spindle speed for rigid tapping (specified with parameters Nos. 5241 to 5243) must also be set for parameter No. 5243 regardless of the number of gear steps. (For a system having a single gear step, set the same value as that of parameter No. 5241 for parameter No. 5243. For a system having two gear steps, set the same value as that of parameter No. 5242 for parameter No. 5243.)

The descriptions given in this section (such as spindle gear switching and M-type/T-type) are based on the explanation given in Section "SPINDLE SPEED CONTROL."
Refer to Section "SPINDLE SPEED CONTROL" as necessary.

- Specification of machining center system/lathe system

The differences in the specifications for rigid tapping for the machining center system and lathe system are described below.

M

Rigid tapping of machining center system

The tapping cycle G84 and the reverse tapping cycle G74 can be used to specify machining center system rigid tapping.
A drilling axis can be arbitrarily selected from the basic axes X, Y, Z, as well as axes parallel to the basic axes, by setting the corresponding parameters accordingly (bit 0 (FXY) of parameter No. 5101).
The spindle operations of G84 and G74 are reversed with respect to each other.

T

Rigid tapping of lathe system

The face tapping cycle G84 and the side tapping cycle G88 can be used to specify lathe system rigid tapping.
Depending on the rigid tapping command, rigid tapping can be performed along the Z-axis (when G84 is used) or the X-axis (when G88 is used).
A reverse tapping cycle, like that supported by machining center system, is not available.

See "Rigid Tapping with Spindle of Another Path" for explanations about rigid tapping between different paths (rigid tapping on a spindle for tool post 2 as directed by a command for tool post 1) in a multi-path system.

- Multi-spindle control

The relationships between rigid tapping and multi-spindle control are described below.

Without multi-spindle control

Rigid tapping can be performed with the first spindle only.

With multi-spindle control

Rigid tapping can be performed by selecting the second through fourth spindles in addition to the first spindle.

10.13.1 Connection Among Spindle, Spindle Motor, and Position Coder

As shown in the figures (Fig. 10.13.1 (a) and Fig. 10.13.1 (b)) below a gear ratio can be inserted between the spindle and spindle motor (n : m), and between the spindle and position coder (N : M).

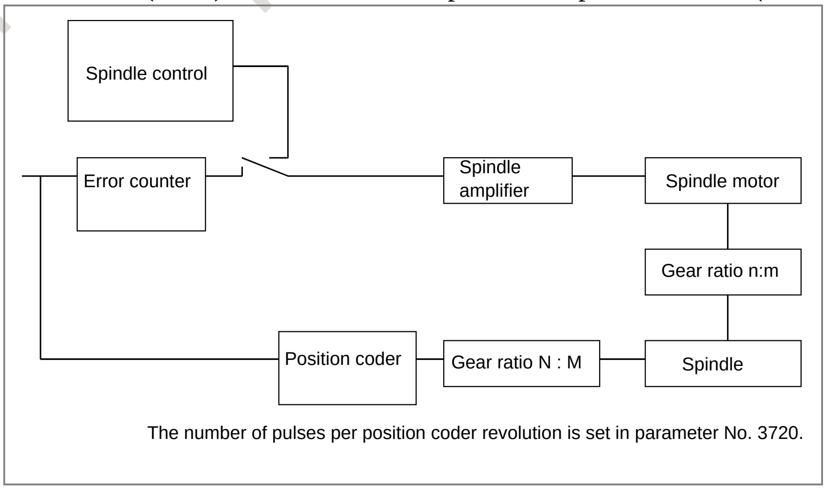


Fig. 10.13.1 (a) When a position coder is externally attached (on the spindle side)

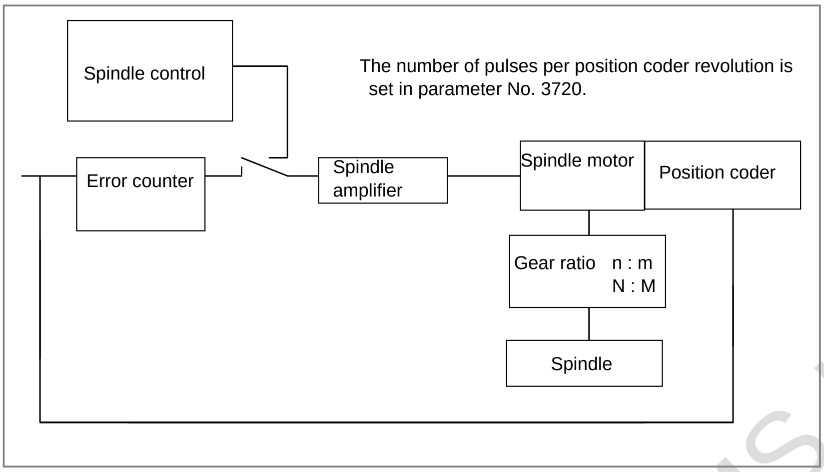

Fig. 10.13.1 (b) When a position coder is built into a spindle motor

(1) Gear between spindle and spindle motor

Up to three gear stages (machining center system) or four gear stages (lathe system) can be provided between the spindle and the spindle motor.

The gear ratio is arbitrary. The distance of spindle rotation per revolution of spindle motor is different, based on the gear ratio. The speed command to the spindle motor will be adjusted.

(2) Gear between spindle and position coder

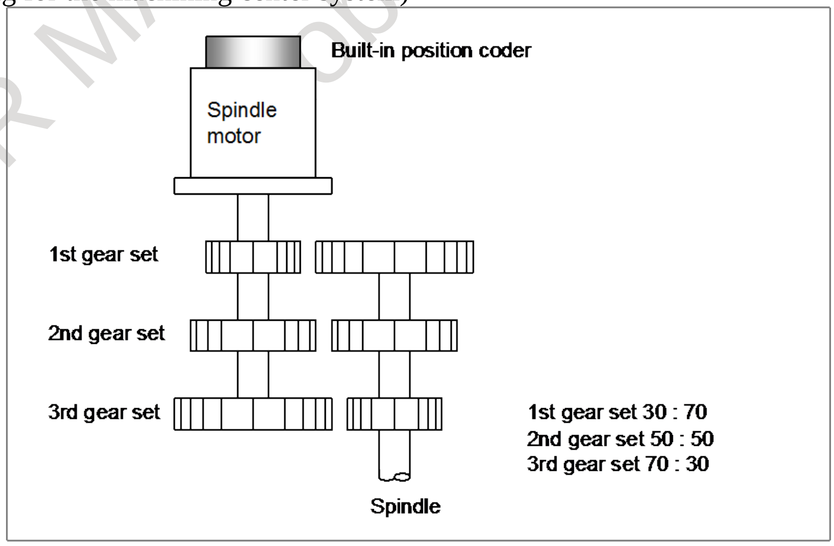
The position coder is used to detect the position of the spindle.

The gear ratio between the spindle and position coder is set in parameters Nos. 5221 to 5224 and 5231 to 5234.

When a position coder is externally attached, the gear ratio between the spindle and position coder is not changed by a gear change between the spindle motor and spindle. So, set the same number of teeth in parameters Nos. 5221 to 5224 and 5231 to 5234.

When a position coder is built into a spindle motor, the gear ratio between the spindle and position coder is changed by a gear change between the spindle motor and spindle. So, set the number of teeth for each gear in parameters Nos. 5221 to 5224 and 5231 to 5234.

Example of setting for the machining center system)



Parameter No.	Set value	Meaning
5221	70	Number of teeth of the 1st gear for the spindle side
5222	50	Number of teeth of the 2nd gear for the spindle side
5223	30	Number of teeth of the 3rd gear for the spindle side
5231	30	Number of teeth of the 1st gear for the position coder side

Parameter No.	Set value	Meaning
5232	50	Number of teeth of the 2nd gear for the position coder side
5233	70	Number of teeth of the 3rd gear for the position coder side

For the lathe system, up to four gear stages can be set.

(3) Rigid tapping and machines with multiple gears

When performing rigid tapping on a machine that has multiple gears, note the points below.

- M type gear selection method

M

The CNC determines whether gears need changing using the gear change specification mentioned in section “SPINDLE SPEED CONTROL”. If the gears need to be changed, the CNC generates the S function code read signal SF <F007.2> and gear selection signals GR1O, GR2O, and GR3O <F034.0-2> to notify the PMC. Change gears using the PMC, based on these signals.

- T type gear selection method

The CNC does not process gear changes. Using the PMC, determine whether gears need changing, and make the change if needed.
When the CNC has the S function code, it outputs signal SF <F007.2> and S function code signals S00 to S31 <F022-F025> to the PMC. (However, parameter No. 3705 and its related parameters need to be set for S code and SF signal output).
The PMC side finds a gear whose spindle speed range includes the spindle speed specified by an S function code. A selected gear is to be output onto the gear selection signals GR1 and GR2 (G028.1,2 for the first spindle, G029.0,1 for the second spindle, G029.2,3 for the third spindle, and G031.4,5 for the fourth spindle) for notification to the CNC. Regardless of the gear selection method, the clutch/gear selection signals CTH2 and CHT1 (G070.3,2 for the first spindle, G074.3,2 for the second spindle, G204.3,2 for the third spindle, and G266.3,2 for the fourth spindle) corresponding to a gear change are to be input for notification through the CNC to the serial spindle control unit.

Changing gears during rigid tapping requires a different process from that for gear changes during normal machining. As described above, changing gears conforms to the gear change specifications mentioned in section "SPINDLE SPEED CONTROL" when the M type gear selection method has been selected. With the T type gear selection method, changing gears conforms to the logic programmed in the PMC.
Regardless of the option's selection, if the range in which the spindle speed specified by the S function code does not correspond to the currently selected gear, the gears are changed.
The Table 10.13.1 (a) lists the spindle speed ranges for each gear during normal machining (assuming no machine restrictions) and rigid tapping:

Table 10.13.1 (a)

Gear	Spindle speed range (normal machining)	
	Lower limit	Upper limit
Low-speed gear	1 revolution	Maximum low-speed gear speed $= \dfrac{\text{Maximum spindle motor speed} \times \text{L\%}}{\text{Low-speed gear ratio}}$
Medium speed gear	Maximum low-speed gear speed + 1 revolution	Maximum medium-speed gear speed $= \dfrac{\text{Maximum spindle motor speed} \times \text{L\%}}{\text{Medium speed gear ratio}}$
High-speed gear	Maximum medium-speed gear speed + 1 revolution	Maximum high-speed gear speed $= \dfrac{\text{Maximum spindle motor speed} \times \text{L\%}}{\text{High-speed gear ratio}}$

> **NOTE**
> Table 10.13.1 (a) shows an example of three gears. L% indicates a spindle motor protection constant (up to 100). L can be specified for each gear using method B for changing in M type gear selection method (bit 2 (SGB) of parameter No. 3705 is set to 1).

The spindle speed range of each gear in rigid tapping must satisfy the Table 10.13.1 (b).

Table 10.13.1 (b)

Gear	Spindle speed range (during rigid tapping)	
	Lower limit	Upper limit
Low-speed gear	1 revolution	Maximum low-speed gear speed $= \dfrac{\text{Basic spindle motor speed} + \alpha}{\text{Low-speed gear ratio}}$
Medium speed gear	Maximum low-speed gear speed + 1 revolution	Maximum medium-speed gear speed $= \dfrac{\text{Basic spindle motor speed} + \alpha}{\text{Medium-speed gear ratio}}$
High-speed gear	Maximum medium-speed gear speed + 1 revolution	Maximum high-speed gear speed $= \dfrac{\text{Basic spindle motor speed} + \alpha}{\text{High-speed gear ratio}}$

> **NOTE**
> This table show an example of three gears. For the basic spindle motor speed, refer to the spindle motor description manual. "+α" means that the spindle motor speed may slightly exceed the basic spindle motor speed.

If the M type gear selection method is used, use gear change method B (bit 3 (SGT) of parameter No. 3705 is set to 1) in the tapping cycle to specify the following:
The table above shows the maximum low-speed gear speed during rigid tapping for gear 1 to gear 2 change point (parameter No. 3761). The table above shows the maximum medium-speed gear speed during rigid tapping for gear 2 to gear 3 change point (parameter No. 3762).
If the T type gear selection method is used, add the rigid tapping logic to the logic programmed in the PMC. See Section "SPINDLE SPEED CONTROL" for details of the spindle gear change specifications.
The loop gain can be specified for each gear. In parameters Nos. 5281 to 5284, set the loop gain of each gear. Set a loop gain multiplier in parameters Nos. 5291 to 5294. Specify the time constant and the maximum spindle speed for each gear.
Use parameters Nos. 5261 to 5264 to specify the time constant.
Use parameters Nos. 5241 to 5244 to specify the maximum spindle speed.
For M type gear selection method, set the maximum spindle speed to parameter No. 5243, irrespective of the number of gear stages used.
Setting bit 2 (TDR) of parameter No. 5201 to 1 enables setting of the time constants used during extraction for each gear set. Specify the extraction time constant for each gear in parameters Nos. 5271 to 5274.
It is recommended that a value of about 1:8 to 8:1 be actually used as the gear ratio between the spindle and position coder.

10.13.2 Rigid Tapping Specification

- Feedrate

In rigid tapping mode, the drilling axis is fed at a rate specified by F. The spindle speed is specified by S 360 [deg/min].
A detailed description of commands for feed per minute and feed per revolution is provided later.

- Acceleration/deceleration after interpolation

Linear acceleration/deceleration or bell-shaped acceleration/deceleration can be applied.
A detailed description is provided later.

- Look-ahead acceleration/deceleration before interpolation

Look-ahead acceleration/deceleration before interpolation is disabled.

- Override

Various types of overrides are disabled. However, the following overrides can be enabled by setting parameters:
- Extraction override
- Override signal

A detailed description is provided later.

- Dry run

Dry run is valid for G84/G74 (for machining center system) or G84/G88 (for lathe system). When the dry run is applied to the drilling axis speed of G84/G74 or G84/G88, tapping is performed. The spindle speed will match the dry run speed.

- Machine lock

When G84/G74 (for machining center system) or G84/G88 (for lathe system) is executed with the machine locked, however the drilling axis and the spindle do not move.

- Reset

When a reset operation is performed during rigid tapping, rigid tapping is stopped. Rigid tapping in-progress signal RTAP<Fn076.3> and spindle enable signal ENB<Fn001.4>, ENB2<Fn038.2>, ENB3<Fn038.3>, ENB4<Fn039.1> are set to "0". Set rigid tapping signal RGTAP<Gn061.0> to "0" when falling edge of spindle enable signal ENB<Fn001.4>, ENB2<Fn038.2>, ENB3<Fn038.3>, ENB4<Fn039.1> is detected. When a reset operation is performed, G code is set as Table 10.13.2 according to bit 5 (CLR) of parameter No.3402, bit 1 (C09) of parameter No.3407 (machining center system), and bit 2 (C10) of parameter No.3407 (lathe system). In restarting operation with G84/G74 (machining center system), G84/G88 (lathe system), command G80 if necessary.

Table 10.13.2

CLR (bit 5 of parameter No.3402)	C09 (bit 1 of parameter No.3407) (machining center system) C10 (bit 2 of parameter No.3407) (lathe system)	G code
0	-	G84/G74 (machining center system) G84/G88 (lathe system)
1	0	G80
1	1	G84/G74 (machining center system) G84/G88 (lathe system)

- Feed hold and single block

Feed hold and single block are disabled in rigid tapping. When bit 6 (FHD) of parameter No.5200 is 1, feed hold and single block are enabled.

- Feed hold
  - Bit 6 (FHD) of parameter No.5200 = 0
    If feed hold is applied between Motion 3 and Motion 5 described at Section "Command Format", the feed hold lamp turns on immediately, but the tool decelerates and stops after moving to Motion 6. If feed hold is applied during Motion 1, Motion 2, and Motion 6, CNC becomes feed hold state and the tool decelerates and stops.
  - Bit 6 (FHD) of parameter No.5200 = 1
    If feed hold is applied between Motion 1 and Motion 6, CNC becomes feed hold state and the tool decelerates and stops.

- Single block
  - Bit 6 (FHD) of parameter No.5200 = 0
    Single block stop points are the end points of Motion 1, Motion 2, and Motion 6.
  - Bit 6 (FHD) of parameter No.5200 = 1
    Single block stop points are the end points of each Motion.

- Manual feed

When performing rigid tapping by using manual handle feed, see the description of the “RIGID TAPPING BY MANUAL HANDLE”.
Rigid tapping cannot be used with other types of manual feed.

- Backlash compensation

In rigid tapping mode, the backlash is compensated for the lost motion at forward and reverse spindle rotations. Set it using parameters Nos. 5321 to 5324. The normal backlash compensation is inserted on the drilling axis.

- C-axis clamp/unclamp

T

An M code can be specified to clamp/unclamp the C-axis mechanically in rigid tapping. By adding an M code for clamping to a block specifying G84/G88 (lathe system), both M codes are output. A description of timing is provided later.
An M code for clamping is to be set in parameter No. 5110. An M code for unclamping assumes the value set in parameter No. 5110 + 1.

No.5110	
0	Other than 0
No M code is output.	M code is output.

10.13.3 Commands for Feed per Minute and Feed per Revolution

In rigid tapping commands for feed per minute and feed per revolution can be specified.

(Example)
The example below specifies rigid tapping in feed per minute mode for cutting a thread with a lead of 1 mm at a spindle speed of 1,000 min^{-1}. (In feed per minute mode, F/S determines the thread lead.)

```
O0002 ;
G94 ;
```

```
  :
M29 S1000 ;
G84 X50. Y30. Z-100. R-20. F1000 ;
  :
G80 ;
```

The example below specifies rigid tapping in feed per revolution mode for cutting the same thread at the same spindle speed as above. (In feed per rotation mode, F determines the thread lead.)

```
O0001 ;
G95 ;
  :
M29 S1000 ;
G84 X50. Y30. Z-100. R-20. F1. ;
  :
G80 ;
```

> **NOTE**
> Even in the feed per revolution mode, pulses distributed for the drilling axis are converted to a command for feed per minute. Thus, feed per rotation mode does not strictly implement feed per rotation. Accordingly, even if the spindle stops for some reason, the drilling axis does not stop.

10.13.4 Acceleration/Deceleration after Interpolation

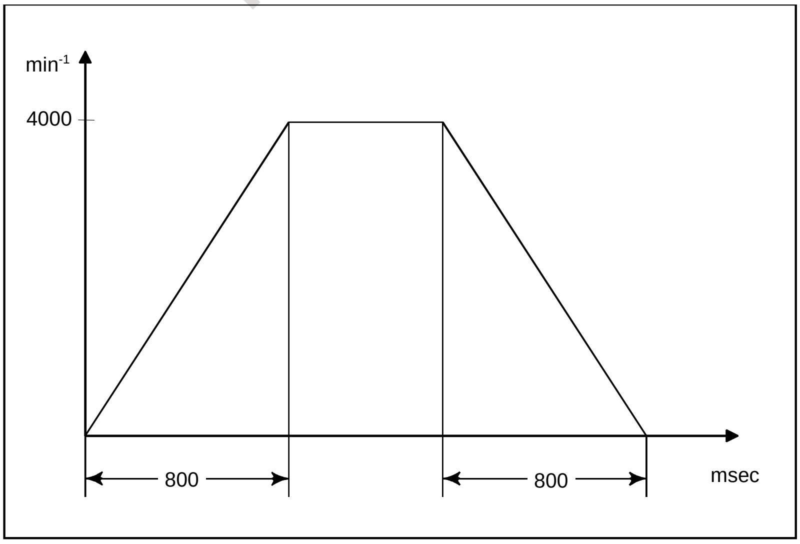
Linear acceleration/deceleration or bell-shaped acceleration/ deceleration can be applied.
When bit 2 (TDR) of parameter No. 5201 is set to 1, time constants for cutting and extraction can be set in separate parameters (Parameters Nos. 5271 to 5274).

- Linear acceleration/deceleration

By setting bit 5 (RBL) of parameter No. 5203 to 0, linear acceleration/deceleration of constant acceleration type can be applied.
In parameters Nos. 5261 to 5264, set a time required to reach a maximum spindle speed.
The actual time constant is the ratio between a maximum spindle speed and S command value.

Example)

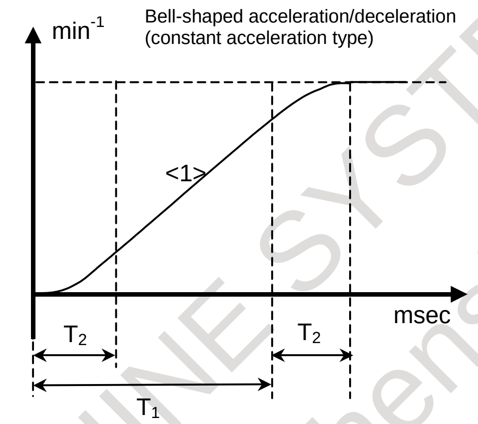
Suppose that the parameters are set as follows: time constant TC = 800 msec and maximum spindle speed S = 4000 min^{-1}.



When S2000 is specified, the acceleration/deceleration time is 400 msec. When S1000 is specified, the acceleration/deceleration time is 200 msec. This means that the acceleration rate in linear acceleration/deceleration at rigid tapping time is constant.

- Bell-shaped acceleration/deceleration

By setting bit 5 (RBL) of parameter No. 5203 to 1, bell-shaped acceleration/deceleration of constant acceleration type can be applied.
In parameters Nos. 5261 to 5264, set a time required to reach a maximum spindle speed (linear portion).
In parameters Nos. 5365 to 5368, set a time for the curved portion.
The actual time constant for the linear portion is the ratio between a maximum spindle speed and S command value.
To the curved portion, not an S command value but a set value is applied.
This means that the actual time constant is [linear portion value obtained by proportional calculation + value for curved portion].



Set time constants T_1 and T_2 in parameters.
(Acceleration rate of linear portion <1> is constant from settings of maximum spindle speed and T_1.)

NOTE

1. Even when bit 2 (TDR) of parameter No. 5201 is set to 1, the values set in parameters Nos. 5365 to 5368 are used for cutting and extraction in the curved portions.
2. When 0 is set in parameters Nos. 5365 to 5368, linear acceleration/deceleration is used.
3. In 3-dimensional rigid tapping, bell-shaped acceleration/deceleration is disabled, and linear acceleration/deceleration is used.

10.13.5 Override

Various types of overrides are disabled. However, the following overrides can be enabled by setting parameters:

- Extraction override
- Override signal

(1) Extraction override

For extraction override, a parameter-set fixed override value or programmed override value can be used at the time of extraction (including extraction operation at peck drilling/high-speed peck drilling).

- Parameter specification

Set bit 4 (DOV) of parameter No. 5200 to 1, and set an override value in parameter No. 5211.
An override value from 0% to 200% can be set in steps of 1%. When bit 3 (OVU) of parameter No. 5201 is set to 1, an override value from 0% to 2000% can be set in steps of 10%.

- Program specification

When bit 4 (DOV) of parameter No. 5200 and bit 4(OV3) of parameter No. 5201 are set to 1, a spindle speed to be used at extraction time can be programmed.
Using address J in a block specifying rigid tapping, specify a spindle speed to be used at extraction time.

Example)
When S = 1000 min^{-1} for cutting and S = 2000 min^{-1} for extraction

```
   :
M29 S1000 ;
G84 Z-100. F1000. J2000 ;
   :
```

The following calculation is made for conversion to an actual override value:

$$\text{Override value (\%)} = \frac{\text{Spindle speed for extraction (}J\text{ command)}}{\text{Spindle speed (}S\text{ command)}} \times 100$$

So, the spindle speed at extraction time may not match the speed specified by address J. If an override value not within the range 100% to 200% is specified, the specification of 100% is assumed.

The table below summarizes the setting of an extraction override value by parameter specification / program specification.

Command \ Parameter setting		DOV=1, OV3=1	DOV=1, OV3=0	DOV=0
Spindle speed for extraction is specified by address J.	**Within the range 100% to 200%**	Program specification	Parameter No. 5211	100%
	Not within the range 100% to 200%	100%		
Spindle speed for extraction is not specified by address J.		Parameter No. 5211		

NOTE

1 When specifying address J, do not use the decimal point.
If the decimal point is used, the specified value is handled as described below.
Example) When the increment system for the reference axis is IS-B
- When calculator-type decimal point input is not used
The specified value is converted to a value considering the least input increment.
"J200.0" is converted to 200000 min^{-1}.
- When calculator-type decimal point input is used
The specified value is converted to a value with the decimal places discarded.
"J200.0" is converted to 200 min^{-1}.

2 When specifying address J, do not use the minus sign.
When the minus sign is used, the specification of a value not within the range 100% to 200% is assumed.

3 Find a maximum allowable extraction override value according to the expression below so that the spindle speed multiplied by an extraction override value does not exceed the maximum speed (parameters Nos. 5241 to 5244) of the gear in use. For this reason, a mismatch with the maximum spindle speed can occur, depending on the override value.

$$\text{Maximum override value (\%)} = \frac{\text{Maximum spindle speed (parameter setting)}}{\text{Spindle speed (}S\text{ command)}} \times 100$$

> **NOTE**
> 4 Address J for specifying a spindle speed for extraction, when specified in the rigid tapping mode, remains valid until the canned cycle is canceled.

(2) Override signals

When bit 4 (OVS) of parameter No. 5203 is set to 1, a cutting/extraction operation in rigid tapping can be overridden as described below.

- Override is applied using the feedrate override signal *FV0 to *FV7 <Gn012>.
  (When the second feedrate override signal is valid, the second feedrate override is applied to the feedrate to which the feedrate override is already applied.
- Override is canceled using the override cancel signal OVC <Gn006.4>.
  The relationship between this function and overriding each operation is described below.
- At the time of cutting
  When the override cancel signal = 0
    Value specified by the override signal
  When the override cancel signal = 1
    100%
- At the time of extraction
  When the override cancel signal = 0
    Value specified by the override signal
  When the override cancel signal = 1
    When extraction override is disabled
      100%
    When extraction override is enabled
      Value specified by an extraction override value

> **NOTE**
> Find a maximum allowable override value according to the expression below so that the spindle speed multiplied by an override value does not exceed the maximum speed (parameters Nos. 5241 to 5244) of the gear in use. For this reason, a mismatch with the maximum spindle speed can occur, depending on the override value.
>
> $$\text{Maximum override value (\%)} = \frac{\text{Maximum spindle speed (parameter setting)}}{\text{Spindle speed (}S\text{ command)}} \times 100$$

10.13.6 Reference Position Return

For serial spindles, setting bit 0 (ORI) of parameter No. 5202 to 1 enables a reference position return to be made for a spindle at the start of rigid tapping.
When a movement is made to a R point in the rigid tapping mode, the reference position return direction is determined on the serial interface spindle side for reference position return. With the grid shift function, the reference position can be shifted within the range 0° to 360°.
Set a reference position return direction in bit 4 (RETSV) of parameter No. 4000. Set a grid shift amount in parameter No. 4073.

> **NOTE**
> 1 A feedrate for reference position return is determined from the position where the tool is stopped when the rigid tapping mode is set, and the amount of travel found from the reference position. Accordingly, no fixed speed is applied.
> 2 When the gear ratio between the spindle and position coder is not $1:2^n$ (n: integer other than 0), the tool may not be able to return to the same reference position.

10.13.7 FANUC Series 15 Program Format Command

M

When bit 1 (FCV) of parameter No. 0001 is set to 1, rigid tapping can be specified in the FANUC Series 15 command format.

```
(1)   :
     Sxxxx ;
     G84.2/G84.3 X_ Y_ Z_ R_ P_ F_ L_ ;
      :
(2)   :
     G84.2/G84.3 X_ Y_ Z_ R_ P_ F_ L_ Sxxxx ;
      :
```

G84.2	: Rigid tapping cycle
G84.3	: Rigid reverse tapping cycle
X,Y	: Tapping position
Z	: Position of the bottom of a hole
R	: Position of a R point
P	: Dwell time at the bottom of a hole and at R point return time
F	: Cutting feedrate
L	: Number of repeats
S	: Spindle speed

> **NOTE**
> This function enables the rigid tapping function to be specified in the FANUC Series 15 command format without changing the rigid tapping sequence (such as handling with the PMC).

T

When bit 1 (FCV) of parameter No. 0001 is set to 1 and bit 3 (F16) of parameter No. 5102 is set to 0, rigid tapping can be specified in the FANUC Series 15 command format.

```
(1)  :
     Sxxxx ;
     G84.2 X_ C_ Z_ R_ P_ F_ L_ ;
     :
(2)  :
     G84.2 X_ C_ Z_ R_ P_ F_ L_ S_ ;
     :
```

G84.2	: Rigid tapping cycle G code
X,C	: Tapping position
Z	: Position of the bottom of a hole
R	: Position of a R point
P	: Dwell time at the bottom of a hole and at R point return time
F	: Cutting feedrate
L	: Number of repeats
S	: Spindle speed

The differences from the FS16 command format are as follows:

- No G code can make a distinction between a face tapping cycle and side tapping cycle. A tapping axis is determined by plane selection (G17/G18/G19). Select a plane that matches a face tapping cycle/side tapping cycle.

Plane select	Drilling axis
G17: Xp-Yp plane	Zp
G18: Zp-Xp plane	Yp
G19: Yp-Zp plane	Xp

Xp : X axis or its parallel axis
Yp : Y axis or its parallel axis
Zp : Z axis or its parallel axis

NOTE
With bit 0 (FXY) of parameter No. 5101, the Z-axis can be used as the tapping axis at all times. If FXY is set to 0, the Z-axis is used as the tapping axis at all times.

- The M code for C-axis clamping cannot be specified.
- The specification of a R point depends on the G code system and parameter setting as described below.
  1. When the bit 3 (F16) of parameter No. 5102 is set 0.

Bit 6 (RAB) of parameter No. 5102		
0	1	
Incremental command at all times	G code system	
	A	B,C
	Absolute command at all times	Follows G90/G91.

Bit 7 (RDI) of parameter No. 5102	
0	1
Diameter command at all times	Follows the diameter specification/radius specification of the tapping axis.

  2. When the bit 3 (F16) of parameter No. 5102 is set 1.
     An incremental command based on radius specification is used, regardless of bit 6 (RAB) and bit 7 (RDI) of parameter No. 5102.

NOTE
This function enables the rigid tapping function to be specified in the FANUC Series 15 command format without changing the rigid tapping sequence (such as handling with the PMC).

10.13.8 Multi-Spindle Control

When multi-spindle control is used, rigid tapping can be performed by selecting spindles from the first to fourth spindles. A spindle can be selected as described below (Table 10.13.8) by parameter setting.

Table 10.13.8

		Machining center system	Lathe system	
			Bit 7 (SRS) of parameter No. 5200	
			0	1
Bit 3 (MPP) of parameter No. 3703	0	Selected using the spindle selection signals SWS1 to SWS4	Selected using the spindle selection signals SWS1 to SWS4	Selected using the rigid tapping spindle selection signals RGTSP1 to RGTSP4
	1	Selected using an NC command (address P)		

For details of the method of selection using the spindle selection signals/rigid tapping spindle selection signals, see the descriptions of signals provided later.
For details of the method of selection using an NC command (address P), see "MULTI-SPINDLE CONTROL" .

10.13.9 3-dimensional Rigid Tapping

By performing rigid tapping in 3-dimensional coordinate conversion mode or Tilted working plane indexing mode, the tapping operation can be directed to the angular direction specified by 3-dimensional conversion command or Tilted working plane indexing command.
Be sure to use this function with 3-dimensional coordinate conversion or Tilted working plane indexing.

10.13.10 Rigid Tapping with Spindle of Another Path

Overview

In multi-path system, rigid tapping with spindle of other path different from specified path can be executed by path spindle control function. The spindle which executes rigid tapping is selected according to the spindle command selection signals.
If multi-spindle control option is provided, not only the path but also the spindle executed with rigid tapping can be selected.

Specifications

- Case in which no multi-spindle control is available

If bit 4 (SPR) of parameter No. 3703 is set to 1, using spindle command select signals, like the S command, makes it possible to specify a path from which rigid tapping command is to be used to control a spindle in a specific path.
The spindle command select signals are described below.
(Example)

2-path system: SLSPA<G063.2> (for a spindle in path 1) and SLSPB<G063.3> (for a spindle in path 2)
3-path system: SLSPA$^{\#1}$<G0063.2>, SLSPB$^{\#1}$<G0063.3> (for a spindle in path 1), SLSPA$^{\#2}$<G1063.2>, SLSPB$^{\#2}$<G1063.3> (for a spindle in path 2), SLSPA$^{\#3}$<G2063.2>, and SLSPB$^{\#3}$<G2063.3> (for a spindle in path 3)

- Case in which the multi-spindle control is available

- Signal-based command
  Setting bit 1 (EMS) of parameter No.3702 to 0 and bit 4 (SPR) of parameter No.3703 to 1 enables an arbitrary spindle in an arbitrary path to be used for rigid tapping.
  Before a rigid tapping command is issued, the spindle to be used for rigid tapping is selected using a signal.
- Address P-based command
  Setting bit 1 (EMS) of parameter No.3702 to 0 and bit 4 (SPR) of parameter No.3703 to 1 enables to use, for rigid tapping, a spindle connected to a path other than the one in which the command is issued. Setting bit 3 (MPP) of parameter No. 3703 to 1 enables a spindle to be selected for use in rigid tapping according to a program (P code).
  Adding address P to the S command for rigid tapping enables a spindle to be selected for use in rigid tapping.
  (Example: **M29 S1000 P22 ;**)
  It is necessary to set, in advance, parameter No. 3781 with relationships between P values and axes selected with specific P values.

  Refer to descriptions of “MULTI-SPINDLE CONTROL” in the related connection manual for explanations about how to use address P to select a spindle.

Example 1 Case in which no multi-spindle control is used

On a 2-path lathe with 2 spindles under 2-path control (bit 0 (2P2) of parameter No. 3703 is set to 1), the following signals are set up as stated when rigid tapping is carried out using the rigid tapping command (machining program) and servo section (Z $^{\#1}$ in the Fig. 10.13.10 (a)) in path 1 and the first spindle (SP1 $^{\#2}$ in the Fig. 10.13.10 (a)) connected to path 2.

<1> SLSPB<G63.3> ="1": The spindle connected to path 2 is controlled by commands in path 1.
<2> SLSPA<G63.2> = "1": The spindle connected to path 1 is controlled by commands in path 2.
Rigid tapping is carried out on the first spindle (SP1$^{\#2}$) in path 2.

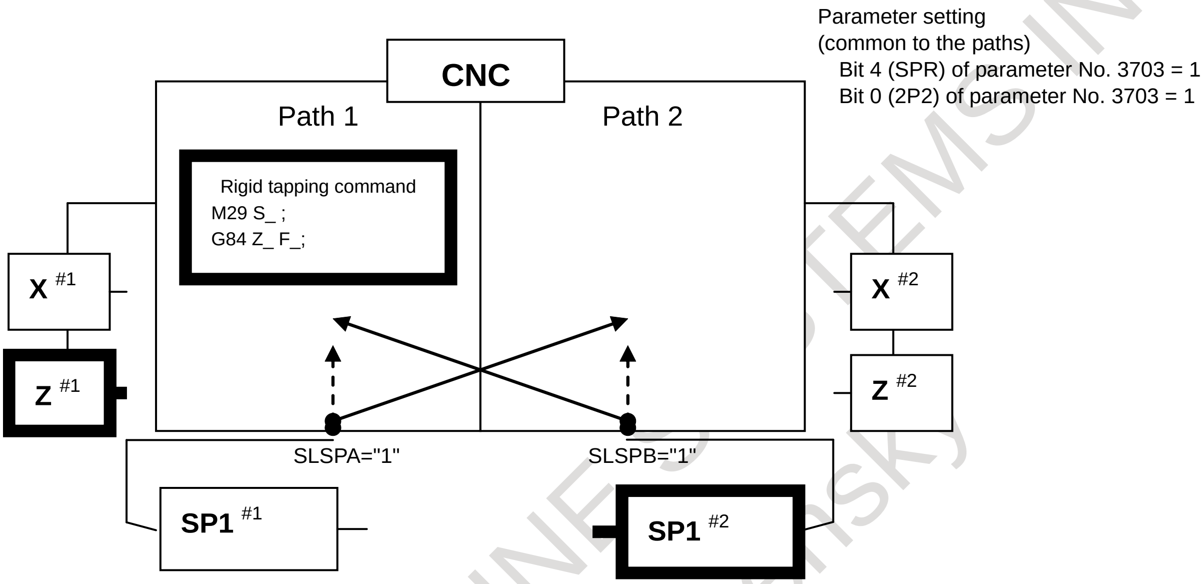


Fig. 10.13.10 (a)

(Supplement)

In the above example system configuration, the signal operation described in <2> is necessary to make each command correspond to the spindles selected by the commands on a one-to-one basis.
The way the spindle select signals are handled may vary according to the number of control paths in the CNC and the number of controlled axes (bits 0 (2P2) and 2 (MPM) of parameter No. 3703).

Example 2 Case in which multi-spindle control is used (signal-based command)

On a 2-path lathe with 4 spindles under 2-path control (bit 0 (2P2) of parameter No. 3703 is set to 1), the following signals are set up as stated beforehand when rigid tapping is carried out using the rigid tapping command (machining program) and servo section (Z $^{\#1}$ in the Fig. 10.13.10 (b)) in path 1 and the second spindle (SP2 $^{\#2}$ in the Fig. 10.13.10 (b)) connected to path 2.

<1> SLSPB<G63.3> = "1": The spindle connected to path 2 is controlled by commands in path 1.
<2> SLSPA<G63.2> = "1": The spindle connected to path 1 is controlled by commands in path 2.
<3> SWS1$^{\#2}$<G1027.0> ＝"0"
<4> SWS2$^{\#2}$<G1027.1> ＝"1": Rigid tapping is carried out on the second spindle (SP2$^{\#2}$) in path 2.

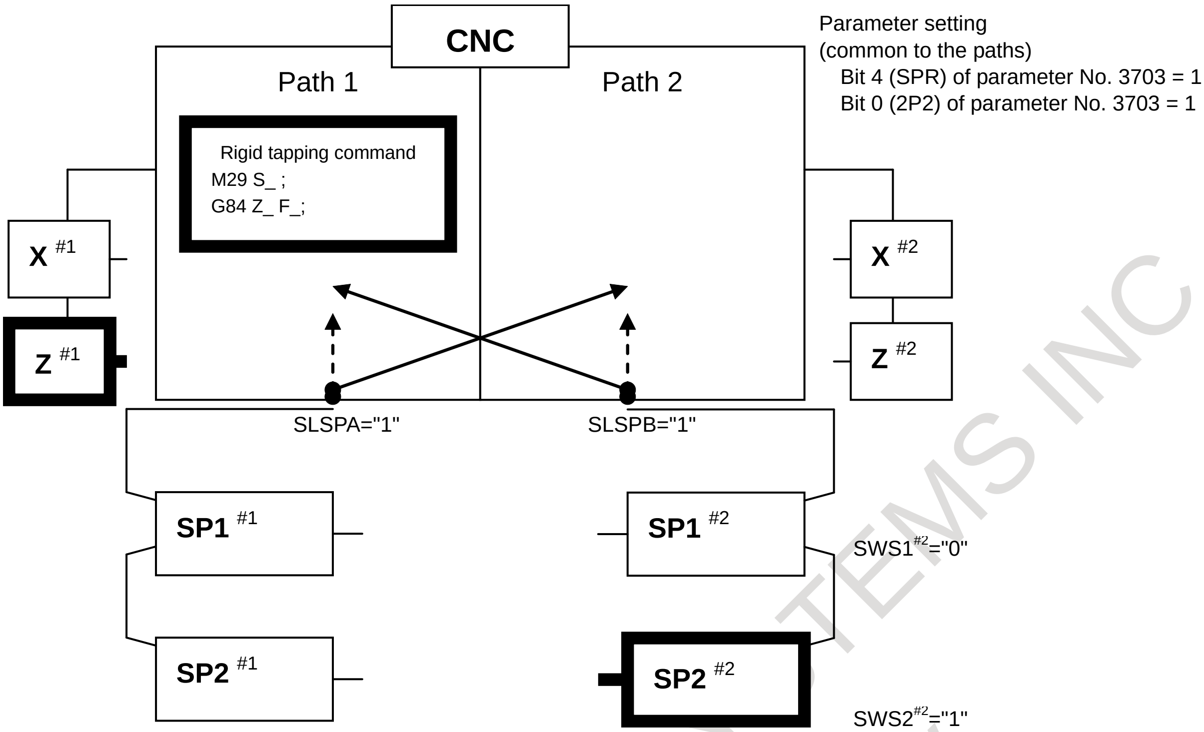

Fig. 10.13.10 (b)

(Supplement)

In the above example system configuration, the signal operation described in <2> is necessary to make each command correspond to the spindles selected by the commands on a one-to-one basis.

The way the spindle select signals are handled may vary according to the number of control paths in the CNC and the number of controlled axes (bits 0 (2P2) and 2 (MPM) of parameter No. 3703).

Example 3 Case in which multi-spindle control is used (address P-based command)

On a 2-path lathe with 4 spindles under 2-path control (bit 0 (2P2) of parameter No. 3703 is set to 1), before a rigid tapping command is issued, the following parameters are set up as stated if rigid tapping is to be carried out using the rigid tapping command (machining program) and servo section (Z $^{\#1}$ in the Fig. 10.13.10 (c)) in path 1 and the second spindle (SP2 $^{\#2}$ in the Fig. 10.13.10 (c)) connected to path 2.

No.3781 $^{\#1}$ S1 (Path 1: P value for selecting the first spindle) = 11
No.3781 $^{\#1}$ S2 (Path 1: P value for selecting the second spindle) = 12
No.3781 $^{\#2}$ S3 (Path 2: P value for selecting the first spindle) = 21
No.3781 $^{\#2}$ S4 (Path 2: P value for selecting the second spindle) = 22

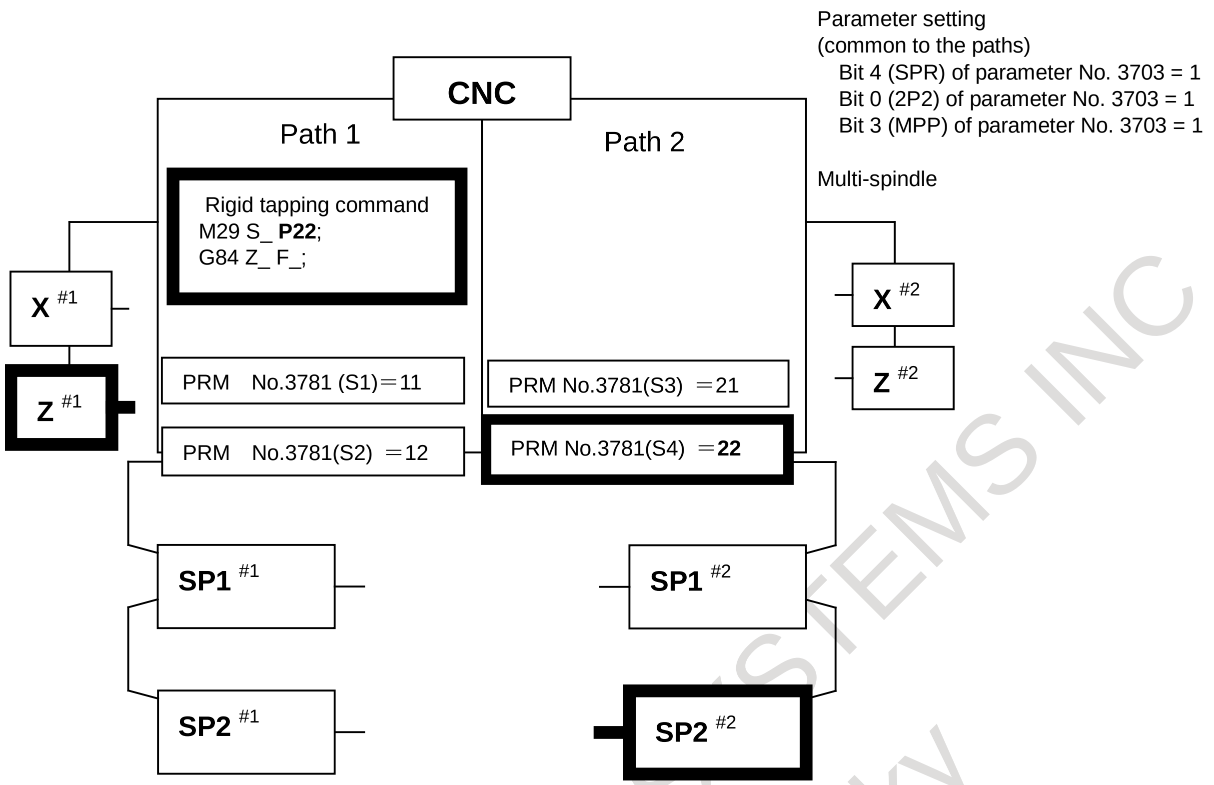

Fig. 10.13.10 (c)

The P code for selecting a spindle is added to the rigid tapping S command to execute a machining program. In this example, SP2 #2 must be controlled. So, the P code is used to issue a value (22) specified by parameter No. 3781 #2 (S4).

Restrictions

Observe the following restrictions.

- Paths issuing rigid tapping commands must correspond to spindles on which rigid tapping is carried out on a one-to-one basis.
- If this function is used to carry out rigid tapping on a spindle in a path other than a command-issuing path, the spindle must be put in the spindle speed control mode in advance.
- This function is unusable for servo motor-based rigid tapping.

The alarms below are raised if a restriction above is not observed, that is, if a condition stated below occurs.

Alarm PS0205 "RIGID MODE DI SIGNAL OFF"

- Rigid tapping commands in multiple paths attempted to carry out rigid tapping on the same spindle simultaneously.
- A rigid tapping command was issued to a spindle control axis with servo motor in a path other than the command issuing path.

Alarm SP0752 "SPINDLE MODE CHANGE ERROR"

- A spindle selected by a rigid tapping command was in a mode other than the spindle control mode.

The modes other than the spindle speed control mode include:

Cs contour axis
Spindle positioning
Spindle-synchronous
Rigid tapping (controlled by commands from another path)

T

inter-spindle polygon machining

[Example] 2-path system with each path having 2 spindles
(Rigid tapping is carried out on a spindle pointed to by an arrowhead)

	Path issuing commands		Spindle on which rigid tapping is carried out	MPP = 0	MPP = 1
Example 1	Path 1		First spindle	Available	Available
			Second spindle		
	Path 2		First spindle		
			Second spindle		
Example 2	Path 1		First spindle	Unavailable Alarm PS0205	Available
			Second spindle		
	Path 2		First spindle		
			Second spindle		
Example 3	Path 1		First spindle	Unavailable Alarm PS0205	Available
			Second spindle		
	Path 2		First spindle		
			Second spindle		
Example 4	Path 1		First spindle	Unavailable Alarm PS0205	Unavailable Alarm PS0205
			Second spindle		
	Path 2		First spindle		
			Second spindle		

If the rigid tapping spindle is not in the spindle speed control mode (for example, is in the Cs contour control mode), rigid tapping cannot be carried out in any of the above cases.

Notes

- This function is enabled when serial spindles are used. Issuing commands to an arbitrary spindle in a path other than a command issuing path requires the multi-spindle control to be enabled (bit 3 (MSP) of parameter No.8133 is 1).
- This function is unusable for rigid tapping with servo motor.
- If rigid tapping is carried out on a spindle in a path other than a command issuing path, the ENB signal is also shifted to the path to which the spindle is connected. Be careful when using the spindle ENB signal in the rigid tapping release sequence.
- Be careful not to issue a spindle mode switching command from one path and a rigid tapping command from another path to the same spindle simultaneously (for example, using an inter-path wait M code).

Example: The Cs contour control function (enabled if bit 2 (SCS) of parameter No.8133 is 1) is executed on the first spindle in path 1. After that, a rigid tapping command is issued from path 2 to that spindle.

Commands in path 1		Commands in path 2
:		:
M20 ; (Enter Cs contour control mode)		:
G00 C90.0 ; (C-axis positioning)		:
M21 ; (Exit from Cs contour control mode)		:
M12000 ;	← Waiting →	M12000 ;
:		M29 S_ P11 ; (Rigid tapping)
:		G84 X_ Z_ F_ ;

M12000: Inter-path wait M code (see descriptions of parameter Nos. 8110 and 8111)
Parameter No.3781 for 1st spindle of path 1 ＝ 11

- If this function is used to carry out rigid tapping on a spindle connected to a path other than a command issuing path, the settings in the path to which the spindle is connected are applied to the following parameters.
  No.5214 (synchronization error width)
  Nos.5221 to 5224 (number of gear teeth on spindle side)
  Nos.5231 to 5234 (number of gear teeth on PC side)
  Nos.5241 to 5244 (maximum rotation speed)
  Nos.5261 to 5264 (acceleration/deceleration constant)
  Nos.5271 to 5274 (acceleration/deceleration constant in extraction)
  Nos.5280 to 5284 (loop gain)
  No.5301, No.5303, No.5305 (spindle effective area (for in-position check))
  No.5311, No.5351, No.5355 (excessive error during spindle movement)
  No.5313, No.5353, No.5357 (excessive error with spindle at stop)
  Nos.5321 to 5324, 5325, 5326, 5327, 5328 (backlash)

10.13.11 Diagnosis Data

For rigid tapping adjustment, the diagnosis screen displays information related to rigid tapping.

- Display of command pulses and position deviation amounts

- Spindle position deviation → Diagnosis data No. 0450
- Number of command pulses distributed to the spindle (momentary value) → Diagnosis data No. 0451
- Cumulative number of command pulses distributed to the spindle → Diagnosis data No. 0454

- Display of rigid tapping synchronization error

- Spindle-converted move command difference → Diagnosis data No. 0455
- Spindle-converted position deviation difference → Diagnosis data No. 0456
- Synchronization error range → Diagnosis data No. 0457
- Spindle-converted move amount difference (maximum value) → Diagnosis data No. 0460
- Spindle-converted machine position difference (momentary value) → Diagnosis data No. 0461
- Spindle-converted machine position difference (maximum value) → Diagnosis data No. 0462

$$\text{Spindle - converted move command difference} = \Sigma \frac{\text{spindle move command}}{\text{gear ratio}} -$$

$$\Sigma \frac{(\text{tapping axis move command}) \times \text{number of pulses per spindle revolution}}{\text{thread lead}}$$

$$\text{Spindle - converted position deviation difference} = \frac{\text{spindle position deviation}}{\text{gear ratio}} -$$

$$\frac{(\text{drilling axis position deviation}) \times \text{number of pulses per spindle revolution}}{\text{thread lead}}$$

$$\text{Synchronization error range} =$$
$$(\text{maximum spindle - converted position deviation difference on the positive side}) -$$
$$(\text{maximum spindle - converted position deviation difference on the negative side})$$

$$\text{Drilling axis machine position} \square \sum [\text{drilling axis move command}] - \text{drilling axis position deviation}$$

$$\text{Spindle machine position} \square \sum [\text{spindle move command}] - \text{spindle position deviation}$$

$$\text{Spindle - converted machine position deviation difference} \square$$
$$\frac{\text{drilling axis machine position} \times \text{number of pulses per spindle revolution}}{\text{thread lead}} \square \frac{\text{spindle machine position}}{\text{gear ratio}}$$

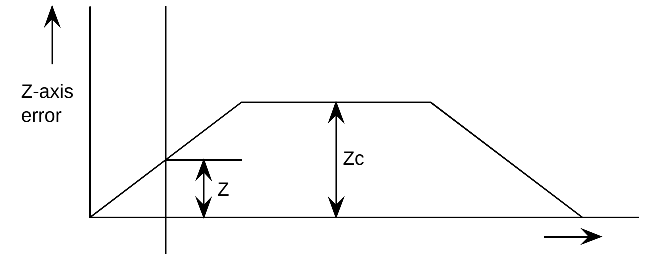
If a maximum allowable synchronization error range is set in parameter No. 5214, the position deviation alarm during spindle movement (alarm SP0741) is issued to indicate that the set synchronization error range has been exceeded. (If 0 is set in parameter No. 5214, no check is performed to detect whether the synchronization error range has been exceeded.)

- Error difference display

- Momentary error difference between the spindle and drilling axis → Diagnosis data No. 0452
- Maximum error difference between the spindle and drilling axis → Diagnosis data No. 0453

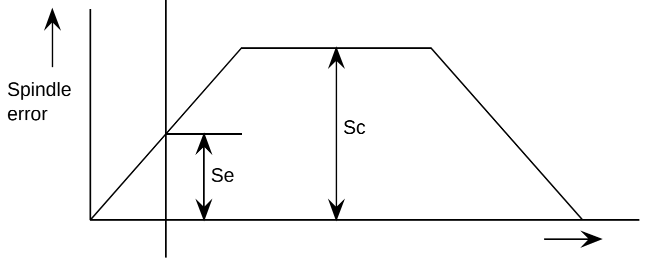
Diagnosis display No. 0452 is cleared to 0 when rigid tapping mode is set or canceled, and diagnosis data No. 0453 is cleared to 0 in the positioning of the rigid tapping cycle.

The following figure shows the tapping axis as the Z axis.



$$Zc = \frac{Speed}{60} \times \frac{1}{Gain} \times \frac{1}{Detection\ unit} \times 10^2 \text{ (Theoretical value)}$$

Ze = Z-axis error counts (measured value)



$$Sc = \frac{Speed \times 360}{60} \times \frac{1}{Gain} \times \frac{1}{Detection\ unit} \times 10^2 \text{ (Theoretical value)}$$

Se = Spindle error counts (measured value)

(Speed : mm/min or inch/min
Gain : 0.01sec^{-1}
Detection unit : mm,inch,or deg
Speed : min^{-1})

$$\Delta Z = \frac{Z}{Zc} \times 100\ [\%]$$

$$\Delta S = \frac{Se}{Sc} \times 100\ [\%]$$

The error difference between the spindle and Z axis can be obtained by ΔS-ΔZ. This value is sampled at intervals of 8 ms.

- Display of spindle position data

Position coder signal pulse data from the spindle one-rotation signal is displayed.

- Position coder signal pulse data of each spindle → Diagnosis data No.0445

NOTE

1 For an unconnected spindle, 0 is displayed.

2 For display of this data, the conditions below must be satisfied.

<1>Serial spindle

<2>Bit 1 (SPP) of parameter No. 3117 must be set to 1.

<3>The state where the serial spindle has detected a one-rotation signal must be set.

To detect a one-rotation signal accurately, spindle orientation must be performed. This orientation operation needs to be performed only once after the power is turned on.

Whether a one-rotation signal has been detected can be known by checking position coder one-rotation signal detection status signal (serial spindle) PC1DTA to PC1DTD<Fn047.0, Fn051.0, Fn170.0, Fn268.0>.

Diagnosis data

- Spindle position data

0445	SPINDLE POSITION DATA

Position coder signal pulse data from the spindle one-rotation signal of each spindle (serial spindle only)

[Unit] Pulse

- Spindle position deviation

0450	SPINDLE MOTION ERROR

Spindle position deviation during rigid tapping

[Unit] Pulse

- Number of pulses distributed to the spindle

0451	SPINDLE MOTION PULSE

Number of pulses distributed to the spindle during rigid tapping

[Unit] Pulse

- Error difference between the spindle and drilling axis (momentary value)

0452	RIGID ERROR

Momentary error difference between the spindle and drilling axis during rigid tapping (signed)

[Unit] %

- Error difference between the spindle and drilling axis (maximum)

0453	RIGID ERROR (MAX)

Maximum error difference between the spindle and drilling axis during rigid tapping (absolute value)

[Unit] %

- Cumulative number of pulses distributed to the spindle during rigid tapping

0454	SPINDLE PULSE (SUM)

Cumulative number of pulses distributed to the spindle during rigid tapping

[Unit] Pulse

- Spindle-converted move command difference during rigid tapping (momentary value)

0455	SYNC. PULSE (SUM)

Momentary spindle-converted move during command difference between the spindle and the drilling axis during rigid tapping

[Unit] Pulse

- Spindle-converted position deviation difference during rigid tapping (momentary value)

0456	SYNC. ERROR

Momentary spindle-converted position deviation difference between the spindle and the drilling axis during rigid tapping

[Unit] Pulse

- Synchronization error range during rigid tapping (maximum value)

0457	SYNC. WIDTH

Synchronization error range during rigid tapping (maximum value)

[Unit] Pulse

- Spindle-converted move command difference during rigid tapping (maximum value)

0460	SYNC. PULSE (MAX)

Maximum spindle-converted move during command difference between the spindle and the drilling axis during rigid tapping

[Unit] Pulse

- Spindle-converted machine position difference during rigid tapping (momentary value)

0461	MACHIN POS ERROR

Spindle-converted machine position difference during rigid tapping (momentary value)

[Unit] Pulse

- Spindle-converted machine position difference during rigid tapping (maximum value)

0462	MACHIN POS ERROR (MAX)

Spindle-converted machine position difference during rigid tapping (maximum value)

[Unit] Pulse

10.13.12 Command Format

T

Command format for the lathe system

The rigid tapping mode can be specified in one of two formats: FANUC Series 16 program format and FANUC Series 15 program format. A usable format can be selected by parameter setting.

Parameter		Executable command format
Bit 1 (FCV) of parameter No. 0001	Bit 3 (F16) of parameter No. 5102	
0	-	FANUC Series 16 program format only (The number of repeats is specified using address K.)
1	0	FANUC Series 15 program format or FANUC Series 16 program format (The number of repeats is specified using address L.)
1	1	FANUC Series 16 program format only (The number of repeats is specified using address L.)

This subsection describes the FANUC Series 16 program command format for rigid tapping on the lathe system. For the machining center system, refer to the description of "RIGID TAPPING" in the Operator's Manual.

- G84 : Face tapping cycle

The first axis of a plane is a drilling axis, and the other axes are positioning axes.

Bit 0 (RTX) of parameter No. 5209	Plane selection	Drilling axis
0	G17: Xp-Yp plane	Xp
	G18: Zp-Xp plane	Zp
	G19: Yp-Zp plane	Yp
1 (Note)		Zp

Xp : X axis or its parallel axis
Yp : Y axis or its parallel axis
Zp : Z axis or its parallel axis
Note) These are invalid in the FANUC Series 15 program format.

1. When the bit 1 (FCV) of parameter No. 0001 is set to 0 :
   G84 X_C_ Z_ R_ P_ F_ K_ M_ ;
   G84 : Face tapping cycle G code
   X C : Tapping position
   Z : Position of the bottom of a hole
   R : Position of an R point (incremental command at all times)
   P : Dwell time at the bottom of a hole
   F : Cutting feedrate
   K : Number of repeats
   M : M code for C-axis clamping

2. When the bit 1 (FCV) of parameter No. 0001 is set to 1 :
   G84 X_C_ Z_ R_ P_ F_ L_ M_ ;
   G84 : Face tapping cycle G code
   X C : Tapping position
   Z : Position of the bottom of a hole
   R : Position of an R point (incremental command at all times)
   P : Dwell time at the bottom of a hole
   F : Cutting feedrate
   L : Number of repeats
   M : M code for C-axis clamping

- G88 : Side tapping cycle

The second axis of a plane is a drilling axis, and the other axes are positioning axes.

Bit 0 (RTX) of parameter No. 5209	Plane selection	Drilling axis
0	G17: Xp-Yp plane	Yp
	G18: Zp-Xp plane	Xp
	G19: Yp-Zp plane	Zp
1 (Note)		Xp

Xp : X axis or its parallel axis
Yp : Y axis or its parallel axis
Zp : Z axis or its parallel axis
Note) These are invalid in the FANUC Series 15 program format.

1. When the bit 1 (FCV) of parameter No. 0001 is set to 0 :
   G88 Z_C_ X_ R_ P_ F_ K_ M_ ;
   G88 : Side tapping cycle G code
   Z C : Tapping position
   X : Position of the bottom of a hole
   R : Position of an R point (incremental command at all times)
   P : Dwell time at the bottom of a hole
   F : Cutting feedrate
   K : Number of repeats
   M : M code for C-axis clamping
2. When the bit 1 (FCV) of parameter No. 0001 is set to 1 :
   G88 Z_C_ X_ R_ P_ F_ L_ M_ ;
   G88 : Side tapping cycle G code
   Z C : Tapping position
   X : Position of the bottom of a hole
   R : Position of an R point (incremental command at all times)
   P : Dwell time at the bottom of a hole
   F : Cutting feedrate
   L : Number of repeats
   M : M code for C-axis clamping

- Method of specification

The rigid tapping mode can be specified using one of three methods:

- Specification of M29S_ before specifying a tapping cycle
- Specification of M29S_ in the same block
- Enabling rigid tapping to be performed without specifying M29S_

When using the third method, specify S_ either before or in a block containing G84 (G88).
Thus, the spindle stops, after which the tapping cycle specified next is placed in rigid tapping mode.
When Spindle selection by address P of Multi spindle is enabled, if S is commanded at G84(G88) block, alarm PS5305, "ILLEGAL SPINDLE NUMBER" is issued. Command S before G84(G88) block.

- Specifying M29 before a block containing G84 (G88)

```
M29    S_;
G84(G88) X_C_(Z_C_) Z_(X_) R_ P_ F_ K_ M_;   ┐
X_C_(Z_C_);                                  │
X_C_(Z_C_);                                  │ Rigid tapping mode
        :                                    │
G80;                                         ┘
```

- Specifying M29 and G84 (G88) in the same block
  (However, the M code for C-axis clamping cannot be specified.)

```
G84(G88) X_C_(Z_C_) Z_(X_) R_ P_ F_ K_ M29 S_;  ┐
X_C_(Z_C_);                                     │
X_C_(Z_C_);                                     │ Rigid tapping mode
        :                                       │
G80;                                            ┘
```

- Converting G84 (G88) to a G code for rigid tapping
  (by setting bit 0 (G84) of parameter No. 5200 to 1)

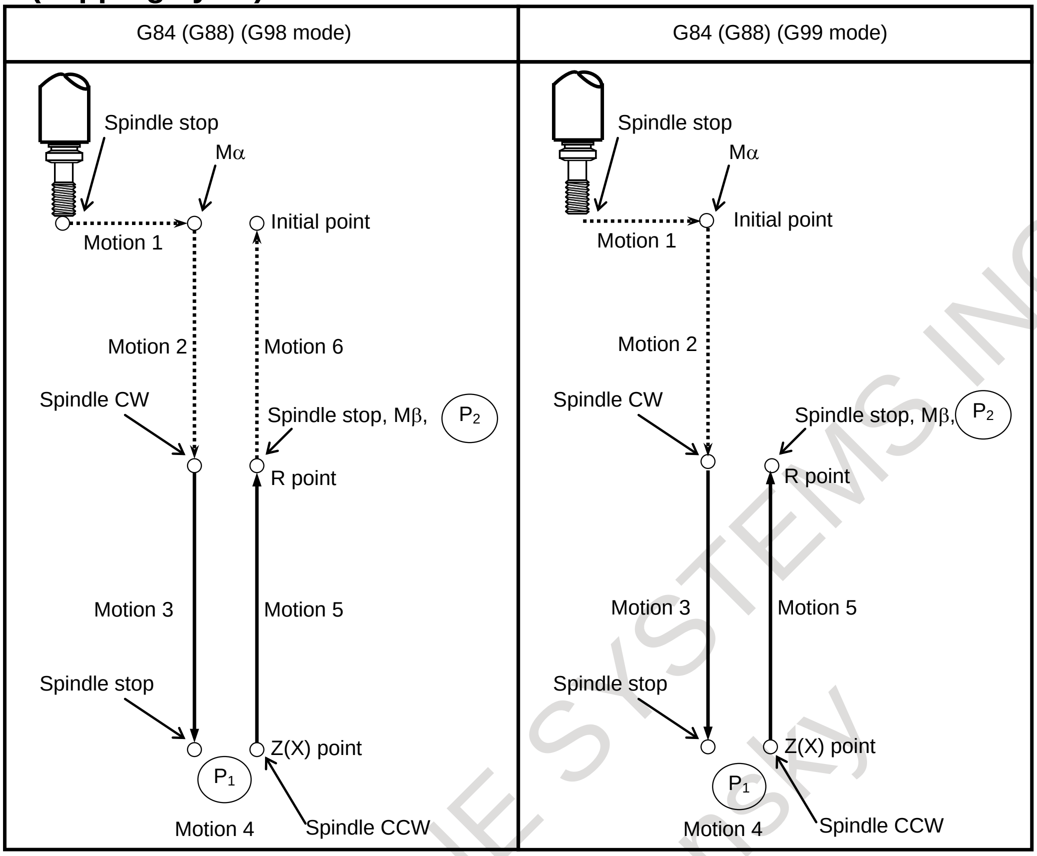
```
G84(G88) X_C_(Z_C_) Z_(X_) R_ P_ F_ K_ S_ M_;   ┐
X_C_(Z_C_);                                     │
X_C_(Z_C_);                                     │ Rigid tapping mode
        :                                       │
G80;                                            ┘
```

- Notes on the lathe system

NOTE

1. In feed per minute mode, F_/S**** determines a thread lead. In feed per revolution mode, F_ specifies a thread lead.
2. S**** must specify a value that does not exceed the value set in the maximum spindle speed parameters Nos. 5241 to 5244 for the gear to be used. Otherwise, an alarm PS0200, "ILLEGAL S CODE COMMAND" is issued in a block containing G84 (G88).
3. F_ must specify a value that does not exceed the maximum cutting feedrate. When 0 is specified, an alarm PS0201, "FEEDRATE NOT FOUND IN RIGID TAP" is issued.
4. Between M29 and G84 (G88), S and a command for movement along an axis must not be specified. Further, M29 must not be specified in a tapping cycle. Otherwise, alarms PS0203, "PROGRAM MISS AT RIGID TAPPING" and PS0204, "ILLEGAL AXIS OPERATION" are issued, respectively.
5. In the rigid tapping mode, G84 and G88 must not be specified in succession. Cancel the rigid tapping mode before specifying G84 and G88 in succession.

G84, G88 (Tapping cycle)



Rapid traverse
Cutting feed
P1 Dwell specified by address P in the program
P2 Dwell set by parameter No. 5111 (not performed in the FANUC Series 15 program format)
Mα Output of an M code for C-axis clamping
Mβ Output of an M code for C-axis unclamping (β=α+1) (not performed in the FANUC Series 15 program format)
Supplement: P1, Mα, Mβ, and P2, when not specified, are not executed and output.

> ⚠ **CAUTION**
> For cutting feed along the Z(X)-axis and override in extraction, see Subsection "Override".

> **NOTE**
> G code system A does not include G98 (return to initial level) and G99 (return to R point level). Return to the initial level is always used.

10.13.13 Position Control Loop Gain Parameter Switching

In rigid tapping, the position control loop gain of the drilling axis must match that of the spindle. Specifically, change the position control loop gain of the drilling axis at the following timings:

(1) A change from a position control loop gain for normal operation to a position control loop gain for rigid tapping must be made when the cutting along the drilling axis is started (when motion 3 is started).

(2) A change from a position control loop gain for rigid tapping to a position control loop gain for normal operation must be made when the operation after the completion of extraction along the drilling axis is started (when motion 6 is started).

While a position control loop gain for rigid tapping is selected, the parameters dedicated to rigid tapping are used for the following parameters for the drilling axis:

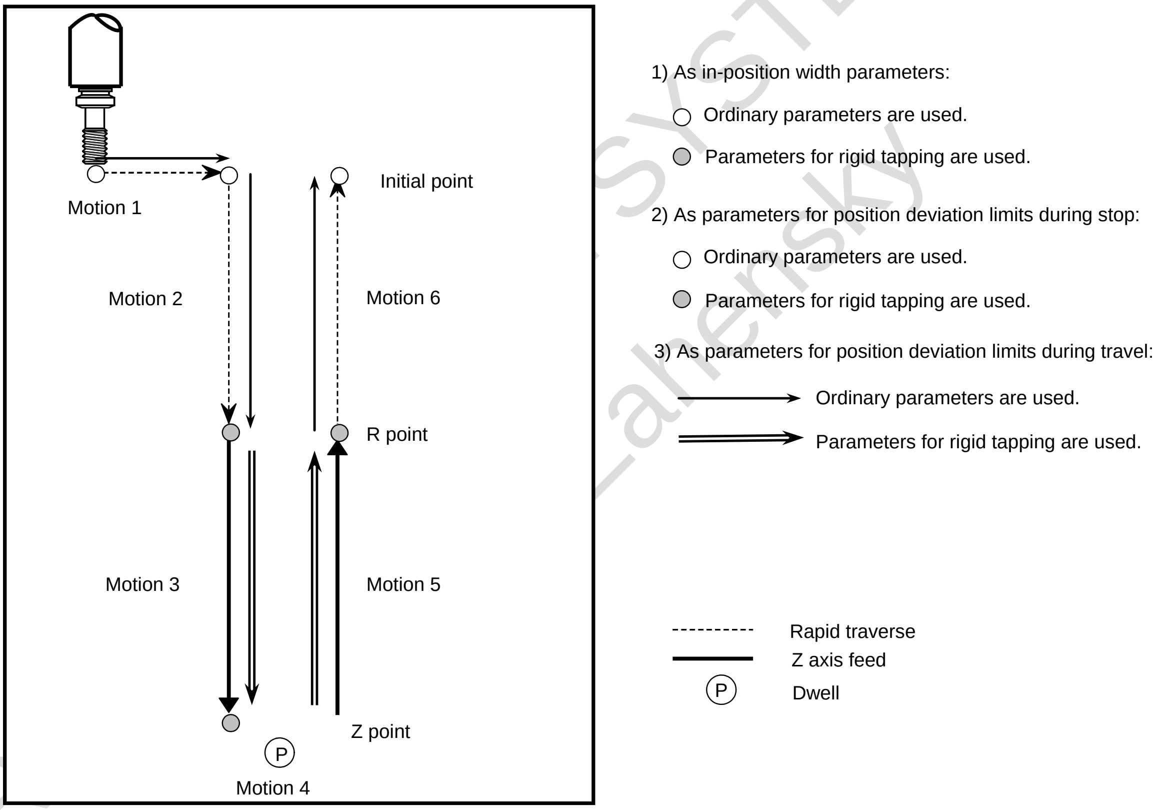
(1) In-position width
(Parameters Nos.5300, 5302, 5304, and 5306)

(2) Position deviation limit during stop
(Parameters Nos.5312, 5352, 5356, and 5360)

(3) Position deviation limit during travel
(Parameters Nos.5310, 5350, 5354, and 5358)

The above parameters dedicated to rigid tapping are usually used to specify the in-position width at the R point for motion 2. However, an ordinary parameter No. 1826 can be selected by using bit 4 (IRR) of parameter No. 5202.

> **NOTE**
> If bit 5 (NCI) of parameter No. 1601 is set to 1, no in-position check is made at the R point for motion 2 except when bit 1 (RIP) of parameter No. 5209 is set to 1.



10.13.14 Signal

10.13.14.1 Signals for the rigid tapping function

Rigid tapping signal RGTAP<Gn061.0>

[Classification] Input signal

[Function] When M29 (miscellaneous function for preparation for rigid tapping) is specified, the PMC enters rigid tapping mode, then turns on this signal to notify the CNC.

1 : The PMC enters in rigid tapping mode.

0 : The PMC does not enter rigid tapping mode.

For an explanation of placing the PMC in rigid tapping mode, see the description of the interface with the PMC, given later.

This signal posts whether the PMC has entered rigid tapping mode. If this signal is not set to 1, even when M29 is specified, alarm (PS0205) "RIGID MODE DI SIGNAL OFF" is issued in a G84/G74(machining center system) or G84/G88(lathe system) block.

Spindle rotation direction signals RGSPM,RGSPP<Fn065.1,0>

[Classification] Output signal

[Function] During rigid tapping, these signals notify the PMC of whether the spindle is rotating in the forward or reverse direction.
→ During rigid tapping, the spindle is:

RGSPP 1 : Rotating in the forward direction (CW).
0 : Not rotating in the forward direction (CW).

RGSPM 1 : Rotating in the reverse direction (CCW).
0 : Not rotating in the reverse direction (CCW).

[Output cond.] These signals are output when the spindle is rotating in rigid tapping mode. This means that, even in rigid tapping mode, these signals are not output, for example, when the spindle is being positioned to a hole position, or a dwell operation is in progress at the bottom of a hole or at an R point.
These signals are not output in the feed hold state or single block stop state. When the spindle is placed in the interlock stop state, machine lock state, or Z-axis ignore state, however, the spindle is not regarded as having stopped; these signals are output.
These signals are valid only in rigid tapping mode. In normal spindle control, these signals are not output; both RGSPP and RGSPM are set to 0.

Rigid tapping in-progress signal RTAP<Fn076.3>

[Classification] Output signal

[Function] This signal notifies the PMC that rigid tapping mode is active.

RTAP 1 : Rigid tapping mode is currently active.
0 : Rigid tapping mode is not currently active.
By latching M29, the PMC knows that rigid tapping mode has been specified, and thus performs the required processing on the PMC side. This signal can substitute for the latching of M29. Even in this case, however, FIN for M29 cannot be omitted.

10.13.14.2 Signals related to S code output

Spindle enable signal ENB<Fn001.4>

[Classification] Output signal

[Function] This signal post whether the spindle output is 0. In rigid tapping mode, this signal is used to cancel rigid tapping in a PMC sequence associated with rigid tapping. For details, see the explanation of the interface with the PMC, given later.

Spindle-speed function code signals (binary output) S00 to S31<Fn022 to Fn025>
Spindle-speed function strobe signals SF<Fn007.2>

[Classification] Output signal

[Function] These signals send S codes specified for the CNC, in binary format, to the PMC.

[Output cond.] When an S code is specified, the specified value is output, in binary format, with these signals. When the new spindle speed data is fully set, the SF signal is set to 1.
Before rigid tapping can be performed, however, parameter setting is required to output these signals, as described below.

Machining center system :
SF output depends on the gear selection method, as described below.
[1] M-type gear selection method
SF output depends on bit 6 (SFA) of parameter No. 3705.

[2] T-type gear selection method
SF output depends on the setting of bit 5 (NSF) of parameter No. 3705.

Lathe system :
The following parameter needs to be set to output S codes and SF:
Bit 4 (EVS) of parameter No. 3705 is set to 1

In rigid tapping, when SF is to be used by the PMC to read an S code output signal for gear switching or output switching, set the above parameters as required.

NOTE

1 The timing charts, given later, give examples of gear switching by setting the parameters as follows:
Machining center system : SFA=0,NSF=0
Lathe system : EVS=1

2 When the constant surface speed control function is being used, an S code (specifying a surface speed) used for constant surface control (G96) is output. Such an S code can be distinguished from an S code used for specifying a rotation speed. One method is to use, for example, the constant surface speed control in-progress signal <F002.2> for the processing performed on the PMC side. Another method is to mask the S code and SF signal, output by setting bit 0 (ESF) of parameter No. 3705.

10.13.14.3 Signals related to gear switching

Gear selection signals (output) GR3O,GR2O,GR1O<Fn034.2,1,0>

M

[Classification] Output signal

[Operation] When M-type gear selection is being used, these signals are used in a PMC sequence for rigid tapping.
The signals post, to the PMC, information about a spindle gear to be used, according to the value of S_ specified at the execution of G84 (G74).
When gear switching becomes necessary, the states of the signals change together with the SF signal.
The PMC should perform gear switching according to the information posted by the gear selection signals.
Reference information:
The table below indicates the relationship between the output signals and gear selection.

	GR3O	GR2O	GR1O
1st (low) speed gear	0	0	1
2nd (medium) speed gear	0	1	0
3rd (high) speed gear	1	0	0

Gear selection signals (input) GR2,GR1<Gn028.2,1>

[Classification] Input signal

[Operation] When T-type gear selection is being used, these signals are used in a PMC sequence for rigid tapping.
The signals post, to the CNC, information about a spindle gear to be used.
Reference information:
The table below shows the relationship between the output signals and spindle gear selection.

	GR1	GR2
1st (low) speed gear	0	0
2nd (medium) speed gear	1	0
3rd (high) speed gear	0	1
4th (high) speed gear	1	1

The serial spindle clutch/gear selection signals <G070.3,2> must be set in addition to the setting of the gear selection signal described above.

NOTE
In machining center system rigid tapping, the specification of the 4th (high) speed gear is invalid. If specified, the system assumes that the 3rd (high) speed gear has been specified.

10.13.14.4 Signals related to the addition of multi-spindle control

Spindle enable signals ENB<Fn001.4>,ENB2,ENB3<Fn038.2,3>,ENB4<Fn039.1>

[Classification] Output signal

[Function] These signals post whether the spindle output to each spindle is 0 in multi-spindle control.
In rigid tapping mode, these signals are used to cancel rigid tapping in a PMC sequence associated with rigid tapping.
For details, see the explanation of the interface with the PMC, given later.

Gear selection signals (input)
GR2,GR1<Gn028.2,1>,GR22,GR21<Gn029.1,0>,GR32,GR31<Gn029.3,2>, GR42,GR41<Gn031.5,4>

[Classification] Input signal

[Operation] When the T-type gear selection method is employed in multi-spindle control, these signals are used with a PMC sequence for rigid tapping.
The signals post, to the CNC, information about a spindle gear to be used.
Reference information:
The table below shows the relationship between the output signals and spindle gear selection.

	GRs1	GRs2
1st (low) speed gear	0	0
2nd (medium) speed gear	1	0
3rd (high) speed gear	0	1
4th (high) speed gear	1	1

(s is -, 2, 3, or 4.)

The serial spindle clutch/gear selection signals (G070.3,2 for the first spindle, G074.3,2 for the second spindle, G204.3,2 for the third spindle, and G266.3,2 for the fourth spindle) must be set in addition to the setting of the gear selection signal described above.

NOTE
In machining center system rigid tapping, the specification of the 4th (high) speed gear is invalid. If specified, the system assumes that the 3rd (high) speed gear has been specified.

Spindle selection signals
SWS1<Gn027.0>,SWS2<Gn027.1>,SWS3<Gn027.2>,SWS4<Gn026.3>
Rigid tapping spindle selection signals
RGTSP1<Gn061.4>,RGTSP2<Gn061.5>,RGTSP3<Gn061.6>,RGTSP4<Gn061.7>

T

[Classification] Input signal

[Operation] SWS1 to SWS4 are used to transfer spindle commands when the multi-spindle control is enabled (bit 3 (MSP) of parameter No.8133 is 1). In rigid tapping, the signals can be shared to select a spindle to be used for rigid tapping. (The signals can be used for this purpose when bit 7 (SRS) of parameter No. 5200 is set to 0.)
RGTSP1, RGTSP2, RGTSP3, and RGTSP4 are used to select a spindle used for rigid tapping, independently of the SWS1 to SWS4 signals, when the multi-spindle control is enabled (bit 3 (MSP) of parameter No.8133 is 1). (The signals can be used when bit 7 (SRS) of parameter No. 5200 is set to 1. These signals are supported only by the lathe system.)
See the tables below for details of the settings of these signals.
When bit 7 (SRS) of parameter No. 5200 is set to 0, to select a spindle to be used for rigid tapping, set the signals as indicated below.

Spindle used for rigid tapping	Signal state			
	SWS1	SWS2	SWS3	SWS4
First spindle	"1"	"0"	"0"	"0"
Second spindle	"0"	"1"	"0"	"0"
Third spindle	"0"	"0"	"1"	"0"
Fourth spindle	"0"	"0"	"0"	"1"
Alarm PS0205 is issued.	"0"	"0"	"0"	"0"

When bit 7 (SRS) of parameter No. 5200 is set to 1, to select a spindle to be used for rigid tapping, set the signals as indicated below.

Spindle used for rigid tapping	Signal state			
	RGTSP1	RGTSP2	RGTSP3	RGTSP4
First spindle	"1"	"0"	"0"	"0"
Second spindle	"0"	"1"	"0"	"0"
Third spindle	"0"	"0"	"1"	"0"
Fourth spindle	"0"	"0"	"0"	"1"
Alarm PS0205 is issued.	"0"	"0"	"0"	"0"

NOTE
1 These signals must be applied before the command for rigid tapping (M29 S....; G84 X...) is specified. The states of these signals must not be changed before rigid tapping has been completed.
2 When multiple signals from SWS1 to SWS4 are set to "1" simultaneously, the signals are checked in the order from SWS1 to SWS2 to SWS3 to SWS4, and the spindle corresponding to the signal that is first found to be set to "1" is assumed to be specified.

> **NOTE**
> 3 Similarly, when multiple signals from RGTSP1 to RGTSP4 are set to "1" simultaneously, the signals are checked in the order from RGTSP1 to RGTSP2 to RGTSP3 to RGTSP4, and the spindle corresponding to the signal that is first found to be set to "1" is assumed to be specified.

Spindle-by-spindle stop signals*SSTP1<Gn027.3>,*SSTP2<Gn027.4>,*SSTP3<Gn027.5>, *SSTP4<Gn026.6>

[Classification] Input signal

[Operation] These signals are used to stop each spindle when the multi-spindle control option is enabled (bit 3 (MSP) of parameter No.8133 is 1). In a PMC sequence for rigid tapping, the ENB1, ENB2, ENB3 and ENB4 signals are used. Accordingly, the logic of the signals used for a spindle selected to perform rigid tapping must match the logic of the spindle stop signal *SSTPs.

*SSTP1 1 : The output to the first spindle is not forced to 0 min^{-1}.
0 : 0 min^{-1} is commanded to first spindle.

*SSTP2 1 : The output to the second spindle is not forced to 0 min^{-1}.
0 : 0 min^{-1} is commanded to second spindle.

*SSTP3 1 : The output to the third spindle is not forced to 0 min^{-1}.
0 : 0 min^{-1} is commanded to third spindle.

*SSTP4 1 : The output to the fourth spindle is not forced to 0 min^{-1}.
0 : 0 min^{-1} is commanded to fourth spindle.

Position coder selection signal PC2SLC<Gn028.7>,PC3SLC<Gn026.0>,PC4SLC<Gn026.1>

[Classification] Input signal

[Operation] This signal is used to select the position coder when the multi-spindle control option is enabled (bit 3 (MSP) of parameter No.8133 is 1). Note, however, that it cannot be used with a spindle selected to perform rigid tapping.
For rigid tapping, this signal is not used. Instead, a position loop is constructed by combining the first spindle with the first position coder, by combining the second spindle with the second position coder, by combining the third spindle with the third position coder, or by combining the fourth spindle with the fourth position coder.
However, the display of the actual speed is switched by this signal, even during rigid tapping.

10.13.14.5 Notes on interface with the PMC

The following describes some notes in designing the interface with the PMC. Refer to the following timing chart about ON/OFF of signals.

- Rigid tapping mode management and ENB (ENB2,ENB3,ENB4)

The PMC must manage rigid tapping mode as follows: rigid tapping mode is set using M29, and is canceled upon the issue of a reset or at the falling edge of the spindle enable signal ENB in rigid tapping mode. ENB is used during rigid tapping in this way, so the spindle stop signal *SSTP must not be set to "0".
However, the spindle orientation function (*SSTP and SOR) may be used for gear switching. To do so, ensure that the PMC does not cancel rigid tapping mode on a falling edge of ENB while *SSTP is "0".
Rigid tapping mode may be set on a rising edge of the RTAP signal instead of by using M29, and canceled on a falling edge of the RTAP signal instead of the ENB signal. In rigid tapping under multi -spindle control, use the spindle enable signal ENBs for the spindle engaged in rigid tapping to exercise control.

- Controlling spindle output by the PMC

When the SIND signal is set to "1", spindle output is controlled by the signals (SSIN, SGN, R1I to R12I) output from the PMC.
At this time, the effect of ENB is as described above. In addition, when rigid tapping mode is canceled in a block containing G80;, the momentary rotation of the spindle, caused by a delay in the PMC processing, can result. Accordingly, the PMC's control over spindle output must be disabled in rigid tapping mode by setting SIND to "0".
In rigid tapping under multi-spindle control, ensure, for a similar reason, that in the rigid tapping mode, PMC-based control is disabled (SINDs = "0") for the spindle used for rigid tapping.

- T-type gear selection method

When T-type gear selection is used, the PMC must determine whether gear switching is to be performed, and subsequently perform gear switching as required. For this purpose, each time a spindle-speed function code is specified, the spindle-speed function code read signal (SF) and spindle-speed function code signals (S00 to S31) must be output to the PMC. The required parameter settings are described below.

- Machining center system :
  Set bit 5 (NSF) of parameter No. 3705 to 0 to output SF.
- Lathe system :
  Set bit 4 (EVS) of parameter No. 3705 to 1 to output SF.

- Gear switching timing

In general, a block containing M29 (miscellaneous function for preparation for rigid tapping) specifies S_, S_ being output when a block containing G84/G74 (machining center system) or G84/G88 (lathe system) is executed. This means that gear switching is performed in the block specifying G84 (G74).

- When rigid tapping mode is specified

M29 (miscellaneous function for preparation for rigid tapping) and S_ specify rigid tapping mode. When M29 is accepted by the PMC, the following processing must be performed:

- Stop the spindle when it is rotating.
- Check speed zero signal SSTs if the spindle has been stopped, then set "1" to rigid tapping signal RGTAP <Gn061.0>.
- Activate the spindle motor. Activate the motor so that a positive speed command rotates the spindle in the forward direction (CCW when viewed from the - side of the tapping axis).
- Return FIN at least 250 ms after activation.

> **NOTE**
> The condition "at least 250 ms after activation" results from there being no way of checking the completion of spindle motor activation. Therefore, this wait period serves as an alternative. The time required for activation to be completed varies with the spindle motor and amplifier. Therefore, this value of 250 ms is given as a guideline only.

In an M29 block, S_ is not executed, merely being read in. Spindle output is equivalent to the specification of S0. S_ is executed in a G84/G74 (machining center system) or G84/G88 (lathe system block). The timing chart is shown in the chart indicating the execution of G84/G74 or G84/G88.

- Execution of G84/G74 (machining center system) or G84/G88 (lathe system block)

When M29S_; is specified, S_ is read in, spindle output being equivalent to the specification of S0;. S_ is output when G84/G74 (machining center system) or G84/G88 (lathe system block) is executed. Thus, the processing described below is performed.

- When M-type gear selection is used

When using a machine that features multiple gear stages for use with the spindle motor and spindle, and the newly programmed S_ is outside the previously selected gear range, the spindle-speed function strobe signal SF <F007.2> and gear selection signals (output) GR3O, GR2O, GR1O <F034.2, 1, 0> are output to the PMC.
At this time, perform gear switching at the PMC.

- When T-type gear selection is used

The spindle-speed function strobe signal SF <F007.2> and spindle-speed function code signals S00 to S31 <F022 to F025> are output to the PMC. (However, parameter setting is required to enable output of the S codes and SF signal. See the description of each bit of parameter No. 3705.)
At this time, the PMC must determine whether gear switching is to be performed, and perform gear switching as required. The selected gear must be reflected in the gear selection signals (input) GR2 and GR1 <G028.2, 1> for notification to the CNC.
From GR2 and GR1, the CNC determines which gear is selected.
However, note the difference between the machining center system and lathe system, as described below.

- Machining center system :

Up to three gear stages are supported. If the fourth gear stage is selected, it is assumed that the third gear stage is selected.

- Lathe system :
  Up to four gear stages are supported.
  (A gear selection is posted to the CNC with the gear selection signal for each spindle.)

- C-axis clamp/unclamp

T

When an M code for C-axis clamping is specified in a block specifying G84/G88, the M codes for C-axis clamping/unclamping are output at the following timings:

- The M code for clamping is output at the time of rapid traverse to the R point level (motion 2). When FIN is returned, tapping (motion 3) starts.
- After extraction from the hole bottom to the R point level (motion 5), the M code for unclamping is output. When FIN is returned, dwell or rapid traverse to the initial level (motion 6) starts.

The rigid tapping mode can be specified in three different methods. One method specifies M29 before G84. The second method specifies M29 and G84 in the same block. The third method uses G84 as a rigid tapping G code. In any method, however, PMC processing is the same. (In any case, the M29 code is output.)

10.13.15 Timing Charts for Rigid Tapping Specification

The timing chart for rigid tapping specification depends on the method used to specify rigid tapping mode, the gear selection method (M-type or T-type), and whether to perform gear switching.
From the table, find the appropriate timing chart and apply the information it contains as necessary.

M

Gear selection method M-type T-type	Gear switching	Specification method		
		M29 is specified before G84/G74.	M29 and G84/G74 are specified in the same block.	By parameter setting, G84/G74 is specified as a G code for rigid tapping.
M-type	Not performed	Fig. 10.13.15.1 (a)	Fig. 10.13.15.2 (a)	Fig. 10.13.15.3 (a)
	Performed	Fig. 10.13.15.1 (b)	Fig. 10.13.15.2 (b)	Fig. 10.13.15.3 (b)
T-type	Not performed	Fig. 10.13.15.1 (c)	Fig. 10.13.15.2 (c)	Fig. 10.13.15.3 (c)
	Performed	Fig. 10.13.15.1 (d)	Fig. 10.13.15.2 (d)	Fig. 10.13.15.3 (d)

T

Gear switching	Specification method		
	M29 is specified before G84/G88.	M29 and G84/G88 are specified in the same block.	By parameter setting, G84/G88 is specified as a G code for rigid tapping.
Not performed	Fig. 10.13.15.4 (a)	Fig. 10.13.15.5 (a)	Fig. 10.13.15.6 (a)
Performed	Fig. 10.13.15.4 (b)	Fig. 10.13.15.5 (b)	Fig. 10.13.15.6 (b)

NOTE

For more information about the M/T type gear selection method, see Section "SPINDLE SPEED CONTROL." Note the following:

Machining center system :

When constant surface speed control is not being used and bit 4 (GTT) of parameter No. 3706 is set to 0. → M-type

When constant surface speed control is being used, or bit 4 (GTT) of parameter No. 3706 is set to 1. → T-type

Lathe system : T-type only

10.13.15.1 When M29 is specified before G84/G74

- M type gear selection method

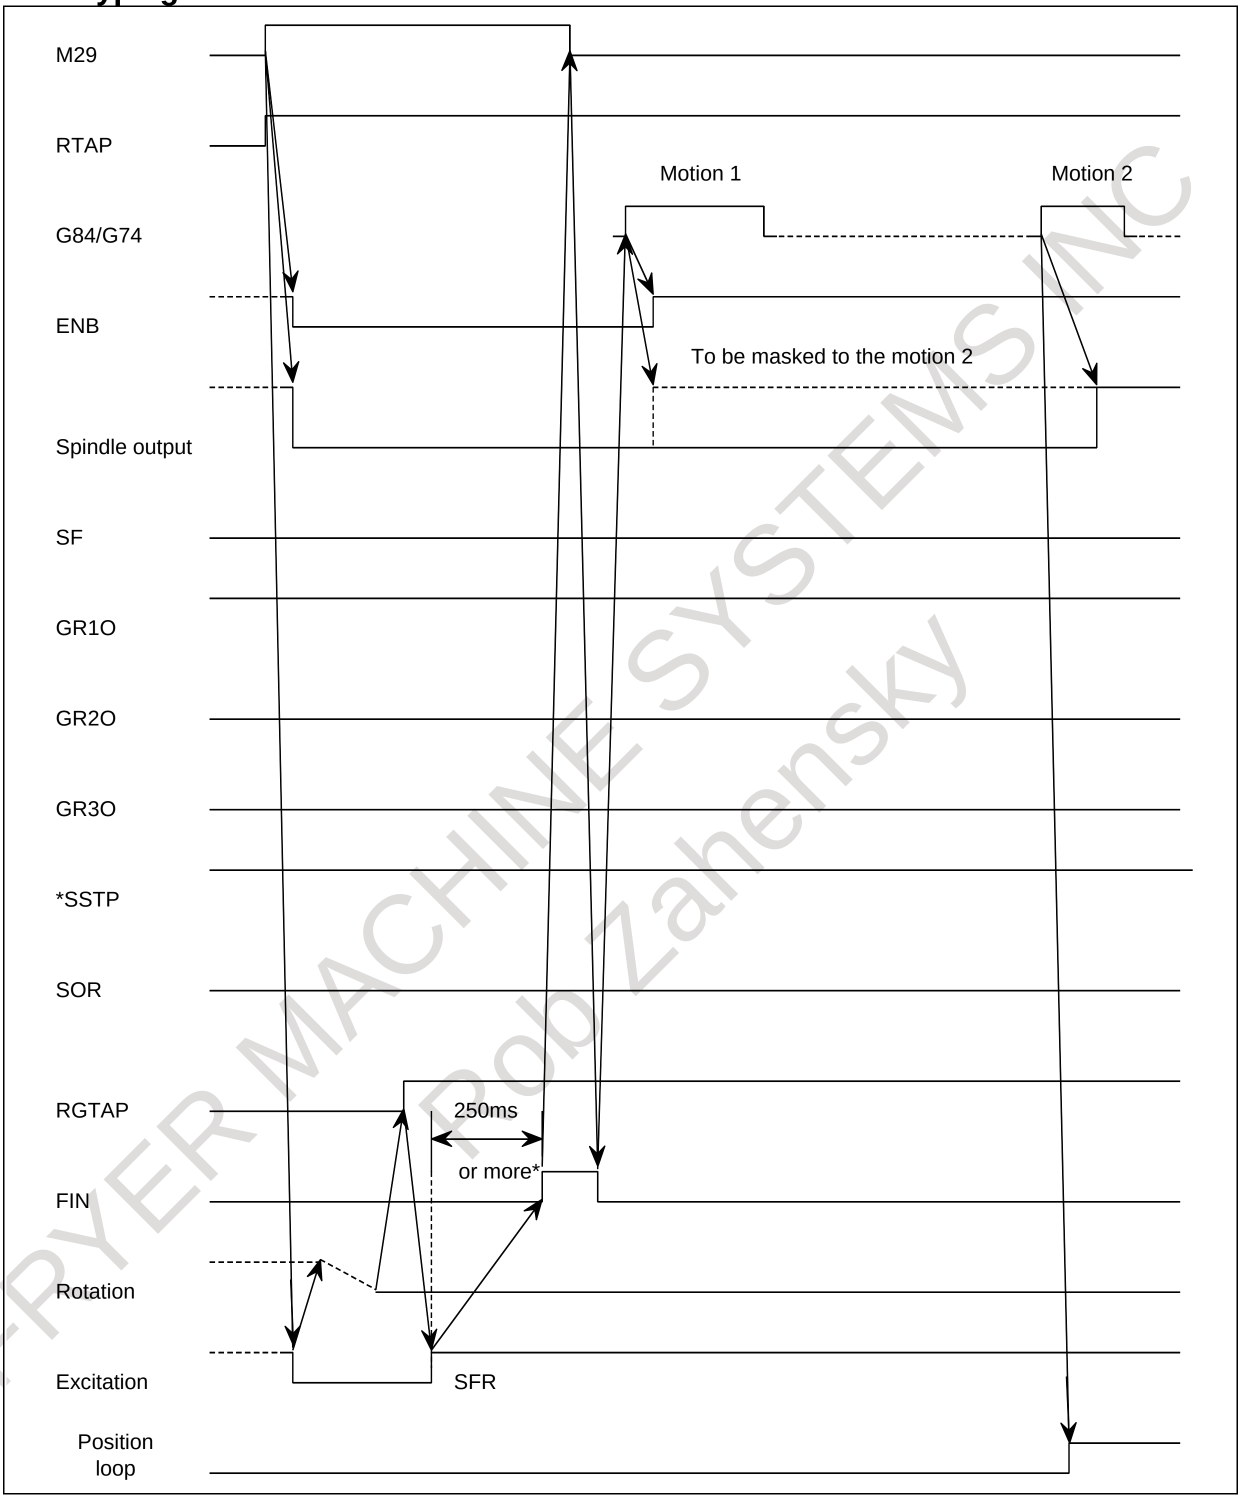

Fig. 10.13.15.1 (a) Gear is not changed

> **NOTE**
> The delay(*) is not necessary, when an appropriate value is set to the parameter No.4099 for the delay time for stable motor excitation.

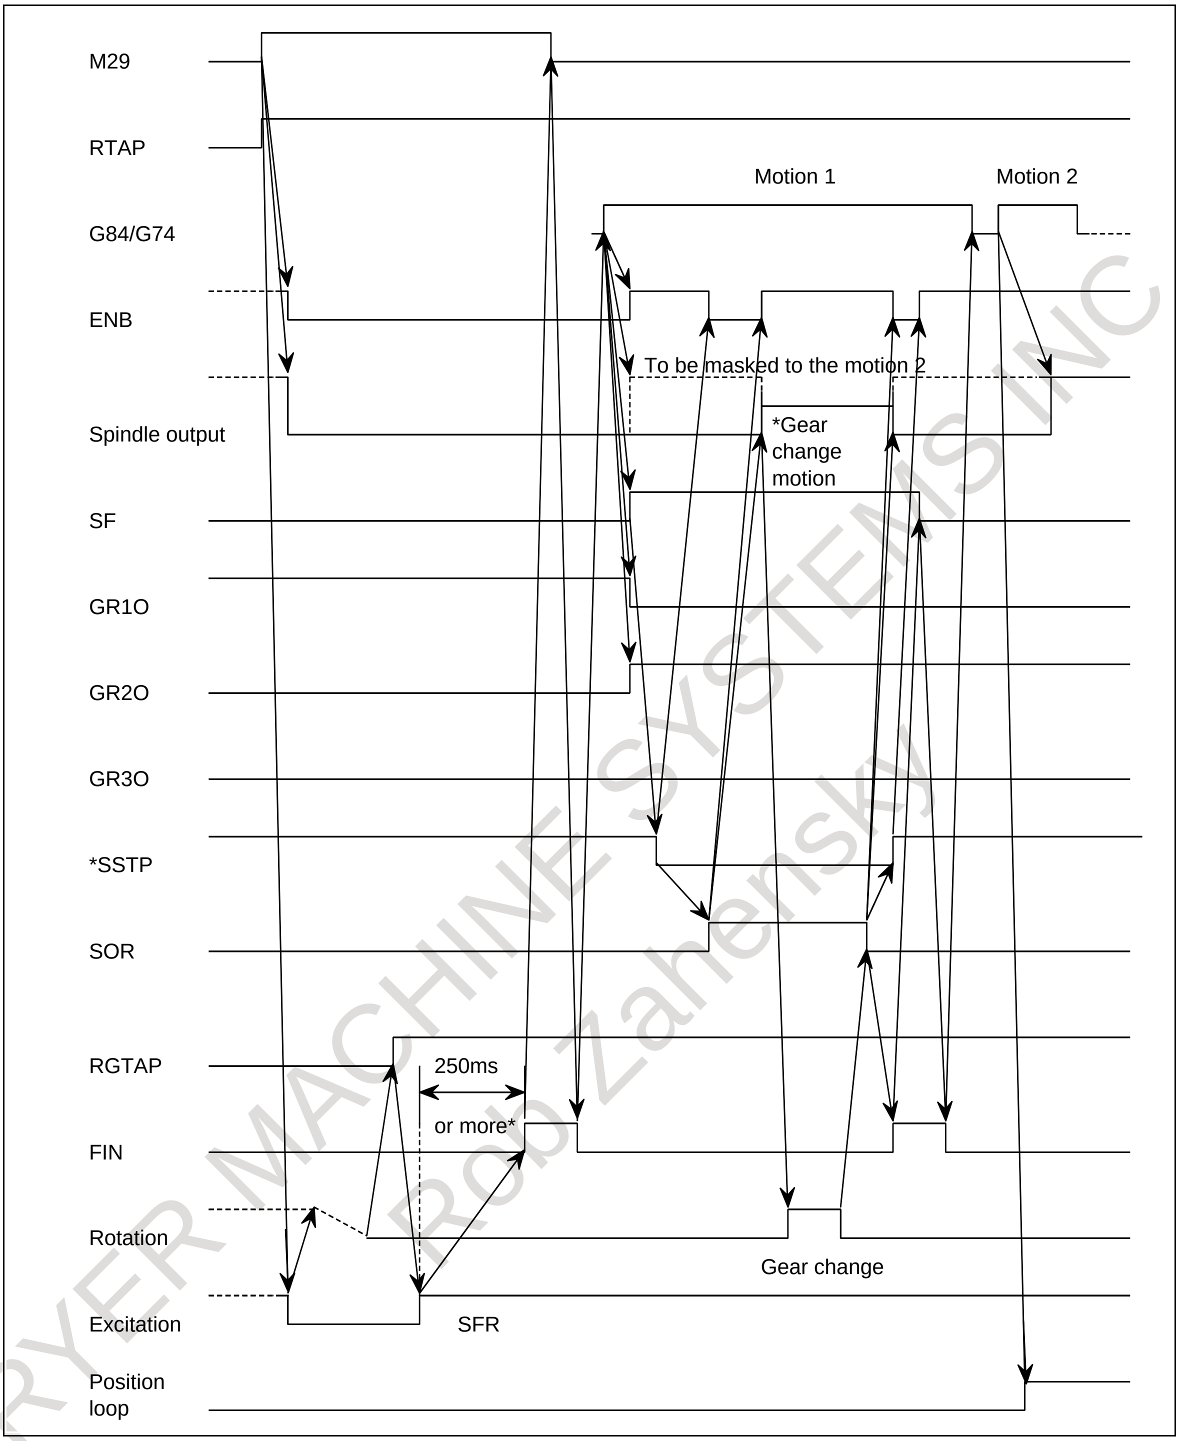

Fig. 10.13.15.1 (b) When gear change is performed (from low to middle gear)

NOTE

1. This time chart show an example where the gear has shifted from low to middle gear. One of the gear select signals (GR1O, GR2O, GR3O) has turned from "1" to "0", and one of the two remaining signals has turned from "0" to "1". This changes the gear.
2. The delay(*) is not necessary, when an appropriate value is set to the parameter No.4099 for the delay time for stable motor excitation.

- T type gear selection method

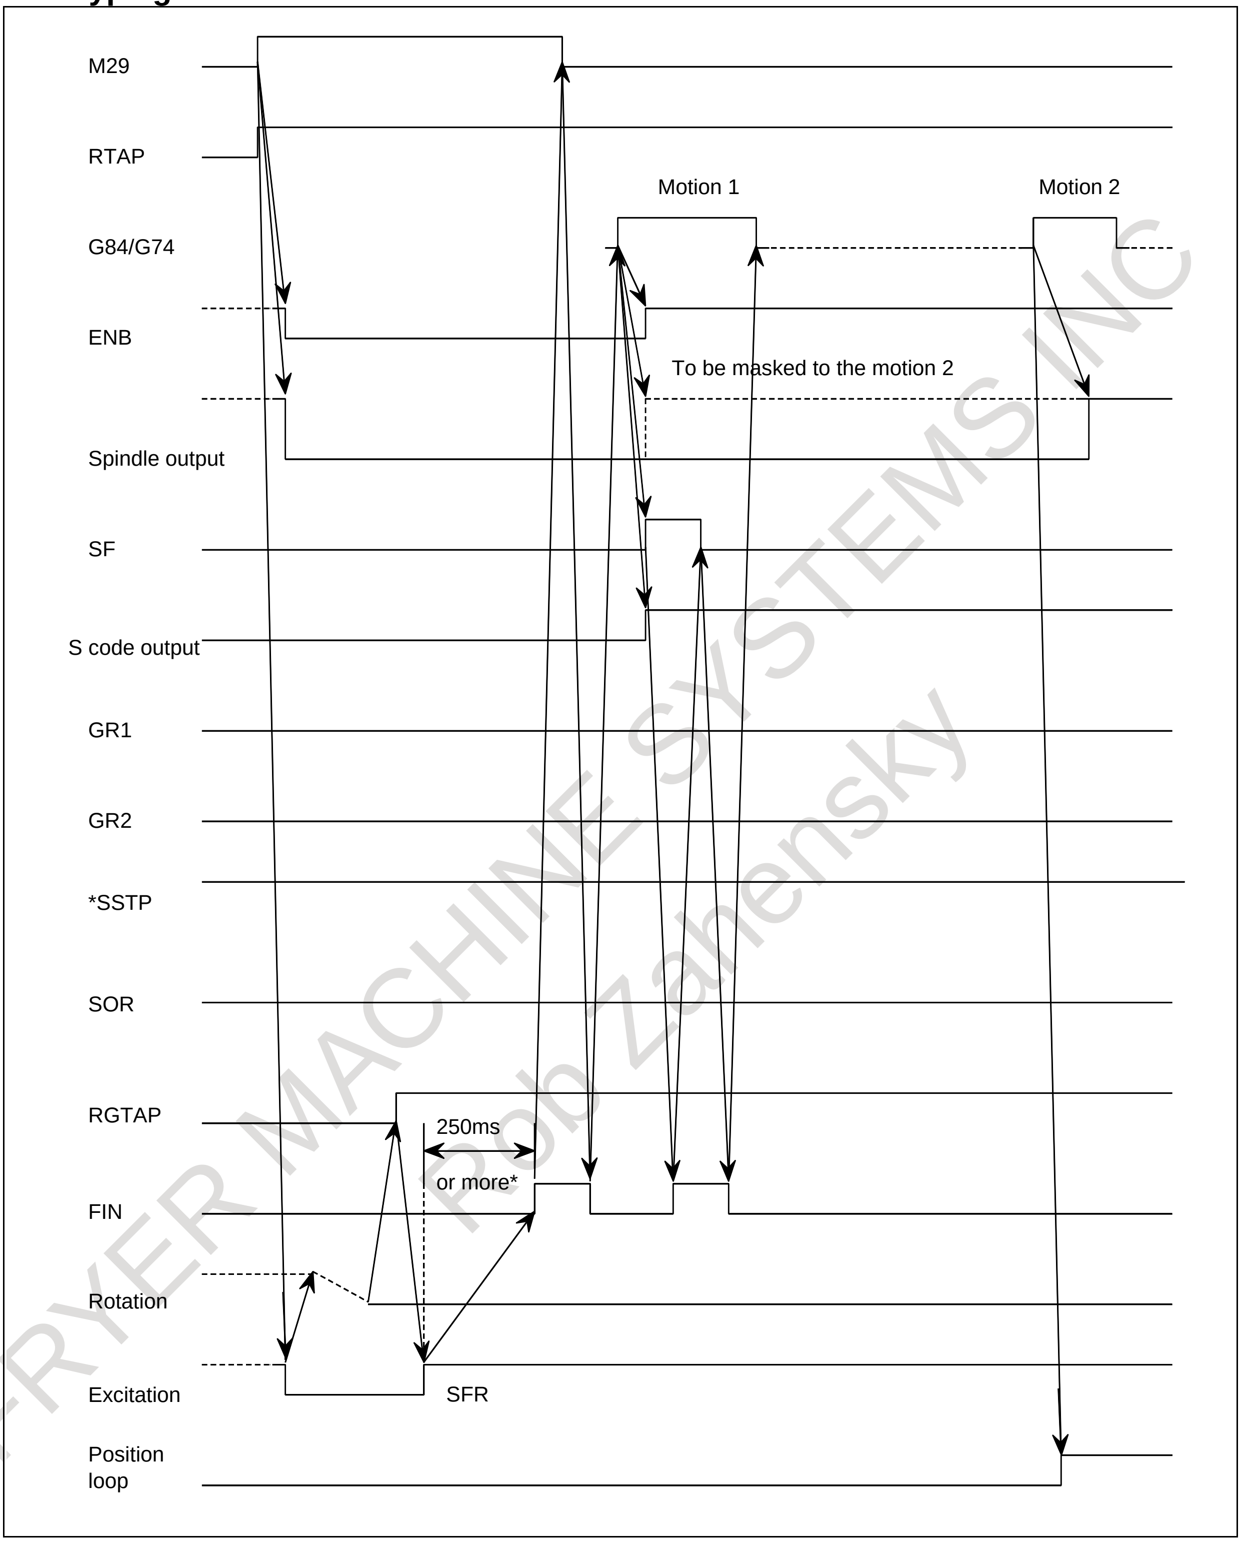

Fig. 10.13.15.1 (c) Gear change is not performed

> **NOTE**
> The delay(*) is not necessary, when an appropriate value is set to the parameter No.4099 for the delay time for stable motor excitation.

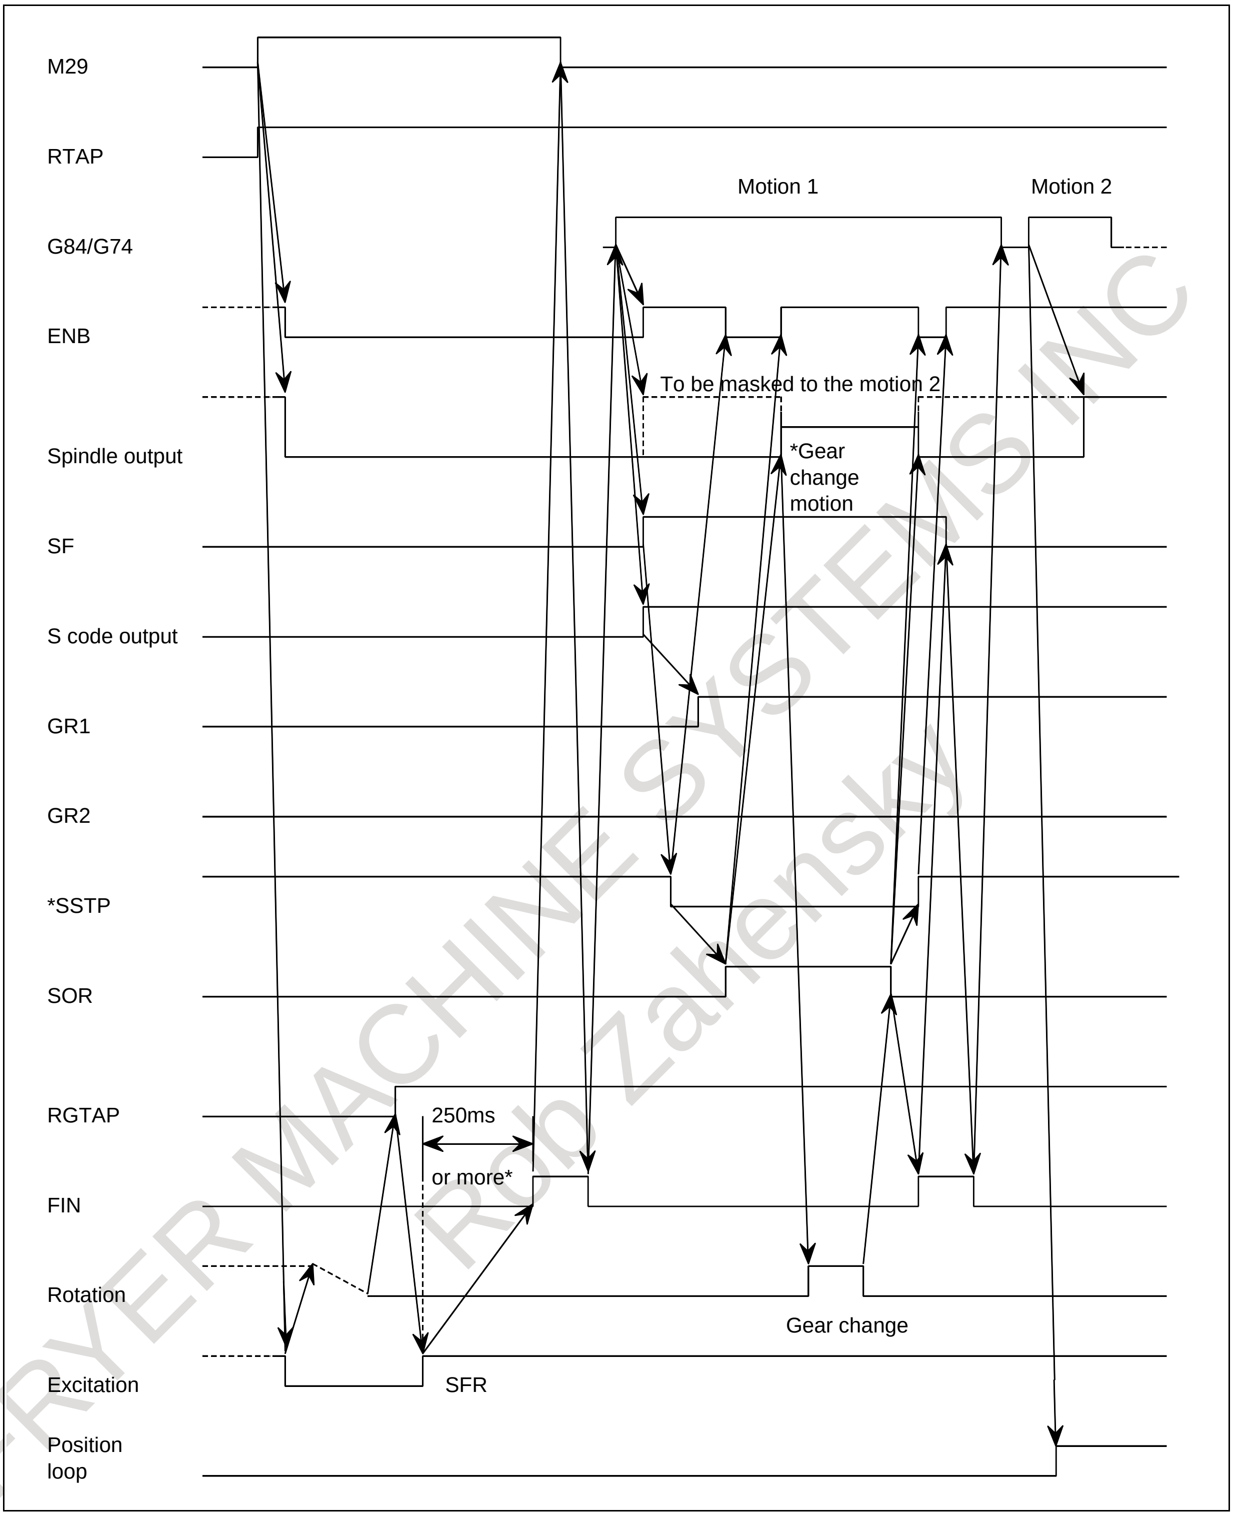

Fig. 10.13.15.1 (d) When gear-change is performed (low to middle gear)

NOTE

1 This time chart shows an example where the gear has changed from low to middle gear. The PMC selects a required gear through an S code output and selects the gear using the GR1 and GR2 signals to inform CNC of the selected gear.

2 The delay(*) is not necessary, when an appropriate value is set to the parameter No.4099 for the delay time for stable motor excitation.

10.13.15.2 M29 and G84/G74 are specified in the same block

- **M type gear selection**

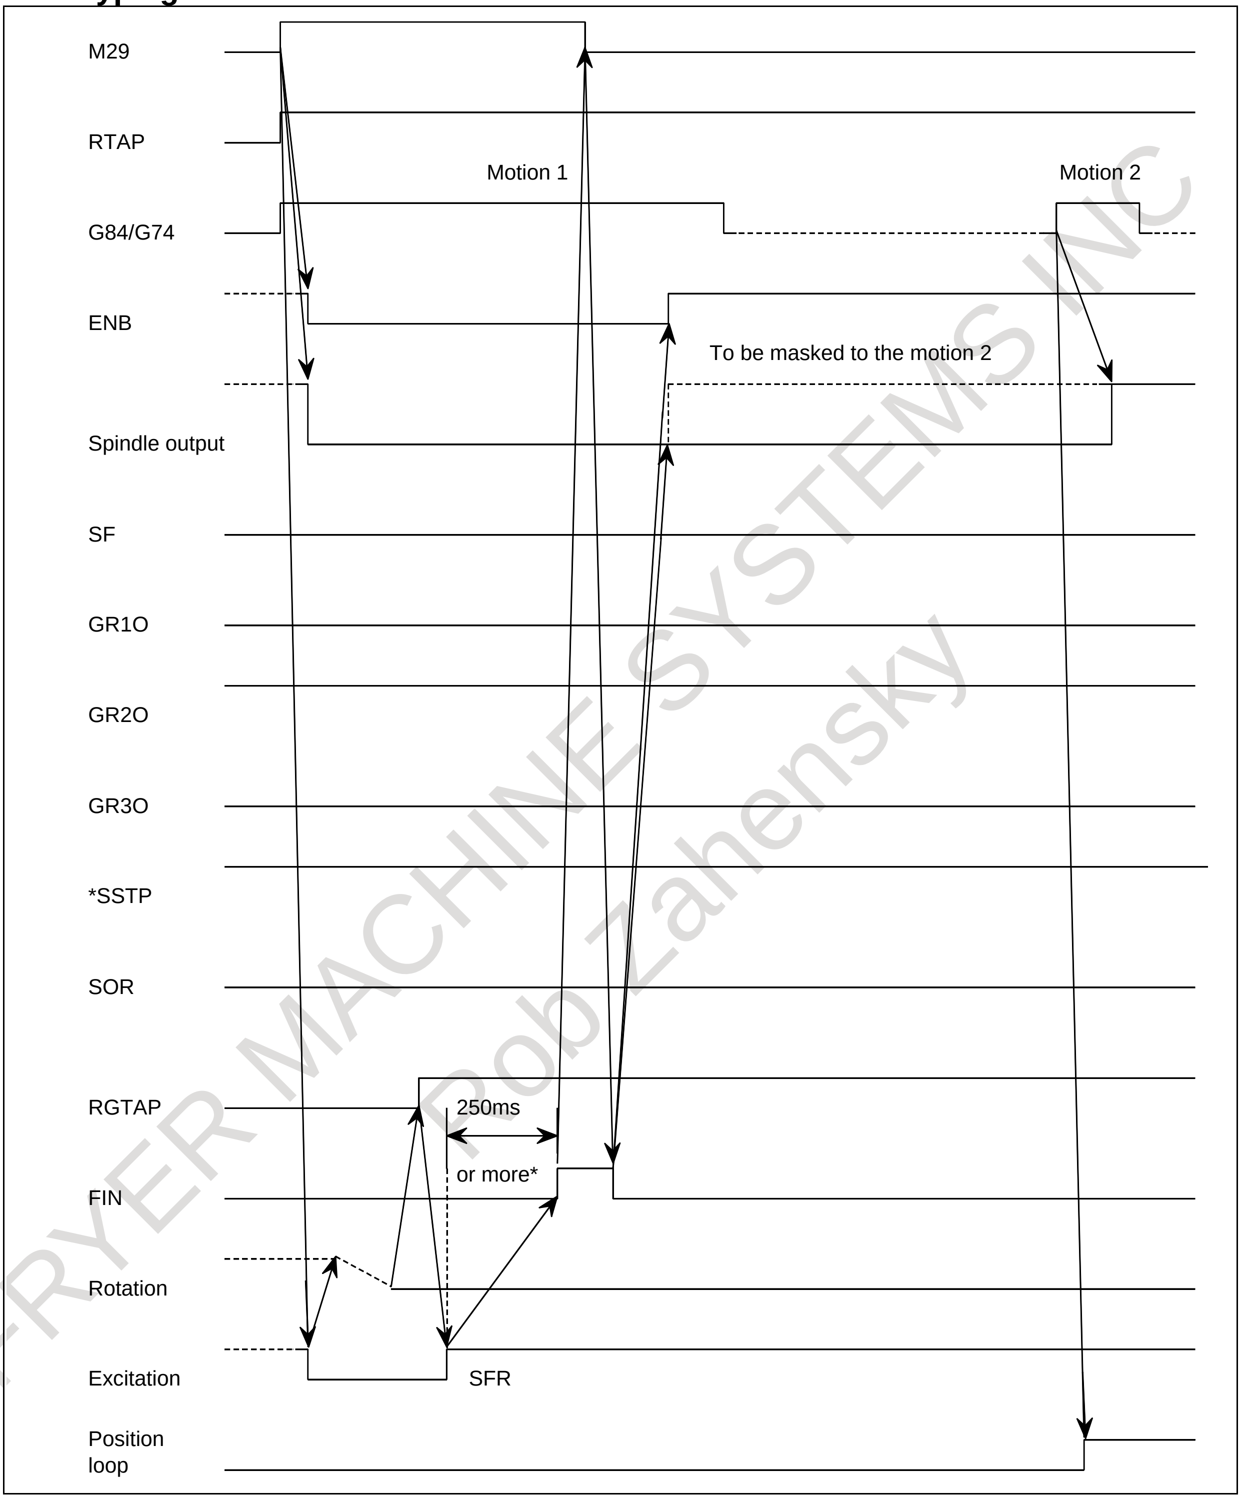

Fig. 10.13.15.2 (a) When gear-change is not performed

> **NOTE**
> The delay(*) is not necessary, when an appropriate value is set to the parameter No.4099 for the delay time for stable motor excitation.

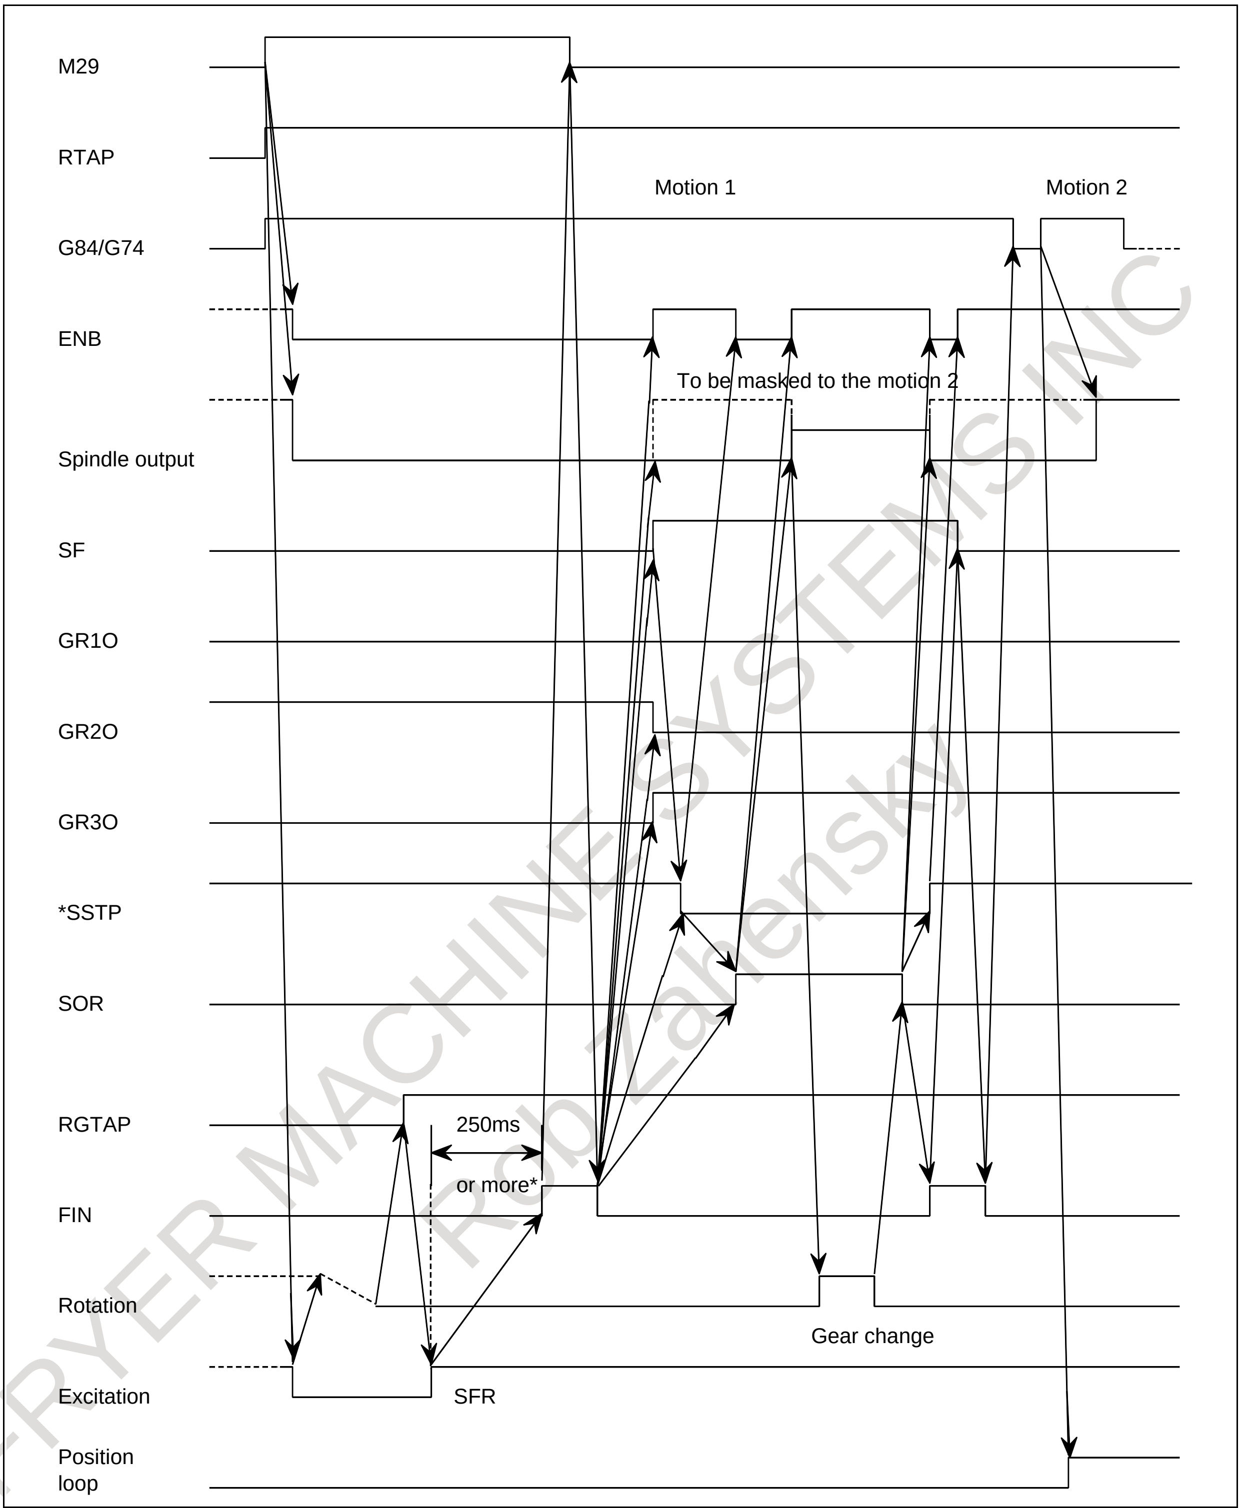

Fig. 10.13.15.2 (b) When gear-change is performed (middle to high gear)

NOTE

1. This time chart shows an example where the gear has shifted from middle to high gear. One of the gear select signals (GR1O, GR2O, GR3O) has turned from "1" to "0", and one of the two remaining signals has tuned from "0" to "1". This changes the gear.
2. The delay(*) is not necessary, when an appropriate value is set to the parameter No.4099 for the delay time for stable motor excitation.

- T type gear selection method

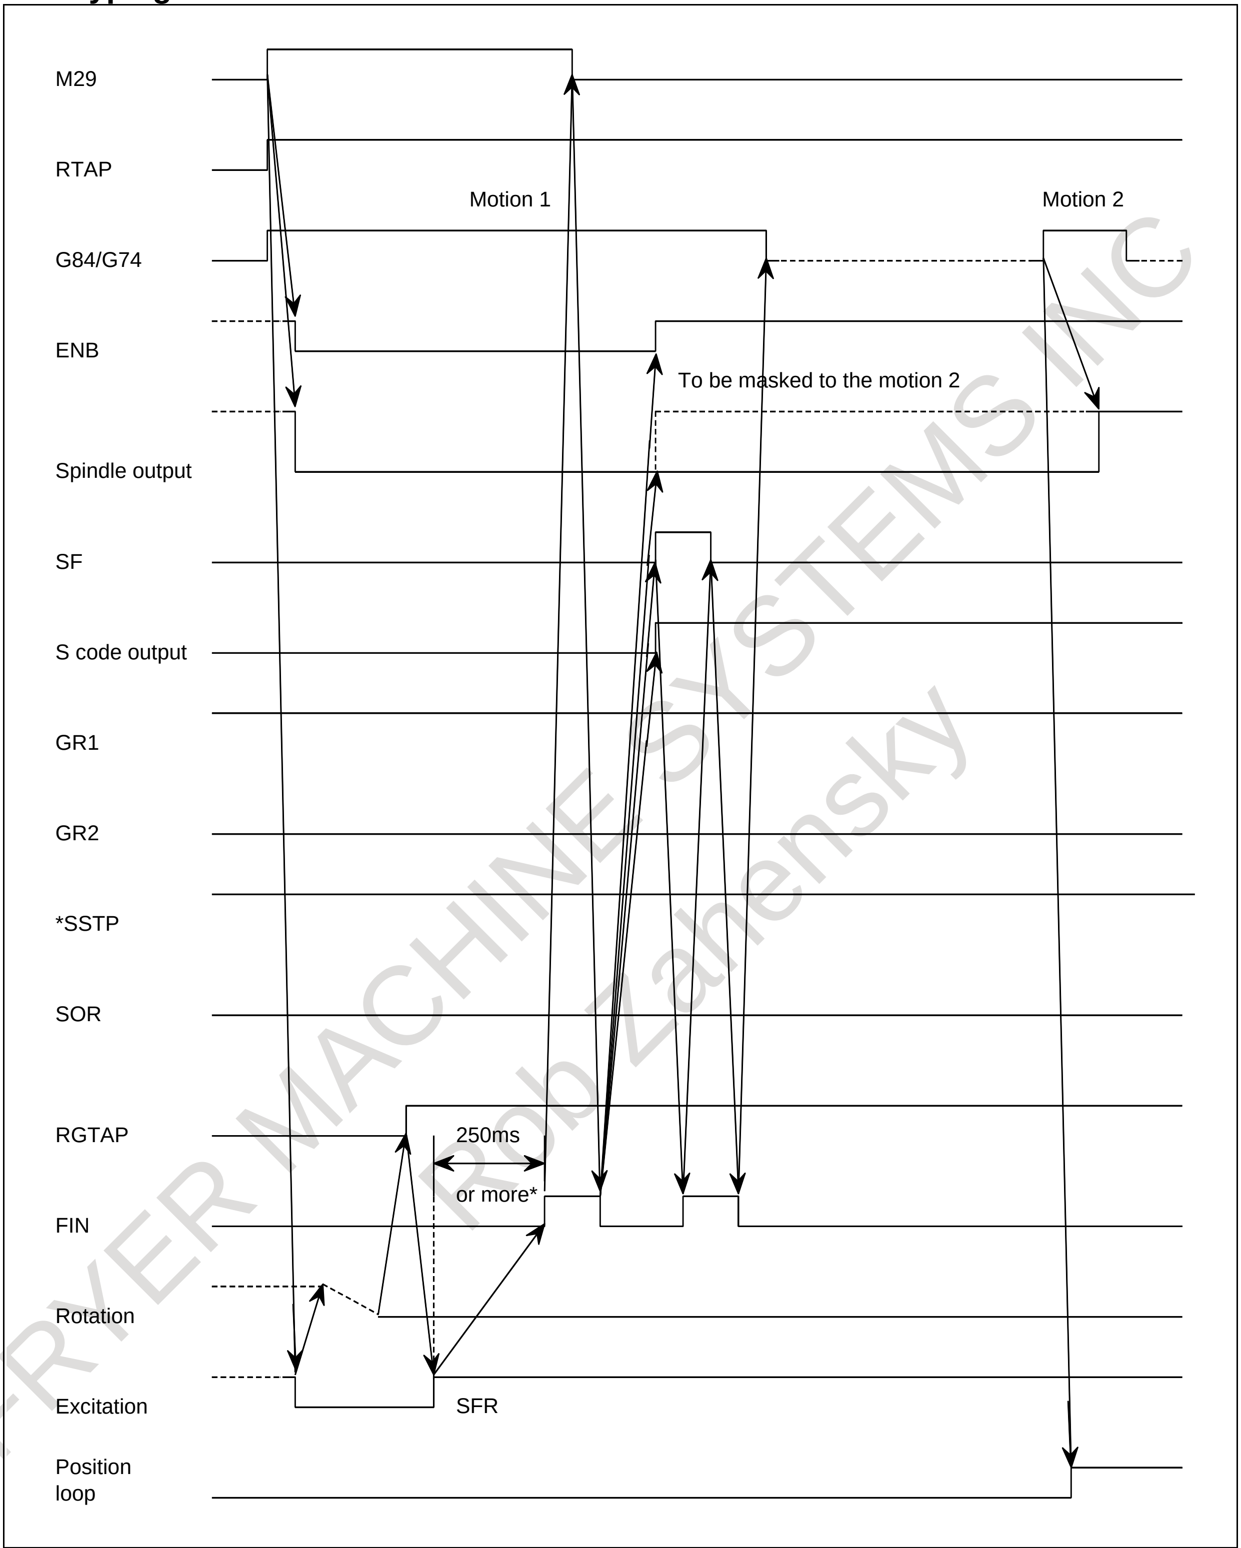

Fig. 10.13.15.2 (c) When gear change is not performed

> **NOTE**
> The delay(*) is not necessary, when an appropriate value is set to the parameter No.4099 for the delay time for stable motor excitation.

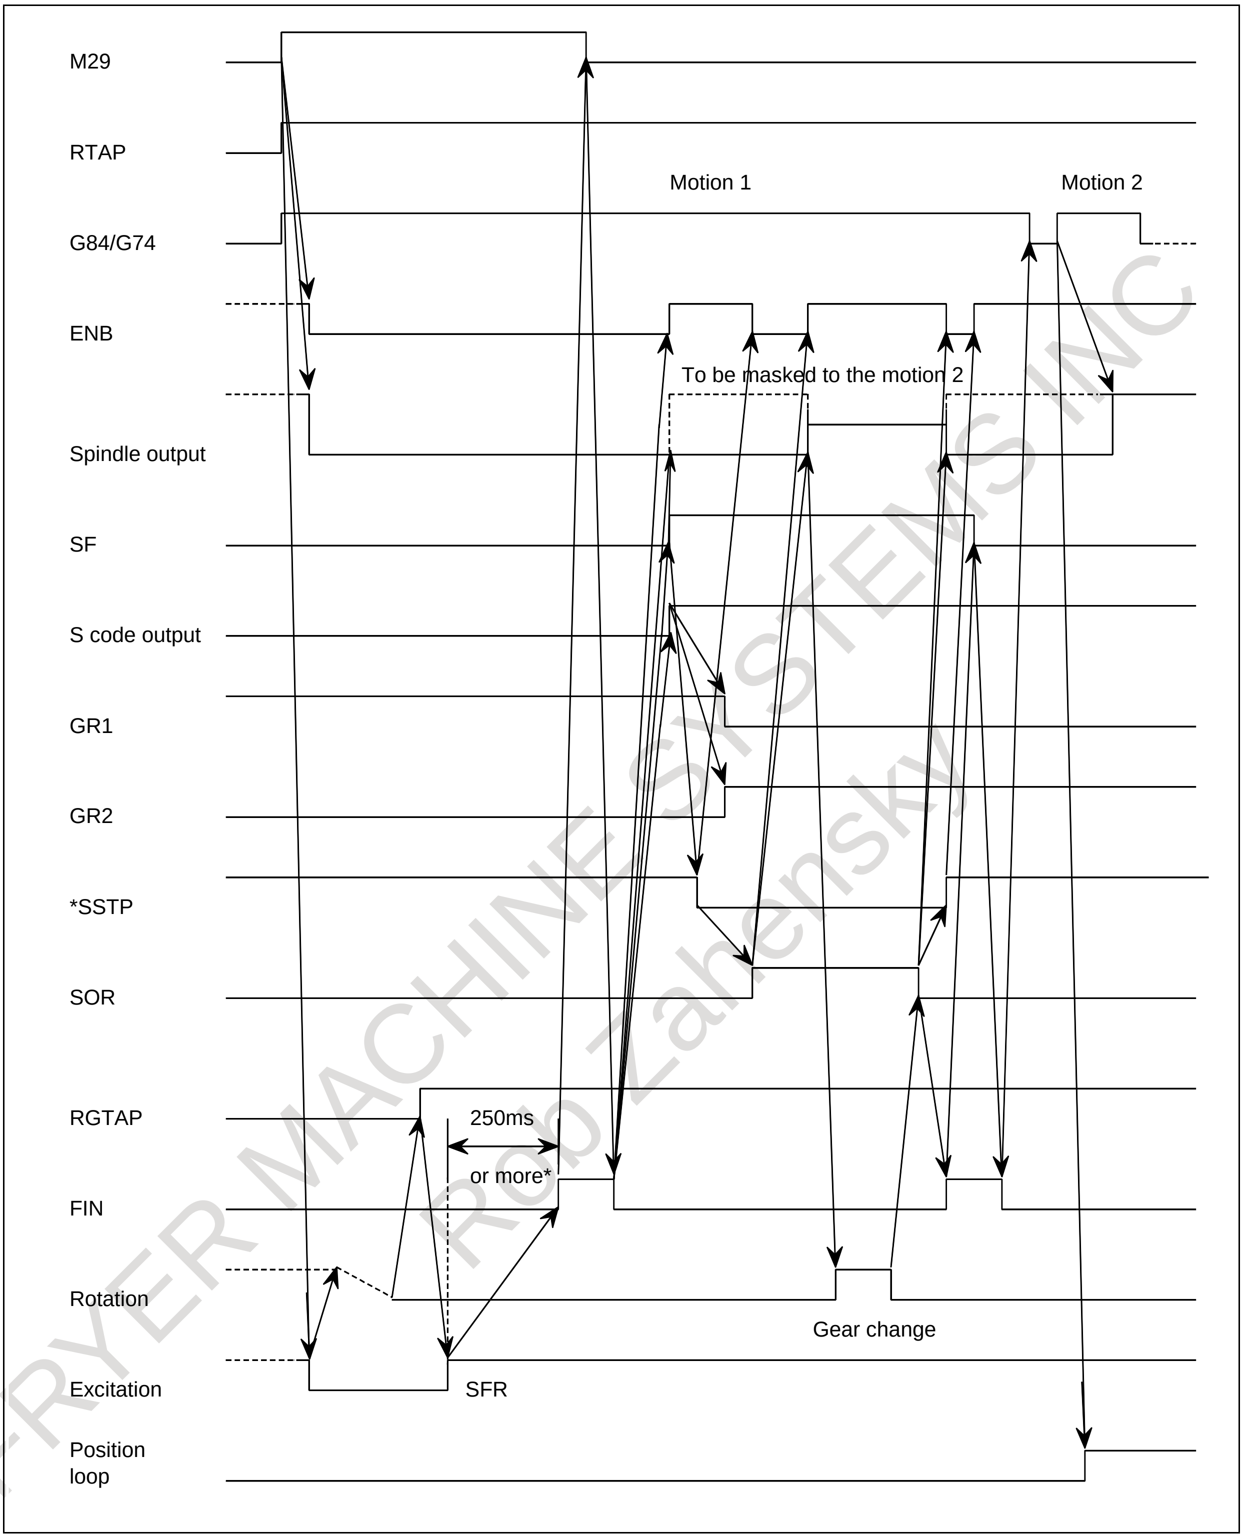

Fig. 10.13.15.2 (d) When gear-change is performed (middle to high gear)

NOTE
1. This time chart shows an example where the gear has changed from middle to high gear. The PMC selects a required gear through an S code output and selects the gear using the GR1 and GR2 signals to inform CNC of the selected gear.
2. The delay(*) is not necessary, when an appropriate value is set to the parameter No.4099 for the delay time for stable motor excitation.

10.13.15.3 Specifying G84/G74 for rigid tapping by parameters

- M type gear selection

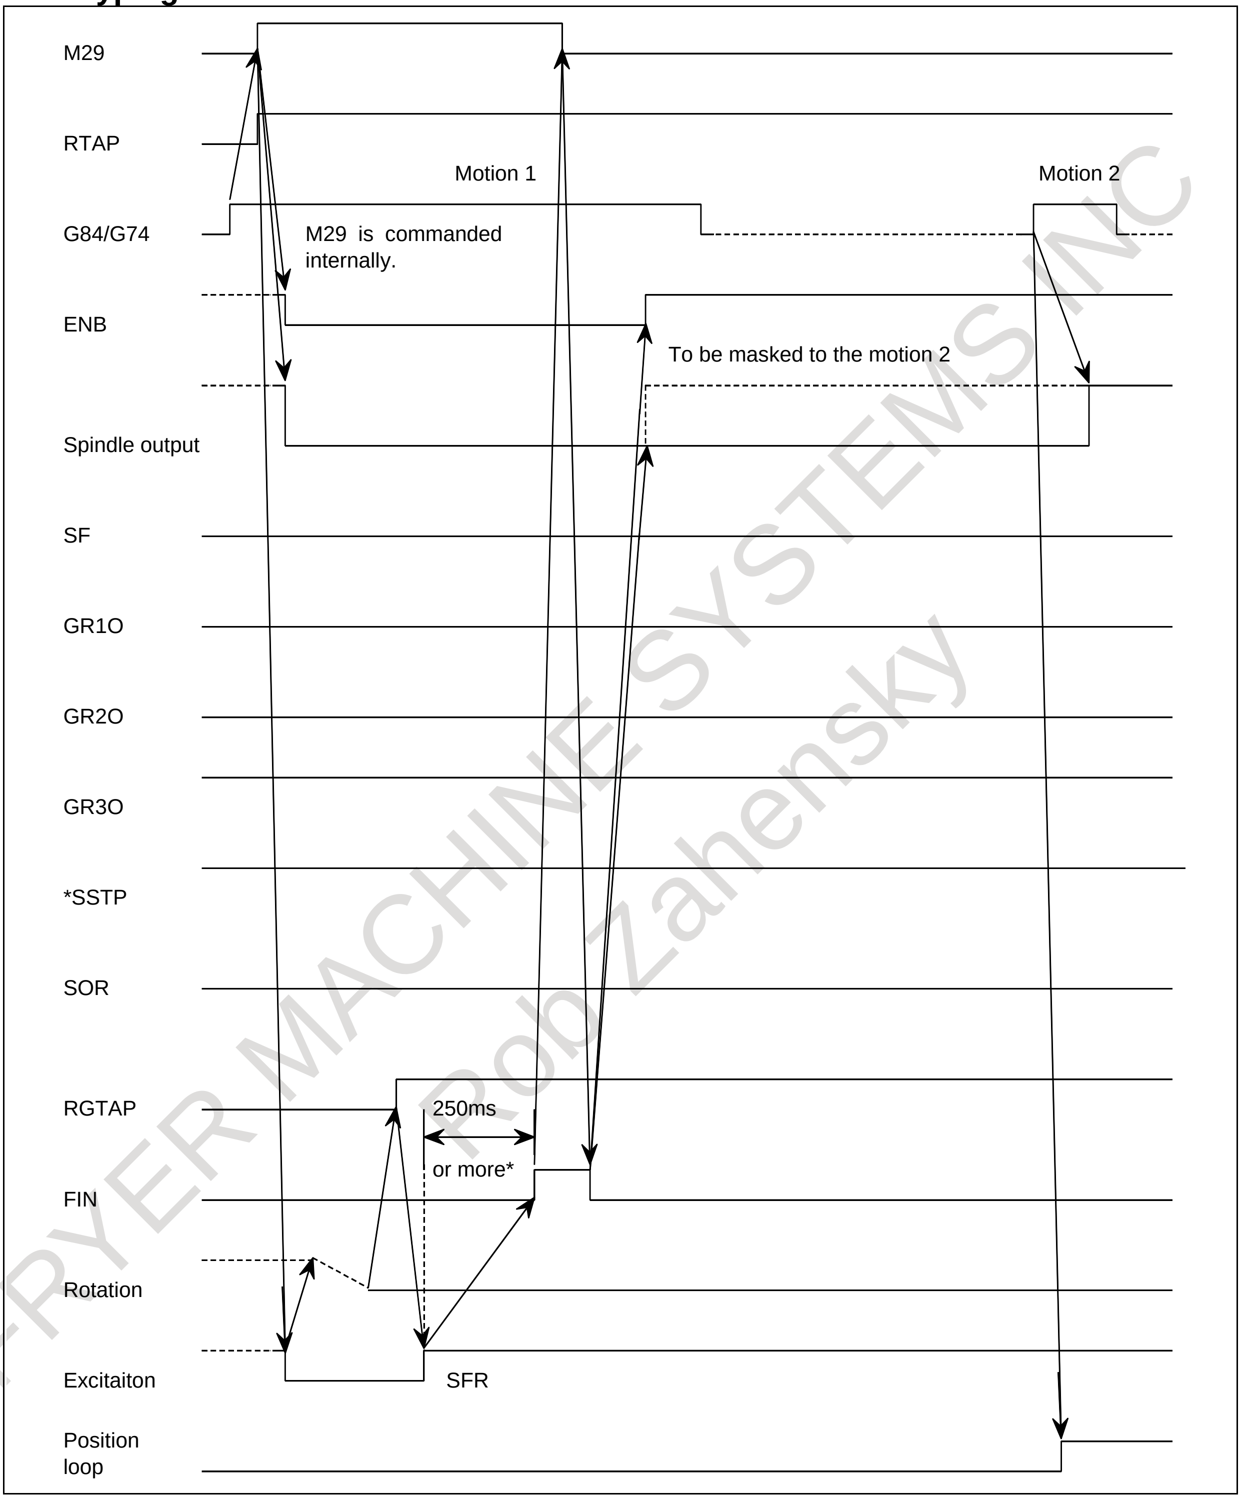

Fig. 10.13.15.3 (a) When gear-change is not performed

> **NOTE**
> The delay(*) is not necessary, when an appropriate value is set to the parameter No.4099 for the delay time for stable motor excitation.

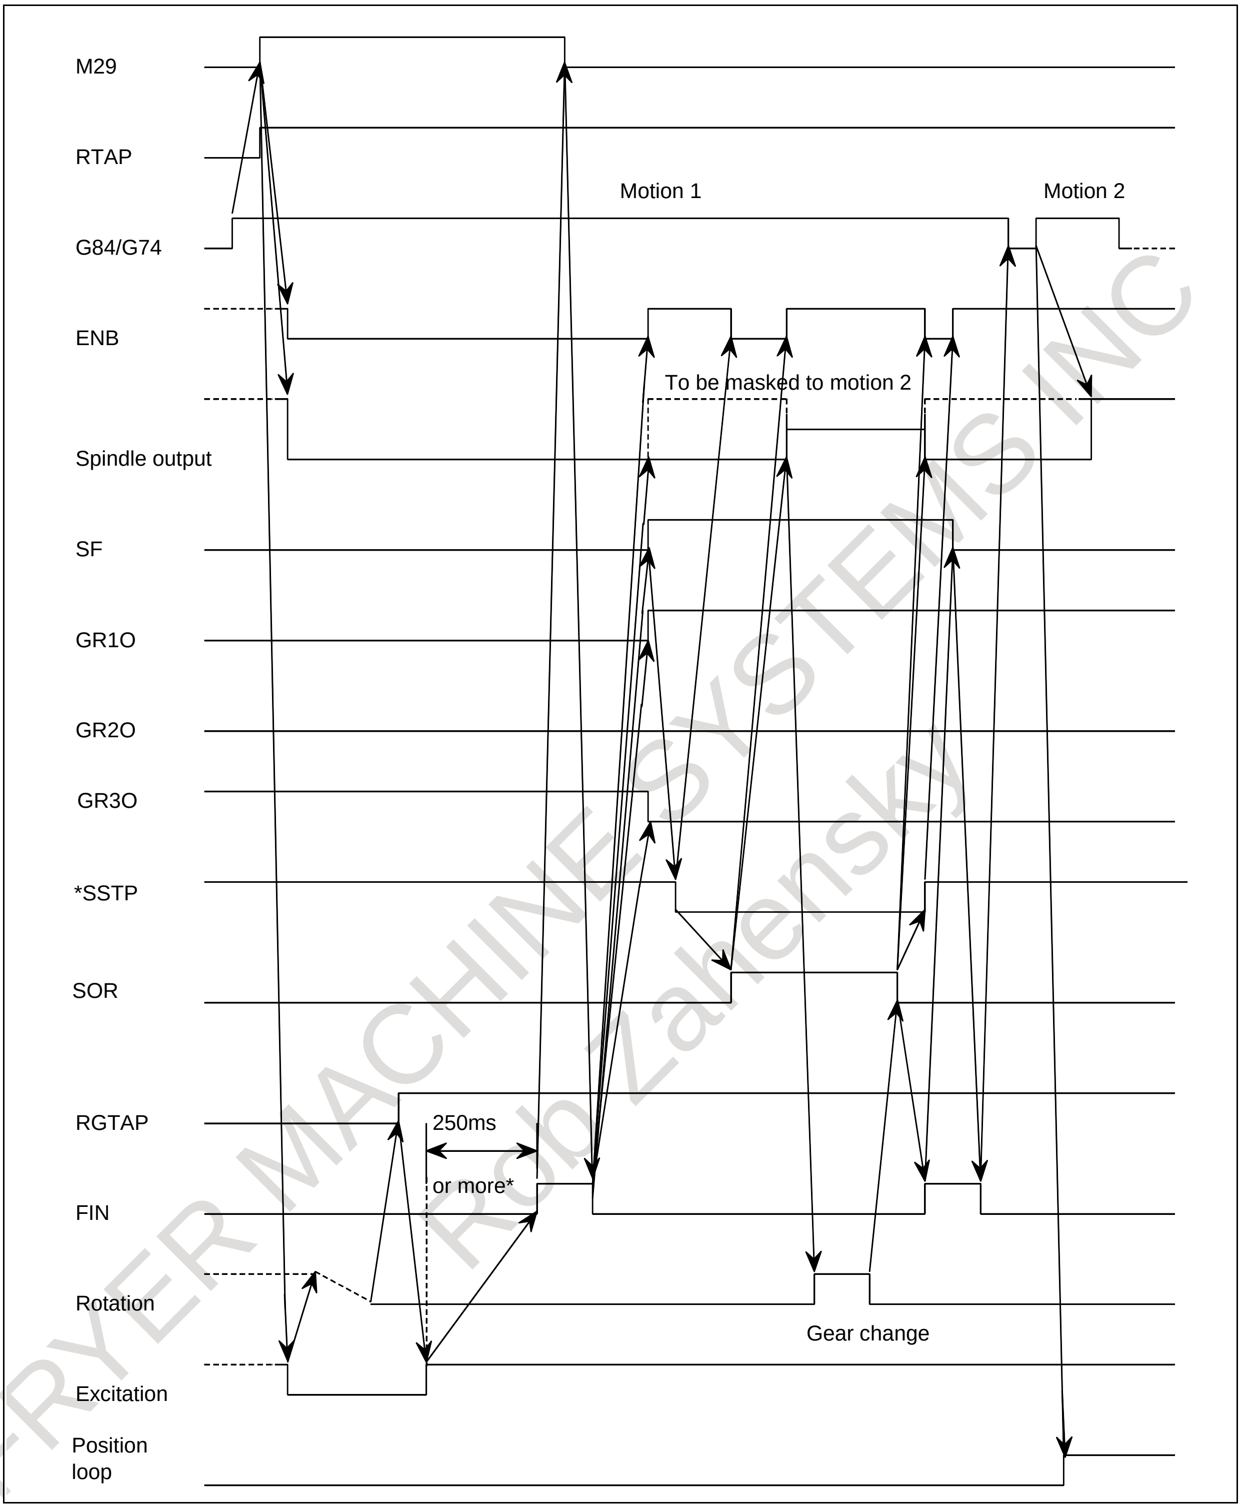

Fig. 10.13.15.3 (b) When gear change is performed (high to low gear)

NOTE

1 This time chart shows an example where the gear has shifted from high to low gear. One of the gear select signals (GR1O, GR2O, GR3O) has turned from "1" to "0", and one of the two remaining signals has turned from "0" to "1". This changes the gear.

2 The delay(*) is not necessary, when an appropriate value is set to the parameter No.4099 for the delay time for stable motor excitation.

- T type gear selection method

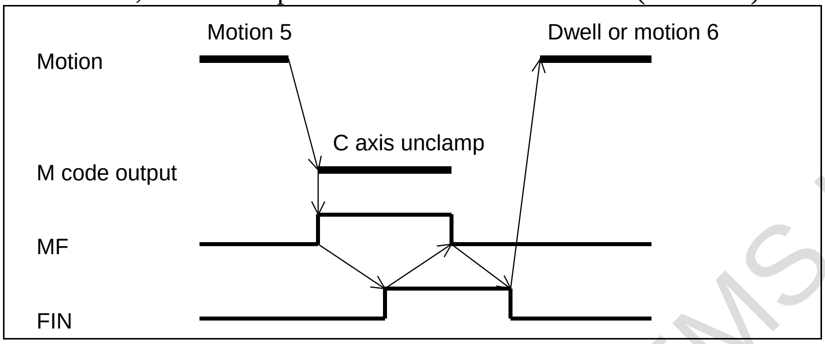
NOTE
The delay(*) is not necessary, when an appropriate value is set to the parameter No.4099 for the delay time for stable motor excitation.

10.13.15.7 Timing of the M code for unclamping

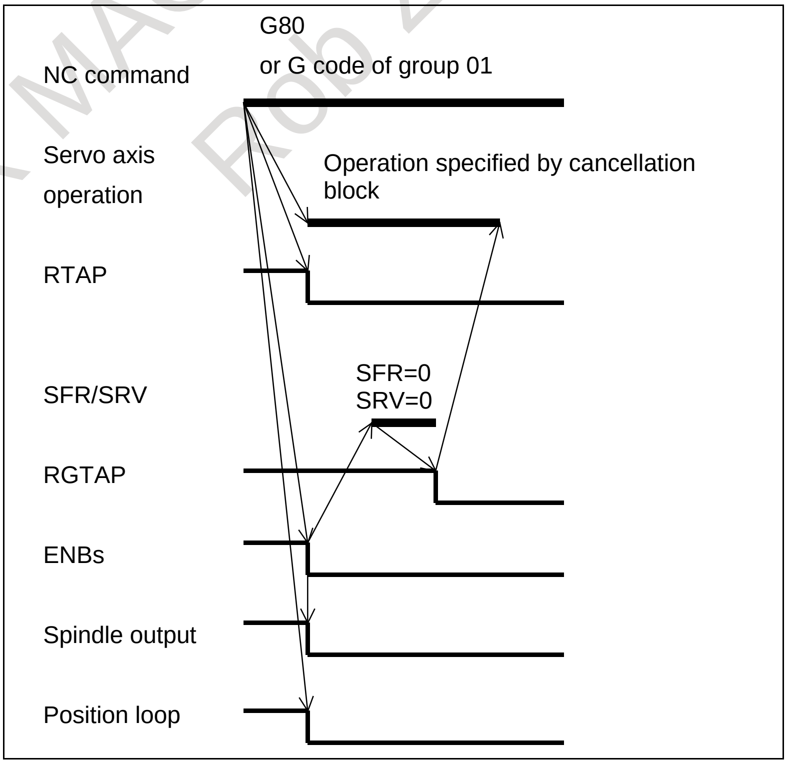
T

After extraction from the hole bottom to the R point level (motion 5), the M code for unclamping is output. When FIN is returned, dwell or rapid traverse to the initial level (motion 6) starts.



10.13.15.8 Timing to cancel rigid tapping mode

When rigid tapping is completed, the mode is canceled if a G code (such as G80, canned cycle G code, or Group 01 G code) is issued.
Spindle output has the effect of execution of S0. On the falling edge of the ENB signal (corresponding ENBs signal in multi-spindle control), cancel the rigid tapping mode of the PMC (for example, by turning off spindle activation) and set the rigid tapping signal to "0". After confirming that the rigid tapping signal is set to "0", proceed to the next block.
When gear change is performed using *SSTP and SOR, the ENB signal can be either "1" or "0". Do not cancel the PMC's rigid tapping mode at the falling edge of the ENB signal under these circumstances. The position loop is also canceled.
When the CNC is reset, the PMC's rigid tapping mode must be canceled.
When bit 2 (CRG) of parameter No. 5200 is 1, the system goes directly to the next block without checking that the rigid tapping signal is "0". Set CRG to 1 for systems in which the rigid tapping signal is always "1".



⚠ **CAUTION**

1 If rigid tapping mode is canceled by a Group 01 G code, such as G00 or G01, the block containing the G code is executed at the same time the ENB signal is turned to "0". Therefore, if the block contains an M code for controlling the spindle, an error may occur during processing in the PMC.

2 When bit 2 (CRG) of parameter No. 5200 is 1, if the next block contains an M code for controlling the spindle, an error may occur during processing in the PMC, when:
  - Rigid tapping mode is canceled by issuing G80
  - Rigid tapping mode is canceled by issuing a Group 01 G code , such as G00 or G01

NOTE

Rigid tapping mode is canceled as described above regardless of the gear selection method of M-type or T-type.

10.13.16 FSSB High-speed Rigid Tapping

Outline

By the FSSB communication between a CNC and a spindle amplifier, rotational position information of a spindle can be transmitted from a spindle amplifier to a servo control on CNC. The FSSB high-speed rigid tapping is a new function that a servo axis follows a spindle axis by utilizing this FSSB communication. And it is a characteristic of this function that the synchronization error becomes better than the ordinary function. And a synchronous error does not become worse even if a spindle error becomes worse by setting a shorter time constant for acceleration/deceleration than that of the former rigid tapping function. Therefore the machining cycle time can be shortened with keeping the synchronous accuracy.

In the following rigid tapping, this function cannot be used.

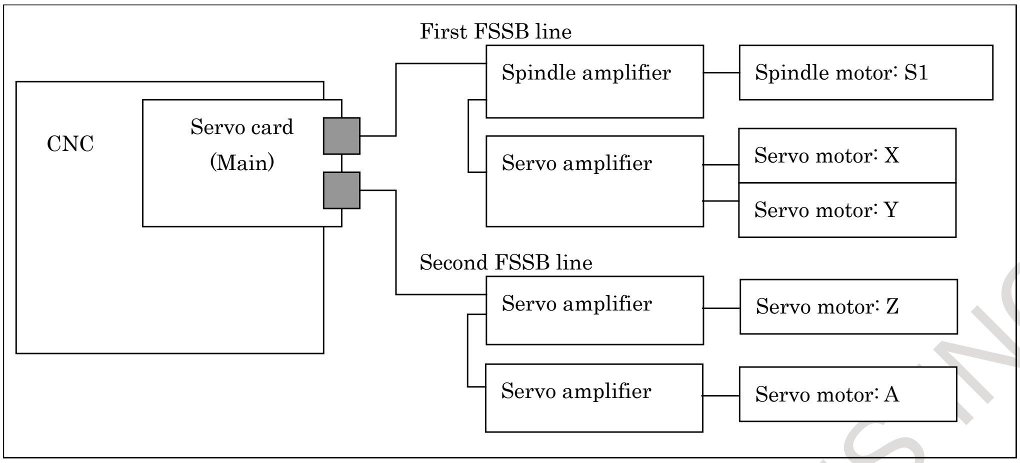
- The rigid tapping by the analog spindle or the spindle control with servo motor.
- The rigid tapping with one servo motor and multiple spindle motors by spindle command synchronous control.

Explanation

The spindle amplifier and the servo amplifier used for FSSB high-speed rigid tapping need to be connected to the main servo card. The spindle amplifier and the servo amplifier used for this function can be connected to both the first FSSB line and the second FSSB line.

Ex.1) FSSB high-speed rigid tapping with Z axis and S1 spindle axis in the one path system

[Example of connection of FSSB]



[Example of parameter setting]

When the bit 0 (FHR) of parameter No.24203 is set to 1, FSSB high-speed rigid tapping is enabled.

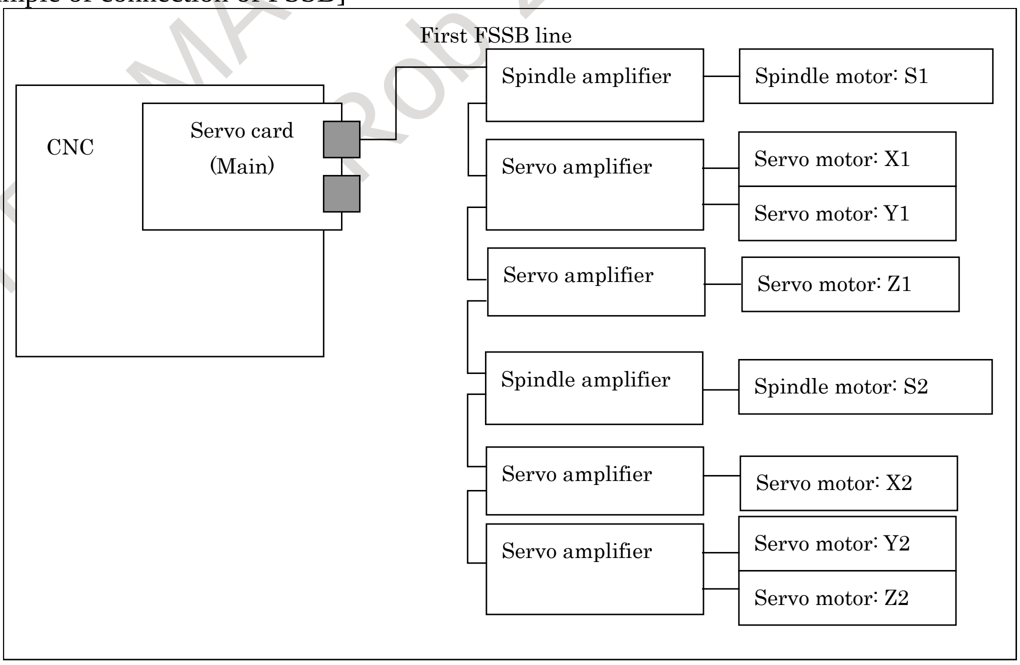
And, the index number of the spindle axis that synchronizes with the servo axis used by FSSB high-speed rigid tapping is set to the parameter (No.24204) as follows.

24204	SP INDEX OF SV FSSB SYNC
X	0
Y	0
Z	1
A	0

In addition, set 1 to the bit 1 (FHRSV) of parameter No.2429 and bit 1 (FEED) of parameter No.2005 of Z axis and the bit 1 (FHRSP) of parameter No.4549 of S1 spindle axis.

Ex.2) Two groups of FSSB high-speed rigid tapping with Z1 - S1 and Z2 - S2 in two paths system

[Example of connection of FSSB]



[Example of parameter setting]

When the bit 0 (FHR) of parameter No.24203 is set to 1, FSSB high-speed rigid tapping is enabled.

And, the index number of the spindle axis that synchronizes with the servo axis used by FSSB high-speed rigid tapping is set to the parameter (No.24204) as follows.

Path 1

24204	SP INDEX OF SV FSSB SYNC
X1	0
Y1	0
Z1	1

Path 2

24204	SP INDEX OF SV FSSB SYNC
X2	0
Y2	0
Z2	2

In addition, set 1 to the bit 1 (FHRSV) of parameter No.2429 and bit 1 (FEED) of parameter No.2005) of Z1 and Z2 axes and the bit 1(FHRSP) of parameter No.4549 of S1 and S2 spindle axes.

Eight or less index numbers of the spindle axis can be set in all system. If nine or more index numbers of the spindle axis or illegal index number of the spindle axis is set , the alarm PW0037, "SV/SP COMBINATION ERROR" is issued.

NOTE

1 Adjust precision and machining time by setting of the time constant for acceleration/deceleration in rigid tapping. In the ordinal rigid tapping, if the time constant for acceleration/deceleration is extremely short, the spindle motor cannot follow to the move command and the synchronization error of rigid tapping increases because the torque command of the spindle motor is saturated in the high speed rotation area. In the FSSB high-speed rigid tapping, even if the setting of the time constant for acceleration/deceleration is short up to the extent with which the torque command of the spindle motor is somewhat saturated, the synchronization precision can be maintained because the servo motor can follow to the rotation of the spindle motor. However, please set within the range where the overshoot is not occurs in the hole bottom.
Refer to the following manual for the details of the tuning way.
FANUC AC SPINDLE PARAMETER MANUAL (B-65280EN)
"Tuning way for FSSB High-speed Rigid Tapping"

2 When the parameter is changed, the power must be turned off before an operation is continued.

3 FSSB high-speed rigid tapping cannot be used with the rigid tapping by the analog spindle or the spindle control with servo motor. If the above rigid tapping is set, the alarm PW0037, "SV/SP COMBINATION ERROR" is issued.

4 FSSB high-speed rigid tapping cannot be used with the rigid tapping with a servo motor and multiple spindle motors by spindle command synchronous control. If the rigid tapping is commanded on the above condition, the alarm PS0203, "PROGRAM MISS AT RIGID TAPPING" is issued.

> **NOTE**
> 5 When FSSB high-speed rigid tapping is used with 3-dimensional rigid tapping, three axes of 3-dimensional rigid tapping need to set the same motor number of the spindle to the parameter (No.24204). If there is an axis whose index number of the spindle axis is different, the alarm PS0203, "PROGRAM MISS AT RIGID TAPPING" is issued on the command of rigid tapping. In addition, three axes of 3-dimensional rigid tapping need to set the bit 1 (FHRSV) of parameter No.2429 and bit 1 (FEED) of parameter No.2005.
> 6 When Peck rigid tapping cycle is used (bit 5 (PCP) of parameter No.5200 is 1), set 1 to the bit 7 (PRA) of parameter No.5209. If the illegal program that the depth of cut is smaller than the cutting start distance is commanded, the alarm PS5560, "ILLEGAL DEPTH OF CUT" can be issued.
> 7 The setting of the optional gear ratio cannot be used.
> 8 If the exchanged axes by flexible path axis assignment or composite control are used by FSSB high-speed rigid tapping, the motor number of the spindle axis that synchronizes with each servo axis (the parameter (No.24204)) need to set. In addition, set 1 to bit1 (FHRSV) of parameter No.2429 and Bit 1 (FEED) of parameter No.2005.
> 9 If the tapping axis of FSSB high-speed rigid tapping is the master axis of axis synchronous control, the same motor number of the spindle (the parameter (No.24204)) need to be set to the slave axes. In FSSB high-speed rigid tapping, synchronization establishment and synchronization error compensation cannot be used.
> 10 If the tapping axis of FSSB high-speed rigid tapping is the master axis of tandem control, it is not necessary to set the same motor number of the spindle (the parameter (No.24204)) to the slave axes.
> 11 With FSSB high-speed rigid tapping, the following servo software functions cannot be used:
> - Dual position feedback function
> If FSSB high-speed rigid tapping is used with either of the above functions, the alarm SV0417, "ILL DGTL SERVO PARAMETER" (Diagnosis data No.4291) is issued.
> 12 With this function, spindle differential speed control cannot be used.
> 13 All of CNC, servo, and spindle software need to support this function. If even one of the software doesn't support it, the ordinal rigid tapping is executed or the excess error alarm is issued.

Limitation

Synchronous control (Synchronous/Composite control)

An axis of synchronous control cannot be used as a tapping axis for FSSB high-speed rigid tapping.

Angular axis control

An angular axis cannot be used as a tapping axis for rigid tapping.

Diagnosis Data

1612	The index number of the spindle axis that synchronizes with each servo axis

[Data Type] Byte axis

The index number of the spindle axis that can use direct communication between a spindle amplifier and a servo amplifier on FSSB connection is displayed.

10.13.16.1 Change the combination for FSSB high-speed rigid tapping

Outline

In FSSB high-speed rigid tapping, the combination of spindle axis and servo axis to synchronize can be changed after power-on.

Explanation

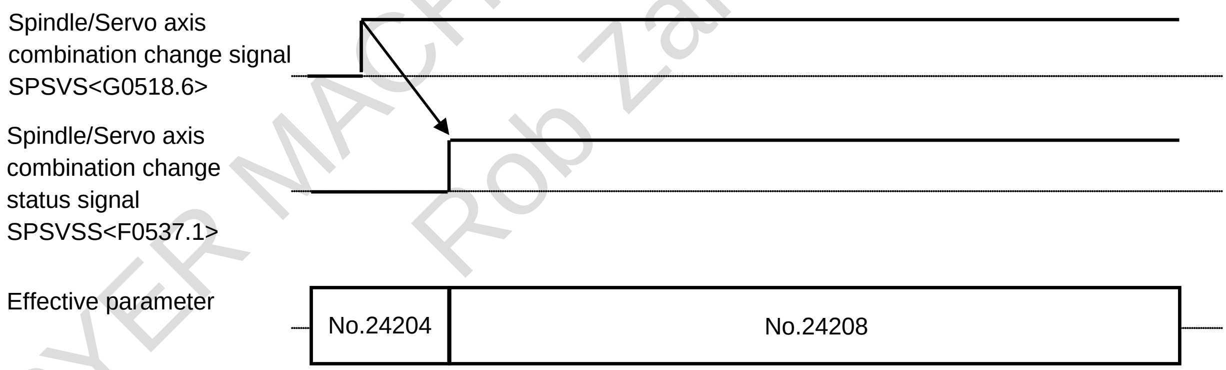
This function makes it possible to choose whether to use parameter No.24204 or No.24208 by PMC input signals to change the combination of spindle axis and servo axis to synchronize.

Spindle/Servo axes combination change (Parameter change from No.24204 to No.24208)

Set Spindle/Servo axis combination change signal SPSVS<G0518.6> from “0” to “1”. After the change of spindle/servo axes combination completes, Spindle/Servo axis combination change status signal SPSVSS<F0537.1> is set from “0” to “1”.

> **NOTE**
> The alarm (DS0092) “SV/SP COMBINATION ERROR” issues in the following cases.
> - Parameter No.24208 is an illegal setting.
> - The function using parameter No.24204 (FSSB high-speed rigid tapping, Servo/Spindle synchronous control (FSSB type), Electronic gear box (FSSB type)) is being applied.
> - Rigid tapping, Servo/Spindle synchronous control or Electronic gear box is being applied in the path that uses parameter No.24208.

Time chart

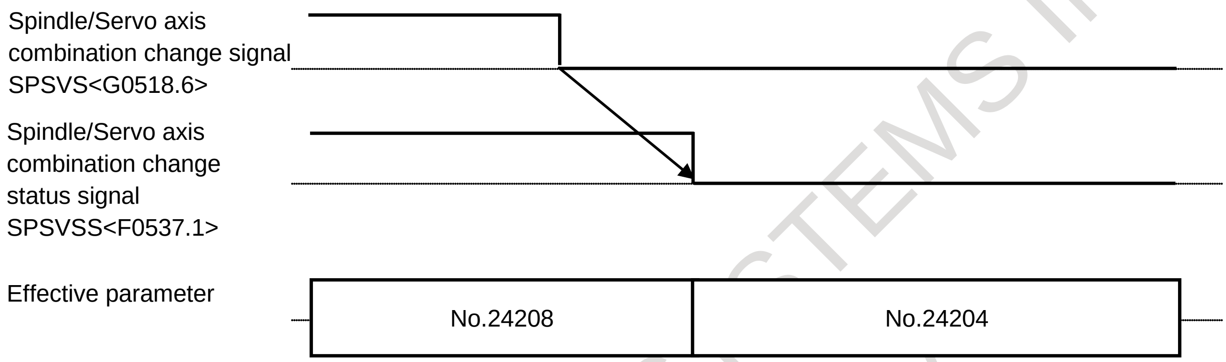


Spindle/Servo axes combination change (Parameter change from No.24208 to No.24204)

Set Spindle/Servo axis combination change signal SPSVS<G0518.6> from “1” to “0”. After the change of spindle/servo axes combination completes, Spindle/Servo axis combination change status signal SPSVSS<F0537.1> is set from “1” to “0”.

> **NOTE**
> The alarm (DS0092) “SV/SP COMBINATION ERROR” issues in the following cases.
> - The function using parameter No.24208 (FSSB high-speed rigid tapping, Servo/Spindle synchronous control (FSSB type), Electronic gear box (FSSB type)) is being applied.
> - Rigid tapping, Servo/Spindle synchronous control or Electronic gear box is being applied in the path that uses parameter No.24204.

Time chart

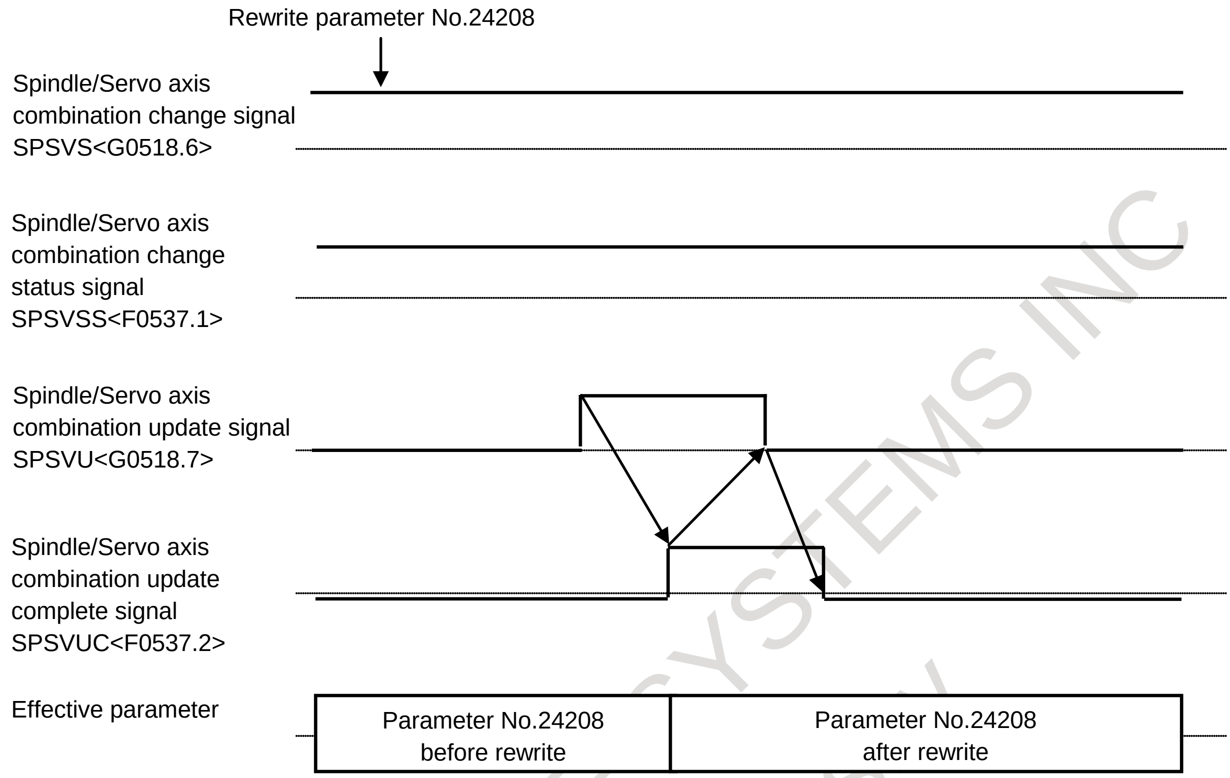


Spindle/Servo axes combination update (Update of parameter No.24208)

Set Spindle/Servo axis combination update signal SPSVU<G0518.7> from “0” to “1” with Spindle/Servo axis combination change status signal SPSVSS<F0537.1> equal to “1”. After the update of spindle/servo axes combination completes, Spindle/Servo axis combination update complete signal SPSVUC<F0537.2> is set to “1”.

> **NOTE**
> The alarm (DS0092) “SV/SP COMBINATION ERROR” issues in the following cases.
> - Parameter No.24208 is an illegal setting.
> - The function using parameter No.24208 (FSSB high-speed rigid tapping, Servo/Spindle synchronous control (FSSB type), Electronic gear box (FSSB type)) is being applied.
> - Rigid tapping, Servo/Spindle synchronous control or Electronic gear box is being applied in the path that uses parameter No.24208.

Time chart



Signal

Spindle/Servo axis combination change signal SPSVS<G0518.6>

[Classification] Input signal

[Function] This signal changes the combination of spindle axis and servo axis to synchronize.

[Operation] When setting this signal from "0" to "1", the parameter to set the combination of spindle axis and servo axis to synchronize is changed from No.24204 to No.24208.
When setting this signal from "1" to "0", the parameter to set the combination of spindle axis and servo axis to synchronize is changed from No.24208 to No.24204.

Spindle/Servo axis combination update signal SPSVU<G0518.7>

[Classification] Input signal

[Function] This signal updates the combination of spindle axis and servo axis to synchronize (Parameter No.24208).

[Operation] When setting this signal from "0" to "1", the combination of spindle axis and servo axis to synchronize (Parameter No.24208) is updated. This signal is valid when Spindle/Servo axis combination change status signal SPSVSS<F0537.1> is equal to "1".

Spindle/Servo axis combination change status signal SPSVSS<F0537.1>

[Classification] Output signal

[Function] This signal indicates the status of the change in the combination of spindle axis and servo axis to synchronize.

[Output condition] This signal is set to "1" in the following case:
- When the parameter to set the combination of spindle axis and servo axis to synchronize is changed to No.24208 by Spindle/Servo axis combination change signal SPSVS<G0518.6>.
This signal is set to "0" in the following case:

- When the parameter to set the combination of spindle axis and servo axis to synchronize is changed to No.24204 by Spindle/Servo axis combination change signal SPSVS<G0518.6>.
- When the combination of spindle axis and servo axis to synchronize is not changed by Spindle/Servo axis combination change signal.

Spindle/Servo axis combination update complete signal SPSVUC<F0537.2>

[Classification] Output signal

[Function] This signal indicates that the combination of spindle axis and servo axis to synchronize (Parameter No.24208) has completed being updated.

[Output condition] This signal is set to “1” in the following case:

- When the combination of spindle axis and servo axis to synchronize (Parameter No.24208) is updated by Spindle/Servo axis combination update signal SPSVU<G0518.7>.

This signal is set to “0” in the following case:

- When Spindle/Servo axis combination update signal SPSVU<G0518.7> is set to “0”.

Signal address

	#7	#6	#5	#4	#3	#2	#1	#0
G0518	SPSVU	SPSVS						

	#7	#6	#5	#4	#3	#2	#1	#0
F0537						SPSVUC	SPSVSS	

Notes

- When the alarm (DS0092) "SV/SP COMBINATION ERROR" is issued, the combination of spindle axis and servo axis is not updated and remains in the last status.
- When controlling Spindle/Servo axis combination change signal SPSVS<G0518.6> or Spindle/Servo axis combination update signal SPSVU<G0518.7> during operation, use M codes that do not perform Buffering.
- Parameter No.24204 can be replaced with parameter No.24208 by this function when applying the functions that use parameter No.24204, other than FSSB high-speed rigid tapping.
- When applying this function, check the ready status with All-spindle operation ready signal SRSRDY<F0034.7> after power-on.

10.13.17 Smart Rigid Tapping

Outline

Smart rigid tapping is the tapping function that uses maximum spindle power in all speed range. As the servo axis follows spindle axis with using FSSB communication, the synchronous error is small.
The fastest rigid tapping can be achieved with no parameter tuning basically.

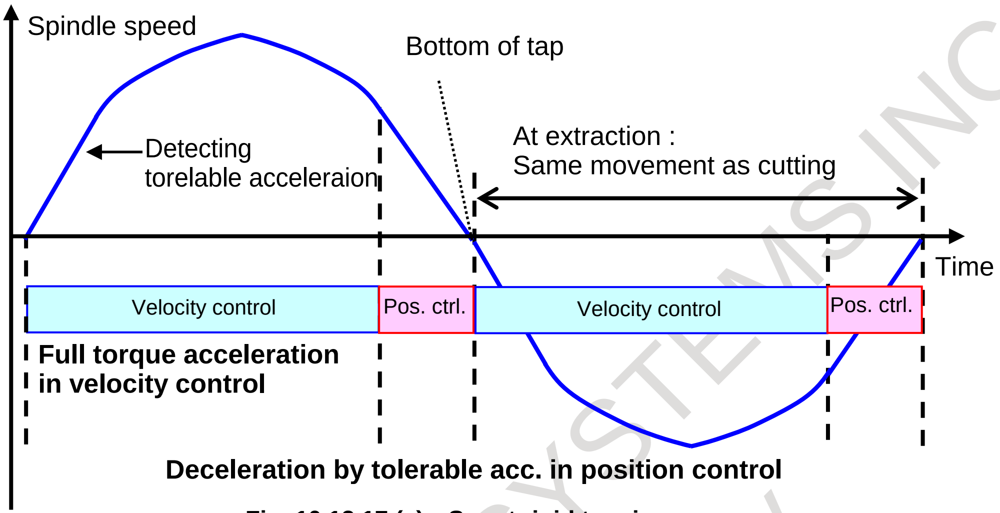


Fig. 10.13.17 (a) Smart rigid tapping

Application example of smart rigid tapping (Pitch 1mm, Length25mm)

Before applying Smart rigid tapping

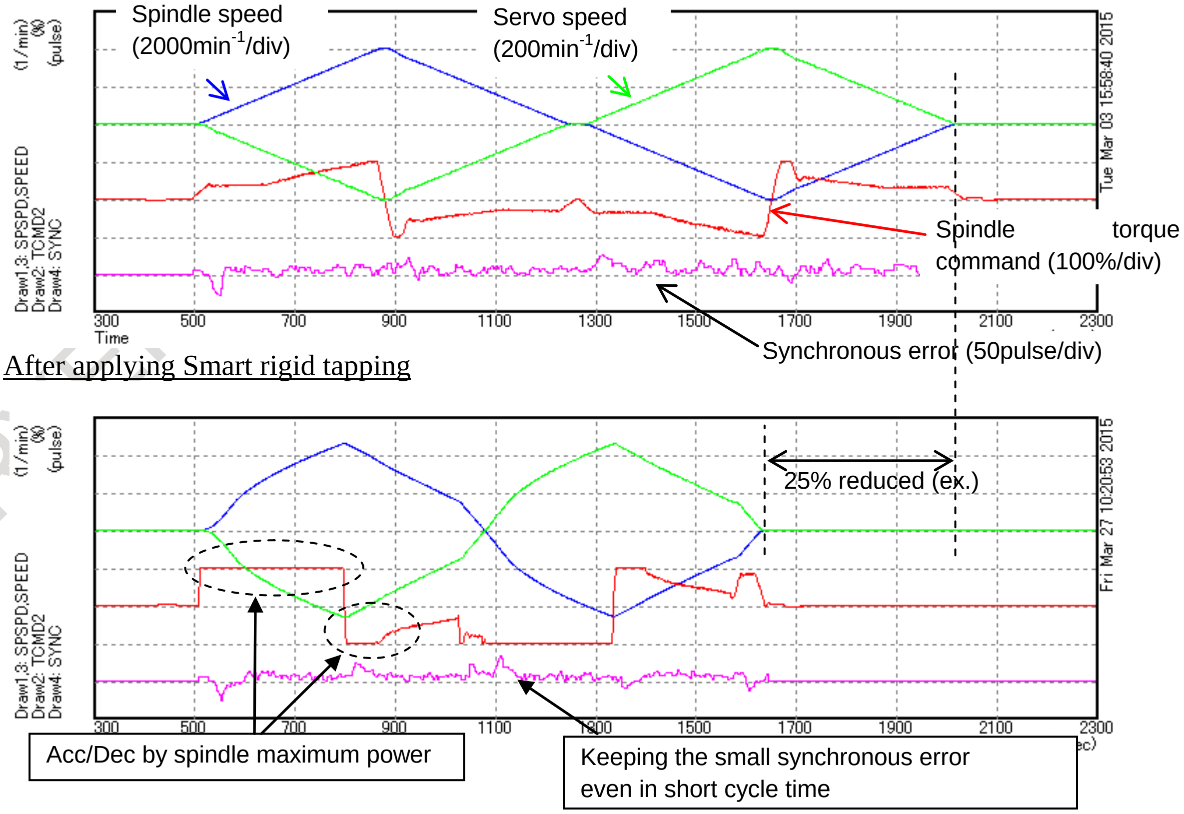

Fig. 10.13.17 (b) Application example of smart rigid tapping

Program Format

The program format for Smart rigid tapping is same as ordinal rigid tapping. But if the moving distance of tapping is larger than over 4096 times of screw pitch, the alarm PS0564, "ILLEGAL COMMAND OF SMART RTAP" will occur.

DI/DO Signals and Sequence

The DI/DO signals and PMC sequence for ordinal rigid tapping can be used without any change. There is no special DI/DO signals and PMC sequence for Smart rigid tapping.
Regarding DI/DO signals and PMC sequence, refer to the chapter of "Signal" and "Timing Charts for Rigid Tapping Specification" in this manual.

Parameters

Settings for FSSB high-speed rigid tapping

Set all parameters related to FSSB high-speed rigid tapping so that the servo axis follows spindle axis. The detail of setting parameters are shown in the chapter of "FSSB high-speed rigid tapping" and "Parameter" in this manual.

Table 10.13.17 (a) Settings for FSSB high-speed rigid tapping

Parameter No.	Contents	Setting value
2005#1	Feed-forward function bit (Servo)	1
2429#1	FSSB high-speed rigid tapping function bit (Servo)	1
2610	Position gain of servo axis during FSSB high-speed rigid tapping	5000
4549#1	FSSB high-speed rigid tapping function bit (Spindle)	1
24203#0	FSSB high-speed rigid tapping function bit (CNC)	1
24204	The index number of the spindle axis that synchronizes to each servo axis	Depends on configuration

Settings for Smart rigid tapping

After setting of following parameters the settings for Smart rigid tapping will be finished in case that the settings for Normal rigid tapping has been already done. In case that the settings for Normal rigid tapping has not been done yet, do it with referring to chapter of "Parameter" in this manual, or the chapter of "Rigid tapping" in FANUC AC SPINDLE MOTOR α*i*/β*i* series BUILT-IN SPINDLE MOTOR B*i* series parameter manual (B-65280EN).

Table 10.13.17 (b) Settings for Smart rigid tapping

Parameter No.	Contents	Setting value
5206#1	Smart rigid tapping function bit	1
2423#2	Setting for the compensation of reverse operation in Smart rigid tapping	1
5214	Setting of an allowable rigid tapping synchronous error range	0
4105 4107	Time constant of magnetic flux for Magnetic flux control	Specific parameter for each motor
4661	Tolerable error value at spindle stop	0

Settings for Each Machine

As Smart rigid tapping accelerates by maximum spindle power, the tuning is not necessary basically. But there may be some cases that a shock occurs in servo axis which follows spindle acc./dec. by maximum power. In such case, use following parameters.

Parameters for tuning Smart rigid tapping

Table 10.13.17 (c) Parameters for tuning Smart rigid tapping

Parameter No.	Contents	Setting value
4666 4667	Bell shape acc./dec. time constant for Smart rigid tapping	0
4668 4669	Upper limit of torque command for Smart rigid tapping	0
4395#5	Improvement of deceleration for Smart rigid tapping	0
4790	Lower limit of torque command for Smart rigid tapping in position control	0
2611	Coefficient of velocity feed-forward for feed axis in Smart rigid tapping	0
2613	Compensation of reverse operation in Smart rigid tapping	0

Settings for Smart thermal control

As Smart rigid tapping uses maximum spindle power in tapping, there is a possibility that the motor overheat alarm (SP9001) might occur in severe duty tapping.
Smart thermal control uses the spindle motor power at the best without motor overheat.
Regarding the detail of Smart thermal control, refer to FANUC AC SPINDLE MOTOR α*i*/β*i* series BUILT-IN SPINDLE MOTOR B*i* series parameter manual (B-65280EN).

Settings for rigid tapping during dry run

Rigid tapping during dry run can be selected by bit 2 (NSD) of parameter No.5206 from Smart rigid tapping or ordinal FSSB high-speed rigid tapping. Set 1 to bit 2 (NSD) of parameter No.5206 which is described below if you make override effective during dry run.

Bit 2 (NSD) of parameter No.5206 is 0

Rigid tapping during dry run is Smart rigid tapping.

- Feedrate cannot be changed by manual feedrate override signal *JV0 to *JV15<Gn010, Gn011> or manual rapid traverse selection signal RT<Gn019.7>.
- If dry run is canceled during Smart rigid tapping in dry run, feedrate is maintained until finishing tapping.
- If dry run is switched during Smart rigid tapping, feedrate is maintained until finishing tapping.

Bit 2 (NSD) of parameter No.5206 is 1

Rigid tapping during dry run is ordinal FSSB high-speed rigid tapping.

- Feedrate can be changed by manual feedrate override signal *JV0 to *JV15<Gn010, Gn011> or manual rapid traverse selection signal RT<Gn019.7>.
- If dry run is canceled during FSSB high-speed rigid tapping in dry run, feedrate is changed from dry run feedrate to feedrate commanded in machining program.
- If dry run is switched during Smart rigid tapping, Smart rigid tapping is continued and feedrate is maintained until finishing tapping.
- Acc./dec. time constant setting is necessary because ordinal FSSB high-speed rigid tapping is executed during dry run. Adjustment of optimal time constant is unnecessary. Set relative long time constant such as 500[msec] to parameter No.5261 to No.5264. Refer to "Parameter list related to Normal rigid tapping" for detail.

Tuning of Rigid Tapping

Common used parameter list

The following parameter list show the common used parameters both for Normal rigid tapping and Smart rigid tapping. In case that the tuning for Normal rigid tapping has finished, it's not necessary to change these parameters. Regarding the detail of each parameter, refer to the chapter of "Parameter" in this manual or the chapter of "Rigid tapping" in FANUC AC SPINDLE MOTOR α*i*/β*i* series BUILT-IN SPINDLE MOTOR B*i* series parameter manual (B-65280EN).

Table 10.13.17 (d) Common used parameter list

Parameter No.	Contents
5210	Rigid tapping mode specification M code
5202#0	Whether to perform orientation (reference position return) when starting rigid tapping
5221 5222 5223 5224	Teeth number of spindle side at arbitrary gear ratio (command) setting (No. 5224 is used for the T series only.)
5231 5232 5233 5234	Teeth number of position coder side at arbitrary gear ratio (command) setting (No. 5234 is used for the T series only.)
5241 5242 5243 5244	Spindle maximum speed at rigid tapping (No.5244 is used for the T series only.)
5200#4	Override selection at extracting
5211	Override value at extracting
5300 5302 5304 5306	In-position width of tapping axis
5301	In-position width of spindle
4000#4	Reference position return direction on servo mode
4002#5	Whether to enable the rotation direction signal (SFR/SRV) on servo mode
4006#7	Setting of the command arbitrary gear ratio function (CMR) on rigid tapping
4017#7	Shortcut function when orientation is specified in stop state
4044 4045	Velocity loop proportional gain on servo mode (It is selected by input signal CTH1A/B.)
4052 4053	Velocity loop integral gain on servo mode (It is selected by input signal CTH1A/B.)
4056 to 4059	Gear ratio between spindle and motor (It is selected by input signal CTH1A or CTH2A)
4065 to 4068	Spindle position gain on servo mode/spindle synchronous control (It is selected by input signal CTH1A or CTH2A)
4073	Grid shift amount on servo mode
4074	Reference position return speed on servo mode
4091	Position gain change ratio at reference position return time on servo mode
4099	Delay time for stable motor excitation
4171 4173	Denominator of an arbitrary gear ratio between the motor sensor and spindle (It is selected by input signal CTH1A or CTH2A.)
4172 4174	Numerator of an arbitrary gear ratio between the motor sensor and spindle (It is selected by input signal CTH1A or CTH2A.)
4406	Acceleration/deceleration time constant for Cs contouring control/servo mode

Parameter list related to Normal rigid tapping

In case of the retraction of rigid tapping after the breakage of tool on cutting by Smart rigid tapping, Normal rigid tapping is necessary even if Smart rigid tapping. To use Normal rigid tapping, the setting of time constant parameter for acc./dec. is required. The following list shows the tuning parameter for Normal rigid tapping. In case that the tuning for Normal rigid tapping has finished, it's not necessary to change these parameters. Regarding the detail of each parameter, refer to the chapter of "Parameter" in this manual or the chapter of "Rigid tapping" in FANUC AC SPINDLE MOTOR α*i*/β*i* series BUILT-IN SPINDLE MOTOR B*i* series parameter manual (B-65280EN).

Table 10.13.17 (e) Parameter list related to Normal rigid tapping

Parameter No.	Contents
5280 5281 to 5284	Position gain of tapping axis at rigid tapping (No. 5284 is used for the T series only.)
5261 5262 5263 5264	Acc/Dec time constant (No. 5264 is used for the T series only.)
5201#2 5271 to 5274	Time constant for acceleration/deceleration in rigid tapping extraction (No. 5274 is used for the T series only.)
5203#2	Feed-forward function at rigid tapping
5310 5350 5354 5358	Allowable level of position error of tapping axis at moving
5311	Allowable level of position error of spindle at moving
5312 5352 5356 5360	Allowable level of position error of tapping axis at stop
5313	Allowable level of position error of spindle at stop
5203#5	Selection of bell shape acc./dec. for rigid tapping
5365 5366 5367 5368	Bell shape acc./ dec. time constant for rigid tapping (No. 5368 is used for the T series only.)
4037	Velocity loop feed-forward coefficient
4344	Advanced preview feed-forward coefficient (This parameter sets the coefficient for rapid traverse when bit 4 of parameter No. 4542 is 1.)
4542#4	Cutting feed/rapid traverse feed-forward function
4627	Advanced preview feed-forward coefficient for cutting feed (This parameter is valid when bit 4 of parameter No. 4542 is 1.)

Restriction

- If you use rough TTL resolution sensor such as α*i* Positioncoder(4096pulse/rev) in spindle position sensor, there is a possibility that the vibration or strange sound might be detected due to the following movement of servo axis to rough feedback data. We don't recommend to use such sensors for Smart rigid tapping. Use analog 1Vpp sensor or serial type sensor.

- You can't use Smart rigid tapping in the following conditions.
  - Using sensor-less motors as spindle motor
  - Using Spindle differential speed control

- Smart rigid tapping becomes invalid in the following kinds of rigid tappings. In these cases, Normal rigid tapping will be executed. When you use them, set some parameters such as time constant which are shown in "Parameter list related to Normal rigid tapping".
    - Peck rigid tapping
    - Rigid tapping by manual handling feed
    - Extraction in rigid tapping
    - Rigid tapping using Spindle control by servo motor
    - Rigid tapping by analog spindle

- In the situation that plural spindle axes are synchronized by Spindle command synchronous control mode, Smart rigid tapping becomes invalid. PS0203 alarm "PROGRAM MISS AT RIGID TAPPING" will occur.

- Smart rigid tapping becomes invalid in the checking mode in manual handle retrace. In the mode, Normal rigid tapping will be executed.

- As Smart rigid tapping executes acc./dec. by spindle maximum power, Acc./dec. after interpolation and Look-ahead acc./dec. before interpolation become invalid.

- In Smart rigid tapping over-ride signals for feed axes *FV0-*FV7<Gn012> and over-ride cancel signal OVC<Gn006.4> become invalid even if parameter OVS(No.5203#4)=1. Over-ride for extraction of rigid tapping is valid.

- In Smart rigid tapping the backlash compensation for spindle becomes invalid. The backlash compensation for feed axis becomes valid.

- Interlock and machine lock become invalid during smart rigid tapping. Axes become interlock state or machine lock state after finishing Smart rigid tapping.

- In Smart rigid tapping feed hold and single block become invalid. The axes don’t stop until the end of 1cycle of tapping.

- Reset and emergency stop during Smart rigid tapping make velocity command 0 stop.

- It’s impossible to change feedrate by external deceleration during Smart rigid tapping. Feedrate at starting cutting or extraction is maintained.

- The following functions become invalid during Smart rigid tapping.
    - General purpose retract
    - Tool retract and recover
    - One-digit F code feed
    - Manual handle interrupt

- When you use 3-dimensional rigid tapping, set D3R (Parameter No.11221#1) to “1”.

- The following settings are not supported for Smart rigid tapping axis.
    - Slave axis of superimposed control
    - Slave axis of flexible synchronization control
    - Slave axis of electronic gear box

- Alarm (SV0048) "SMART RIGID TAPPING STOP" will occur with the following alarms during Smart rigid tapping and the excitation of servo motor will be turned off. Alarm (SV0048) can be canceled with reset.
    - Alarm (SP9xxx) (when spindle motor is deactivated)

- Alarm (SP0741) (when synchronous error range exceeds the setting value of parameter (No.5214))

- When SRT(No.5206#1) is 1 and the spindle software, which doesn't support Smart rigid tapping, is used, alarm PS0564 "ILLEGAL COMMAND OF SMART RTAP" will occur at rigid tapping.

10.13.18 Parameter

	#7	#6	#5	#4	#3	#2	#1	#0
2005							FEED	

[Input type] Parameter input
[Data type] Bit axis

#1 FEED Feed forward function is:
0: Disabled.
1: Enabled.

> **NOTE**
> Set 1 to the synchronizing servo axis with spindle axis on FSSB high-speed rigid tapping.
> In FSSB high-speed rigid tapping mode, the feed forward coefficient becomes 100 percent.

> **NOTE**
> This parameter is initial setting parameter. For details, refer to the appendix "Automatic setting / Initial setting parameter" in CONNECTION MANUAL (FUNCTION) (B-64693EN-1).

	#7	#6	#5	#4	#3	#2	#1	#0
2423						RGDBLA		

[Input type] Parameter input
[Data type] Bit axis

#2 RGDBLA Setting for the compensation of reverse operation in Smart rigid tapping
0: Compensation invalid
1: Compensation valid

	#7	#6	#5	#4	#3	#2	#1	#0
2429							FHRSV	

[Input type] Parameter input
[Data type] Bit axis

#1 FHRSV Servo axis control of FSSB high-speed rigid tapping is:
0: Disabled.
1: Enabled.

> **NOTE**
> Set 1 to the synchronizing servo axis of a spindle axis on FSSB high-speed rigid tapping.

2610	Position control loop gain for the tapping axis in FSSB high-speed rigid tapping

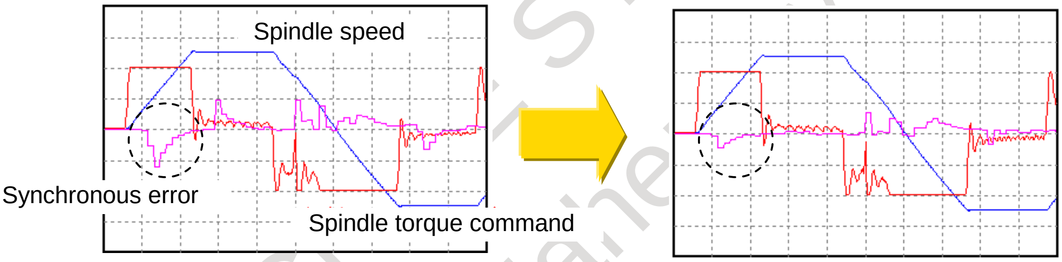
[Input type] Parameter input
[Data type] Word axis
[Valid data range] 0 to 32767

The position control loop gain for the tapping axis (servo axis) in FSSB high-speed rigid tapping can be set.
If the setting value of this parameter is 0, the position control loop gain is the same as the position gain (parameters Nos.5280 to 5284) of conventional rigid tapping used by both of servo axis and spindle axis.

2611	Coefficient of velocity feed-forward for feed axis in smart rigid tapping

[Input type] Parameter input
[Data type] Word axis
[Unit of data] 1%
[Standard setting] 0

Use this parameter to improve the axis response in case that the synchronous error is large at the start point of tapping as follow figure. Increase this value to every 100 with watching the synchronous error. There is a possibility that the torque command of servo axis might become vibrating at acc./dec. if the value is too large.

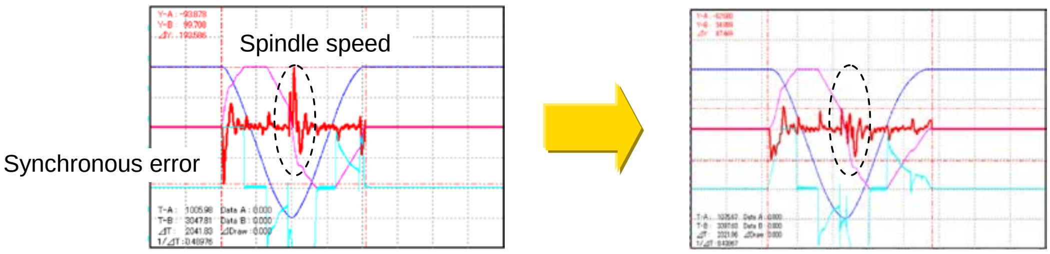


No.2611=0 No.2611=350

2613	Compensation of reverse operation in Smart rigid tapping

[Input type] Parameter input
[Data type] Word axis
[Unit of data] 0.01%
[Valid data range] 0 to 10000
[Standard setting] 0

Use this parameter to improve the axis response in case that the synchronous error becomes large at the reversal point of tapping. Please increase this value to every 100 with watching the synchronous error.



No.2613=0 No.2613=700

	#7	#6	#5	#4	#3	#2	#1	#0
3702							EMS	

[Input type] Parameter input
[Data type] Bit path

#1 EMS The multi-spindle control is:
0: Used.
1: Not used.

	#7	#6	#5	#4	#3	#2	#1	#0
3703				SPR	MPP	MPM		2P2

[Input type] Parameter input
[Data type] Bit

> **NOTE**
> When at least one of these parameters is set, the power must be turned off before operation is continued.

#0 2P2 When a multi-path system is used, inter-path spindle control allows:
0: Configuration where the spindle that belongs to one path only is shared between path 1 and path 2.
1: Configuration where the spindles that belong to path 1 and 2 are shared between the two paths.
When the spindle that belongs to an arbitrary path is shared between arbitrary paths, set bit 2 (MPM) of parameter No. 3703. (The meanings of signals used vary, so that ladder program modifications need to be made.)

#2 MPM When a multi-path system is used, the configuration allowed by inter-path spindle control:
0: Follows the setting of bit 0 (2P2) of parameter No. 3703.
1: Allows the sharing of the spindle that belongs to a path between arbitrary paths.

#3 MPP In multi-spindle control, a spindle selection using a programmed command instead of using the signals (SWS1 to SWS4<Gn027.0 to 2, Gn026.3>) is:
0: Not made.
1: Made.

> **NOTE**
> When this parameter is set to 1, set parameter No. 3781 at the same time.

#4 SPR Rigid tapping with spindle of another path function is:
0: Not available.
1: Available.
The "rigid tapping with spindle of another path" function can be combined with the address P-based spindle select function. This combination enables program commands (P code) to be used to select a spindle in a path other than the command issuing path for rigid tapping.

	#7	#6	#5	#4	#3	#2	#1	#0
3705				EVS	SGT			ESF
		SFA	NSF		SGT			ESF

[Input type] Parameter input
[Data type] Bit path

#0 ESF When the spindle control function (Spindle analog output or Spindle serial output) is used, and the constant surface speed control function is used or bit 4 (GTT) of parameter No. 3706 is set to 1:

0: S codes and SF are output for all S commands.
1: For the lathe system:
 S codes and SF are not output for an S command in the constant surface speed control (G96) mode and a command for maximum spindle speed clamping (G92 S_; (G50 for G code system A)).
 For the machining center system:
 S codes and SF are not output for an S command in the constant surface speed control (G96) mode.

> **NOTE**
> The operation of this parameter varies between the lathe system and machining center system.
> For the lathe system:
> This parameter is valid when bit 4 (EVS) of parameter No. 3705 is set to 1.
> For the machining center system:
> For an S command for maximum spindle speed clamping (G92 S_;), SF is not output, regardless of the setting of this parameter.

#3 SGT Gear switching method during tapping cycle (G84 and G74) is:

0: Method A (Same as the normal gear switching method)
1: Method B (Gears are switched during tapping cycle according to the spindle speed set in parameters Nos. 3761 and 3762).

#4 EVS When the spindle control function (Spindle analog output or Spindle serial output) is used, S codes and SF are:

0: Not output for an S command.
1: Output for an S command.

The output of S codes and SF for an S command in constant surface speed control mode (G96), or for an S command used to specify maximum spindle speed clamping (G92 S_; (G50 for G code system A)) depends on the setting of bit 0 (ESF) of parameter No. 3705.

#5 NSF For the M series, when a T type gear is selected (with bit 4 (GTT) of parameter No. 3706 set to 1 or constant surface speed control is enabled (bit 0 (SSC) of parameter No. 8133 is 1)), and an S code is specified:

0: SF is output.
1: SF is not output.

> **NOTE**
> This parameter does not affect S code output. For an S command for maximum spindle speed clamping (G92 S_;), SF is not output, regardless of the setting of this parameter.

#6 SFA The SF signal is output:
0: When gears are switched.
1: Irrespective of whether gears are switched.

	#7	#6	#5	#4	#3	#2	#1	#0
3706								
				GTT				

[Input type] Parameter input
[Data type] Bit path

#4 GTT Spindle gear selection method is:
0: M type.
1: T type.

> **NOTE**
> 1 This parameter is effected for M system.
> 2 M type
> The gear selection signal is not input. The CNC selects a gear based on the speed range of each gear set by a parameter beforehand according to S codes, and the selected gear is posted by outputting the gear selection signal. Moreover, the spindle speed matching the gear selected by the output gear selection signal is output.
> T type
> The gear selection signal is input. The spindle speed matching the gear selected by this signal is output.
> 3 When the constant surface speed control is enabled (bit 0 (SSC) of parameter No. 8133 is 1), T type is selected, regardless of whether this parameter is specified.
> 4 When T type spindle gear switching is selected, the following parameters have no effect:
> No.3705#2(SGB), No.3751, No.3752,
> No.3705#1(GST), No.3705#3(SGT), No.3761, No.3762,
> No.3705#6(SFA), No.3735, No.3736
> On the other hand, parameter No. 3744 becomes usable.
> 5 When multi spindle control is used, select to T type.

3720	Number of position coder pulses

> **NOTE**
> When this parameter is set, the power must be turned off before operation is continued.

[Input type] Parameter input
[Data type] 2-word spindle
[Unit of data] Detection unit
[Valid data range] 1 to 32767
Set the number of position coder pulses.

3761	
	Spindle speed when switching from gear 1 to gear 2 during tapping

3762	Spindle speed when switching from gear 2 to gear 3 during tapping

[Input type] Parameter input
[Data type] 2-word path
[Unit of data] min^{-1}
[Valid data range] 0 to 99999999

When method B is selected as the gear change method in the tapping cycle (when bit 3 (SGT) of parameter No. 3705 is set to 1), set the spindle speed at a change point of each gear.

	#7	#6	#5	#4	#3	#2	#1	#0
4000				RETSV				

[Input type] Parameter input
[Data type] Bit spindle

#4 RETSV Reference position return direction in the servo mode (rigid tapping, etc.)
0: The spindle returns to the reference position counterclockwise (CCW).
1: The spindle returns to the reference position clockwise (CW).

NOTE
This parameter is valid only when a serial spindle is used.

4073	Grid shift amount in the servo mode

[Input type] Parameter input
[Data type] Word spindle

[Unit of data] 1 pulse (360°/4096)
[Valid data range] 0 to 4095
Set this data when the reference position is to be shifted in the servo mode (rigid tapping, etc.).
When plus data is specified, the reference position for the spindle is shifted CCW by the set number of pulses.

> **NOTE**
> This parameter is valid only when a serial spindle is used.

4105	Time constant of magnetic flux for Magnetic flux control (for high-speed output switching characteristics)

4107	Time constant of magnetic flux for Magnetic flux control (for low-speed output switching characteristics)

[Input type] Parameter input
[Data type] Word spindle
The magnetic flux control is used to suppress the swelling of output power at acc./dec. in induction motors. These parameters are used for the function and the value is specific constant in each motor. When you use Smart rigid tapping, the setting of this parameter is necessary. If these parameters are 0 even after automatic parameter initialization, please ask FANUC of the setting value.

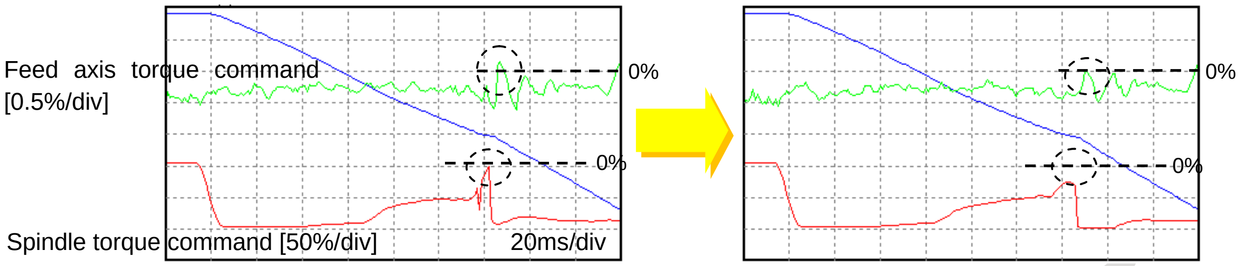
> **NOTE**
> When you use synchronous spindle motor (No.4012#6=1), the magnetic flux control is not necessary. Don’t set these parameters.

	#7	#6	#5	#4	#3	#2	#1	#0
4395			SRTDIF					

[Input type] Parameter input
[Data type] Bit spindle

#5 SRTDIF Improvement of deceleration for Smart rigid tapping is:
0: Invalid.
1: Valid.
These are some cases that shock sounds can be heard in the feed axis at the point where the spindle control changes from velocity control to position control during deceleration in tapping, if the torque command for spindle reverses and the torque command for feed axis reverses also as the result.
When this improvement becomes valid, the change from velocity control to positon control in spindle becomes smooth, and reverse of the spindle torque command is suppressed.
When you can’t suppress shock sounds even if this improvement is applied, use No.4790 together to set lower limit of torque command.

Spindle speed [500min^{-1}/div]



No.4395#5=0 No.4395#5=1

	#7	#6	#5	#4	#3	#2	#1	#0
4549							**FHRSP**	

[Input type] Parameter input
[Data type] Bit spindle

#1 FHRSP Spindle control of FSSB high-speed rigid tapping is:
0: Disabled.
1: Enabled.

> **NOTE**
> Set 1 to the synchronizing spindle axis with the servo axis on FSSB high-speed rigid tapping.

4661	**Tolerable error value at spindle stop**

[Input type] Parameter input
[Data type] Word spindle
[Unit of data] 1/4096 revolution of spindle
[Valid data range] 0 to 2048
[Standard setting] 0

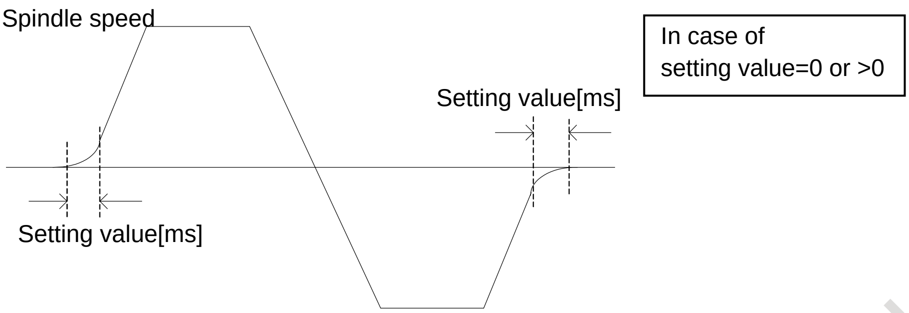
The tolerable error value at spindle stop should be set in No.4661. If the error at spindle stop becomes over this value, the alarm (SP9170) will occur.
The setting value 0 is treated as 1024. The standard setting value is 0.

4666	**Bell shape acc./dec. time constant for Smart rigid tapping CTH1A=0**

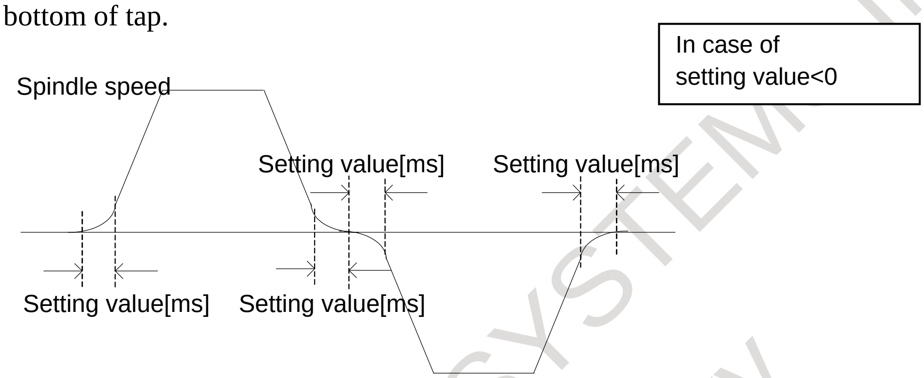
4667	**Bell shape acc./dec. time constant for Smart rigid tapping CTH1A=1**

[Input type] Parameter input
[Data type] Word spindle
[Unit of data] 1ms
[Valid data range] -180 to 180
[Standard setting] 0

These parameters specify the bell shape acc./dec. time constant at starting from R point or ending point to R point. If there is a shock at acceleration or at deceleration in servo or spindle axis, please tune these parameters. The setting value 0 is treated as 30 (30ms).



When the setting value is negative, the bell shape acc./dec. becomes effective also at bottom of tap.



4668	Upper limit of torque command for Smart rigid tapping CTH1A=0

4669	Upper limit of torque command for Smart rigid tapping CTH1A=1

[Input type] Parameter input
[Data type] Word spindle
[Unit of data] 1%
[Valid data range] 0 to 100
[Standard setting] 0

These parameters specify the upper limit of torque command for Smart rigid tapping. If the following limits have been already applied, they are valid also in Smart rigid tapping.

- Torque limit by parameter No.4025 and DI signal TLMH,L
- Power limit by parameter No.4028 and 4029

In such cases, it's not necessary to set these parameters. The setting value 0 is treated as 100 (100%).

4790	Lower limit of torque command for Smart rigid tapping in position control

[Input type] Parameter input
[Data type] Word spindle
[Unit of data] 1%
[Valid data range] 0 to 25
[Standard setting] 0

This parameter specifies the lower limit of torque command for spindle in position control and it clamps the torque command so that the torque command for spindle doesn't reverse. When you don't want the spindle torque command becomes under n%, Set n in this parameter.
If you set 0 in this parameter, the clamp of torque command is not done.

	#7	#6	#5	#4	#3	#2	#1	#0
5101								FXY

[Input type] Parameter input
[Data type] Bit path

#0 FXY The drilling axis in the drilling canned cycle, or cutting axis in the grinding canned cycle is:
0: Z-axis at all times.
1: Axis selected by the program

> **NOTE**
> In the case of the lathe system, this parameter is valid only for the drilling canned cycle in the FANUC Series 15 program format.

	#7	#6	#5	#4	#3	#2	#1	#0
5200	SRS	FHD	PCP	DOV	SIG	CRG		G84
		FHD	PCP	DOV	SIG	CRG		G84

[Input type] Parameter input
[Data type] Bit path

#0 G84 Method for specifying rigid tapping:
0: An M code specifying the rigid tapping mode is specified prior to the issue of the G84 (or G74) command. (See parameter No. 5210).
1: An M code specifying the rigid tapping mode is not used. (G84 cannot be used as a G code for the tapping cycle; G74 cannot be used for the reverse tapping cycle.)

#2 CRG Rigid mode when a rigid mode cancel command is specified (G80, 01 group G code, reset, etc.) :
0: Canceled after rigid tapping signal RGTAP is set to 0.
1: Canceled before rigid tapping signal RGTAP is set to 0.

#3 SIG When gears are changed for rigid tapping, the use of SINDs is:
0: Not permitted.
1: Permitted.

#4 DOV Override during extraction in rigid tapping:
0: Invalidated
1: Validated (The override value is set in parameter No. 5211. However, set an override value for retraction for rigid tapping in parameter No. 5381.)

#5 PCP Rigid tapping:
0: Used as a high speed peck tapping cycle
1: Not used as a high speed peck tapping cycle

#6 FHD Feed hold and single block in rigid tapping:
0: Invalidated
1: Validated

#7 SRS To select a spindle used for rigid tapping in multi-spindle control:
0: The spindle selection signals SWS1, SWS2, SWS3, and SWS4 are used. (These signals are used also for multi-spindle control.)
1: The rigid tapping spindle selection signals RGTSP1, RGTSP2, RGTSP3, and RGTSP4 are used. (These signals are provided expressly for rigid tapping.)

	#7	#6	#5	#4	#3	#2	#1	#0
5201				OV3	OVU	TDR		

[Input type] Parameter input
[Data type] Bit path

#2 TDR Cutting time constant in rigid tapping:
0: Uses a same parameter during cutting and extraction (Parameters Nos. 5261 to 5264)
1: Not use a same parameter during cutting and extraction
Parameters Nos. 5261 to 5264: Time constant during cutting
Parameters Nos. 5271 to 5274: Time constant during extraction

#3 OVU The increment unit of the override parameter No. 5211 for tool rigid tapping extraction is:
0: 1%
1: 10%

#4 OV3 A spindle speed for extraction is programmed, so override for extraction operation is:
0: Disabled.
1: Enabled.

	#7	#6	#5	#4	#3	#2	#1	#0
5202				IRR				ORI

[Input type] Parameter input
[Data type] Bit path

> **NOTE**
> When this parameter is set, the power must be turned off before operation is continued.

#0 ORI When rigid tapping is started:
0: Spindle orientation is not performed.
1: Spindle orientation is performed.
This parameter can be used only for a serial spindle.
This spindle orientation performs reference position return in the serial spindle/servo mode. The stop position can be changed using the serial spindle parameter No. 4073.

#4 IRR As the in-position width at point R after movement from point I to point R in rigid tapping:
0: The in-position widths dedicated to rigid tapping (parameters Nos. 5300, 5302, 5304, and 5306) are selected.
1: The normal in-position width (parameter No. 1826) is selected.

	#7	#6	#5	#4	#3	#2	#1	#0
5203			RBL	OVS		RFF		

[Input type] Parameter input
[Data type] Bit path

#2 RFF In rigid tapping, feed forward is:
0: Disabled.
1: Enabled. (Recommended)

As the standard setting, set 1.
At the same time, set the parameter for the advanced preview feed forward coefficient for the tapping axis and the parameter for the advance preview feed forward coefficient for the spindle so that these values match.

- Advanced preview feed forward coefficient for the tapping axis: Parameter No. 2092 (or parameter No. 2144 if the cutting/rapid traverse feed forward function is enabled (bit 4 (FFCHG) of parameter No. 2214 is set to 1))
- Advanced preview feed forward coefficient for the spindle: Parameter No. 4344

> **NOTE**
> This parameter is valid when a serial spindle is used.

> **NOTE**
> This parameter is automatic setting parameter. For details, refer to the appendix "Automatic setting / Initial setting parameter" in CONNECTION MANUAL (FUNCTION) (B-64693EN-1).

#4 OVS In rigid tapping, override by the feedrate override select signal and cancellation of override by the override cancel signal is:
0: Disabled.
1: Enabled.
When feedrate override is enabled, extraction override is disabled.
The spindle override is clamped to 100% during rigid tapping, regardless of the setting of this parameter.

#5 RBL As acceleration/deceleration for rigid tapping cutting feed:
0: Linear acceleration/deceleration is used.
1: Bell-shaped acceleration/deceleration is used.

> **NOTE**
> This parameter is initial setting parameter. For details, refer to the appendix "Automatic setting / Initial setting parameter" in CONNECTION MANUAL (FUNCTION) (B-64693EN-1).

	#7	#6	#5	#4	#3	#2	#1	#0
5206	RSP					NSD	SRT	

[Input type] Parameter input
[Data type] Bit

#1 SRT Smart rigid tapping function bit
0: Function invalid
1: Function valid

#2 NSD Rigid tapping during dry run is:
- 0: Smart rigid tapping (Change of manual feedrate override signal *JV0 to *JV15<Gn010, Gn011> or manual rapid traverse selection signal RT<Gn019.7> is not effective.).
- 1: FSSB high-speed rigid tapping (Change of manual feedrate override signal *JV0 to *JV15<Gn010, Gn011> or manual rapid traverse selection signal RT<Gn019.7> is effective.).

#7 RSP Rigid tapping synchronization error range is:
- 0: After reaching point R and the changing of the loop gain and parameter of position control being completed, the calculation of rigid tapping synchronization error starts with the movement of tapping axis.
- 1: After reaching point R and the changing of the loop gain and parameter of position control being completed, the calculation of rigid tapping synchronization error starts immediately.

	#7	#6	#5	#4	#3	#2	#1	#0
5209	PRA	CSA				DWP	RIP	RTX
	PRA	CSA					RIP	

[Input type] Parameter input
[Data type] Bit path

#0 RTX In rigid tapping in a lathe system, the tapping axis is:
- 0: Selected by selecting a plane.
- 1: Always assumed to be the Z-axis for G84 or the X-axis for G88.

> **NOTE**
> This parameter becomes invalid when bit 1 (FCV) of parameter No. 0001 is set to 1, and rigid tapping is specified using the FANUC Series 15 program format.

#1 RIP When a movement from the initial point to point R is made, the in-position check is:
- 0: Dependent on the setting of bit 5 (NCI) of parameter No. 1601.
- 1: Performed.

> **NOTE**
> This parameter is valid when bit 5 (NCI) of parameter No. 1601 is set to 1 and bit 4 (IRR) of parameter No. 5202 is set to 0.
> If bit 5 (NCI) of parameter No. 1601 is set to 0, the in-position check is performed regardless of the setting of this parameter.

#2 DWP When a dwell (address P) command is not included in a block for lathe-system rigid tapping:
- 0: Dwelling at the bottom of a hole is not performed.
- 1: The dwell (address P) command specified in the block for drilling is valid.

> **NOTE**
> This parameter becomes invalid if rigid tapping is specified in the FANUC Series 15 program format with bit 1 (FCV) of parameter No. 0001 set to 1.

#6 CSA If Constant surface speed control is commanded in Rigid tapping mode:
0: Alarm is not issued.
1: Alarm PS0200, "ILLEGAL S CODE COMMAND" is issued.

> **NOTE**
> This parameter is automatic setting parameter. For details, refer to the appendix "Automatic setting / Initial setting parameter" in CONNECTION MANUAL (FUNCTION) (B-64693EN-1).

#7 PRA On the peck rigid tapping, if the depth of cut (Q) is smaller than the cutting start distance (d):
0: Alarm is not issued.
1: Alarm PS5560, "ILLEGAL DEPTH OF CUT" is issued.

> **NOTE**
> 1 When High-speed peck rigid tapping cycle is not used (bit 5 (PCP) of parameter No.5200 is 1), this parameter is effective.
> 2 When FSSB high-speed rigid tapping is used, set 1 to this parameter.

> **NOTE**
> This parameter is automatic setting parameter. For details, refer to the appendix "Automatic setting / Initial setting parameter" in CONNECTION MANUAL (FUNCTION) (B-64693EN-1).

5210	Rigid tapping mode specification M code

[Input type] Parameter input
[Data type] 2-word path
[Valid data range] 0 to 65535
This parameter sets an M code that specifies the rigid tapping mode.
The M code is judged to be 29 (M29) when 0 is set.

5211	Override value during rigid tapping extraction

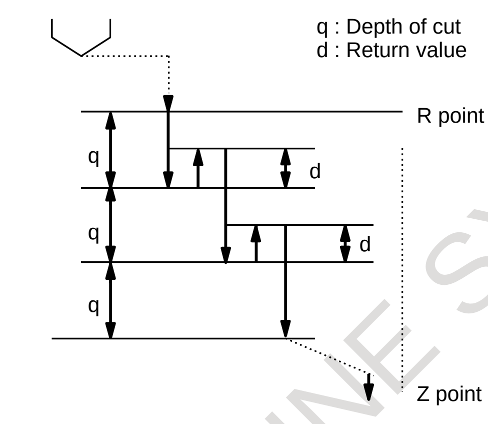
[Input type] Parameter input
[Data type] Word path
[Unit of data] 1% or 10%
[Valid data range] 0 to 200
The parameter sets the override value during rigid tapping extraction.

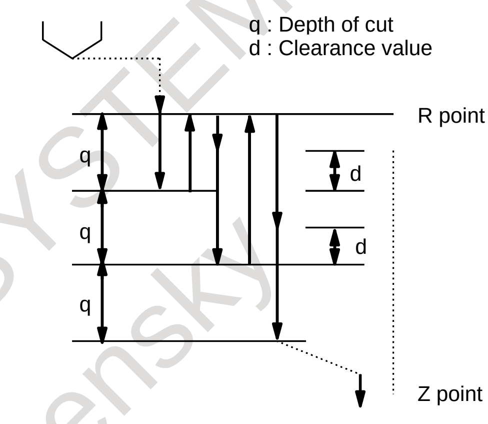
> **NOTE**
> 1 The override value is valid when bit 4 (DOV) of parameter No. 5200 is set to 1. When bit 3 (OVU) of parameter No. 5201 is set to 1, the unit of set data is 10% and an override of up to 2000% can be applied to extraction.
> 2 If the setting value is less than or equal to 0, it is treated as 100%. Also, if the setting value is greater than 200, it is treated as 2000% or 200%.

5213	Return in peck rigid tapping cycle

[Input type] Setting input
[Data type] Real path
[Unit of data] mm, inch (input unit)
[Min. unit of data] Depend on the increment system of the drilling axis
[Valid data range] 0 or positive 9 digit of minimum unit of data (refer to the standard parameter setting table (B))
(When the increment system is IS-B, 0.0 to +999999.999)

This parameter sets the return or clearance in the peck tapping cycle.
If the setting value is negative value, it is treated as absolute value.

When the bit 5 (PCP) of parameter No. 5200 is set to 0. (High speed peck tapping cycle)	When the bit 5 (PCP) of parameter No. 5200 is set to 1. (Peck tapping cycle)
	




> **NOTE**
> CNC reads a setting value of parameter No.5213 when a block of peck rigid tapping cycle is read (buffered). If a setting value of parameter No.5213 is changed during automatic operation, a setting value has to be changed when buffering is prevented by M code preventing buffering and so forth.

5214	Setting of an allowable rigid tapping synchronization error range

[Input type] Parameter input
[Data type] 2-word spindle
[Unit of data] Detection unit
[Valid data range] 0 to 99999999

This parameter sets an allowable synchronization error range in rigid tapping.
If a synchronous error range exceeding the setting of this parameter is detected, the alarm SP0741, “RIGID TAP ALARM : EXCESS ERROR” is issued. When 0 is set in this parameter, no synchronization error check is made.

<u>For Smart rigid tapping</u>
Synchronization error check is always executed in Smart rigid tapping. In regard to spindle using Smart rigid tapping, the setting value 0 is treated as 400. The standard setting value is 0, but change it if you need.

5221	Number of gear teeth on the spindle side in rigid tapping (first gear)
5222	Number of gear teeth on the spindle side in rigid tapping (second gear)
5223	Number of gear teeth on the spindle side in rigid tapping (third gear)
5224	Number of gear teeth on the spindle side in rigid tapping (fourth gear)

[Input type] Parameter input
[Data type] Word spindle
[Valid data range] 1 to 32767

Each of these parameters is used to set the number of gear teeth on the spindle side for each gear in rigid tapping.

> **NOTE**
> When a position coder is attached to the spindle, set the same value for all of parameters Nos. 5221 to 5224.

5231	Number of gear teeth on the position coder side in rigid tapping (first gear)
5232	Number of gear teeth on the position coder side in rigid tapping (second gear)
5233	Number of gear teeth on the position coder side in rigid tapping (third gear)
5234	Number of gear teeth on the position coder side in rigid tapping (fourth gear)

[Input type] Parameter input
[Data type] Word spindle
[Valid data range] 1 to 32767

Each of these parameters is used to set the number of gear teeth on the position coder side for each gear in rigid tapping.

> **NOTE**
> When a position coder is attached to the spindle, set the same value for all of parameters Nos. 5231 to 5234.

5241	Maximum spindle speed in rigid tapping (first gear)
5242	Maximum spindle speed in rigid tapping (second gear)
5243	Maximum spindle speed in rigid tapping (third gear)
5244	Maximum spindle speed in rigid tapping (fourth gear)

[Input type] Parameter input
[Data type] 2-word spindle
[Unit of data] min^{-1}
[Valid data range] 0 to 9999

Spindle position coder gear ratio
1 : 1 0 to 7400
1 : 2 0 to 9999
1 : 4 0 to 9999
1 : 8 0 to 9999

Each of these parameters is used to set a maximum spindle speed for each gear in rigid tapping.

Set the same value for both parameters Nos. 5241 and 5243 for a one-stage gear system. For a two-stage gear system, set the same value as set in parameter No. 5242 in parameter No. 5243. Otherwise, alarm PS0200, "ILLEGAL S CODE COMMAND" will be issued. This applies to the machining center system.

5261	Time constant for acceleration/deceleration in rigid tapping for each gear (first gear)
5262	Time constant for acceleration/deceleration in rigid tapping for each gear (second gear)
5263	Time constant for acceleration/deceleration in rigid tapping for each gear (third gear)
5264	Time constant for acceleration/deceleration in rigid tapping for each gear (fourth gear)

[Input type] Parameter input
[Data type] Word spindle
[Unit of data] msec
[Valid data range] 0 to 4000

Each of these parameters is used to set a linear acceleration/ deceleration time constant for the spindle of each gear and the tapping axis in rigid tapping.
Set the period required to reach each maximum spindle speed (parameters Nos. 5241 to 5244).
The set time constant, multiplied by the ratio of a specified S value to a maximum spindle speed, is actually used as a time constant.
For bell-shaped acceleration/deceleration, set a time constant for a linear portion.

5271	Time constant for acceleration/deceleration in rigid tapping extraction (first gear)
5272	Time constant for acceleration/deceleration in rigid tapping extraction (second gear)
5273	Time constant for acceleration/deceleration in rigid tapping extraction (third gear)
5274	Time constant for acceleration/deceleration in rigid tapping extraction (fourth gear)

[Input type] Parameter input
[Data type] Word spindle
[Unit of data] msec
[Valid data range] 0 to 4000

Each of these parameters is used to set a linear acceleration/ deceleration time constant for the spindle of each gear and tapping axis in extraction operation during rigid tapping.
For bell-shaped acceleration/deceleration, set a time constant for a linear portion.

NOTE

These parameters are enabled when the parameter TDR (bit 2 of parameter No. 5201) is set to 1.

5280	Position control loop gain for the spindle and tapping axis in rigid tapping (common to gears)
5281	Position control loop gain for the spindle and tapping axis in rigid tapping (first gear)
5282	Position control loop gain for the spindle and tapping axis in rigid tapping (second gear)
5283	Position control loop gain for the spindle and tapping axis in rigid tapping (third gear)

5284	Position control loop gain for the spindle and tapping axis in rigid tapping (fourth gear)

[Input type] Parameter input
[Data type] Word spindle
[Unit of data] 0.01/sec
[Valid data range] 1 to 9999

Each of these parameters is used to set a position control loop gain for the spindle and tapping axis in rigid tapping. These parameters significantly affect the precision of threading. Optimize these parameters as well as the loop gain multipliers by conducting a cutting test.

NOTE
To use a varied loop gain on a gear-by-gear basis, set parameter No. 5280 to 0, and set a loop gain for each gear in parameters Nos. 5281 to 5284. The specification of a loop gain on a gear-by-gear basis is disabled if parameter No. 5280 is set to a value other than 0. In such a case, the value set in parameter No. 5280 is used as a loop gain that is common to all the gears.

5291	Loop gain multiplier for the spindle in rigid tapping (first gear)
5292	Loop gain multiplier for the spindle in rigid tapping (second gear)
5293	Loop gain multiplier for the spindle in rigid tapping (third gear)
5294	Loop gain multiplier for the spindle in rigid tapping (fourth gear)

[Input type] Parameter input
[Data type] Word spindle
[Valid data range] 1 to 32767

Each of these parameters is used to set a loop gain multiplier for the spindle in rigid tapping each gear.
These parameters significantly affect the precision of threading. Optimize these parameters as well as the loop gains by conducting a cutting test.
Loop gain multiplier GC is obtained from the following equation:

$$GC = \frac{2048000 \times 360 \times PC \times E}{PLS \times SP \times L}$$

PLS Number of pulses output from the position coder (pulses/rev)
SP Number of gear teeth on the spindle side
PC Number of gear teeth on the position coder side
E Specified voltage (V) for turning the spindle motor at 1000 min^{-1}
L Angular displacement of the spindle (degrees) per spindle motor rotation

[Example] For the spindle motor and gear ratio given below, GC is calculated as follows:

$$GC = \frac{2048000 \times 360 \times 1 \times 2.2}{4096 \times 1 \times 360} = 1100$$

PLS = 4096 pulse/rev
SP = 1
PC = 1
E = 2.2 V
L = 360 deg

(Note) On the assumption that the spindle motor used turns at 4500 min^{-1} at 10 V, 2.2 V is required to turn the spindle motor at 1000 min^{-1}.

> **NOTE**
> These parameters are used for analog spindles.

5300	Tapping axis in-position width in rigid tapping (first spindle)

5302	Tapping axis in-position width in rigid tapping (second spindle)

5304	Tapping axis in-position width in rigid tapping (third spindle)

5306	Tapping axis in-position width in rigid tapping (fourth spindle)

[Input type] Parameter input
[Data type] Word axis
[Unit of data] Detection unit
[Valid data range] 0 to 32767

This parameter sets a tapping axis in-position width when rigid tapping is performed using the each spindle.
If the setting value is negative value, in-position check is not completed.

5301	Spindle in-position width in rigid tapping

[Input type] Parameter input
[Data type] Word spindle
[Unit of data] Detection unit
[Valid data range] 0 to 32767

This parameter are used to set spindle in-position width in rigid tapping.
If the setting value is negative value, in-position check is not completed.

> **NOTE**
> If an excessively large value is specified, the threading precision will deteriorate.

5310	Positional deviation limit imposed during tapping axis movement in rigid tapping (first spindle)

5350	Positional deviation limit imposed during tapping axis movement in rigid tapping (second spindle)

5354	Positional deviation limit imposed during tapping axis movement in rigid tapping (third spindle)

5358	Positional deviation limit imposed during tapping axis movement in rigid tapping (fourth spindle)

[Input type] Parameter input
[Data type] 2-word axis
[Unit of data] Detection unit
[Valid data range] 0 to 99999999

This parameter sets a positional deviation limit imposed during tapping axis movement in rigid tapping using the each spindle.

5311	Limit value of spindle positioning deviation during movement in rigid tapping

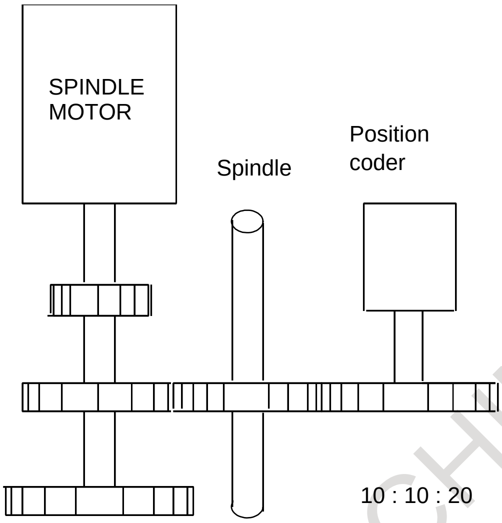
[Input type] Parameter input
[Data type] 2-word spindle
[Unit of data] Detection unit
[Valid data range] 0 to 99999999

This parameter sets the limit value of a spindle positioning deviation during movement in rigid tapping.
Find a value to be set from the following expression:

$$Setting\ value = \frac{S \times PLS \times 100 \times SP \times C}{60 \times G \times PC}$$

S Maximum spindle speed in rigid tapping (min^{-1})
(Setting value of parameters Nos. 5241 and to 5244)
PLS Number of pulses output from the position coder (pulses/rev)
SP Number of gear teeth on the spindle side
PC Number of gear teeth on the position coder side
G Loop gain in the rigid tapping ($0.01sec^{-1}$)
(Setting value of parameters Nos. 5281 and to 5284)
C Coefficient 1.5

[Calculation example]



S = 3600
PLS = 4096
SP = 10
PC = 20
G = 3000
C = 1.5

$$Setting\ value = \frac{3600 \times 4096 \times 100 \times 10 \times 1.5}{60 \times 3000 \times 20} = 6144$$

5312	**Positional deviation limit imposed while the tapping axis is stopped in rigid tapping (first spindle)**
5352	**Positional deviation limit imposed while the tapping axis is stopped in rigid tapping (second spindle)**
5356	**Positional deviation limit imposed while the tapping axis is stopped in rigid tapping (third spindle)**
5360	**Positional deviation limit imposed while the tapping axis is stopped in rigid tapping (fourth spindle)**

[Input type] Parameter input
[Data type] Word axis
[Unit of data] Detection unit
[Valid data range] 0 to 32767

This parameter sets a positional deviation limit imposed while the tapping axis is stopped in rigid tapping using the each spindle.

5313	**Positional deviation limit imposed while the spindle is stopped in rigid tapping**

[Input type] Parameter input
[Data type] 2-word spindle
[Unit of data] Detection unit
[Valid data range] 0 to 99999999

This parameter is used to set a positional deviation limit imposed while the spindle is stopped in rigid tapping.

5321	Spindle backlash in rigid tapping (first-stage gear)
5322	Spindle backlash in rigid tapping (second-stage gear)
5323	Spindle backlash in rigid tapping (third-stage gear)
5324	Spindle backlash in rigid tapping (fourth-stage gear)

[Input type] Parameter input
[Data type] Word spindle
[Unit of data] Detection unit ([detection unit]=[spindle rotation angle per one rotation of position coder]/4096 for αi position coder)
[Valid data range] -9999 to 9999
Each of these parameters is used to set a spindle backlash in rigid tapping.

5365	Bell-shaped acceleration/deceleration time constant in rigid tapping (first-stage gear)
5366	Bell-shaped acceleration/deceleration time constant in rigid tapping (second-stage gear)
5367	Bell-shaped acceleration/deceleration time constant in rigid tapping (third-stage gear)
5368	Bell-shaped acceleration/deceleration time constant in rigid tapping (fourth-stage gear)

[Input type] Parameter input
[Data type] Word spindle
[Unit of data] msec
[Valid data range] 0 to 512
Each of these parameters is used to set a time constant for a curved portion when bell-shaped acceleration/deceleration is selected in rigid tapping. When 0 is set in this parameter, linear acceleration/ deceleration is performed.

NOTE
This parameter is enabled when the bit 5 (RBL) of parameter No. 5203 is set to 1.

	#7	#6	#5	#4	#3	#2	#1	#0
24203								FHR

NOTE
When the parameter is set, the power must be turned off before operation is continued.

[Input type] Parameter input
[Data type] Bit

#0 FHR Position data transmission by FSSB is:
0: Disabled.
1: Enabled.

NOTE
1 In addition, it is necessary to set parameter No.24204.
2 When FSSB high-speed rigid tapping is used, set 1 to this parameter.

24204	The index number of the spindle axis that synchronizes to each servo axis

> **NOTE**
> When the parameter is set, the power must be turned off before operation is continued.

[Input type] Parameter input
[Data type] Byte axis
[Valid data range] 0 to the maximum number of spindles

In FSSB high-speed rigid tapping, set the index number of the spindle axis that synchronizes to servo axis.

> **NOTE**
> 1 When the bit 0 (FHR) of parameter No.24203 is 1, this parameter is enabled.
> 2 Eight or less index numbers of the spindle axis can be set in the system. If nine or more index numbers of the spindle axis are set, the alarm PW0037, "SV/SP COMBINATION ERROR" is issued.

24208	The index number of the spindle axis that synchronizes to each servo axis (2nd set)

[Input type] Parameter input
[Data type] Byte axis
[Valid data range] 0 to the maximum number of spindles

This parameter sets the index number of the spindle synchronizing with the servo axis used in FSSB high-speed rigid tapping. Whether to use parameter No.24204 or this parameter can be changed by Spindle/Servo axis combination change signal SPSVS<G0518.6>.

> **NOTE**
> 1 This parameter is effective when parameter FHR (No.24203#0)=1.
> 2 Eight or less index numbers of the spindle axis can be set in the system. If nine or more are set, the alarm (DS0092) "SV/SP COMBINATION ERROR" is issued.

Alarm and message

Number	Message	Description
PS0200	ILLEGAL S CODE COMMAND	(1) In the rigid tap, an S value was out of range or was not specified. The parameters Nos. 5241 to 5243 setting is an S value which can be specified for the rigid tapping. Correct the parameters or modify the program. (2) Rigid tapping is commanded during constant surface speed control. Command rigid tapping after canceling constant surface speed control.
PS0201	FEEDRATE NOT FOUND IN RIGID TAP	The command F code for a cutting feedrate is a zero. If the value of F command is much smaller than that of the S command, when a rigid tapping command is specified, this alarm is generated. This is because cutting is not possible by the lead specified by the program.
PS0202	POSITION LSI OVERFLOW	In the rigid tap, spindle distribution value is too large. Decrease spindle speed.

Number	Message	Description
PS0203	PROGRAM MISS AT RIGID TAPPING	(1) In the rigid tap, position for a rigid M code (M29) or an S command is incorrect. Modify the program. (2) FSSB high-speed rigid tapping cannot be used on the rigid tapping with one servo motor and multiple spindle motors by spindle command synchronous control. (3) In FSSB high-speed rigid tapping, parameter setting is wrong (bits 1 and 2 of parameter No.2429, and bits 1 and 2 of parameter No.4549). (4) In FSSB high-speed rigid tapping, parameter No.24204 is wrong. Set the same index number of the spindle synchronizing to three axes of 3-dimensional rigid tapping.
PS0204	ILLEGAL AXIS OPERATION	In the rigid tap, an axis movement is specified between the rigid M code (M29) block and G84 (or G74) block. Modify the program.
PS0205	RIGID MODE DI SIGNAL OFF	(1) Although a rigid M code (M29) is specified in rigid tapping, the rigid mode DI signal (Gn061.0) is not ON during execution of the G84 (or G74) block. Check the PMC ladder diagram to find the reason why the DI signal is not turned on. (2) In rigid tapping, no spindle has selected commands in the path of interest. Alternatively, spindles in two or more paths have selected commands in the same path. Check the spindle command select signal. (3) A spindle specified for rigid tapping is already being used in another path. (4) In a machine provided with the multi-spindle control, no spindle has been selected for attempted rigid tapping. (5) Rigid tapping command is issued to a spindle control axis with servo motor in a path other than the command issuing path.
PS0206	CAN NOT CHANGE PLANE (RIGID TAP)	Plane changeover was instructed in the rigid mode. Modify the program.
PS0207	RIGID DATA MISMATCH	The specified distance was too short or too long in rigid tapping.
PS0564	ILLEGAL COMMAND OF SMART RTAP	The command for Smart rigid tapping is illegal. The reason of this alarm is in the followings. - The moving distance of feed axis is larger than 4096 times of screw pitch. - The used spindle software doesn't support Smart rigid tapping.
PS5560	ILLEGAL DEPTH OF CUT	On the peck rigid tapping, the depth of cut (Q) is smaller than the cutting start distance (d).
SV0048	SMART RIGID TAPPING STOP	The excitation of servo motors is turned off because smart rigid tapping is stopped. This alarm is accompanied by spindle alarm.
SV0410	EXCESS ERROR (STOP)	The amount of positional deviation during stopping exceeded the parameter No. 1829 setting value.
SV0411	EXCESS ERROR (MOVING)	The amount of positional deviation during traveling became excessive than the parameter setting value.
SV0417	ILL DGTL SERVO PARAMETER	A digital serve parameter setting is incorrect.
SP0740	RIGID TAP ALARM : EXCESS ERROR	The positional deviation of the stopped spindle has exceeded the set value of parameter No.5313 during rigid tapping.

Number	Message	Description
SP0741	RIGID TAP ALARM : EXCESS ERROR	(1) The positional deviation of the moving spindle has exceeded the set value of parameter No.5311 during rigid tapping. (2) Rigid tapping synchronization error has exceeded the set value of parameter No.5214.
SP0742	RIGID TAP ALARM : LSI OVERFLOW	An LSI overflow has occurred for the spindle side during rigid tapping.
SP0752	SPINDLE MODE CHANGE ERROR	The spindle is in a mode (such as Cs contour control or spindle synchronous control) other than the spindle control mode. When the "rigid tapping with spindle of another path" function is used, the spindle to be used for rigid tapping must be switched to the spindle control mode before the start of rigid tapping.
PW0037	SV/SP COMBINATION ERROR	(1) The servo axis might be a setting of the dummy axis. Check to see the parameters No.1023, bit 0 of No.2009, and bit 4 of No.11802. (2) The index number of spindle axis that synchronizes servo axis is wrong. Check to see the parameters bit 0 of No.3716, No.3717, and No.24204. (3) FSSB high-speed rigid tapping cannot be used with the analog spindle or the spindle control with servo motor.
DS0092	SV/SP COMBINATION ERROR	1. The servo axis might be a setting of the dummy axis. Check to see the parameters No.1023, bit 0 of No.2009, and bit 4 of No.11802. 2. The index number of spindle axis that synchronizes servo axis is wrong.. Check parameters (bit 0 of No.3716, No.3717, No.24208). 3. One of the following functions is applied. Turn it off. - Rigid tapping - Servo/Spindle synchronous control - Electronic gear box

10.13.19 Notes

- Notes on spindles

Note

NOTE

1 A spindle pitch error is not compensated for in rigid tapping mode.

2 The limits to the number of pulses assigned to each spindle are as follows (displayed with diagnosis data No. 0451):
- Serial spindle: 32767 pulses every 8 msec
- Analog spindle: 4095 pulses every 8 msec

These values vary with the position coder gear ratio setting and rigid tapping specification. If a value greater than the maximum allowable number is specified, an alarm PS0202 is issued.

3 If rigid tapping is commanded during constant surface speed control, alarm PS0200, "ILLEGAL S CODE COMMAND" is issued. Command rigid tapping after canceling constant surface speed control.

- Other cautions

⚠ CAUTION

1 When the spindle orientation function is to be used at the same time
The spindle orientation function positions the spindle by using sensors and the PMC, without being directly controlled by the CNC.
The CNC has no direct control over this processing, instead following the specifications of the spindle orientation function being used.

2 When the spindle positioning function is to be used at the same time
When the spindle positioning function is to be used together with rigid tapping, rigid tapping mode must not be specified in spindle indexing mode, and spindle indexing mode must not be specified in rigid tapping mode. (Spindle positioning and rigid tapping cannot be performed simultaneously for a single spindle.)
This is not applicable when multi-spindle control is used together and a spindle used for spindle position indexing is different from a spindle used for rigid tapping.

⚠ **CAUTION**

3 When the Cs contouring control function is to be used at the same time
When the Cs contouring control function for the serial spindle is used together with the rigid tapping function, the same motor is used for spindle rotation control, Cs contouring control, and rigid tapping modes. The following points must be noted:

(1) Whether to enter Cs contouring control mode or spindle rotation control mode is selected by the CON (Cs contouring control switch signal) signal; however, the system can enter rigid tapping mode regardless of the state of the CON signal. When the rigid tapping mode is canceled the system enters spindle rotation control mode or Cs contouring control mode according to the state of the CON signal.

(2) Since the system can change to rigid tapping mode directly from the Cs contouring control mode, use of the Cs contouring control function enables the tapping tool to be positioned before rigid tapping begins. Accurate positioning is not guaranteed. As a matter of course, if the rigid tapping cycle executes gear change or output range changing, it becomes invalid when losing the position of the spindle..

(3) Although the system can change to rigid tapping mode directly from Cs contouring control mode, positions designated in Cs contouring control mode are not preserved if rigid tapping mode is canceled by G80 etc. When the system is changed to rigid tapping mode directly from Cs contouring control mode and wanting to set Cs contouring control mode again, then returns to the Cs contouring control mode, G00 or G28 must be issued to return to the reference position.

(4) In systems with the serial spindle Cs contouring control function, the spindle motor is in a state called servo mode when it is operating in rigid tapping mode. In servo mode, it can accept jog feed and manual handle feed. To prevent this, inhibit jog feed and manual handle feed of the Cs contouring axis in the PMC logic during rigid tapping.

(5) The servo-off signal for the Cs contour control axis should be masked on the PMC side during rigid tapping. It should be masked on the PMC side as required.

(6) When multi-spindle control is used together and a spindle used for Cs contour control is different from a spindle used for rigid tapping, rigid tapping can be specified with one spindle while the other spindle is placed in the Cs contour control mode.

(7) The Cs contour control axis cannot be a drilling axis. If it is specified as a drilling axis, alarm PS0203 is issued.

4 Program restart
The program cannot be restarted in a block placed in the rigid tapping mode. (The program cannot be restarted in blocks between an M29 command and G80 command.)

5 Specification of multiple M codes in one block
Specify an M code for specifying the rigid tapping mode as an independent M code. (Multiple M codes must not be specified in one block.)

6 Positioning by optimum accelerations
Positioning by optimum accelerations is disabled during rigid tapping.

- Position control loop gain switching and serial spindle parameters

In rigid tapping, the loop gain of the drilling axis is switched so that the loop gains for position control of the drilling axis and spindle match each other.
This switching processing is specified by parameters Nos. 5281 to 5284.
The spindle loop gain depends on the setting of serial spindle parameters and the input gear signals (CTH2, CTH1).
So, in order to perform rigid tapping with a serial spindle, the position control loop gain of the spindle must be set in the parameters for the serial spindle used for rigid tapping.
When multi-spindle control is used, a spindle other than the first spindle can be used for rigid tapping. So, set the parameters below for the serial spindle used for rigid tapping.
The parameters indicated below are the major serial spindle parameters required for the setting and adjustment needed to use a serial spindle.
For details of the serial spindle parameters, refer to the "FANUC AC SPINDLE MOTOR α*i*-B / β*i*-B series DESCRIPTIONS (B-65452EN)" or "FANUC AC SPINDLE MOTOR α*i* series PARAMETER MANUAL (B-65280EN)".

4044	Proportional gain of the velocity loop in servo mode (gear 1, gear 2)

4045	Proportional gain of the velocity loop in servo mode (gear 3, gear 4)

[Unit of data]
[Valid data range] 0 to 32767
Set a proportional gain for the velocity loop in a servo mode (such as rigid tapping mode).

4052	Integral gain of the velocity loop in the servo mode (gear 1, gear 2)

4053	Integral gain of the velocity loop in the servo mode(gear 3, gear 4)

[Unit of data]
[Valid data range] 0 to 32767
Set an integral gain of the velocity loop in a servo mode (such as rigid tapping mode).

4065	Position gain in the servo mode (HIGH)

4066	Position gain in the servo mode (MEDIUM HIGH)

4067	Position gain in the servo mode (MEDIUM LOW)

4068	Position gain in the servo mode (LOW)

[Unit of data] 0.01sec^{-1}
[Valid data range] 0 to 65535
Set a servo loop gain in a servo mode (such as rigid tapping mode).

⚠ **CAUTION**
Set a loop gain for spindle position control in rigid tapping using a serial spindle. In these parameters, basically, set the same values as those set in parameters Nos. 5281 to 5284 (loop gains for position control of the tapping axis).
Which serial spindle parameter (i.e., loop gain) is actually used to operate the spindle depends on the serial spindle clutch/gear selection signals CTH1 and CTH2. Accordingly, which parameter is to be used must be determined by considering the gear switching and PMC software.

The table below indicates the relationship between the spindle gear selection signals and selected gear numbers.

CTH1	CTH2	Gear selected	Parameter No. to be used		
0	0	HIGH	4065	4044	4052
0	1	MIDEUM HIGH	4066		
1	0	MIDEUM LOW	4067	4045	4053
1	1	LOW	4068

10.14 SPINDLE SYNCHRONOUS CONTROL

Overview

This function can exercise synchronous control on spindles. This function can also control the rotation phase of spindles, so that not only a round rod but also a non-standard workpiece can be grasped by either of two spindles.
A combination of a master spindle and slave spindle in spindle synchronous control can be selected arbitrarily from spindles.

This function can be used with serial spindles.

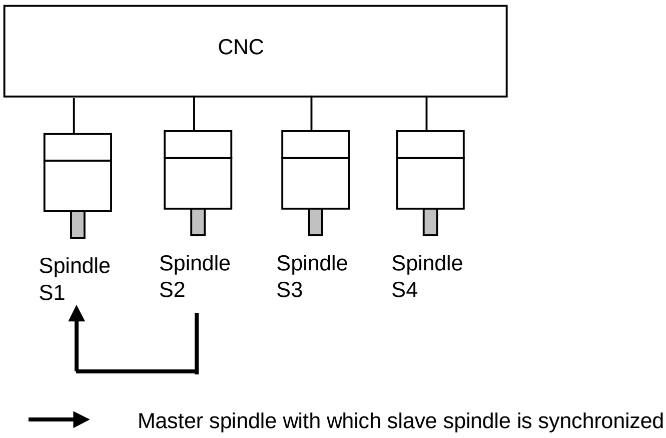
Explanation

- Synchronous-spindle configuration (when the one path system is used)

In spindle synchronous control, the spindle to which an S command is issued is called the master spindle. A spindle which ignores any S command that is issued for it, instead rotating synchronously with the master spindle, is called the slave spindle.

When the bit 4 (SSS) of parameter No.3704 is set to 0
The configuration of synchronized spindles is as follows:

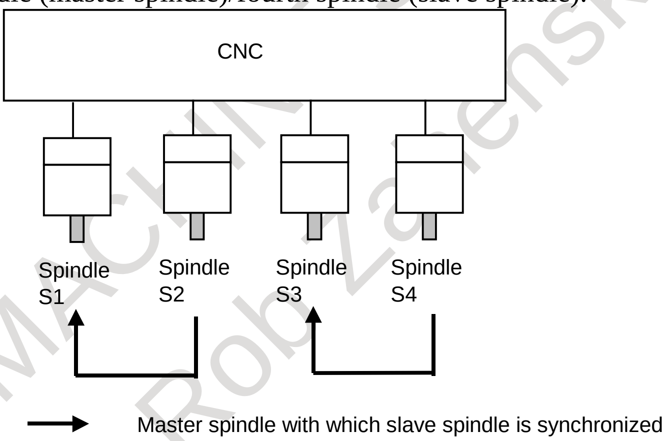
Master spindle	Slave spindle
First spindle	Second spindle



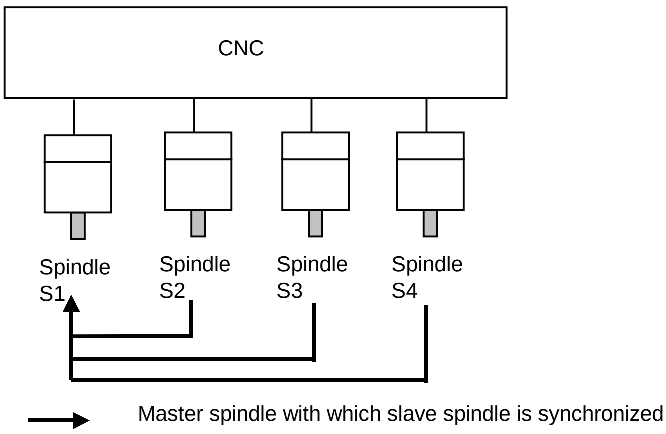
When the bit 4 (SSS) of parameter No. 3704 is se to 1
Which slave spindle is synchronized with which master spindle is set using parameter No. 4831.

Master spindle	Slave spindle
Arbitrary spindle	Arbitrary spindle

- When four spindles are involved, two combinations of spindles can be formed for spindle synchronization.
  Example)
  Two combinations are possible: first spindle (master spindle)/second spindle (slave spindle) and third spindle (master spindle)/fourth spindle (slave spindle).



- Multiple slave spindles can be synchronized with one master spindle.
  Example)
  A combination of first spindle (master spindle)/second, third, and fourth spindles (slave spindles) is possible.

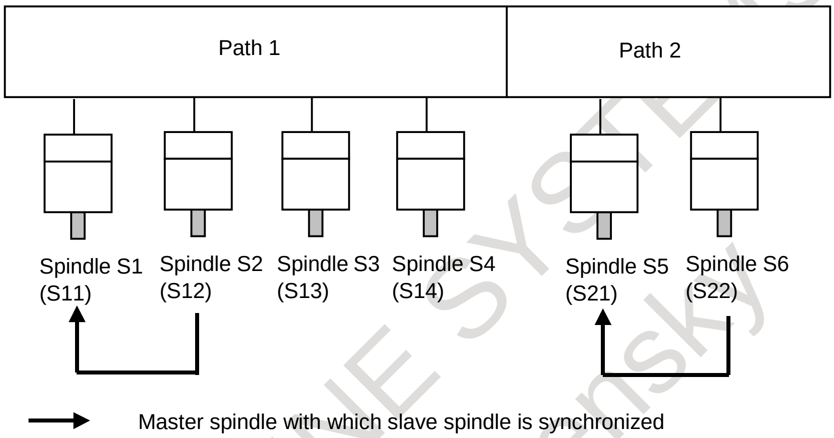


NOTE
1. A combination that uses a slave spindle as a master spindle is not allowed.
2. When multiple slave spindles are configured for synchronous control, a restriction is imposed on phase matching operation. See the description of the spindle phase synchronization control signal.

- Configuration of synchronized spindles (in a multi-path system)

- When the bit 4 (SSS) of parameter No.3704 is set to 0
  The configuration of synchronized spindles is as follows:

Master spindle	Slave spindle
First spindle of each path	Second spindle of each path



- When the bit 4 (SSS) of parameter No.3704 is set to 1
  Spindle synchronization can be performed by combining arbitrary spindles.
  Which slave spindle is synchronized with which master spindle is set using parameter No. 4831/4832.

Master spindle	Slave spindle
Arbitrary spindle of each path	Arbitrary spindle of each path

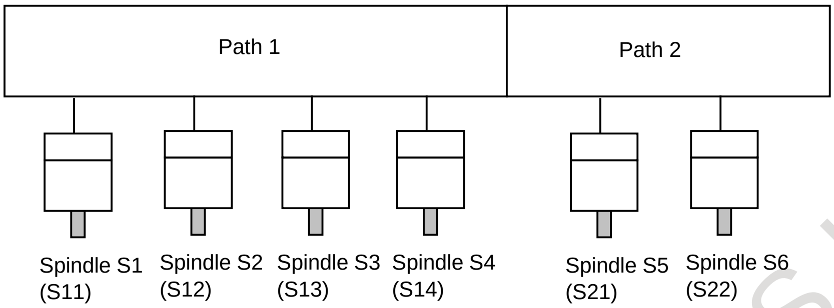
Set a master spindle for each slave in parameter No.4831.
As a master spindle, set a spindle number in the same path as for a slave spindle.

By setting a logic spindle number common to the system in parameter No.4832, such spindle synchronization that an arbitrary spindle belonging to a different path is used as a master spindle can be exercised.
The spindle number of a master spindle to be set is a logic spindle number common to the system. In this case, set 0 in parameter No.4831 for all.
For the path to which a slave spindle belongs and the path to which a master spindle belongs, bit 4 (SSS) of parameter No.3704 needs to be set to 1 (to enable spindle synchronization using arbitrary axes).

Example of parameter setting)
Spindle configuration of each path
Six spindles (four spindles of path 1 + two spindles of path 2)

Logic spindle number common to system	Path number + intra-path spindle number
First spindle (S1)	First spindle of path 1 (S11)
Second spindle (S2)	Second spindle of path 1 (S12)
Third spindle (S3)	Third spindle of path 1 (S13)
Fourth spindle (S4)	Fourth spindle of path 1 (S14)

Logic spindle number common to system	Path number + intra-path spindle number
Fifth spindle (S5)	First spindle of path 2 (S21)
Sixth spindle (S6)	Second spindle of path 2 (S22)

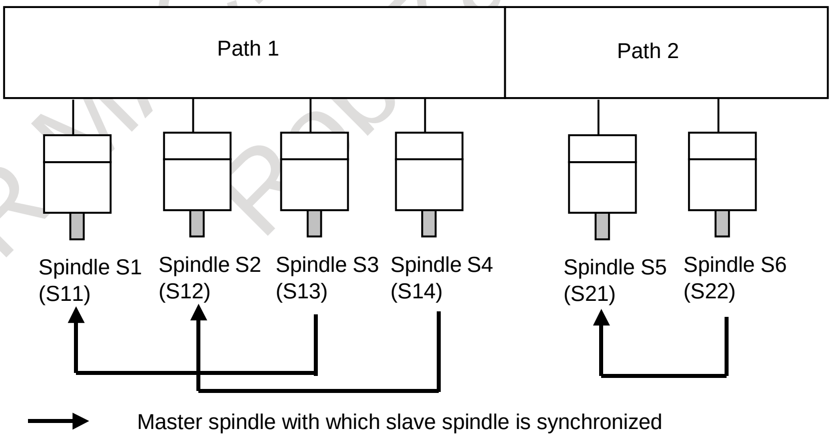


Example 1:

Combining spindles of the same path for spindle synchronization

Parameter setting
Bit 4 (SSS) of parameter No.3704 (PATH1)=1, (PATH2)=1
Parameter No.4831(S1) =0, (S2) =0,(S3) =1,(S4) =2,(S5) =0,(S6) =1
Parameter No.4832(ALL) =0
or
Parameter No.4831(ALL) =0
Parameter No.4832(S1) =0, (S2) =0,(S3) =1,(S4) =2,(S5) =0,(S6) =5

Master spindle	Slave spindle
First spindle of path 1 (S11)	Third spindle of path 1 (S13)
Second spindle of path 1 (S12)	Fourth spindle of path 1 (S14)
First spindle of path 2 (S21)	Second spindle of path 2 (S22)

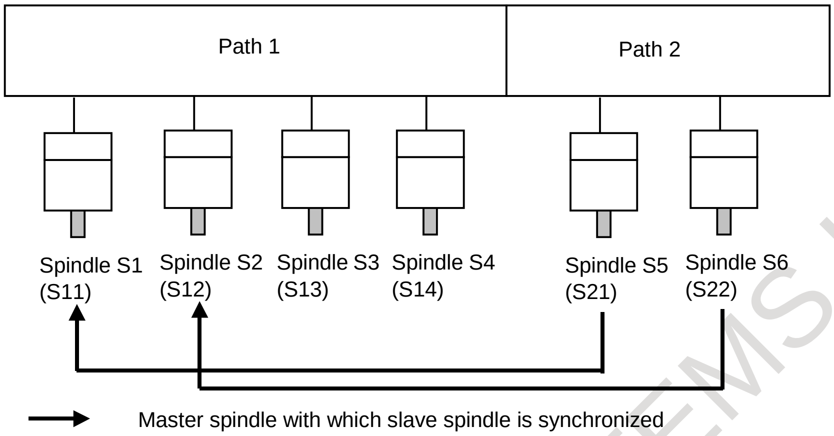


Example 2:

Combining spindles of different paths for spindle synchronization

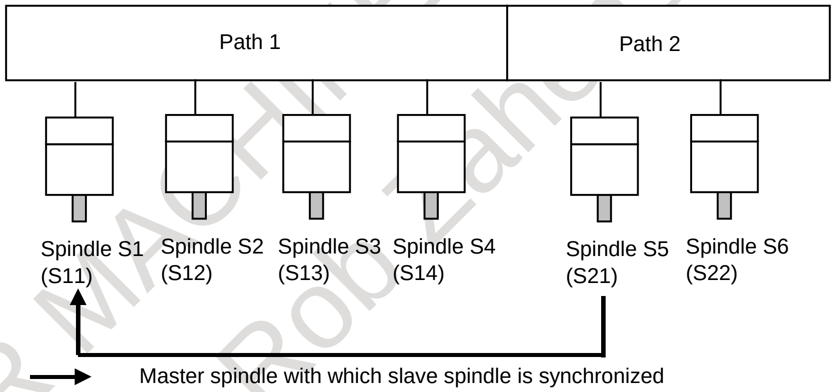
Parameter setting
Bit 4 (SSS) of parameter No.3704 (PATH1)=1, (PATH2)=1
Parameter No.4831(ALL) =0
Parameter No.4832(S1) =0, (S2) =0,(S3) =0,(S4) =0,(S5) =1,(S6) =2

Master spindle	Slave spindle
First spindle of path 1 (S11)	First spindle of path 2 (S21)
Second spindle of path 1 (S12)	Second spindle of path 2 (S22)



- When the bit 5 (SCB) of parameter No.4800 is set to 1
  The configuration of synchronized spindles is as follows (regardless of the setting of bit 4 (SSS) of parameter No.3704):

Master spindle	Slave spindle
First spindle of path 1	First spindle of path 2



As control signals, the 16TT system compatible signal interface becomes usable.

- Speed synchronization

- When the spindle synchronous control signal is set to “1”, the spindle synchronous control mode is set.
  When spindle synchronous control is specified, each spindle is accelerated or decelerated to a specified speed then enters the synchronous control state.
- The spindle synchronous speed control completion signal is output when the two spindles have reached the speed matching a specified spindle synchronous speed and the speed difference between the two spindles is within the value set in parameter No.4033.

- Phase matching

- Spindle phase synchronization is executed by setting the spindle phase synchronization control signal to 1 in the spindle synchronous control mode (after the output of the spindle synchronous speed control completion signal).
  The synchronous state between the two axes is not maintained during spindle phase synchronization operation (until the spindle phase synchronization control completion signal is set to 1).

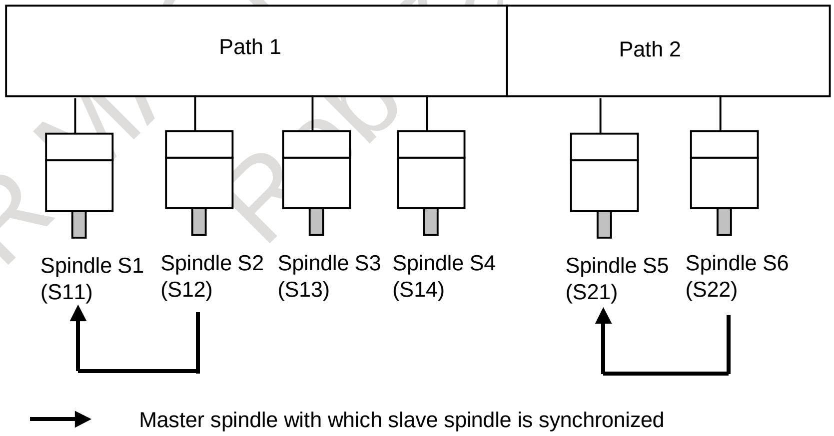
- The spindle phase synchronization completion signal is output when the error difference between the two spindles lies within the allowable number of pulses set in the NC parameter No. 4810.
  If spindle phase synchronization is specified after spindle phase synchronization completion, another spindle phase synchronization operation is performed.
  When the two spindles hold a workpiece, do not specify spindle phase synchronization.

- Speed specification

- In the spindle synchronous control mode, the specification of a speed for the master spindle is valid.
- In the spindle synchronous control mode, a speed for the master spindle can be specified in the same way as for an ordinary S command.
  Moreover, signals such as the PMC-based spindle output control signals (SIND, SSIN, SSGN, and R01I to R12I), *SSTP, and SOR are valid as usual.
  If a speed is specified using a PMC-based spindle output control command, however, the parameters Nos. 3741, 3742, 3743, and 3744 for specifying the maximum speeds of the individual spindle gears must be correctly set beforehand.
  When 0 is set in the parameter corresponding to a selected gear, the spindle does not make a synchronous rotation.
- An S command specified for a master spindle and a speed specified for PMC-based spindle output control before the spindle synchronous control mode is set are valid even in the spindle synchronous control mode.
  A speed command for a master spindle during spindle synchronous control is also valid as a command for the master spindle after spindle synchronous control is canceled.

- Speed ratio control

- Spindle synchronous control can be exercised to set a speed ratio of master spindle: slave spindle to 1:n.
  Speed ratio control is exercised in spindle synchronization by setting the spindle synchronous speed ratio control signal SBRT <Gn038.1> to “1” in the spindle synchronous control mode. At this time, the speed ratio of master spindle: slave spindle is 1:n (n: value set in the parameter No.7635).



Mater spindle : Speed ratio setting for the slave spindle 1:2
When the speed S100 is specified for master spindle S1
Spindle S1 : Spindle speed S100(1/min)
Spindle S2 : Placed in synchronous control state with spindle speed S200 (1/min).

If the speed of each slave spindle specified by multiplying the speed specified for the master spindle by a speed ratio exceeds the value set in the parameter No.7636, the speed of each slave spindle is clamped to a set maximum allowable speed. At the same time, the speed of the master spindle is clamped to the speed that maintains the speed ratio.
When the speeds of multiple slave spindles are clamped, all spindles are clamped to the speeds that can maintain the speed ratios for synchronization control.

When the speed of a slave spindle is clamped, the spindle synchronous speed ratio control clamp signal RSMAX <Fn065.2> is set to “1”.

- Supplement

- To monitor an error mutually between two spindles in the spindle synchronous control mode, the spindle phase error monitor signal SYCAL <Fn044.4> (SYCAL1 to SYCAL4 <Fn043.0> to <Fn043.3>) is available. A synchronization error between two spindles is monitored at all times. When a synchronization error exceeding the value (absolute number of error pulses) set in parameter No.4811 is detected, this signal is set to “1”. When the synchronization error does not exceed the value set in parameter No.4811, the signal is set to “0”.
- Even when two spindles hold a workpiece in the synchronous control state, constant surface speed control can be exercised. Even if the speed of a spindle changes, however, the synchronous speed changes within the parameter-set range (acceleration/deceleration time constant in spindle synchronous control).
- In spindle synchronous control, the spindle speed offset value (parameter No.3731) is invalid.

For details of synchronous-spindle connection, see the description of serial spindles.

Limitation

- When spindles are placed in a mode other than a spindle rotation mode such as the Cs contouring control mode, rigid tapping, and spindle command synchronous, the spindle synchronous control mode cannot be used. In the spindle rotation mode, switch the mode of the master and slave spindles to the spindle synchronous control mode.
- For spindles placed in the spindle synchronous control mode, commands for Cs contouring control, rigid tapping, spindle command synchronous, and so forth cannot be specified.
- The maximum speed in spindle synchronous control depends on the maximum speed (parameter No. 4020) of the spindle motor of the master spindle.

  Example)

  Maximum speed of the spindle motor of a master spindle: 6000 min^{-1}

  Maximum speed of the spindle motor of a slave spindle: 4500 min^{-1}

  In the example above, 6000 min^{-1} is specified as the maximum speed of the master spindle for 12bit = 4095. However, when 6000 min^{-1} is specified in spindle synchronous control, the excessive-speed alarm (spindle unit side alarm AL-07) is issued with the slave spindle.

  So, do not specify a speed exceeding 4500 min^{-1} in the example above.

Diagnosis data

0418	**Position deviation of each spindle**

When spindles are involved in a position loop, the position deviation of each spindle is indicated.
The unit of a detector used in each mode is used.

0425	**Synchronization error of each spindle**

The absolute value of the synchronization error of each spindle in spindle synchronization is indicated.
A synchronization error is indicated with a slave spindle.

Spindle tuning screen (spindle synchronous control)

In the spindle synchronous control mode, the spindle tuning screen displays the information below.
"Spindle position deviation" indicates the position deviation of the spindle currently displayed.
"Synchronous deviation " indicates the absolute value of a synchronization error in spindle synchronization. The value of a synchronization error is displayed on the spindle tuning screen for the slave spindle.
When bit 3 (SVP) of parameter No.3799 is set to 1, "synchronous deviation" indicates the peak hold value of a synchronization error.

For details, refer to Spindle tuning screen of MAINTENANCE MANUAL (B-64695EN).

Motor speed Spindle speed Spindle position deviation S1 Spindle position deviation S2 Synchronous deviation

Signal

Spindle synchronous control signal SPSYC<Gn038.2>

[Classification] Input signal

[Function] This signal specifies switching to the spindle synchronous control mode for the first/second spindles.

[Operation] When this signal is set to “1”, the spindle synchronous control mode for the first/second spindles is set.
When this signal is set to “0”, the spindle synchronous control mode for the first/second spindles is canceled.

This signal is valid only when bit 4 (SSS) of parameter No.3704 is set to 0.
When bit 5 (SCB) of parameter No.4800 is set to 1, an address of n = 0 is valid.

Spindle synchronous control signal of each spindle SPSYC1 to SPSYC4<Gn288.0 - Gn288.3>

[Classification] Input signal

[Function] These signals specify the switching of each spindle to the spindle synchronous control mode.

[Operation] When each of these signals is set to “1”, the spindle synchronous control mode with a spindle set as a slave spindle is set.
When each of these signals is set to “0”, the spindle synchronous control mode with a spindle set as a slave spindle is canceled.
When SPSYCs is set to “1”, spindle synchronization with a spindle set as a slave spindle is performed.

These signals are valid only when bit 4 (SSS) of parameter No.3704 is set to 1 and bit 5 (SCB) of parameter No.4800 is set to 0.
Which spindle is synchronized with which spindle is set using parameter No.4831 or 4832.

> **NOTE**
> For the correspondence between the signal of each spindle and actual signal address, see the description of "Signal address".

Spindle phase synchronization control signal SPPHS<Gn038.3>

[Classification] Input signal

[Function] This signal specifies the spindle phase synchronization control mode (phase matching) for the first/second spindles.

[Operation] When this signal makes a transition from “0” to “1”, spindle phase synchronization control for the first/second spindles is exercised.
This signal is valid when the spindle synchronous control signal SPSYC is set to “1”.
Specify this signal after the spindle synchronous speed control completion signal FSPSY is set to “1”.
A spindle phase synchronization control operation is started on the rising edge of this signal.

So, phase matching once performed is not lost when this signal is set to “0”.
However, when this signal is set to “1” from “0” again, a phase matching operation is performed.

This signal is valid only when bit 4 (SSS) of parameter No.3704 is set to 0.
Set a phase shift amount in parameter No.4034.
When bit 5 (SCB) of parameter No.4800 is set to 1, an address of n = 0 is valid.

> **NOTE**
> Before specifying this signal, ensure that the spindle synchronous speed control completion signal FSPSY is set to “1”. When the spindle synchronous speed control completion signal FSPSY is set to “0”, phase matching operation is not performed.

Spindle phase synchronization control signal of each spindle SPPHS1 to SPPHS4<Gn289.0 to Gn289.3>

[Classification] Input signal

[Function] These signals specify the spindle phase synchronization control mode (phase matching) for each spindle.

[Operation] When each of these signals is set to “1”, spindle phase matching is performed in the spindle synchronous control mode with a spindle set as a slave spindle.
These signals are valid when the spindle synchronous control signal SPSYCs for each spindle is set to “1”.
Specify each of these signals after the spindle synchronous speed control completion signal FSPSYs for each spindle is set to “1”.
A spindle phase synchronization control operation is started on the rising edge of each of these signals.
So, phase matching once performed is not lost when each of these signals is set to “0”.
However, when each of these signals is set to “1” from “0” again, a phase matching operation is performed.

These signals are valid only when bit 4 (SSS) of parameter No.3704 is set to 1 and bit 5 (SCB) of parameter No.4800 is set to 0.
Set a phase shift amount in parameter No.4034.

> **NOTE**
> 1 Before specifying these signals, ensure that the spindle synchronous speed control completion signal FSPSYx is set to “1”. When the spindle synchronous speed control completion signal FSPSYx is set to “0”, phase matching operation is not performed.
> 2 Phase matching in the state where spindles are rotating in synchronism is enabled only for one slave spindle synchronized with one master spindle. When phase matching is to be performed in the state where multiple slave spindles are rotating in synchronism with one master spindle, do not specify spindle phase synchronization control on multiple spindles.
> 3 Before performing phase matching of one master spindle with multiple slave spindles, ensure that all spindles are stopped.
> 4 For the correspondence between the signal of each spindle and actual signal address, see the description of "Signal address".

Spindle synchronous speed control completion signal FSPSY<Fn044.2>

[Classification] Output signal

[Function] This signal posts that spindle synchronous control (speed synchronization) for the first/second spindles is completed.

[Output cond.] This signal is set to “1” in the following case:

- This signal is output when two spindles have reached the speed equivalent to a specified spindle synchronous speed and the speed difference between the two spindles is equal to or less than the value set in parameter No.4033 in the spindle synchronous control mode.

This signal is set to “0” in the following cases:

- In the spindle synchronous control mode, two spindles have not reached the speed equivalent to a specified spindle synchronous speed.
- In the spindle synchronous control mode, the speed difference between two spindles is greater than the value set in parameter No.4033.
- The spindle synchronization control mode is not set.

This signal is valid only when bit 4 (SSS) of parameter No.3704 is set to 0.
When bit 5 (SCB) of parameter No.4800 is set to 1, an address of n = 0 is valid.

NOTE

Even if this signal is once set to “1”, this signal is set to “0” when the speed difference exceeds the value set in parameter No.4033 for a cause such as cutting load variation.

Spindle synchronous speed control completion signal for each spindle FSPSY1 to FSPSY4<Fn288.0 to Fn288.3>

[Classification] Output signal

[Function] These signals post that spindle synchronous control (speed synchronization) with each spindle set as a slave spindle is completed.

[Output cond.] This signal is set to “1” in the following case:

- This signal is output when two spindles have reached the speed equivalent to a specified spindle synchronous speed and the speed difference between the two spindles is equal to or less than the value set in parameter No.4033 in the spindle synchronous control mode.

This signal is set to “0” in the following cases:

- In the spindle synchronous control mode, two spindles have not reached the speed equivalent to a specified spindle synchronous speed.
- In the spindle synchronous control mode, the speed difference between two spindles is greater than the value set in parameter No.4033.
- The spindle synchronization control mode is not set.

These signals are valid only when bit 4 (SSS) of parameter No.3704 is set to 1 and bit 5 (SCB) of parameter No.4800 is set to 0.

NOTE

1 Even if this signal is once set to “1”, this signal is set to “0” when the speed difference exceeds the value set in parameter No.4033 for a cause such as cutting load variation.

2 For the correspondence between the signal of each spindle and actual signal address, see the description of "Signal address".

Spindle phase synchronization control completion signal FSPPH<Fn044.3>

[Classification] Output signal

[Function] This signal posts that spindle phase synchronization control (phase matching) for the first/second spindles is completed.

[Output cond.] This signal is set to “1” in the following case:

- This signal is output when phase matching is completed with the spindle phase synchronization control signal (when the error pulse difference between the two spindles is equal to or less than the value set in parameter No.4810) after the two spindles have reached the speed equivalent to a specified spindle synchronous speed in the spindle synchronous control mode.

This signal is set to “0” in the following cases:

- In the spindle synchronous control mode, the phase matching of two spindles is not completed.
- In the spindle synchronous control mode, the error pulse difference between two spindles is greater than the value set in parameter No.4810.
- The spindle synchronous control mode is not set.
- The spindle phase synchronization control mode is not set.

This signal is valid only when bit 4 (SSS) of parameter No.3704 is set to 0.
When bit 5 (SCB) of parameter No.4800 is set to 1, an address of n = 0 is valid.

> **NOTE**
> Even if this signal is once set to “1”, this signal is set to “0” when the speed difference exceeds the value set in parameter No.4810 for a cause such as cutting load variation.

Spindle phase synchronization control completion signal of each spindle FSPPH1 to FSPPH4<Fn289.0 to Fn289.3>

[Classification] Output signal

[Function] These signals post that spindle phase synchronization control (phase matching) with each spindle set as a slave spindle is completed.

[Output cond.] This signal is set to “1” in the following case:

- This signal is output when phase matching is completed with the spindle phase synchronization control signal (when the error pulse difference between the two spindles is equal to or less than the value set in parameter No.4810) after the two spindles have reached the speed equivalent to a specified spindle synchronous speed in the spindle synchronous control mode.

This signal is set to “0” in the following cases:

- In the spindle synchronous control mode, the phase matching of two spindles is not completed.
- In the spindle synchronous control mode, the error pulse difference between two spindles is greater than the value set in parameter No.4810.
- The spindle synchronous control mode is not set.
- The spindle phase synchronization control mode is not set.

These signals are valid only when bit 4 (SSS) of parameter No.3704 is set to 1 and bit 5 (SCB) of parameter No. 4800 is set to 0.

NOTE
1 Even if this signal is once set to “1”, this signal is set to “0” when the speed difference exceeds the value set in parameter No.4810 for a cause such as cutting load variation.
2 For the correspondence between the signal of each spindle and actual signal address, see the description of "Signal address".

Spindle phase error monitor signal SYCAL<Fn044.4>

[Classification] Output signal

[Function] This signal posts that in the spindle synchronous control mode for the first/second spindles, the error pulse difference between the two spindles is greater than a parameter-set value.

[Output cond.] This signal is set to “1” in the following case:

- In the spindle synchronous control mode, the error pulse difference between two spindles is greater than the value set in parameter No.4811 after spindle synchronous control is completed.

This signal is set to “0” in the following cases:

- The spindle synchronous control mode is not set.
- In the spindle synchronous control mode, the error pulse difference between two spindles is equal to or less than the value set in parameter No.4811.

This signal is valid only when bit 4 (SSS) of parameter No.3704 is set to 0.
When bit 5 (SCB) of parameter No.4800 is set to 1, an address of n = 0 is valid.

Spindle phase error monitor signal for each spindle SYCAL1 to SYCAL4<Fn043.0 to Fn043.3>

[Classification] Output signal

[Function] These signals post that in the spindle synchronous control mode with each spindle set as a slave spindle, the error pulse difference between two spindles is greater than a parameter-set value.

[Output cond.] This signal is set to “1” in the following case:

- In the spindle synchronous control mode, the error pulse difference between two spindles is greater than the value set in parameter No.4811 after spindle synchronous control is completed.

This signal is set to “0” in the following cases:

- The spindle synchronous control mode is not set.
- In the spindle synchronous control mode, the error pulse difference between two spindles is equal to or less than the value set in parameter No.4811.

These signals are valid only when bit 4 (SSS) of parameter No.3704 is set to 1 and bit 5 (SCB) of parameter No.4800 is set to 0.

NOTE
For the correspondence between the signal of each spindle and actual signal address, see the description of "Signal address".

Spindle synchronous speed ratio control signal SBRT<Gn038.1>

[Classification] Input signal

[Function] This signal specifies switching to speed ratio control in spindle synchronous control.

[Operation] When this signal is set to “1”, speed ratio control is set.
When this signal is set to “0”, speed ratio control is canceled.

This signal is common to all slave spindles that belong to the same path.

When bit 5 (SCB) of parameter No.4800 is set to 1, an address of n = 0 is valid.

Spindle synchronous speed ratio control clamp signal RSMAX<Fn065.2>

[Classification] Output signal

[Function] This signal posts the rotation state of a slave spindle under speed ratio control in spindle synchronous control.

[Output cond.] This signal is set to “1” in the following case:

- The speed of a slave spindle is clamped to the value set in the parameter No.7636 under speed ratio control in spindle synchronous control.

This signal is set to “0” in the following cases:

- The speed of any slave spindle is not clamped to the value set in the parameter No. 7636 under speed ratio control in spindle synchronous control.
- The spindle synchronization control mode is not set.

This signal is common to all slave spindles that belong to the same path.
When bit 5 (SCB) of parameter No.4800 is set to 1, an address of n = 0 is valid.

Signal address

	#7	#6	#5	#4	#3	#2	#1	#0
Gn038					SPPHS	SPSYC	SBRT	
Gn288					SPSYC4	SPSYC3	SPSYC2	SPSYC1
Gn289					SPPHS4	SPPHS3	SPPHS2	SPPHS1
Fn044				SYCAL	FSPPH	FSPSY		
Fn065						RSMAX		
Fn288					FSPSY4	FSPSY3	FSPSY2	FSPSY1

Fn043					SYCAL4	SYCAL3	SYCAL2	SYCAL1

- Signal allocation of spindle-type signals

The signal allocation of spindle-type varies according to the path number to which each spindle belongs and intra-path spindle number.

Here, the address allocation of the spindle synchronous control signal for each spindle SPSYCs, which is a spindle-type signal, is described below.

- When the one path system is used :
  When four spindles of path 1 are used

Logic spindle number	Path number + intra-path spindle number	Signal symbol	Signal address
First spindle (S1)	First spindle of path 1 (S11)	SPSYC1	G0288.0
Second spindle (S2)	Second spindle of path 1 (S12)	SPSYC2	G0288.1
Third spindle (S3)	Third spindle of path 1 (S13)	SPSYC3	G0288.2
Fourth spindle (S4)	Fourth spindle of path 1 (S14)	SPSYC4	G0288.3

- When the multi path system is used :
  When six spindles consisting of three spindles of path 1 and three spindles of path 2 are used

Logic spindle number	Path number + intra-path spindle number	Signal symbol	Signal address
First spindle (S1)	First spindle of path 1 (S11)	SPSYC1	G0288.0
Second spindle (S2)	Second spindle of path 1 (S12)	SPSYC2	G0288.1
Third spindle (S3)	Third spindle of path 1 (S13)	SPSYC3	G0288.2
Fourth spindle (S4)	First spindle of path 2 (S21)	SPSYC1	G1288.0
Fifth spindle (S5)	Second spindle of path 2 (S22)	SPSYC2	G1288.1
Sixth spindle (S6)	Third spindle of path 2 (S23)	SPSYC3	G1288.2

Parameter

	#7	#6	#5	#4	#3	#2	#1	#0
3799					SVPs			

[Input type] Parameter input
[Data type] Bit spindle

#3 SVPs As synchronization errors displayed on the spindle tuning screen:
0: Monitor values are displayed.
1: Peak-hold values are displayed.
Spindle synchronization errors are displayed on the side of the spindle that functions as a slave axis in spindle synchronization control.

	#7	#6	#5	#4	#3	#2	#1	#0
3704				SSS				

[Input type] Parameter input
[Data type] Bit path

NOTE
When this parameter is set, the power must be turned off before operation is continued.

#4 SSS Synchronous spindle control by each spindle is:
0: Not performed.
1: Performed.
The master axis and slave axis of synchronous spindle control can be selected from the arbitrary spindles.
The target spindle of synchronous spindle control is specified in parameter No.4831.
In addition, the following signals affect the control.
- Synchronous spindle signals of each spindle SPSYCs
- Signals of synchronous control of the spindle phase for each spindle SPPHSs

	#7	#6	#5	#4	#3	#2	#1	#0
3716								A/Ss

[Input type] Parameter input
[Data type] Bit spindle

NOTE
When this parameter is set, the power must be turned off before operation is continued.

#0 A/Ss Spindle motor type is :
0: Analog spindle.
1: Serial spindle.

3717	Spindle amplifier number to each spindle

> **NOTE**
> When this parameter is set, the power must be turned off before operation is continued.

[Input type] Parameter input
[Data type] Byte spindle
[Valid data range] 0 to Maximum number of controlled axes
Set a spindle amplifier number to be assigned to each spindle.
0: No spindle amplifier is connected.
1: Spindle motor connected to amplifier number 1 is used.
2: Spindle motor connected to amplifier number 2 is used.
to
n: Spindle motor connected to amplifier number n is used.

4032	Acceleration / deceleration time constant for spindle synchronous control

[Input type] Parameter input
[Data type] Word spindle
[Data unit] $1min^{-1}/sec$
[Valid data range] 0 to 32767
This parameter sets an acceleration value for linear acceleration/deceleration when the synchronous speed command for spindle synchronous control is changed.

> **NOTE**
> 1 Set exactly the same data for a master axis spindle and a slave axis. When different data is set, synchronization between the two spindles is not guaranteed.
> 2 When this parameter is set to 0, acceleration/deceleration of a spindle is not applied. Set an appropriate value.

4033	Detection level for spindle synchronous speed

[Input type] Parameter input
[Data type] Word spindle
[Data unit] $1min^{-1}/sec$
[Valid data range] 0 to 32767
For the synchronous speed command at spindle synchronous control, if the error of the respective spindle motor speeds are within the setting level, the spindle synchronous control complete signal (FSPSY) becomes “1”.

4034	The shift amount in spindle phase synchronization control

[Input type] Parameter input
[Data type] Word spindle
[Data unit] 1 pulse unit (360°/4096)
[Valid data range] 0 to 4095

Sets the shift amount from the reference point at spindle phase synchronous control (one-rotation signal).

	#7	#6	#5	#4	#3	#2	#1	#0
4800			SCB	SYM				

[Input type] Parameter input
[Data type] Bit

NOTE
When this parameter is set, the power must be turned off before operation is continued.

#4 SYM In spindle synchronous control, spindle maximum speed uses:
0: the one of a master axis.
1: low one either a master axis or a slave axis.

NOTE
This parameter is valid only for T type gear selection method.

#5 SCB The combination of a master spindle and slave spindle for spindle synchronization control depends on:
0: Setting of bit 4 (SSS) of parameter No.3704.
When bit 4 (SSS) of parameter No.3704 is set to 0
The first spindle and second spindle of each path can be selected as the master spindle and slave spindle, respectively, for spindle synchronization.
When bit 4 (SSS) of parameter No.3704 is set to 1
A combination of arbitrary spindles of each path can be selected for spindle synchronization.
Set a master spindle for each slave spindle in parameter No.4831. Set a spindle number of each path.
By setting a spindle number common to the system in parameter No.4832, an arbitrary spindle that belongs to a different path can be selected as a master spindle for spindle synchronization. Set a spindle number common to the system. Set parameter No.4831 to 0. Spindle synchronization based on arbitrary spindles must be enabled for the path to which a slave spindle belongs and for the path to which a master spindle belongs.
1: Conventional 16TT system compatible specifications.
The first spindle of path 1 and the first spindle of path 2 can be selected as the master spindle and slave spindle, respectively, for spindle synchronization.
As control signals, the signal interface of the 16TT system compatible specifications can be used.

	#7	#6	#5	#4	#3	#2	#1	#0
4801								SNDs

[Input type] Parameter input
[Data type] Bit spindle

NOTE
When this parameter is set, the power must be turned off before operation is continued.

#0 SNDs During spindle synchronization control, the rotation direction of each spindle motor is:
0: Same as the specified sign.
1: Opposite to the specified sign.

	#7	#6	#5	#4	#3	#2	#1	#0
4809								**NSY**

[Input type] Parameter input
[Data type] Bit

> **NOTE**
> When this parameter is set, the power must be turned off before operation is continued.

#0 NSY When the spindle speed changes during spindle synchronization control, resolution improvement is:
0: Disabled. (Speed change in units of about 3.7 [min^{-1}])
1: Enabled. (Speed change in units of about 0.03 [min^{-1}] at minimum but not higher than maximum spindle speed/4095 [min^{-1}])

This parameter is valid when spindle synchronization control or spindle-spindle polygon turning is used.
Using high-precision spindle speed control and spindle synchronization control simultaneously requires setting the parameter to 1.

> **NOTE**
> Using this function requires the serial spindle software that supports it.

4810	**Error pulse between two spindles when synchronizing phases in the spindle synchronization control mode**

[Input type] Parameter input
[Data type] Word spindle
[Unit of data] Detection unit
[Valid data range] 0 to 255

Set an allowable error pulse value between two spindles at phase synchronization time in the spindle synchronization control mode.
This parameter is used to check the completion of phase synchronization performed in the spindle synchronization control mode and to check the phase difference during spindle synchronization control.
When the error pulse value between two spindles become equal to or less than the value set in this parameter, the spindle phase synchronization control completion signals FSPPH<F044.3> and FSPPH1 to 4<F289.0 to 3> are set to “1”.

4811	**Allowable error count for the error pulses between two spindles in the spindle synchronization control mode**

[Input type] Parameter input
[Data type] Word spindle
[Unit of data] Detection unit
[Valid data range] 0 to 32767

Set the allowable error count for the error pulses between two spindles in the spindle synchronization control mode.

This parameter is used to check a spindle synchronization error phase difference.
When a spindle synchronization error equal to or greater than the value set in this parameter is detected, the phase error monitor signals SYCAL<Fn044.4> and SYCAL1 to 4<Fn043.0 to Fn043.3> are set to “1”.

4831	Master axis of each slave spindle under spindle synchronous control

> **NOTE**
> When this parameter is set, the power must be turned off before operation is continued.

[Input type] Parameter input
[Data type] Byte spindle
[Valid data range] 0 to Maximum number of controlled spindle axes (within a path)

When a spindle is set as a slave spindle in spindle synchronization control on each spindle, set which spindle (master spindle) the slave spindle is to be synchronized with.
[Examples of parameter setting]

- When spindle synchronization control is exercised with the first spindle selected as a master spindle and the second spindle selected as a slave spindle:
  No. 4831(1)=0
  No. 4831(2)=1
  No. 4831(3)=0
  No. 4831(4)=0

- When spindle synchronization control is exercised with four spindles under the following combinations:
  (Two combinations, namely, first spindle (master spindle)/second spindle (slave spindle), and third spindle (master spindle)/fourth spindle (slave spindle))
  No. 4831(1)=0
  No. 4831(2)=1
  No. 4831(3)=0
  No. 4831(4)=3

- When spindle synchronization control is exercised with one master spindle and multiple slave spindles:
  (First spindle (master spindle)/second spindle (slave spindle)/third spindle (slave spindle)/fourth spindle (slave spindle))
  No. 4831(1)=0
  No. 4831(2)=1
  No. 4831(3)=1
  No. 4831(4)=1

> **NOTE**
> 1 This parameter is valid only if bit 4 (SSS) of parameter No.3704 is set to 1.
> 2 The setting of a slave spindle as a master spindle is invalid.
> This parameter must be set to 0 for a spindle to be set as a master spindle.
> 3 In this parameter, set a spindle number within the same path.
> When a spindle not belonging to the local path is to be selected as a master spindle for spindle synchronization, set a spindle number common to the system in parameter No.4832. In such a case, set 0 in this parameter.

4832	Master spindle of each slave spindle under spindle synchronization control (spindle number common to the system)

NOTE
When this parameter is set, the power must be turned off before operation is continued.

[Input type] Parameter input
[Data type] Byte spindle
[Valid data range] 0 to Maximum number of controlled spindle axes (common to the system)

When a spindle is set as a slave spindle in spindle synchronization control on each spindle, set which spindle (master spindle) the slave spindle is to be synchronized with.

NOTE
1. This parameter is valid if bit 4 (SSS) of parameter No.3704 is set to 1.
   Bit 4 (SSS) of parameter No.3704 must be set to 1 (to enable spindle synchronization based on arbitrary spindles) for the path to which a slave spindle belongs and for the path to which a master spindle belongs.
2. The setting of a slave spindle as a master spindle is invalid.
   This parameter must be set to 0 for a spindle to be set as a master spindle.
3. In this parameter, set a spindle number common to the system.
4. When this parameter is used, parameter No.4831 is set to 0.

	#7	#6	#5	#4	#3	#2	#1	#0
7603						SBR		

[Input type] Parameter input
[Data type] Bit path

#2 SBR For spindle synchronization control, speed ratio control is:
0: Not used.
1: Used.

7635	Ratio of slave spindle speed in spindle synchronization control

[Input type] Parameter input
[Data type] Byte spindle
[Valid data range] 0 to 9

This parameter sets the ratio of master spindle speed: slave spindle speed (1:n) in spindle synchronization control.

NOTE
This parameter is valid only when bit 2 (SBR) of parameter No. 7603 is set to 1.

7636	Maximum allowable slave spindle speed in spindle synchronization control

[Input type] Parameter input
[Data type] Word spindle

[Unit of data] min^{-1}
[Valid data range] 0 to 19999

The speed of the slave spindle under speed ratio control in spindle synchronization control is clamped so that the speed does not exceed the value set in this parameter.

> **NOTE**
> 1 This parameter is valid only when bit 2 (SBR) of parameter No. 7603 is set to 1.
> 2 When speed ratio control in spindle synchronization control is used, be sure to set this parameter.
> 3 When 0 is set, the speed is clamped to 0, disabling rotation under spindle synchronization.

Alarm and message

Number	Message	Description
PS0194	SPINDLE COMMAND IN SYNCHRO-MODE	A Cs contour control mode, spindle positioning command, or rigid tapping mode was specified during the spindle synchronous control mode or spindle command synchronous control mode.

Caution

> ⚠ **CAUTION**
> 1 Phase error monitor signal SYCAL is used for monitoring a phase shift in spindle synchronous control. The processing performed when a phase shift is detected depends on the specifications determined by the machine tool builder.
> 2 A gear ratio of 1:1 only is allowed between the spindle and position coder.
> 3 A CNC system restriction is imposed on the maximum number of spindles.

Reference item

For details of the parameters Nos.4000 to 4539, signals, and alarms for the serial spindle control unit, refer to the manuals related to serial spindles listed below.
FANUC AC SPINDLE MOTOR αi series PARAMETER MANUAL (B-65280EN)

10.14.1 Arbitrary Spindle Position Phase Synchronization Function

Overview

In spindle synchronous control, when workpiece whose cross section is non-circular is gripped between master spindle and slave spindle, phase of master and slave has to be synchronized. In order to synchronize the phase of master spindle and slave spindle by spindle phase synchronous control so far, phase difference between master spindle and slave spindle has to measure by hand, and set to parameter.
This function can detect master and slave spindle position automatically by setting DI signal, and save spindle positions to parameters. In spindle phase synchronous control, phase can synchronize by loading saved spindle positions. Therefore, setup time for spindle phase synchronous control can be shortened.
Besides, master and slave spindle position can save up to 4 pairs. DI signal can select which of spindle position pairs will be loaded. Therefore, plural non-circular workpieces can be applied.
This function can use with serial spindles.

Explanation

Save of spindle position

In order to grip workpiece whose cross section is non-circular between master spindle and slave spindle, master and slave spindle positions are detected automatically, and saved to parameters Nos.4840 to 4843.

Master and slave spindle position can save up to 4 pairs. Master and slave spindle position are saved to parameters Nos.4840 to 4843 by the following procedure.

(1) Detect one-rotation signal of both master spindle and slave spindle beforehand. Check whether one-rotation signal has been detected or not by position coder one-rotation signal detection status signal PC1DT <Fn047.0, Fn051.0, Fn170.0, Fn268.0>.
(2) Command “S0 ;” to both master spindle and slave spindle so as not to rotate spindles.
(3) Turn off excitation of master spindle and slave spindle.
(4) Set a workpiece whose cross section is non-circular with master spindle and slave spindle.
(5) Turn on excitation of master spindle and slave spindle.
(6) Set spindle position save start signal SPMST1 to SPMST4 <Gn587.0 to Gn587.3> of slave spindle to “1”. Spindle position can save whether the spindle is stopping or rotating. If spindle position is saved during rotating spindles by spindle synchronous control, set spindle position save start signal SPMST1 to SPMST4 <Gn587.0 to Gn587.3> to “1” after having become spindle synchronous speed control completion signal FSPSY <Fn044.2> (or <Fn288.0 to Fn288.3>) “1”.
(7) When spindle position save start signal SPMST1 to SPMST4 <Gn587.0 to Gn587.3> is set from “0” to “1”, position coder one-rotation signal detection status signals PC1DT <Fn047.0, Fn051.0, Fn170.0, Fn268.0> of both master spindle and slave spindle are checked. If position coder one-rotation signal detection status signal <Fn047.0, Fn051.0, Fn170.0, Fn268.0> of master spindle or slave spindle is “0”, spindle position save error signal SPMER1 to SPMER4 <Fn577.4 to Fn577.7> becomes “1” because spindle position cannot be detected.
(8) When spindle position save start signal SPMST1 to SPMST4 <Gn587.0 to Gn587.3> is set from “0” to “1”, spindle position saving parameter Nos.4840 to No.4843 is selected by setting spindle position save selection signal SMSL11 to SMSL14 <Gn588.0 to Gn588.3>, SMSL21 to SMSL24 <Gn588.4 to Gn588.7> of slave spindle.
(9) Spindle positions of both master spindle and slave spindle are saved to parameter selected by (8), and spindle position save completion signal SPMFN1 to SPMFN4 <Fn577.0 to Fn577.3> of slave spindle becomes “1”. Besides, one of bit 0 to 3 (SM1 to SM4) of parameter No.4803 becomes 1.

Table 10.14.1 (a) Relationship between spindle position save selection signal and spindle position saving parameter

spindle position saving parameter	parameter notifying spindle position save is completed or not	Spindle position save selection signal	
		SMSL21 toSMSL24 <Gn588.4 toGn588.7>	SMSL11 toSMSL14 <Gn588.0 to Gn588.3>
No.4840	No.4803#0	0	0
No.4841	No.4803#1	0	1
No.4842	No.4803#2	1	0
No.4843	No.4803#3	1	1

(10) Set spindle position save start signal SPMST1 to SPMST4 <Gn587.0 to Gn587.3> to “0” after having become spindle position save completion signal SPMFN1 to SPMFN4 <Fn577.0 to Fn577.3> “0”.
(11) If spindle position save start signal SPMST1 to SPMFN4 <Fn577.0 to Fn577.3> is set to “0”, spindle position save completion signal SPMFN1 to SPMFN4 <Fn577.0 to Fn577.3> becomes “0”.

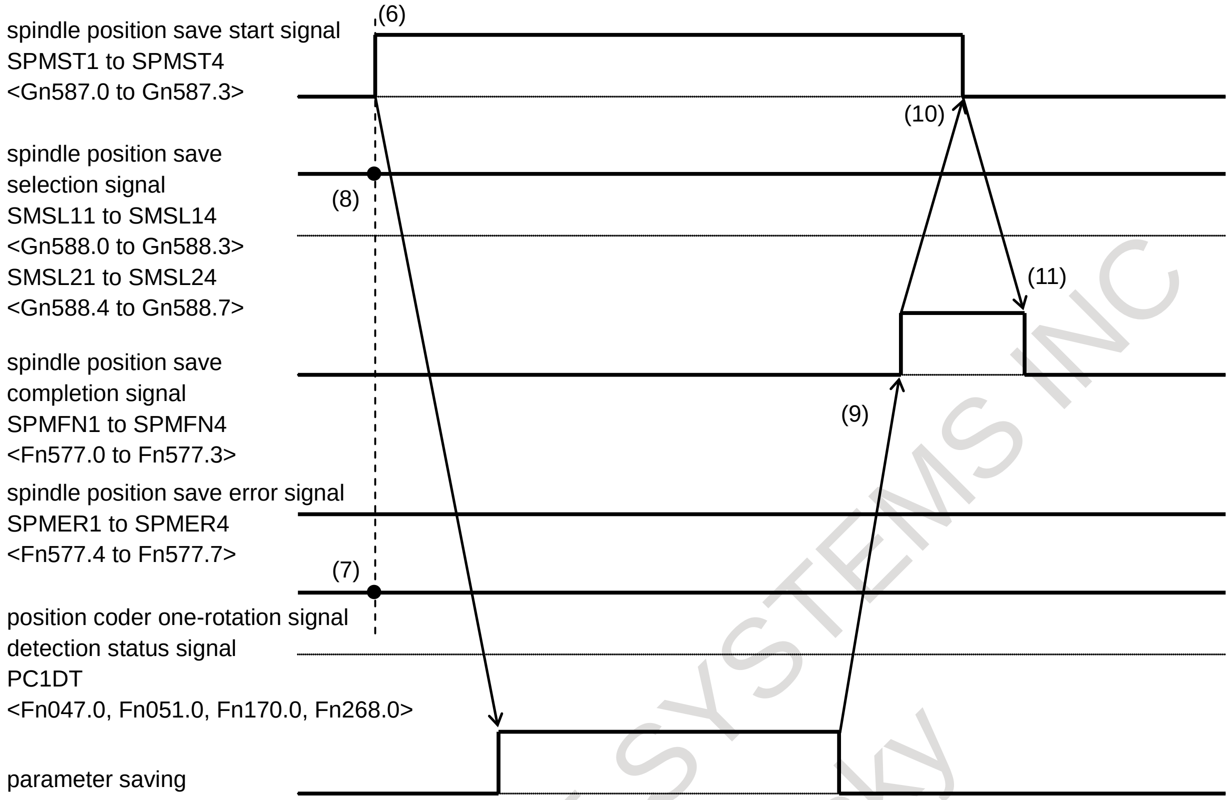

Fig.10.14.1 (a) Spindle position save

NOTE

Set bit 0 to 3 (SM1 to SM4) of parameter No.4803 to 0 if spindle position has to be saved again, for example, motor or detector is exchanged, parameter file of other machine is inputted, and so on.

Spindle position save error signal SPMER1 to SPMER4 <Fn577.4 to Fn577.7> of slave spindle becomes “1” in the following cases, because spindle position cannot be saved.

- Position coder one-rotation signal detection status signal PC1DT<Fn047.0, Fn051.0, Fn170.0, Fn268.0> of master spindle or slave spindle is ”0”.
- Spindle position save start signal SPMST1 to SPMST4 <Gn587.0 to Gn587.3> is set to “0” before having become spindle position save completion signal SPMFN1 to SPMFN4 <Fn577.0 to Fn577.3> “1”.
- Spindle position save to a parameter cannot be completed correctly.
- Spindle positions save start signal SPMST1 to SPMST4 <Gn587.0 to Gn587.3> of a slave spindle is set to “1” during saving spindle position of other master-slave pair (in the case of plural slave spindles for master spindle).

If spindle position save error signal SPMER1 to SPMER4 <Fn577.4 to Fn577.7> becomes “1”, bit 0 to 3 (SM1 to SM4) of parameter No.4803 corresponding to bit position of the signal becomes 1. If spindle position save error signal SPMER1 to SPMER4 <Fn577.4 to Fn577.7> becomes “1”, spindle position save start signal SPMST1 to SPMST4 <Gn587.0 to Gn587.3> has to be set to “0”. If spindle position save start signal SPMST1 to SPMST4 <Gn587.0 to Gn587.3> is set to “1” again, spindle position save error signal SPMER1 to SPMER4 <Fn577.4 to Fn577.7> becomes “0”.

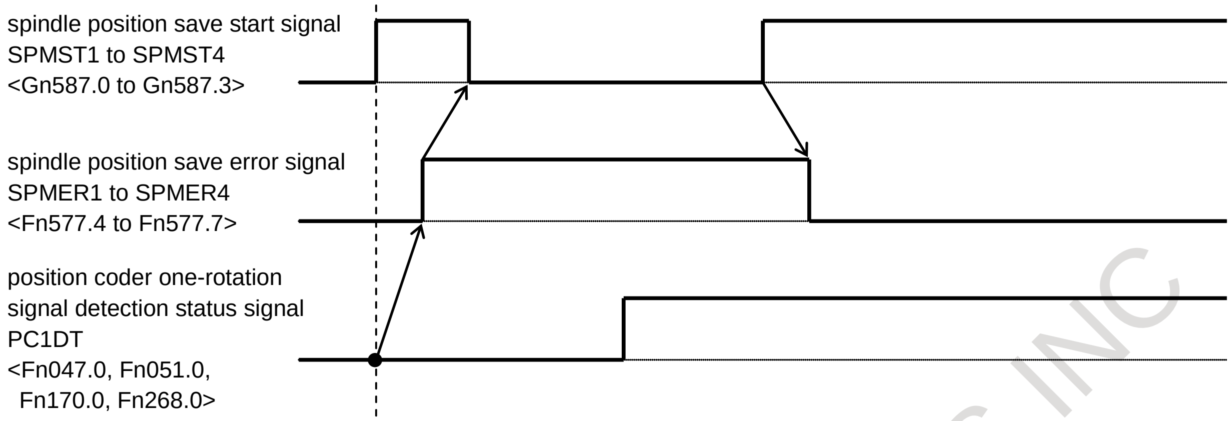

Fig.10.14.1 (b) Example of becoming spindle position save error signal “1”

Arbitrary spindle position phase synchronous control

In spindle phase synchronous control, phase between master spindle and slave spindle is synchronized based on parameter No.4034 (shift amount for spindle phase synchronous control). This function can use spindle position saved to parameter Nos.4840 to 4843 as phase shift amount (The value of parameter (No.4034) (shift amount for spindle phase synchronous control) is disabled for this function.). Up to 4 spindle positions can be memorized. Phase adjustment is performed for various non-standard workpieces. If spindle phase synchronous control signal SPPHS <Gn038.3> (or <Gn289.0 to Gn289.3>) is set to “1” with arbitrary spindle position phase synchronization control signal SPAPH1 to SPAPH4 <Gn587.4 to Gn587.7> of slave spindle “1”, phase synchronization whose shift amount is parameter Nos.4840 to 4843 is started. Spindle position save selection signal SMSL11 to SMSL14 <Gn588.0 to Gn588.3>, SMSL21 to SMSL24 <Gn588.4 to Gn588.7> of slave spindle can select which of parameter Nos.4840 to 4843 will be used. Relationship between spindle position save selection signal SMSL11 to SMSL14 <Gn588.0 to Gn588.3>, SMSL21 to SMSL24 <Gn588.4 to Gn588.7> and parameter Nos.4840 to 4843 is shown at Table 10.14.1 (a). If spindle position is not saved, and selected the pair of spindle position, alarm SP1256, “SPINDLE PHASE-SYNC IMPOSSIBLE” is issued to master spindle and slave spindle when arbitrary spindle position phase synchronous control is started. Bit 0 to 3 (SM1 to SM4) of parameter No.4803 of slave spindle can check whether spindle position save has been completed or not.

NOTE

1 Set bit 0 to 3 (SM1 to SM4) of parameter No.4803 to 0 if spindle position has to be saved again, for example, motor or detector is exchanged, parameter file of other machine is inputted, and so on.
2 Set bit 0 to 3 (SM1 to SM4) of parameter No.4803 to 0 if the saved spindle position (parameter Nos. 4840 to 4843) will not be used.
3 If bit 0 to 3 (SM1 to SM4) of parameter No.4803 is set to 1 by MDI unit or G10 command, alarm SP1256, “SPINDLE PHASE-SYNC IMPOSSIBLE” is not issued. Don’t set bit 0 to 3 (SM1 to SM4) of parameter No.4803 to 1 by MDI unit or G10 command, if spindle position of phase synchronization is not saved to parameter Nos.4840 to 4843.

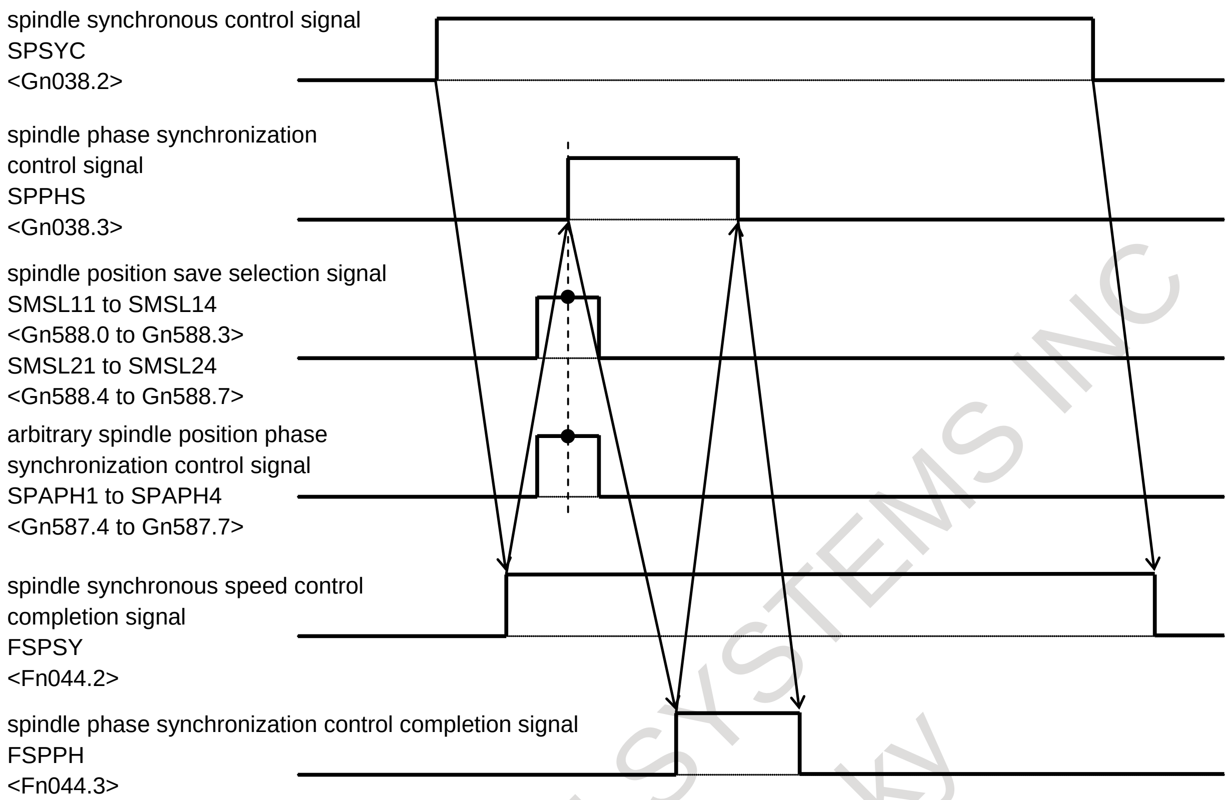

Fig.10.14.1 (c)　Arbitrary spindle position phase synchronous control

Limitation

Plural slave spindles

If there are plural slave spindles for master spindle, 3 or more spindles are synchronized as shown in Fig.10.14.1 (d), this function cannot be used.

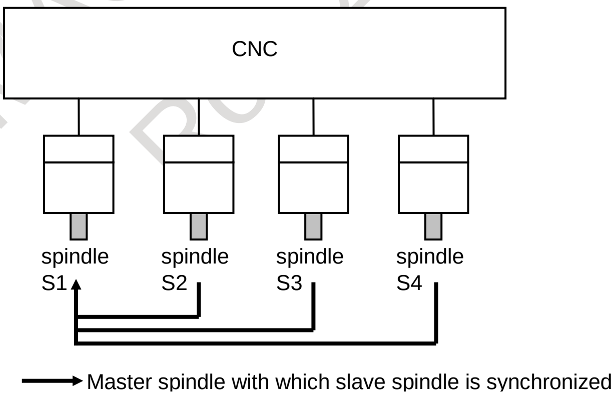

Fig.10.14.1 (d)　Example of plural slave spindles

Spindle synchronous control for spindle control with servo motor

This function cannot be used for spindle synchronous control for spindle control with servo motor.

Signal

Spindle position save start signal SPMST1 to SPMST4 <Gn587.0 to Gn587.3>

[Classification] Input signal

[Function] Spindle position save is started.

[Operation] If this signal of slave spindle is set to “1”, spindle position save of both master spindle and slave spindle is started.

Spindle position save selection signal SMSL11 to SMSL14 <Gn588.0 to Gn588.3> SMSL21 to SMSL24 <Gn588.4 to Gn588.7>

[Classification] Input signal

[Function] Parameter which saves spindle position is selected. Besides, parameter which is used as phase shift amount for spindle phase synchronous control is selected.

[Operation] When spindle position save start signal SPMST is from "0" to "1", parameter which saves spindle position is selected by setting this signal of slave spindle as shown in Table 10.14 (b).

Table 10.14.1 (b) Relationship between spindle position save selection signal and spindle position saving parameter

spindle position saving parameter	parameter notifying spindle position save is completed or not	Spindle position save selection signal	
		SMSL21 to SMSL24 <Gn588.4 to Gn588.7>	SMSL11 to SMSL14 <Gn588.0 to Gn588.3>
No.4840	No.4803#0	0	0
No.4841	No.4803#1	0	1
No.4842	No.4803#2	1	0
No.4843	No.4803#3	1	1

Besides, parameter which is used for spindle phase synchronous control with spindle position memorized in the parameter as phase shift amount is selected as shown in Table 10.14 (b).

Arbitrary spindle position phase synchronization control signal SPAPH1 to SPAPH4 <Gn587.4 to Gn587.7>

[Classification] Input signal

[Function] Spindle phase synchronous control whose phase shift amount is spindle position saved to parameter is executed.

[Operation] If spindle phase synchronous control signal SPPHS is set to "1" with this signal of slave spindle "1", spindle phase synchronous control whose phase shift amount is spindle position saved to parameter is started.

Spindle position save completion signal SPMFN1 to SPMFN4 <Fn577.0 to Fn577.3>

[Classification] Output signal

[Function] These signals notify whether spindle position save is completed or not.

[Output cond.] These signals become "1" under the following condition:

- Spindle position is saved to parameter.

These signals become "0" under the following condition:

- Spindle position save is completed, and spindle position save start signal SPMST is set to "0".
- Spindle position save is not executed.

Spindle position save error signal SPMER1 to SPMER4 <Fn577.4 to Fn577.7>

[Classification] Output signal

[Function] These signals notify the error of spindle position save to have occurred.

[Output cond.] These signals become "1" under the following condition:

- Spindle position save is started when position coder one-rotation signal detection status signal PC1DT of master spindle or slave spindle is "0".
- Spindle position save start signal SPMST is set to "0" before having become spindle position save completion signal SPMFN "1"
- Spindle position save cannot be completed correctly.

- Spindle positions save start signal SPMST1 to SPMST4 of a slave spindle is set to “1” during saving spindle position of other master-slave pair (in the case of plural slave spindles for master spindle).

These signals become “0” under the following condition:

- Spindle position save start signal SPMST is set to “0” after having become spindle position save error signal SPMER “1”, and spindle position save start signal SPMST is set to “1” again.
- Spindle position save is not executed.

[Data type] Bit spindle

#0 SM1 Spindle position save to parameter No.4840 is:
0: Not completed.
1: Completed.

#1 SM2 Spindle position save to parameter No.4841 is:
0: Not completed.
1: Completed.

#2 SM3 Spindle position save to parameter No.4842 is:
0: Not completed.
1: Completed.

#3 SM4 Spindle position save to parameter No.4843 is:
0: Not completed.
1: Completed.

NOTE
Set bit 0 to 3 (SM1 to SM4) of parameter No.4803 to 0 if spindle position has to be saved again, for example, motor or detector is exchanged, parameter file of other machine is inputted, and so on.

4840	Spindle position 1 used as phase shift amount

4841	Spindle position 2 used as phase shift amount

4842	Spindle position 3 used as phase shift amount

4843	Spindle position 4 used as phase shift amount

[Input type] Parameter input
[Data type] Word spindle
[Unit of data] Detection unit
[Valid data range] 0 to 4095

Spindle position is saved by CNC. Spindle phase synchronous control whose phase shift amount is spindle position saved to this parameter can be executed.

Alarm and message

Number	Message	Description
SP1256	SPINDLE PHASE-SYNC IMPOSSIBLE	Arbitrary spindle position phase synchronous control cannot be executed. Save the spindle position.

10.15 SPINDLE ORIENTATION

Overview

This function stops the spindle at a specified position. The spindle can be stopped in either of the following two ways.

-The spindle is stopped by applying a function of the spindle control unit.
-The spindle is stopped using mechanical stop.

Explanation

- Using the spindle control unit

Some spindle control units can position the spindle motor by using sensors and position coders. The CNC itself does not control positioning by using these units.

- Mechanical stop

To mechanically stop the spindle by using, for example, a shot pin, rotate the spindle at a constant low speed and drive the pin into the spindle. The spindle can be rotated at a low constant speed by applying either of the following methods.

- Spindle orientation signal SOR<Gn029.5>
- Spindle output control by the PMC

- Serial spindle orientation by a position coder

Two methods of serial interface spindle orientation are available:

- Spindle orientation by a magnetic sensor
- Spindle orientation by a position coder

Spindle orientation by a position coder is described below.

For the function of spindle orientation by a magnetic sensor, refer to "FANUC SPINDLE MOTOR α*i* series PARAMETER MANUAL (B-65280EN)".

Two methods of spindle orientation by a position coder are available:

- Orientation with the fixed stop position
- Orientation with the stop position set externally

(1) Orientation with the fixed stop position: Bit 0 (ORT) of parameter No.3729 = 0
By inputting the spindle orientation command signal, the spindle can always be stopped at an orientation stop position set beforehand with a parameter.

(2) Orientation with the stop position set externally: Bit 0 (ORT) of parameter No.3729 = 1

By externally setting the 12-bit orientation external stop position command signal and inputting the spindle orientation command signal, the spindle can always be stopped at an arbitrary orientation position within one spindle rotation.

- Least input increment

Least input increment of the stop position for spindle orientation can be changed by bit 0 (ORPUNT) of parameter No.4542.
Moreover, data range are changed at the stop position (parameters Nos.4031 and 4204), stop position shift amount (parameters Nos.4077 and 4228), in-position width (parameters Nos.4075 and 4226) and spindle orientation signals with the stop position externally set . Detail is shown in Table 10.15 (a) below.

Table 10.15 (a)

	Bit 0 (ORPUNT) of No.4542	
	0	**1**
Least input increment [deg]	360/4096=0.08789	360/32768=0.01098
Stop position for orientation Data range of parameters Nos.4031,4204	0 to 4095	0 to 32767
Stop position shift amount for orientation Data range of parameters Nos.4077,4228	-4095 to 4095	-32767 to 32767
Detection level for the spindle orientation completion signal Data range of parameters Nos.4075,4226	0 to 100	0 to 1000
Spindle orientation signals with the stop position externally set Data range of signals below SH00A to SH14A<Gn078,Gn079>, SH00B to SH14B<Gn080,Gn081>, SH00C to SH14C<Gn208,Gn209>, SH00D to SH14D<Gn270,Gn271>	0 to 4095	0 to 32767

- Wait time after changing signals with stop position externally set

When bit 0 (ORPUNT) of parameter No.4542 is set to 1, the wait time from the spindle orientation signals with the stop position externally set change to the commanded orientation command signal is reduced. Table 10.15 (b) is shown the wait time.

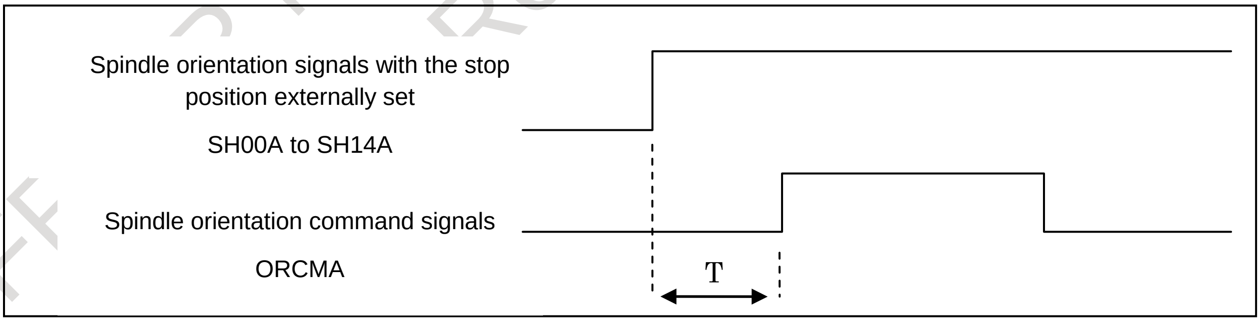

Table 10.15 (b)

	Bit 0 (ORPUNT) of No.4542	
	0	**1**
Wait time T[msec]	50	0

For the function of spindle orientation by a position coder, refer to "FANUC SPINDLE MOTOR α *i* series PARAMETER MANUAL (B-65280EN)", too.

Signal

Spindle orientation signal SOR<Gn029.5>

[Classification] Input signal

[Function] The spindle or the spindle motor is rotated at a constant

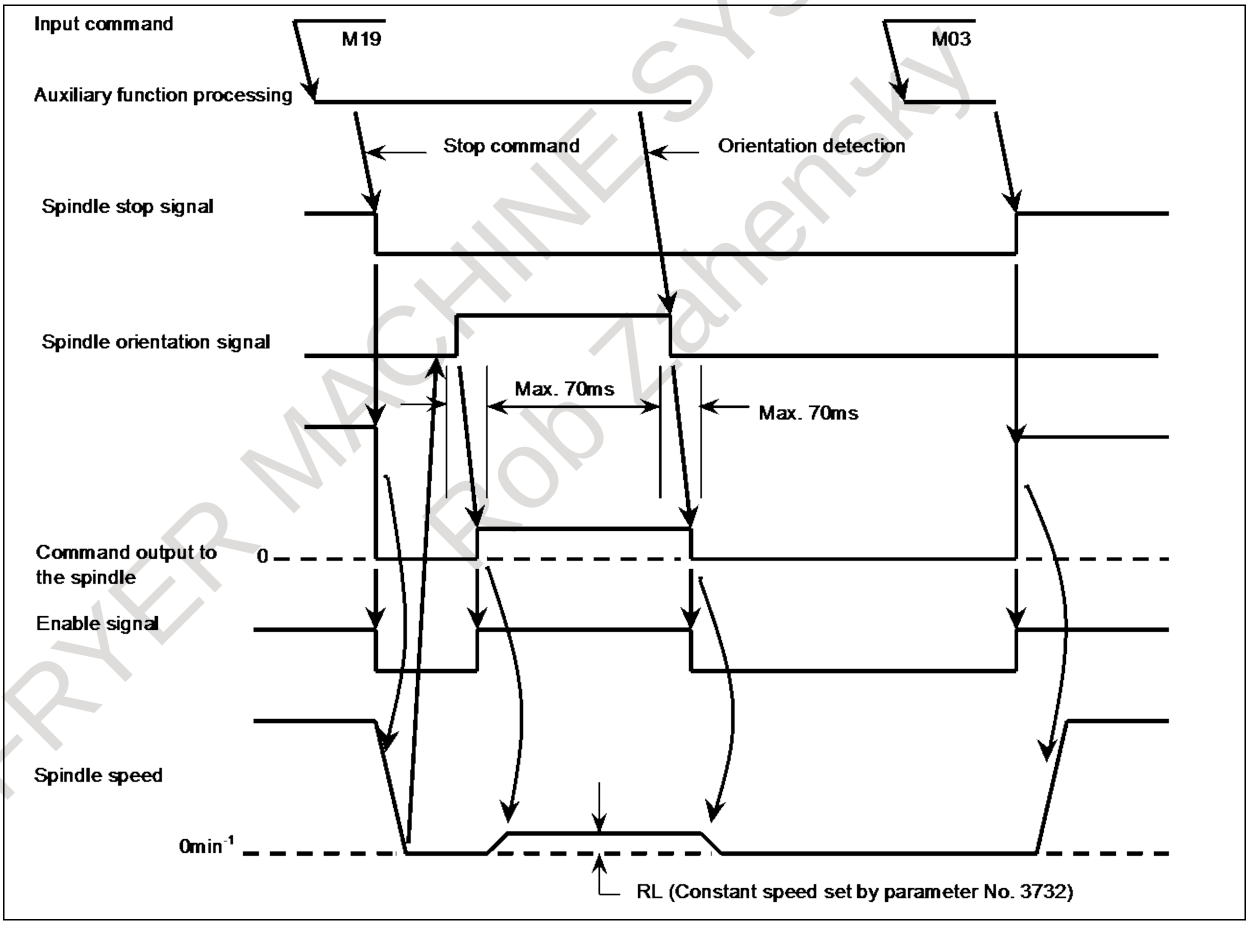
[Operation] When the spindle orientation signal turns to “1” and the spindle stop signal *SSTP turns to “0”, a spindle speed command which lets the spindle rotate at the constant speed set by parameter No. 3732 is output. The enable signal ENB also turns to “1”. This signal is disabled when the spindle stop signal is “1”.

In the machining center system, when the spindle speed for orientation is set by bit 1 (GST) of parameter No. 3705 and the SOR signal is input, the CNC outputs the spindle speed command corresponding to the speed set to parameter 3732 with an output polarity set by bit 5 (ORM) of parameter No. 3706, but the gear select signal does not change.

For example, if the SOR signal is turned to 1 with high gear selected, and the speed set to parameter No. 3732 is in the low gear range, the gear select signal does not change and the command output is calculated and output to obtain the set speed at high gear.

When the spindle motor speed is set by bit 1 (GST) of parameter No. 3705=1, the command output is output regardless of gear select signal. When the spindle motor speed is set, it is used for gear shift.

Example of usage is shown below:



Spindle orientation command signals
ORCMA<Gn070.6> : For first spindle
ORCMB<Gn074.6> : For second spindle
ORCMC<Gn204.6> : For third spindle
ORCMD<Gn266.6> : For fourth spindle

[Classification] Input signal

[Function] These signals specify spindle orientation for serial spindle amplifiers.
For details of the sequence, refer to "FANUC SPINDLE MOTOR αi series PARAMETER MANUAL (B-65280EN)".

Spindle orientation signals with the stop position externally set
SH00A to SH14A<Gn078,Gn079> : For first spindle
SH00B to SH14B<Gn080,Gn081> : For second spindle
SH00C to SH14C<Gn208,Gn209> : For third spindle
SH00D to SH14D<Gn270,Gn271> : For fourth spindle

[Classification] Input signal

[Function] This command is used for specifying a stop position with an absolute position within one rotation in the following equation:

- Bit 0(ORPUNT) of parameter No.4542 is set to 0 :
  Effective 12bit (SH00A to SH11A, SH00B to SH11B, SH00C to SH11C, SH00D to SH11D)

$$\textit{Stop position}\ (\mathrm{deg}) = \frac{360}{4096} \times \sum_{i=0}^{11} (2^i \times \mathrm{Pi})$$

- Bit 0(ORPUNT) of parameter No.4542 is set to 1 :
  Effective 15bit (SH00A to SH14A, SH00B to SH14B, SH00C to SH14C, SH00D to SH14D)

$$\textit{Stop position}\ (\mathrm{deg}) = \frac{360}{32768} \times \sum_{i=0}^{14} (2^i \times \mathrm{Pi})$$

where Pi = 0 when SHiA = 0, or Pi = 1 when SHiA = 1.
For details of the sequence, refer to "FANUC SPINDLE MOTOR αi series PARAMETER MANUAL (B-65280EN)".

> **NOTE**
> When bit 0 (ORPUNT) of parameter No.4542 is set to 0, after the spindle orientation signals with the stop position externally set is set, change the orientation signals ORCM after waiting for 50msec or more.
> When bit 0 (ORPUNT) of parameter No.4542 is set to 1, the wait time is unnecessary.

Parameter

	#7	#6	#5	#4	#3	#2	#1	#0
3729								ORTs

[Input type] Parameter input
[Data type] Bit spindle

#0 ORTs When a serial spindle is used, the spindle orientation function of stop position external setting type based on the position coder is:
0: Not performed.
1: Performed.

> **NOTE**
> When bit 0 (ORPUNT) of parameter No.4542 is set to 1, if bit 0 (ORTs) of parameter No.3729 is changed, the power must be turned off before operation is continued.

4031	Stop position in orientation by a position coder (MAIN spindle)
4204	Stop position in orientation by a position coder (SUB spindle)

[Input type] Parameter input
[Data type] Word spindle
[Unit of data] Detection unit
[Valid data range] Depend on the bit 0 (ORPUNT) of parameter No.4542 setting (Refer to the table below)

Bit 0 (ORPUNT) of No.4542	Least input increment	Valid data range
0	360/4096= 0.08789	0 to 4095
1	360/32768= 0.01098	0 to 32767

Each of these parameters specifies a stop position in orientation by a position coder.
These parameters are valid when bit 0 (ORT) of parameter No.3729 is set to 0.

4075	Orientation completion signal detection level (limits of in-position)（MAIN spindle）
4226	Orientation completion signal detection level (limits of in-position)（SUB spindle）

[Input type] Parameter input
[Data type] Word spindle
[Unit of data] Detection unit
[Valid data range] Depend on the bit 0 (ORPUNT) of parameter No.4542 setting (Refer to the table below)

Bit 0 (ORPUNT) of No.4542	Valid data range
0	0 to 100
1	0 to 1000

This data is used to set the detecting level of orientation completion signal (ORARA). ORARA is assumed to be 1 if the position error is within the setting.

4077	Stop position shift amount in orientation by a position coder(MAIN spindle)
4228	Stop position shift amount in orientation by a position coder(SUB spindle)

[Input type] Parameter input
[Data type] Word spindle
[Unit of data] Detection unit
[Valid data range] Depend on the bit 0 (ORPUNT) of parameter No.4542 setting (Refer to the table below)

Bit 0 (ORPUNT) of No.4542	Least input increment	Valid data range
0	360/4096= 0.08789	-4095 to 4095
1	360/32768= 0.01098	-32767 to 32767

Each of these parameters specifies a stop position shift amount in orientation by a position coder.
This parameter is valid no matter what the setting of bit 0 (ORT) of parameter No.3729 is.

	#7	#6	#5	#4	#3	#2	#1	#0
4542								ORPUNT

[Input type] Parameter input
[Data type] Bit spindle

#0 ORPUNT Least input increment for Stop position of spindle orientation, Stop position shift amount, In-position width
0: 360/4096 = 0.08789 [deg]
1: 360/32768 = 0.01098 [deg]

> ⚠ **CAUTION**
> In the α*i* position coder, the effect is not achieved by the fine resolution application of stop position because the sensor resolution is 4096p/rev.

> **NOTE**
> To use this function, the corresponding serial spindle software is required.

Alarm and message

Number	Message	Description
SP1258	ILLEGAL SPINDLE PARAMETER SETTING (SOFT)	The parameter is an illegal setting. Check as follows. - Bit 0 (ORPUNT) of parameter No.4542 is set to 1 the spindle control software that does not support this function. Set 0 to the bit 0 (ORPUNT) of parameter No.4542.

Diagnosis data

445	Position data of position coder (pulse)

[Data type] 2-word spindle
[Unit of data] Pulse
[Valid data range] Depend on the bit 0 (ORPUNT) of parameter No.4542 setting (Refer to the table below)

Bit 0 (ORPUNT) of No.4542	Valid data range
0	0 to 4095
1	0 to 32767

In serial spindle, position coder signal pulse data from one-rotation signal is displayed as the spindle position data. It's effective when bit 1 (SPP) of parameter No.3117 is set to 1. For displaying spindle position data, spindle orientation must be executed once.

449	Position data of position coder (angle)

[Data type] Real spindle
[Unit of data] Refer to the table below
[Valid data range] 0 to 359.999[deg]

Diagnosis data No.449 indicates spindle angle from the one-rotation signal when bit 1 (SPP) of parameter No.3117 is set to 1. Spindle angle displays to three decimal places. It is available for serial spindle. To display spindle angle, spindle orientation must be performed once. Unit of spindle angle data is as follows.

Bit 0 (ORPUNT) of No.4542	Unit of data [deg]
0	0.088
1	0.011

NOTE

Once spindle orientation is performed after power-on, position data can be read. To read position data, set bit 1(SPP) of parameter No. 3117 to 1.
(Except when maintenance is performed, bit 1(SPP) of parameter No. 3117 must be set to 0.)

Caution

⚠ CAUTION

1 To perform spindle orientation by using the spindle control unit, the signals of the spindle control unit must be used.
To perform serial spindle orientation by using a position coder (to perform serial spindle orientation with the stop position set externally), the serial spindle control unit signals must be used.
2 When the function of spindle orientation with the stop position set externally is used, the parameters for stop positions in orientation by a position coder (parameters Nos.4031 and 4204) are invalid.
3 In the αi position coder, the effect is not achieved by the fine resolution application of stop position because the sensor resolution is 4096p/rev.
4 The precision for stop position is depended by the specification of sensor.

Note

NOTE
1. Stop position external setting type orientation cannot be used in Magnetic sensor method spindle orientation.
2. Spindle orientation with the spindle positioning function differs from that described in this section. For details, see "Spindle Positioning."

FANUC AC SPINDLE MOTOR αi series PARAMETER MANUAL (B-65280EN)	Position coder method spindle orientation

10.16 SPINDLE OUTPUT SWITCHING

Overview

Spindle output switching switches between the two motor windings, one for low speed and the other for high speed, incorporated into the special spindle motors. This ensures that the spindle motor demonstrates stable output characteristics over a wide range.
Since spindle output switching is a function of the spindle control unit, also refer to the manual for the spindle control unit being used.
This section describes the relationship between spindle output switching and the spindle control function in the CNC.

NOTE
Ladder sequence of the spindle output switching can be easily incorporated by using PMC function. The FANUC LADDER-III CD, function block that can be incorporated easily spindle output switching is stored in the form of a library. For details on library of function block, refer to the documents in the FANUC LADDER-III CD. For details on function block, refer to the PMC PROGRAMMING MANUAL (B-64513EN).

Explanation

- Operation of spindle output-switchable spindle motor

To switch the spindle output characteristics, the windings are usually switched using a relay. Prior to the completion of winding switching, the spindle rotates free from drive power.
Output switching changes the relationship between a speed command, issued from the CNC to the spindle, and the output characteristics of the spindle motor. However, the relationship between the speed command and spindle motor speed is not changed.

- Spindle output switching timing

During actual machining, the spindle is usually controlled in the following way.
(1) Constant spindle speed during cutting, such as milling
(2) Continuously changing spindle speed during cutting, such as in constant surface speed control
(3) Controlling the position loop including the spindle motor during rigid tapping, spindle positioning, Cs contour control, etc.

For applications such as those in (1), we recommend switching the output characteristics for low speed and high speed by using the spindle motor speed detection signal of the spindle control unit.
For applications such as those described in (2) and (3), the spindle must not rotate with no drive power applied during cutting or positioning. It is necessary for the output characteristics to be switched appropriately before machining or for output switching to be masked by using a PMC ladder sequence.

- Output switching and gear switching

Spindle output switching ensures that the spindle motor demonstrates stable characteristics over a wide range, and eliminates the requirement of a mechanical spindle gear switching mechanism.
In creating a PMC ladder sequence for output switching, however, using the gear switching of the CNC's spindle control function may facilitate programming.
Note the following points when using gear switching for CNC spindle control for output switching with a machine tool having no mechanical gear switching mechanism.

- When gear selection output signals, GR1O and GR2O <Fn034.0, 1>, are used (for machining centers in which constant surface speed control is not provided and GTT, bit 4 of parameter No. 3706, is set to 0)
  Set two gears, which are almost the same.
  (Example: Value of parameter No.3741 = value of parameter No.3742 - 1, value of No.3742 = Maximum spindle speed)
  When parameter No.3741 is equal to parameter No.3742, the CNC judges that one gear is used, and does not output the GR2O signal.
- The parameters related to gear switching points, SGT, bit 3 of parameter No.3705, and SGB, bit 2 of parameter No.3705, parameters Nos.3761 and 3751 can be used.
- In usual spindle control, depending on the speed at switching points, the speed specified by the spindle speed command may differ slightly from the actual speed in the area where the maximum spindle speed is set to the maximum speed - 1. (This is because the spindle motor speed, specified by the speed command, is calculated based on the settings of parameters Nos.3741 to 3744.)
  This does not apply to rigid tapping. (Because the machine tool is controlled using the feedback signal from the detector in the position loop.)
- When gear selection input signals, GR1 and GR2 <Gn028.1, 2>, are used (for lathes or machining centers in which constant surface speed control is provided or GTT, bit 4 of parameter No.3706, is set to 1)
  Parameter settings are read according to the input signal information. Unlike the GR2O and GR1O signals, these signals do not require special parameter settings.
  Example)
  When parameters Nos.3741 and 3742 are set to the maximum spindle speed.
  Create a PMC sequence that specifies the following.
  For gear 1, set GR1 and GR2 <Gn028.1, 2> to "0".
  For gear 2, set GR2 <Gn028.2> to "0" and set GR1 <Gn028.1> to "1".
  The PMC must determine the switching timing on the basis of some information.

10.17 SPINDLE COMMAND SYNCHRONOUS CONTROL

Overview

Spindles can be synchronized with each other for control.
Two spindles can be combined, one as a master spindle and the other as a slave spindle, so that Cs contouring control, rigid tapping, spindle positioning, and normal spindle rotation control can also be used with the slave spindle under control by the master spindle.
A master spindle and slave spindle to be placed under spindle command synchronous control can be freely selected from the first to fourth spindles.
Multiple combinations of a master spindle and slave spindle can be placed under spindle command synchronous control.
This function can be used with serial spindles.

Unlike spindle synchronous control, spindle command synchronous control does not guarantee spindle operation synchronization between a master spindle and slave spindle. Moreover, applicable spindle functions differ.
The major differences from spindle synchronous control are indicated below.
For details, see also Section of "SPINDLE SYNCHRONOUS CONTROL".

Function		Spindle command synchronous control	Spindle synchronous control
Combination with other spindle functions	**Spindle rotation control**	∆(Same speed command is used.)	O(Synchronization/phase matching is possible.)
	Cs contour control	O	X
	Rigid tapping	O	X
	Spindle positioning	O	X
Synchronization of multiple combinations		O	O
Synchronization of multiple slave spindles		O	O
Parking function		O	X

Explanation

When the spindle command synchronous control signal ESRSYC<Gn064.6> (ESSYC1-ESSYC4 <Gn264.0>-<Gn264.3> when bit 5 (SSY) of parameter No.3704 is set to 1.) is input from the PMC, the spindle command synchronous control mode is selected.

In spindle command synchronous control, a command for the master spindle also functions as a command for the slave spindle.
The ordinary specification method for a master spindle can be used without modification in the spindle rotation control mode, Cs contouring control mode, rigid tapping mode, and spindle positioning mode.

The parking function can stop each spindle under spindle command synchronous control.

- Configuration of synchronized spindles

In spindle command synchronous control, a spindle that accepts an S command/move command is referred to as a master spindle, and a spindle that ignores a command for itself and performs operation in synchronism with the master spindle is referred to as a slave spindle.

When bit 5 (SSY) of parameter No.3704 is set to 0
The configuration of spindles placed under spindle command synchronous control is as follows:

	Master spindle	**Slave spindle**
Spindle number	First spindle	Second spindle

When bit 5 (SSY) of parameter No.3704 is set to 1
Which slave spindle is placed under spindle command synchronous control with which master spindle is set using parameter No.4821.

	Master spindle	Slave spindle
Spindle number	Second, third, or fourth spindle	First spindle
	First, third, or fourth spindle	Second spindle
	First, second, or fourth spindle	Third spindle
	First, second, or third spindle	Fourth spindle

- When four spindles are involved, two combinations of spindles can be formed for spindle synchronization.
  Example)
    Two combinations are possible: first spindle (master spindle)/second spindle (slave spindle) and third spindle (master spindle)/fourth spindle (slave spindle).

- Multiple slave spindles can be synchronized with one master spindle.
  Example)
    A combination of the first spindle (master spindle)/the second, third, and fourth spindles (slave spindles) is possible.

- A combination that uses a slave spindle as a master spindle is not allowed.

- Operation in each control mode

(1) Spindle rotation control mode
The slave spindle rotates upon the issue of the same command as that used for the master spindle.
The command does not specify the speed of the spindle, instead specifies the ratio of the spindle motor speed to the maximum speed. So, only when the spindle unit configuration of master and slave spindles (parameter settings for a maximum motor speed, motor-spindle gear ratio, and so forth) is the same, the two spindles rotate at about the same speed. (However, the synchronous state is not guaranteed.)
For details of spindle rotation control, see “SPINDLE SPEED CONTROL.”

(2) Cs contour control mode
When the Cs contouring control is used together, Cs contouring control on a slave spindle operating in synchronism with the master spindle is possible. (Control independent of the master spindle is impossible.)
A move command address and position are displayed only for the master spindle.
In reference position return operation, the two spindles are checked for reference position return completion before the reference position return completion signal is turned “1”.
In spindle command synchronous control, switching between the spindle rotation control mode and the Cs contouring control mode is possible.
For details of Cs contouring control, see "Cs CONTOUR CONTROL".

(3) Rigid tapping
When the rigid tapping is selected, the slave spindle supports rigid tapping under the control of a rigid tapping command for the master spindle. (Rigid tapping for the slave spindle cannot be performed independently of the master spindle.)
For details of rigid tapping, see “RIGID TAPPING.”

(4) Spindle positioning
When the spindle positioning is selected, the spindle positioning function for the slave spindle is enabled under the control of a spindle positioning command for the master spindle. (The spindle positioning function for the slave spindle cannot be used independently of the master spindle.)

In the same way as with Cs contour axis control, the display of command address and position data is limited to the master spindle. Operations such as orientation are performed in the same way as usual. However, both spindles are checked for the completion of orientation, and the spindle positioning sequence is processed only after the completion of positioning by both spindles has been confirmed.
For details of spindle positioning, see “SPINDLE POSITIONING.”

- Parking function

The parking function stops the rotation and movement of each of master and slave spindles placed in the spindle command synchronous control mode, regardless of the spindle control mode (spindle rotation control, Cs contouring control, rigid tapping, or spindle positioning).
In the parking state, the spindle is placed in the following state, depending on its mode:

Spindle rotation control mode:
Rotation is stopped in the same way as when S0 is specified.
Other modes:
Movement is stopped in the same way as in the case of no distribution pulse.

With a move command for positioning of a Cs contouring control axis or spindle in the parking state, only the movement of the spindle in the parking state is stopped by updating the coordinate system.

Reference position return operation for a Cs contouring control axis and spindle orientation operation for spindle positioning are disabled for a spindle placed in the parking state.
If reference position return operation in the Cs contouring control mode or spindle orientation in the spindle positioning mode is specified with one spindle placed in the parking state, the reference position return completion signal is turned “1” when the spindle not placed in the parking state has completed a reference position return operation.

The parking function stops the movement of only a spindle that is placed in the parking state. So, the parking function can be used, for example, to continue machining by stopping one spindle no longer required or to perform Cs contouring control, rigid tapping, and spindle positioning with the slave spindle by placing the master spindle in the parking state.

NOTE

1 In the spindle command synchronous control mode, the two spindles are checked for a position error at all times, regardless of the parking state. The excessive error alarm (SV0410 or others) is issued when a spindle has moved due to a load from the position where the spindle was stopped by the parking function.
2 The parking function stops the movement of only a spindle that is placed in the parking state. So, if parking is applied to a spindle after a reference position return operation or spindle orientation operation is once performed, the spindle position is shifted from the machine coordinates. Until another reference position return operation or spindle orientation operation is performed after parking is canceled, the relationship between the spindle position and machine coordinates is not guaranteed.
3 The parking signal becomes immediately valid in the spindle command synchronous control mode. However, even if the parking signal is input during reference position return operation in the Cs contouring control mode or during spindle orientation operation in the spindle positioning mode, the reference position return operation or spindle orientation operation continues until it is completed. Parking starts immediately after completion of such an operation.

> **NOTE**
>
> 4 Do not specify a reference position return operation in the Cs contouring control mode or a spindle orientation operation in the spindle positioning mode while the two spindles are placed in the parking state. When the two spindles are placed in the parking state, the reference position return operation cannot be completed.
>
> 5 When using parking signal PK7 or PK8 for spindle synchronous control while both spindle command synchronous control and spindle synchronous control are being used, set the SPK bit (bit 7 of parameter No.4800) to 1. This sets parking signals PKESS1 and PKESS2, used for spindle command synchronous control, to bits 6 and 7 of G031.

- Simple spindle synchronization and phase error monitor signal

Spindle command synchronous control does not guarantee synchronous spindle operation. In spindle control involving a position loop as in the case of Cs contouring control, rigid tapping, and spindle positioning, however, the synchronous state of the two spindles can be maintained by matching the position gains of the two spindles.

For monitoring of the synchronous state of two spindles in such a case, the phase error monitor signal SYCAL<Fn044.4> is available. The error between two spindles is monitored at all times. When a synchronization error exceeding the value set in parameter No.4826 is detected, this signal is set to “1”. When a synchronization error not exceeding the value set in parameter No.4826 is detected, this signal is set to 0.

In the spindle rotation control mode, however, synchronous state monitoring is not performed. So, the phase error monitor signal has no effect, and is set to 0 at all times.

Note that even if phase error monitor signal SYCAL is output, no CNC alarm is issued. This signal is designed to be used by the PMC to monitor the machine synchronization state. Its usage varies depending on the machine tool builder. The use of this signal is not mandatory.

> **NOTE**
>
> During spindle command synchronous control, a reference position return operation in the Cs contouring control mode, a spindle orientation operation in the spindle positioning mode, or a function (such as spindle orientation) that is directly specified for a spindle with a PMC signal is performed for each spindle independently, so that synchronization is not guaranteed.

- Relationship between spindle command synchronous control and spindle synchronous control

The spindle synchronous control mode and the spindle command synchronous control mode cannot be selected for the same spindle at the same time.
In a mode other than spindle synchronous control mode, no restriction is imposed on the selection timing of spindle command synchronous control. Usually, select spindle command synchronous control when the master spindle is not executing a move command in the spindle rotation control mode or in the Cs contouring control mode.
No restriction is imposed on the timing of spindle command synchronous control cancellation. Usually, cancel spindle command synchronous control when no command is executed in any spindle control mode. When spindle command synchronous control is canceled, the mode of the slave spindle switches to the spindle rotation control mode. The master spindle maintains the selected spindle control mode.

The table below indicates the spindle control mode switching of the master and slave spindles based on the transitions of the spindle command synchronous control signal and spindle synchronous control signal.

Spindle control mode switching	Switching when the spindle command synchronous control signal makes a transition from “0” to “1” in each spindle control mode selection state			
Master spindle	SP → SP(ESY)	CT → CT(ESY)	SV → SV(ESY) Note 3	SY → SY Note 4
Slave spindle	SP → SP(ESY) Note 1	SP → CT(ESY) Note 2	SP → SV(ESY) Note 3	SY → SY Note 4

Spindle control mode switching	Switching when the spindle command synchronous control signal makes a transition from “1” to “0” in each spindle command synchronous control mode selection state		
Master spindle	SP(ESY) → SP	CT(ESY) → CT	SV(ESY) → SV
Slave spindle	SP(ESY) → SP	CT(ESY) → SP	SV(ESY) → SP

Spindle control mode switching	Switching when the spindle synchronous control signal makes a transition from “0” to “1” in each spindle command synchronous control mode selection state		
Master spindle	SP(ESY) → SP(ESY) Note 4	CT(ESY) → CT(ESY) Note 4	SV(ESY) → SV(ESY) Note 4
Slave spindle	SP(ESY) → SP(ESY) Note 4	CT(ESY) → CT(ESY) Note 4	SV(ESY) → SV(ESY) Note 4

The symbols used in the tables above have the following meanings:

SP : Spindle rotation control mode
CT : Cs contour control mode
SV : Rigid tapping mode or spindle positioning mode
SP(ESY) : Spindle rotation control mode during spindle command synchronous control
CT(ESY) : Cs contouring control mode during spindle command synchronous control
SV(ESY) : Rigid tapping or spindle positioning mode during spindle command synchronous control
SY : Spindle synchronous control mode

NOTE

1. After initialization to the spindle rotation control mode, operation is performed with a speed command for the master spindle. So, a speed change can occur.
2. Even if the master spindle is already at the reference position, the slave spindle is not at the reference position yet when the mode of the slave spindle is just switched to the Cs contouring control mode by spindle command synchronous control. So, perform a reference position return operation again.
3. When the master spindle is placed in the rigid tapping or spindle positioning mode, the input of the spindle command synchronous control signal is masked in the CNC, so that the mode is not switched to the spindle command synchronous control mode. After the rigid tapping or spindle positioning mode of the master spindle is canceled, the master spindle and slave spindle are placed in the spindle command synchronous control mode. After the spindle command synchronous control mode is once set, the specification or cancellation of the rigid tapping or spindle positioning mode of the master spindle is applied to both of the master spindle and slave spindle.
4. The spindle control mode currently selected is maintained. As an alarm indicating that the spindle control mode is not switched, alarm PS0194, “SPINDLE COMMAND IN SYNCHRO-MODE” is displayed. This alarm can be cleared by resetting the signal input later to “0”.

> **NOTE**
> 5 Switch to the spindle command synchronous control mode when the slave spindle is placed in the spindle rotation control mode.
> 6 For the slave spindle placed in the spindle command synchronous control mode, the switching to a spindle mode such as Cs contouring control, rigid tapping, spindle positioning, and spindle synchronous control cannot be specified.

- Spindle rotation direction

In the spindle command synchronous control mode, the same speed command and move command are issued to the master spindle and slave spindle.
The specified rotation direction of a spindle can be changed using a PMC signal (spindle forward/reverse rotation command signal SFR or SRV) or serial spindle parameter according to the control mode.

- Position deviation check and alarm display

When spindle command synchronous control is used in a mode other than the spindle rotation control mode, the master spindle and slave spindle are checked for a position deviation.
An in-position check is made to see if the position deviation of each of the two spindles is within a parameter-set range.
Position deviation excessive error checks at stop time and move time are made to see if the position deviation of each spindle exceeds a parameter-set value.
The parameters set for the master spindle are used for both spindles.
An alarm for an excessive error is displayed for the master spindle. Which of the master spindle and slave spindle has entered the excessive error state cannot be identified on the screen.

Limitation

- Both of the master spindle and slave spindle must have hardware such as a spindle-related detector required for the functions (Cs contouring control, rigid tapping, and spindle positioning) that use spindle command synchronous control.

Diagnosis data

418	Position deviation of each spindle

When spindles are involved in a position loop, the position deviation of each spindle is indicated.
The unit is pulses. The detection unit per pulse varies from one spindle control mode to another.

425	Synchronization error of each spindle

The absolute value of the synchronization error of each spindle in spindle command synchronous control is indicated.
A synchronization error is indicated with a slave spindle.
In the spindle rotation control mode, the synchronization error is 0 at all times.

Spindle tuning screen

In the spindle command synchronous control mode, the display dedicated to the spindle command synchronous control mode is not provided. Instead, a spindle control mode selected in the spindle command synchronous control mode is displayed.
When the Cs contouring control mode is set in spindle command synchronous control, the Cs contouring control mode is displayed.
For details, refer to Spindle tuning screen of MAINTENANCE MANUAL (B-64695EN).

Signal

Spindle command synchronous control signal ESRSYC<Gn064.6>

[Classification] Input signal

[Function] This signal specifies switching to the spindle command synchronous control mode for the first/second spindles.

[Operation] When this signal is set to “1”, the spindle command synchronous control mode for the first/second spindles is set.
When this signal is set to “0”, the spindle command synchronous control mode for the first/second spindles is canceled.
This signal is valid only when bit 5 (SSY) of parameter No.3704 is set to 0.

Spindle command synchronous control signal for each spindle
ESSYC1<Gn264.0> : For first spindle
ESSYC2<Gn264.1> : For second spindle
ESSYC3<Gn264.2> : For third spindle
ESSYC4<Gn264.3> : For fourth spindle

[Classification] Input signal

[Function] These signals specify switching to the spindle command synchronous control mode for each spindle.

[Operation] When each of these signals is set to “1”, the spindle command synchronous control mode with the corresponding spindle set as a slave spindle is set.
When each of these signals is set to “0”, the spindle command synchronous control mode with the corresponding spindle set as a slave spindle is canceled.
When ESSYC1 is set to “1”: Spindle command synchronous control with the first spindle set as a slave spindle is exercised.
When ESSYC2 is set to “1”: Spindle command synchronous control with the second spindle set as a slave spindle is exercised.
When ESSYC3 is set to “1”: Spindle command synchronous control with the third spindle set as a slave spindle is exercised.
When ESSYC4 is set to “1”: Spindle command synchronous control with the fourth spindle set as a slave spindle is exercised.
These signals are valid only when bit 5 (SSY) of parameter No.3704 is set to 1.
Which spindle is synchronized with which spindle is set using parameter No.4821.

First spindle command synchronous parking signal
PKESS1<Gn122.6> or PKESS1<Gn031.6>

[Classification] Input signal

[Function] This signal parks the first spindle in spindle command synchronous control.

[Operation] When this signal is set to “1”, the first spindle is placed in the parking state.
When this signal is set to “0”, the parking state of the first spindle is canceled.
When bit 7 (SPK) of parameter No.4800 is set to 1, <Gn031.6> is used.
This signal is valid only when bit 5 (SSY) of parameter No.3704 is set to 0.

Second spindle command synchronous parking signal
PKESS2<Gn122.7> or PKESS2<Gn031.7>

[Classification] Input signal

[Function] This signal parks the second spindle in spindle command synchronous control.

[Operation] When this signal is set to “1”, the second spindle is placed in the parking state.
When this signal is set to “0”, the parking state of the second spindle is canceled.
When bit 7 (SPK) of parameter No.4800 is set to 1, <Gn031.7> is used.
This signal is valid only when bit 5 (SSY) of parameter No.3704 is set to 0.

Spindle command synchronous parking signal for each spindle
PKESE1<Gn265.0> : For first spindle
PKESE2<Gn265.1> : For second spindle
PKESE3<Gn265.2> : For third spindle
PKESE4<Gn265.3> : For fourth spindle

[Classification] Input signal

[Function] These signals park each spindle in spindle command synchronous control.

[Operation] When each of these signals is set to “1”, the corresponding spindle is placed in the parking state.
When each of these signals is set to “0”, the parking state of the corresponding spindle is canceled.
When PKESE1 is set to “1”: The first spindle is placed in the parking state.
When PKESE2 is set to “1”: The second spindle is placed in the parking state.
When PKESE3 is set to “1”: The third spindle is placed in the parking state.
When PKESE4 is set to “1”: The fourth spindle is placed in the parking state.
This signal is valid only when bit 5 (SSY) of parameter No.3704 is set to 0.

Phase error monitor signal SYCAL<Fn044.4>

[Classification] Output signal

[Function] This signal posts that in the spindle command synchronous control mode for the first/second spindles, the error pulse difference between the two spindles is greater than a parameter-set value.

[Output cond.] This signal is set to “1” in the following case:
- In the spindle command synchronous control mode, the error pulse difference between two spindles is greater than the value set in parameter No.4826 after spindle command synchronous control is completed.

This signal is set to “0” in the following cases:
- The spindle command synchronous control mode is not set.
- In the spindle command synchronous control mode, the error pulse difference between two spindles is equal to or less than the value set in parameter No.4826.

This signal is valid only when bit 5 (SSY) of parameter No.3704 is set to 0.

Phase error monitor signal for each spindle
SYCAL1<Fn043.0> : For first spindle
SYCAL2<Fn043.1> : For second spindle
SYCAL3<Fn043.2> : For third spindle
SYCAL4<Fn043.3> : For fourth spindle

[Classification] Output signal

[Function] These signals post that in the spindle command synchronous control mode with each spindle set as a slave spindle, the error pulse difference between two spindles is greater than a parameter-set value.

[Output cond.] Each of these signals is set to “1” in the following case:
- In the spindle command synchronous control mode, the error pulse difference between two spindles is greater than the value set in parameter No.4826 after spindle command synchronous control is completed.

Each of these signals is set to “0” in the following cases:
- The spindle command synchronous control mode is not set.
- In the spindle command synchronous control mode, the error pulse difference between two spindles is equal to or less than the value set in parameter No.4826.

These signals are valid only when bit 5 (SSY) of parameter No.3704 is set to 1.

Even in the spindle command synchronous control mode, the signals that need to be input/output or are used to control those functions (such as spindle orientation) directly specified from the PMC for the spindle control unit are provided independently for each spindle.
For first spindle : (DI:G0070 to G0073, DO:F0045 to F0048)
For second spindle: (DI:G0074 to G0077, DO:F0049 to F0052)
For third spindle : (DI:G0204 to G0207, DO:F0168 to F0171)
For fourth spindle : (DI:G0266 to G0269, DO:F0266 to F0269)
When using the spindle command synchronous control function, exercise control on the spindle command synchronous control signals and also manipulate the signals for each spindle as required.
(Such a signal state that the master spindle and slave spindle under spindle command synchronous control can make the same movement needs to be set.)

> **NOTE**
> In the spindle command synchronous control mode, the states of both the master spindle and slave spindle are checked. So, if spindle command synchronous control is specified in the Cs contouring control mode before the slave spindle is not activated yet, for example, the VRDY OFF alarm may be issued. Pay attention to control on the PMC signals for the slave spindle as well.

Signal address

	#7	#6	#5	#4	#3	#2	#1	#0
Gn031	PKESS2	PKESS1						
Gn064		ESRSYC						
Gn122	PKESS2	PKESS1

3704			SSY					

[Input type] Parameter input
[Data type] Bit path

> **NOTE**
> When this parameter is set, the power must be turned off before operation is continued.

#5 SSY Simple synchronous spindle control by each spindle is:
0: Not performed.
1: Performed.
The master axis and slave axis of simple synchronous spindle control can be selected from the arbitrary spindles.

The target spindle of simple synchronous spindle control is set in parameter No. 4821.
In addition, the following signals affect the control.

- Signals of simple synchronous control of each spindle ESSYCs
- Parking signals of simple synchronous control of each spindle PKESEs

	#7	#6	#5	#4	#3	#2	#1	#0
4800	SPK	EPZ						

[Input type] Parameter input
[Data type] Bit

> **NOTE**
> When at least one of these parameters is set, the power must be turned off before operation is continued.

#6 EPZ When the parking signal is switched in the reference position established state during Cs contour control exercised using spindle command synchronous control:
0: Reference position established state is continued.
1: Reference position established state is canceled.
If this parameter is set, the same reference position return operation as manual reference position return is performed with the G28 command immediately after the parking signal is switched.
The G00 command performs a positioning operation including reference position return (when bit 1 (NRF) of parameter No.3700 is set to 0).

#7 SPK As the parking signals for spindle command synchronous control:
0: PKESS1<Gn122.6> (first spindle) and PKESS2<Gn122.7> (second spindle) are used.
1: PKESS1<Gn031.6> (first spindle) and PKESS2<Gn031.7> (second spindle) are used.

> **NOTE**
> 1 This parameter is valid only when bit 5 (SSY) of parameter No. 3704 is set to 0.
> 2 If the parking signals PK7 and PK8 for synchronization control are used when spindle command synchronous control and synchronization control are used at the same time, set bit 7 (SPK) of parameter No.4800 to 1 to use the parking signals PKESS1 and PKESS2 for spindle command synchronous control as <Gn031.6,Gn031.7>.

	#7	#6	#5	#4	#3	#2	#1	#0
3716								A/Ss

[Input type] Parameter input

> When this parameter is set, the power must be turned off before operation is continued.

#0 A/Ss Spindle motor type is :
0: Analog spindle.

1: Serial spindle.

3717	Spindle amplifier number to each spindle

> **NOTE**
> When this parameter is set, the power must be turned off before operation is continued.

[Input type] Parameter input
[Data type] Byte spindle
[Valid data range] 0 to Maximum number of controlled axes

Set a spindle amplifier number to be assigned to each spindle.

0: No spindle amplifier is connected.
1: Spindle motor connected to amplifier number 1 is used.
2: Spindle motor connected to amplifier number 2 is used.
to
n: Spindle motor connected to amplifier number n is used.

4821	Master axis of each slave spindle under simple synchronous spindle control

> **NOTE**
> When this parameter is set, the power must be turned off before operation is continued.

[Input type] Parameter input
[Data type] Byte spindle
[Valid data range] 0 to Maximum number of controlled spindle axes (within a path)

When a spindle is set as a slave spindle in spindle command synchronous control on each spindle, set which spindle (master spindle) the slave spindle is to be synchronized with.

[Examples of parameter setting]

- When spindle command synchronous control is exercised with the first spindle selected as a master spindle and the second spindle selected as a slave spindle:
  No.4821(1)=0
  No.4821(2)=1
  No.4821(3)=0
  No.4821(4)=0

- When spindle command synchronous control is exercised with four spindles under the following combinations:
  (Two combinations, namely, first spindle (master spindle)/ second spindle (slave spindle), and third spindle (master spindle)/fourth spindle (slave spindle))
  No.4821(1)=0
  No.4821(2)=1
  No.4821(3)=0
  No.4821(4)=3

NOTE
1 This parameter is valid if bit 5 (SSY) of parameter No.3704 is set to 1.
2 The setting of a slave spindle as a master spindle is invalid. Be sure to set 0 for a spindle that is to function as a master spindle.
3 In this parameter, set a spindle number within the same path.

4826	Allowable error count for the error pulses between two spindles in the simple synchronization spindle control mode

[Input type] Parameter input
[Data type] Word spindle
[Unit of data] Detection unit
[Valid data range] 0 to 32767

Set the allowable error count for the error pulses between two spindles in the simple synchronization spindle control mode.
This parameter is used to check a spindle synchronization error phase difference.
When a spindle synchronization error equal to or greater than the value set in this parameter is detected, the spindle phase error monitor signals SYCAL<Fn044.4> and SYCALs are set to “1”.

NOTE
1 The detection unit per pulse depends on the spindle control mode (Cs contour control, rigid tapping, or spindle positioning).
2 Set this parameter for a spindle that is to function as a slave spindle. Set 0 for the master spindle.
3 In the spindle rotation control mode, synchronization error detection is not performed.

Alarm and message

Number	Message	Description
PS0194	SPINDLE COMMAND IN SYNCHRO-MODE	A Cs contour control mode, spindle positioning command, or rigid tapping mode was specified during the spindle synchronous control mode or spindle command synchronous control mode.

Caution

⚠ **CAUTION**
1 As an output signal for monitoring a phase error during spindle command synchronous control, the phase error monitor signal SYCAL is available. The action to be taken when a phase error is detected depends on the specifications of the machine tool builder.
2 In multi-path control, spindle command synchronous control cannot be exercised on spindles each belonging to a different path.

Reference item

For details of the parameters Nos.4000 to 4539, signals, and alarms for the serial spindle control unit, refer to the manuals related to serial spindles listed below.
FANUC AC SPINDLE MOTOR α*i* series PARAMETER MANUAL (B-65280EN)

10.18 SPINDLE COMMAND SYNCHRONOUS CONTROL INDEPENDENT PITCH ERROR COMPENSATION FUNCTION

Overview

When Cs contouring control axes are placed under spindle command synchronous control, pitch error compensation can be exercised on the master spindle and slave spindle independently of each other.

With the bi-directional pitch error compensation option, bi-directional pitch error compensation can also be enabled.

Explanation

When the master spindle is exercising Cs contouring control in spindle command synchronous control, the slave spindle is also placed in the Cs contouring control mode.
An address and position related to a move command are displayed only for the master spindle, and the slave spindle performs the same operation as specified by the move command for the master spindle. The same pitch error compensation as applied to the master spindle is applied to the slave spindle.
The same timing and compensation amount of pitch error compensation are used for the master spindle and slave spindle.

A pitch error compensation amount different from that for the master spindle can be applied to the slave spindle by setting bit 1 (EPC) of parameter No.3601 to 1 and setting the parameters for the slave spindle (pitch error compensation reference position compensation number, minus side compensation point number, and plus side compensation point number) and pitch error compensation data for the slave spindle.
The same timing of pitch error compensation application is applied to the master spindle and slave spindle.
The parameter settings of a pitch error compensation interval and compensation magnification for the master spindle are valid.
Pitch error compensation point numbers specific to the slave spindle are required in addition to those used for the master spindle.

When bi-directional pitch error compensation is used, a different type of pitch error compensation can be applied to a movement in each of the positive and negative directions.

- Example of setting spindle command synchronous control independent pitch error compensation)

- Parameter setting

Parameter number	Description	Setting value
3601#1	Enable independent pitch error compensation for Cs contouring control axes	1
3620	Reference position compensation number (master spindle)	60
3621	Minus side compensation point number (master spindle)	61
3622	Plus side compensation point number (master spindle)	68
3623	Compensation magnification (common)	2
3624	Compensation point interval (common)	45000
3661 (slave spindle number)	Reference position compensation number (slave spindle)	69
3666 (slave spindle number)	Minus side compensation point number (slave spindle)	70
3671 (slave spindle number)	Plus side compensation point number (slave spindle)	77

- Pitch error compensation data (master spindle side)

Compensation number	60	61	62	63	64	65	66	67	68
Setting value	+1	-2	+1	+3	-1	-1	-3	+2	+1
Compensation value	+2	-4	+2	+6	-2	-2	-6	+4	+2

- Pitch error compensation data (slave spindle side)

Compensation number	69	70	71	72	73	74	75	76	77
Setting value	+3	+2	+4	-3	-4	-6	+4	0	+3
Compensation value	+6	+4	+8	-6	-8	-12	+8	0	+6

Suppose that the settings above are made. When the master spindle under spindle command synchronous control outputs the compensation pulses (+2) of compensation number 60, for example, the compensation pulses (+6) of compensation number 69 are output to the slave spindle.

Parameter

	#7	#6	#5	#4	#3	#2	#1	#0
3601							EPC	

[Input type] Parameter input
[Data type] Bit path

> **NOTE**
> When this parameter is set, the power must be turned off before operation is continued.

#1 EPC The pitch error compensation on an axis of Cs contour control on the slave spindle side during simple synchronous spindle control is:
0: The same as that on the master spindle.
1: Just for the slave spindle.

3661	Number of a pitch error compensation position for the reference position for each slave axis when independent pitch error compensation is performed under spindle command synchronous control

> **NOTE**
> When this parameter is set, the power must be turned off before operation is continued.

[Input type] Parameter input
[Data type] Word spindle
[Valid data range] 0 to 1535
Set the number of a pitch error compensation position for the reference position.

> **NOTE**
> 1 This parameter is valid if pitch error compensation on an axis of Cs contour control on the salve side during simple synchronous spindle control is carried out just for the slave axis (bit 1 (EPC) of parameter No.3601 is set to 1).
> 2 The usable number of pitch error compensation positions and their range depend on the option configuration.

3666	Number of the pitch error compensation position at extremely negative position for each slave axis when independent pitch error compensation is performed under spindle command synchronous control

NOTE
When this parameter is set, the power must be turned off before operation is continued.

[Input type] Parameter input
[Data type] Word spindle
[Valid data range] 0 to 1535

Set the compensation position number at the farthest end in the negative direction.

NOTE
1. This parameter is valid if pitch error compensation on an axis of Cs contour control on the salve side during simple synchronous spindle control is carried out just for the slave axis (bit 1 (EPC) of parameter No.3601 is set to 1).
2. When using the both-direction pitch error compensation function, set a compensation position number for a movement in the positive direction.
3. The usable number of pitch error compensation positions and their range depend on the option configuration.

3671	Number of the pitch error compensation position at extremely positive position for each slave axis when independent pitch error compensation is performed under spindle command synchronous control

NOTE
When this parameter is set, the power must be turned off before operation is continued.

[Input type] Parameter input
[Data type] Word spindle
[Valid data range] 0 to 1535

Set the compensation position number at the farthest end in the positive direction.

NOTE
1. This parameter is valid if pitch error compensation on an axis of Cs contour control on the salve side during simple synchronous spindle control is carried out just for the slave axis (bit 1 (EPC) of parameter No.3601 is set to 1).
2. When using the both-direction pitch error compensation function, set a compensation position number for a movement in the positive direction.
3. The usable number of pitch error compensation positions and their range depend on the option configuration.

3676	Number of the pitch error compensation position at extremely negative position for each slave axis when independent both-direction pitch error compensation is performed under spindle command synchronous control

NOTE
When this parameter is set, the power must be turned off before operation is continued.

[Input type] Parameter input
[Data type] Word spindle
[Valid data range] 0 to 1535

When using both-direction pitch error compensation, set the compensation position number at the farthest end in the negative direction for a movement in the negative direction.

NOTE
1 This parameter is valid if pitch error compensation on an axis of Cs contour control on the salve side during simple synchronous spindle control is carried out just for the slave axis (bit 1 (EPC) of parameter No.3601 is set to 1).
2 The usable number of pitch error compensation positions and their range depend on the option configuration.

3681	Pitch error compensation value at the reference position when a movement is made to the reference position in the direction opposite to the reference position return direction for each slave axis in the case where independent both-direction pitch error compensation is performed under spindle command synchronous control

NOTE
When this parameter is set, the power must be turned off before operation is continued.

[Input type] Parameter input
[Data type] Word spindle
[Valid data range] -32767 to 32767

By using an absolute value, set a pitch error compensation value at the reference position when a movement is made in the negative direction if the reference position return direction (bit 5 (ZMI) of parameter No.1006) is positive or when a movement is made in the positive direction if the reference position return direction (bit 5 (ZMI) of parameter No.1006) is negative.

NOTE
This parameter is valid if pitch error compensation on an axis of Cs contour control on the salve side during simple synchronous spindle control is carried out just for the slave axis (bit 1 (EPC) of parameter No.3601 is set to 1).

Caution

Usable numbers and ranges of pitch error compensation points

Option configuration	Number of pitch error compensation points	Pitch error compensation range
Stored type pitch error compensation only	1536	0 to 1535

Option configuration	Number of pitch error compensation points	Pitch error compensation range
Stored type pitch error compensation + bi-directional pitch error compensation	3072	0 to 1535 3000 to 4535 (Note)

NOTE
Such a setting that the data of one axis extends beyond a pitch error compensation range is prohibited.

Example) A setting that extends from 1535 to 3000 is prohibited.

10.19 SPINDLE SPEED FLUCTUATION DETECTION

Overview

With this function, an overheat alarm OH0704, "OVERHEAT:SPINDLE" is raised and the spindle speed fluctuation detection alarm signal SPAL is issued when the spindle speed deviates from the specified speed due to machine conditions.
This function is useful, for example, for preventing the seizure of the guide bushing.
G26 enables spindle speed fluctuation detection.
G25 disables spindle speed fluctuation detection.

Explanation

The function for detecting spindle speed fluctuation checks whether the actual speed varies for the specified speed or not. Si or Sr, whichever is greater, is taken as the allowable fluctuation speed (Sm). An alarm OH0704 "OVERHEAT:SPINDLE" is activated when the actual spindle speed varies for the commanded speed (Sc) under the condition that the variation width exceeds the allowable variation width (Sm).

$|Sc - Sa| > Sm$

Sc : Specified spindle speed
Sa : Actual spindle speed
Si : The allowable constant variation width which is independent of the specified spindle speed (parameter No.4913)
Sr : The allowable variation width which is obtained by multiplying Sc (commanded spindle speed) by r (constant ratio) (r = parameter No.4912)

Bit 0 (FLR) of parameter No. 4900 = 0	Bit 0 (FLR) of parameter No. 4900 = 1
$Sr = Sc \times \frac{r}{100}$	$Sr = Sc \times \frac{r}{1000}$

Sm: Si or Sr, whichever is greater

- Conditions to start spindle speed fluctuation detection

If the specified spindle speed Sc changes, spindle speed fluctuation detection starts when one of the conditions below is met.
If bit 7 (FDTs) of parameter No.4900 is 1, spindle speed fluctuation detection starts when condition (2) is met.

(1) The actual spindle speed falls in a range of (Sc - Sq) to (Sc + Sq)
Sc : Specified spindle speed
Sq : Tolerance within which the spindle is assumed to attain the programmed speed (parameter No.4911)

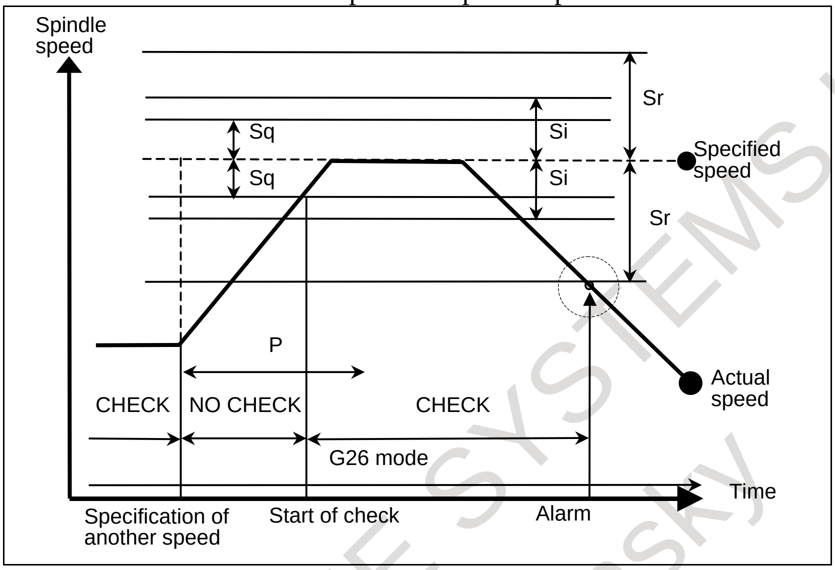
Bit 0 (FLR) of parameter No. 4900= 0	Bit 0 (FLR) of parameter No. 4900= 1
$Sq = Sc \times \frac{q}{100}$	$Sq = Sc \times \frac{q}{1000}$

(2) When time p specified in parameter No.4914 elapses after the specified speed Sc changes.

- Examples of spindle speed fluctuation detection

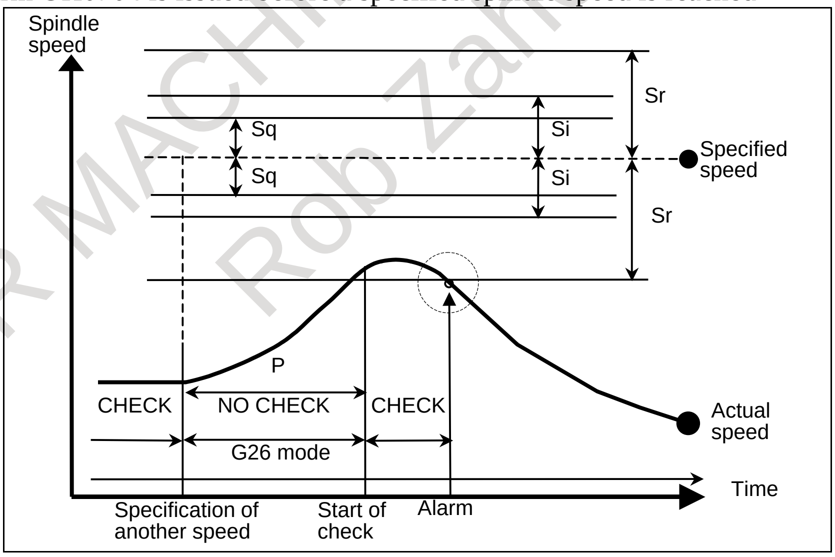
(Example 1)

When an alarm OH0704 is issued after a specified spindle speed is reached



(Example 2)

When an alarm OH0704 is issued before a specified spindle speed is reached



Specified speed : (Speed specified by address S and five-digit value) × (spindle override)

Actual speed : Speed detected with a position coder

p : Period after a change occurs in the actual spindle speed until detection starts
Parameter No.4914, address P

Sq : (Specified spindle speed) × (Detection start tolerance (q))
Parameter No.4911, address Q

Bit 0 (FLR) of parameter No. 4900 = 0	Bit 0 (FLR) of parameter No. 4900 = 1
$\frac{q}{100}$	$\frac{q}{1000}$

Sr : (Specified spindle speed) × (Allowable variation (r))
Parameter No.4912, address R

Bit 0 (FLR) of parameter No. 4900 = 0	Bit 0 (FLR) of parameter No. 4900 = 1
$\frac{r}{100}$	$\frac{r}{1000}$

Si : Allowable variation width
Parameter No.4913, address I

If the difference between the specified speed and actual speed exceeds both Sr and Si, an alarm OH0704 is raised.

- Relationship between spindle speed control and each spindle

Spindle / Function	Serial spindle			
	1st spindle	2nd spindle	3rd spindle	4th spindle
Spindle speed fluctuation detection	Possible	Possible(*1)	Possible(*1)	Possible(*1)

Spindle / Function	Analog spindle			
	1st spindle			
Spindle speed fluctuation detection	Possible			

NOTE

1 Please enable the multi spindle control (bit 3 (MSP) of parameter No.8133 is 1).

2 The spindle speed fluctuation detection function is effective for a single spindle. The function cannot be executed for two or more spindles.
The spindle speed fluctuation detection function is effective for a spindle on which the currently selected position coder is mounted. Just a single position coder can be selected. Multiple position coders cannot be selected. For the selection of a position coder, see the section of "Multi-spindle control."
* Position coder selection signals (PC2SLC<Gn028.7>, PC3SLC<Gn026.0>, PC4SLC<Gn026.1>)

3 The parameters that become valid are the parameters of the spindle speed fluctuation detection function (No.4911, No.4912, No.4913, No.4914) for the spindle on which the currently selected position coder is mounted.

- Spindle that can be subjected to the spindle speed fluctuation detection function, depending on the relationship between system configuration and spindle

The table below show some examples explaining the spindle to be subjected to the spindle speed fluctuation detection function, depending on the system configuration and spindle assignment.

NOTE

1 If path control is performed, the spindle speed fluctuation detection function is carried out for the axis on which the currently selected position coder is mounted.
* Position coder selection signals (PC2SLC<Gn028.7>, PC3SLC<Gn026.0>, PC4SLC<Gn026.1>)

2 Under multi-path control, if the feedback pulse of a position coder mounted on a spindle belonging to a path is used, the selected path feedback must be considered in addition to the selection of the position coder. Great attention should be given to the selection statuses of relative signals.
* Path spindle feedback selection signals (SLPCA<Gn064.2>, SLPCB<Gn064.3>, SLPCC<Gn403.4>, SLPCD<Gn403.5>)

> **NOTE**
> 3 It is assumed that the reader has understood the individual functions described in this manual. If necessary, see the sections of "spindle control for each path," "spindle control," and "multi-spindle control."

Examples of spindles subjected to detection

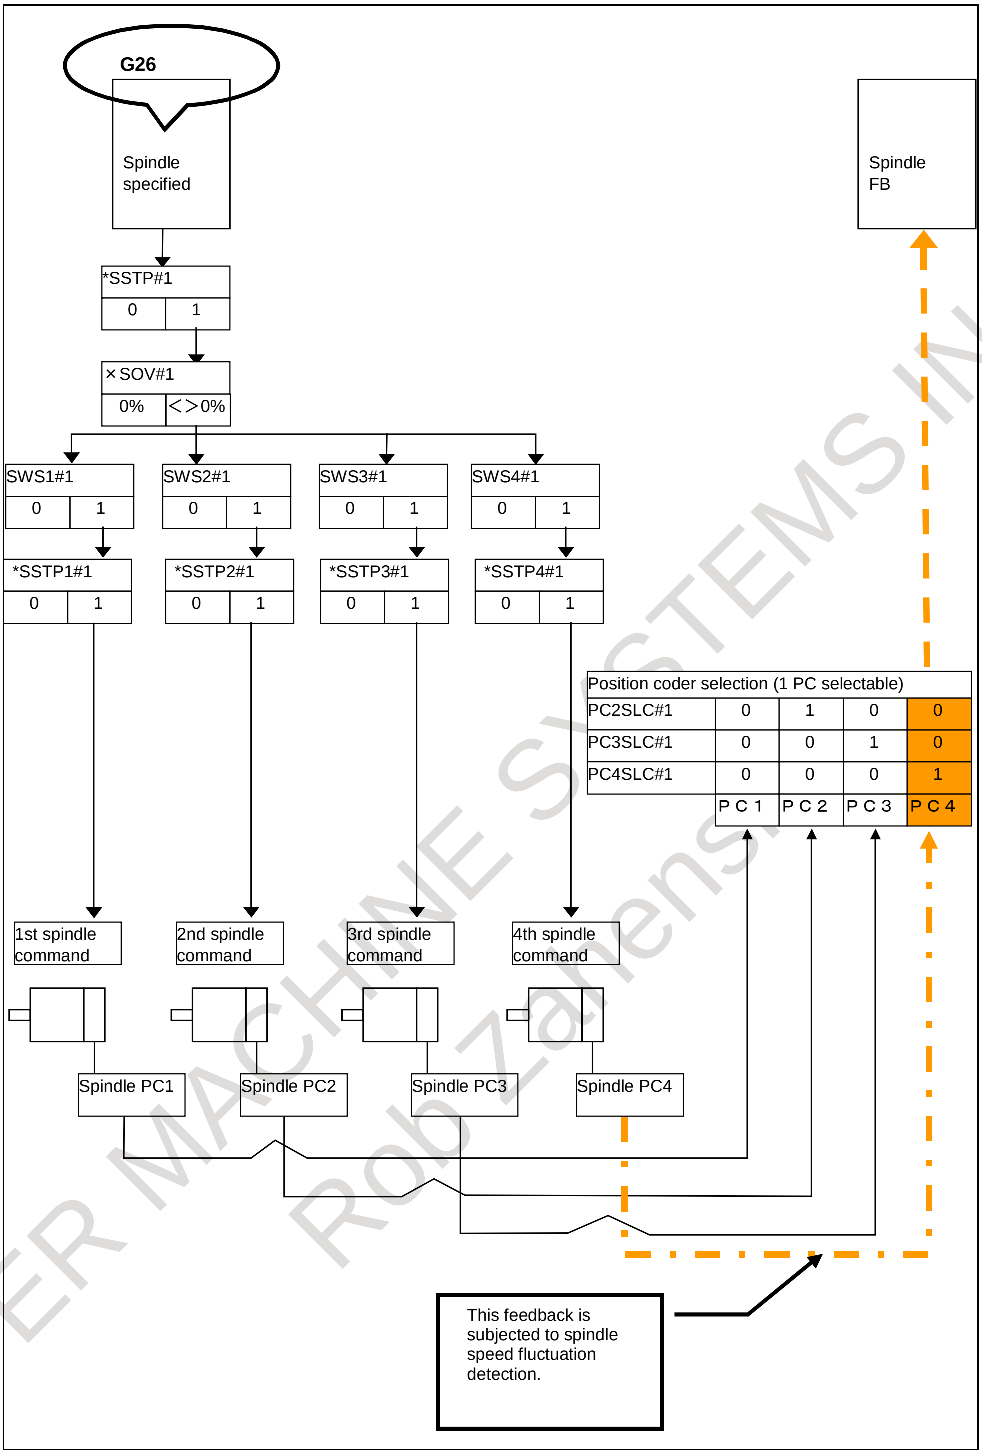
- Specified spindle : Indicates which path is specifying which spindle.
- Feedback pulse : Indicates the contents of the feedback pulse to be used, depending on a selected position coder.
- Feedback subjected to detection : Indicates the feedback subjected to the spindle speed fluctuation detection function.
- G26 : Indicates whether the spindle speed fluctuation detection function is enabled in which path.
- Detection : Indicates whether spindle speed fluctuation detection is possible in which path.

System configuration	Path	Specified spindle	Feedback pulse	Feedback subjected to detection	G26 (Multi-path)	Detection
Single path control + Non-multi-spindle control +1 spindle	—	Address S → 1st spindle	Feedback ← 1st spindle PC1	←○	○	○
Single path control + Multi-spindle control + 4 spindles	—	Address S → 1st spindle → 2nd spindle → 3rd spindle → 4th spindle	Feedback ← 1st spindle PC1 2nd spindle PC2 3rd spindle PC3 4th spindle PC4 (selected)	←× ←× ←× ←○	○	○
Multi-path control + Non-multi-spindle control +	Signal of spindle control for each path: Type A (*1.)					
	Path 1	Address S → 1st spindle	Feedback ← 1st spindle PC1	←○	○	○
	Path 2		Feedback ←	—	○	○
	Signal of spindle control for each path: Type A (*1.)					
	Path 1	Address S → 1st spindle	Feedback ← 1st spindle PC1	←○	×	×
	Path 2		Feedback ←	—	○	○
Multi-path control + Multi-spindle control + 2 spindles per path	Signal of spindle control for each path: Type C (*2.)					
	Path 1	Address S → 1st spindle → 2nd spindle	Feedback ← 1st spindle PC1 (selected) 2nd spindle PC2	←○ ←×	○	○
	Path 2	Address S → 1st spindle → 2nd spindle	Feedback ← 1st spindle PC1 2nd spindle PC2 (selected)	←× ←○	×	×
	Signal of spindle control for each path: Type C (*3.)					
	Path 1	Address S → 1st spindle → 2nd spindle	Feedback ← 1st spindle PC1 (selected) 2nd spindle PC2	←○ ←×	○	○
	Path 2	1st spindle 2nd spindle	Feedback ← 1st spindle PC1 2nd spindle PC2 (selected)	←× ←×	○	○

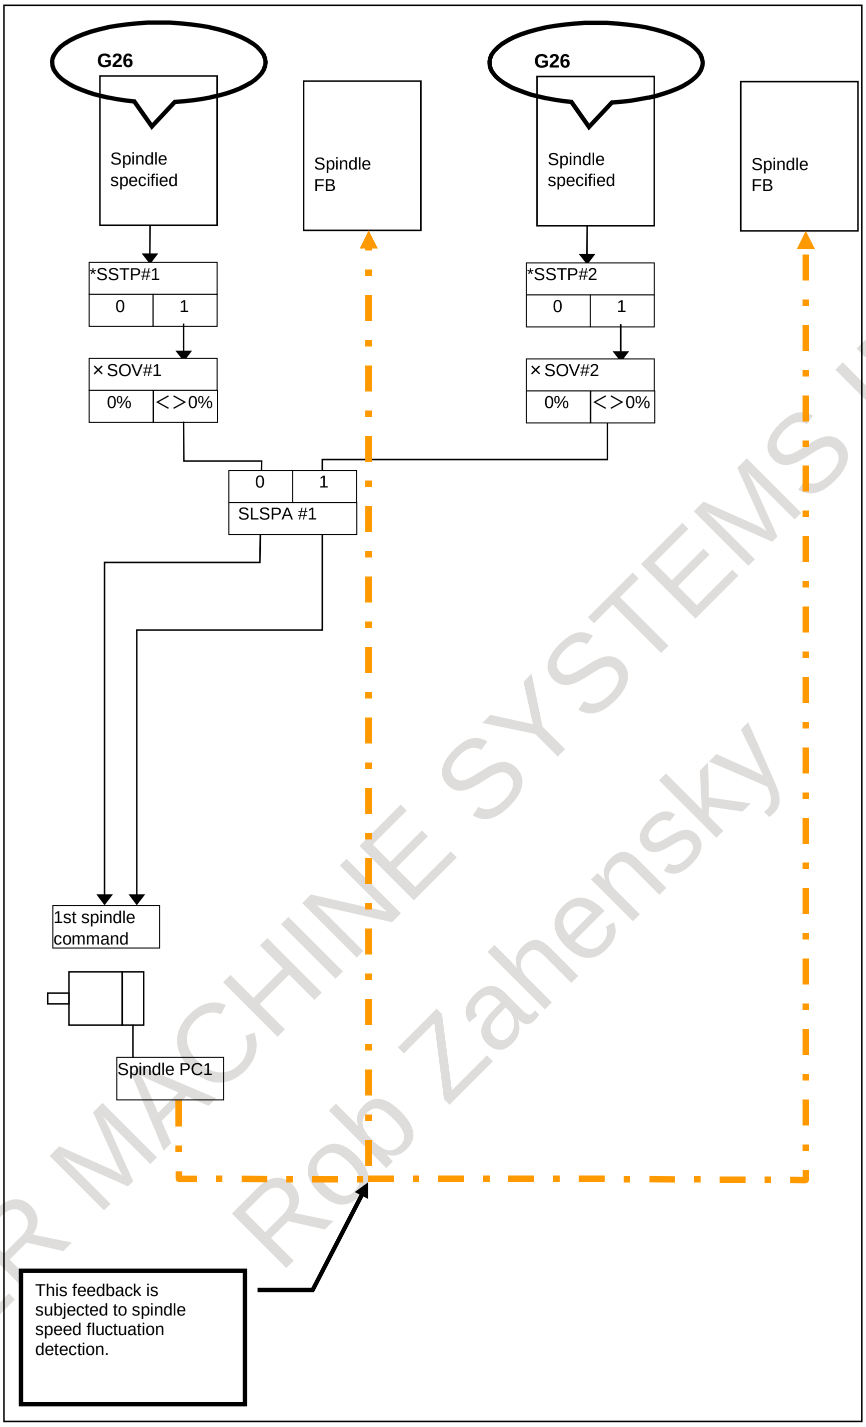
*1 The feedback pulse can be obtained from path 1 in this example.

*2 The signals for selecting spindle feedback of each path (SLPCA<Gn064.2>, SLPCB<Gn064.3>, SLPCC<Gn403.4>, SLPCD<Gn403.5>) are set to select feedback in each path, for both path 1 and path 2.

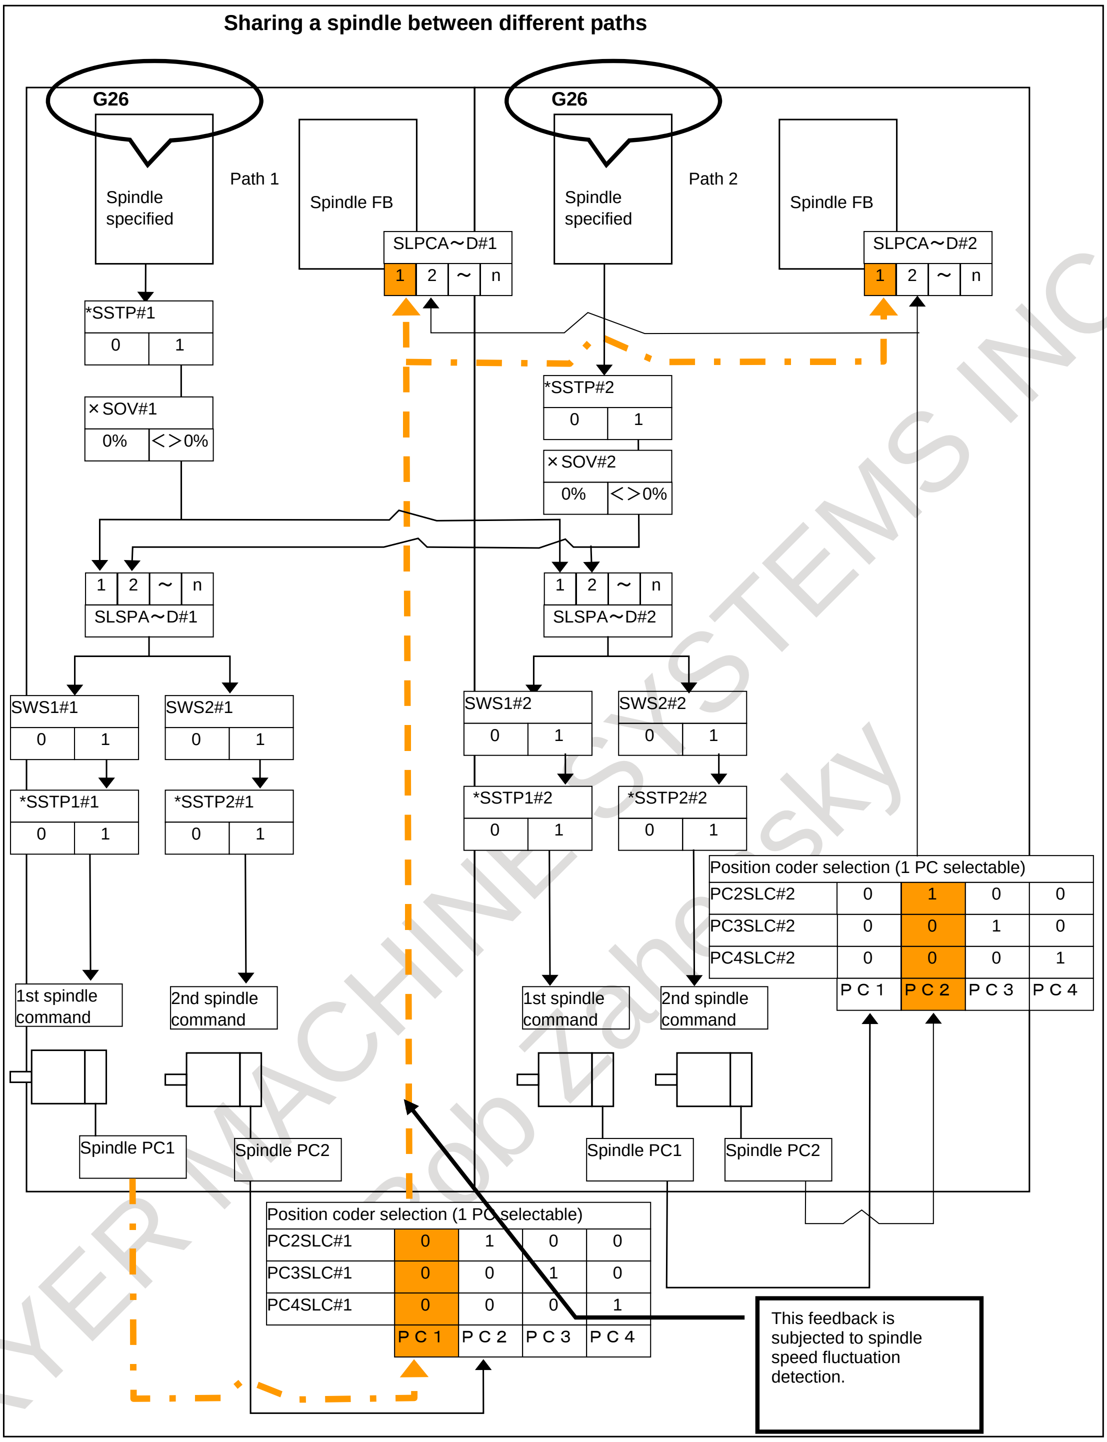
*3 The signals for selecting spindle feedback of each path (SLPCA<Gn064.2>, SLPCB<Gn064.3>, SLPCC<Gn403.4>, SLPCD<Gn403.5>) are set to select the feedback pulse of path 1 for path 2.



System controlling four spindles by one path



System controlling one spindle by two paths



Sharing a spindle between different paths

- About spindle speed fluctuation detection at power-on or cleared state

At power-on or cleared state, G25 mode (spindle speed fluctuation detection is disabled) is usually selected. If bit 0 (G26) of parameter No.4902 is set to 1, G26 mode (spindle speed fluctuation detection is enabled) is selected.

Placing the G25/G26 group in the cleared state requires the following parameter settings:

- Bit 6 (CLR) of parameter No. 3402 is set to 1
- Bit 0 (C08) of parameter No. 3407 is set to 1 (T series) / Bit 3 (C19) of parameter No. 3408 is set to 1 (M series)

About these parameters and G25/G26 mode state at power-on or reset, refer to following.

G26(No.4902#0)	CLR(No.3402#6)	(T series) C08(No.3407#0) (M series) C19(No.3408#3)	At power-on	At reset in G25 mode	At reset in G26 mode
0	0	0	G25	G25	G26
		1	G25	G25	G26
	1	0	G25	G25	G25
		1	G25	G25	G26
1	0	0	G26	G25	G26
		1	G26	G25	G26
	1	0	G26	G26	G26
		1	G26	G25	G26

- Parameters of spindle speed fluctuation detection at power-on

At power-on if bit 6 (UDPs) of parameter No.4900 is set to 1, parameters Nos. 4921 to 4924 (dp, dq, dr, di) are valid and parameters Nos. 4911 to 4914 (p, q, r, i) are invalid. Because of specified address P, Q, R, I in the machining program, value of parameters Nos. 4911 to 4914 (p, q, r, i) are changed and value of parameters Nos. 4921 to 4924 (dp, dq, dr, di) are not changed. So, parameters Nos. 4921 to 4924 (dp, dq, dr, di)are used as default parameter at power-on.

When parameters Nos. 4921 to 4924 (dp, dq, dr, di) are valid, if address P, Q, R, I are specified in the machining program even once as following,
G26 Pp Qq Rr Ii ;
the specified values are set for parameters Nos. 4911 to 4914 (p, q, r, i) and these parameters are valid as parameters of spindle speed fluctuation detection. If address P, Q, R, I are not specified in the machining program, parameters Nos. 4921 to 4924 (dp, dq, dr, di) are still valid. Examples of valid spindle speed fluctuation detection parameters are shown below.

(Example 1)

Current mode and valid parameters

G25 mode		p		q		r		i	
G26 mode	○	dp	○	dq	○	dr	○	di	○

↓ G26 Pp Qq Rr Ii ; ——— machining program

G25 mode		p	○	q	○	r	○	i	○
G26 mode	○	dp		dq		dr		di	

(Example 2)

G25 mode		p		q		r		i	
G26 mode	○	dp	○	dq	○	dr	○	di	○

↓ G26 Rr Ii ;

G25 mode		p		q		r	○	i	○
G26 mode	○	dp	○	dq	○	dr		di	

At cleared state, G25 / G26 mode changes according to parameter bit 0 (G26) of parameter No.4902, but valid parameters of spindle speed fluctuation detection don't change. And, When mode is change into

G25 mode, valid state of the parameters of spindle speed fluctuation detection is held. After that, when mode is change into G26 mode again, this valid state is applied. Examples are shown below.

(Example 3)

G25 mode		p		q		r		i	
G26 mode	○	dp	○	dq	○	dr	○	di	○

↓ G26 Rr Ii ;

G25 mode		p		q		r	○	i	○
G26 mode	○	dp	○	dq	○	dr		di	

↓ clear (bit 0 (G26) of parameter No.4902 is set to 1)

G25 mode		p		q		r	○	i	○
G26 mode	○	dp	○	dq	○	dr		di	

↓ G25 ;

G25 mode	○	p		q		r		i	
G26 mode		dp		dq		dr		di	

↓ G26 ;

G25 mode		p		q		r	○	i	○
G26 mode	○	dp	○	dq	○	dr		di	

(Example 4)

G25 mode		p		q		r	○	i	○
G26 mode	○	dp	○	dq	○	dr		di	

↓ G25 ;

G25 mode	○	p		q		r		i	
G26 mode		dp		dq		dr		di	

↓ clear (bit 0 (G26) of parameter No.4902 is set to 1)

G25 mode		p		q		r	○	i	○
G26 mode	○	dp	○	dq	○	dr		di	

NOTE

Alarm PS1305 is issued because value of specified address P, Q, R, I in the machining program is out of valid data range. At this time, about address of value out of valid data range, if type of parameters Nos. 4921 to 4924 (dp, dq, dr, di) are valid before machining program, type of parameters Nos. 4921 to 4924 (dp, dq, dr, di) are still valid.

Signal

Spindle speed fluctuation detection alarm signal SPAL <Fn035.0>

[Classification] Output signal

[Function] This signal indicates that the actual spindle speed is not within a tolerance to the specified speed.

[Output cond.] The signal becomes logical “1” when:

- The actual spindle speed goes out of tolerance to the specified speed.

The signal becomes logical “0” when:

- No alarm OH0704 condition has been detected for spindle speed fluctuation.
- An alarm condition is cleared by resetting the NC when the signal is logical 1.

Signal address

	#7	#6	#5	#4	#3	#2	#1	#0
Fn035								SPAL

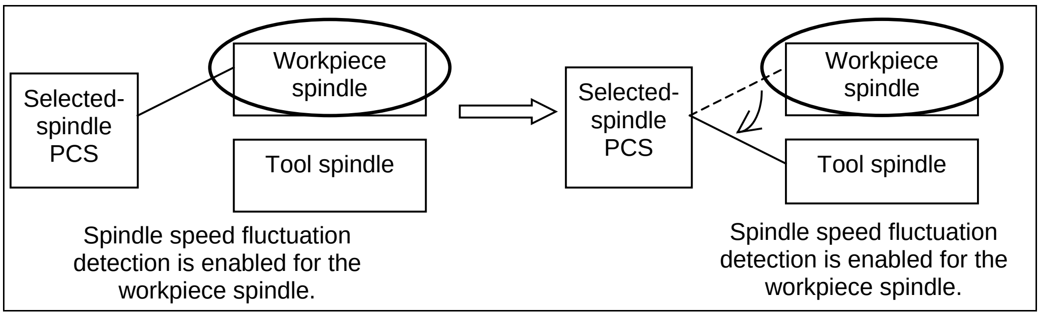
Parameter

	#7	#6	#5	#4	#3	#2	#1	#0
4900	FDTs	UDPs		FDEs				FLRs

[Input type] Parameter input
[Data type] Bit spindle

#0 FLRs When the spindle speed fluctuation detection function is used, the unit of parameters No. 4911(q), No. 4912(r), No. 4921(dq), No. 4922(dr) and diagnoses No. 1591, No. 1592 (allowable ratio and fluctuation ratio) is:
0: 1%.
1: 0.1%.

#4 FDEs Spindle speed fluctuation detection function is:
0: Enabled.
1: Disabled.
If the position coder selection signal is selected for a spindle for which this parameter is 1, the target spindle of spindle speed fluctuation detection remains unchanged. Spindle speed fluctuation detection stays enabled for the spindle for which spindle speed fluctuation detection was enabled before the selection of the position coder selection signal.
An example is given below.
[Example]
Bit 4 (FDE) of parameter No.4900 (Workpiece spindle) = 0
Bit 4 (FDE) of parameter No.4900 (Tool spindle) = 1
Even when the position coder selection signal is switched from the workpiece spindle to the tool spindle, the target spindle of spindle speed fluctuation detection remains unchanged, that is, the function stays enabled for the workpiece spindle.



Note) The selected spindle varies depending on the state of the position coder selection signal.

NOTE

1. If bit 4 (FDE) of parameter No.4900 is 0 for all spindles, spindle speed fluctuation detection is enabled for the spindle selected with the position coder selection signal as is conventionally. If the bit 4 (FDE) of parameter No.4900 is 1 for all spindles, spindle speed fluctuation detection is enabled for the spindle selected with the position coder selection signal.
2. When the bit 4 (FDE) of parameter No.4900 is 0 for all spindles, setting the bit 4 (FDE) of parameter No.4900 for the spindle selected with the position coder selection signal to 1 does not cause an immediate change to the target spindle, which stays as the target until the next position coder selection signal is issued.
3. If the bit 4 (FDE) of parameter No.4900 for the first spindle is 1 and the first spindle is the tool spindle when the power is turned on, spindle speed fluctuation detection remains enabled for the first spindle until a spindle for which the bit 4 (FDE) of parameter No.4900 is 0 is selected.

#6 UDPs About parameters of spindle speed fluctuation detection at power-on:
0: Parameters Nos. 4911 to 4914 (p, q, r, i) are valid.
1: Parameters Nos. 4921 to 4924 (dp, dq, dr, di) are valid.

NOTE

This parameter (UDPs) is referenced at only power-on. So, even when this parameter (UDPs) is changed after power-on, valid parameters about spindle speed fluctuation detection are not changed.

#7 FDTs Spindle speed fluctuation detection is started:
0: When the actual spindle speed reaches a specified range or when the time specified with valid parameter (p(No.4914) or dp(No.4924)) elapses.
1: When the time specified with valid parameter (p(No.4914) or dp(No.4924)) elapses.

4902								G26

[Input type] Parameter input
[Data type] Bit path

#0 G26 When power is turned on or when the control is cleared:
0: G25 mode (spindle speed fluctuation detection is disabled) is selected.
1: G26 mode (spindle speed fluctuation detection is enabled) is selected.

4911	Allowable speed ratio (q) used to assume that the spindle has reached a specified speed

[Input type] Parameter input
[Data type] Word spindle
[Unit of data] 1%, 0.1%
[Valid data range] 1 to 100, 1 to 1000

When the spindle speed fluctuation detection function is used, set an allowable speed ratio (q) used to assume that the spindle has reached a specified speed.

> **NOTE**
> The unit of data is determined by bit 0 (FLR) of parameter No. 4900.

4912	Spindle speed fluctuation ratio (r) for not issuing a spindle speed fluctuation detection alarm

[Input type] Parameter input
[Data type] Word spindle
[Unit of data] 1%, 0.1%
[Valid data range] 1 to 100, 1 to 1000

When the spindle speed fluctuation detection function is used, set a spindle speed fluctuation ratio (r) for not issuing an alarm.

> **NOTE**
> The unit of data is determined by bit 0 (FLR) of parameter No. 4900.

4913	Spindle speed fluctuation width (i) for not issuing a spindle speed fluctuation detection alarm

[Input type] Parameter input
[Data type] 2-word spindle
[Unit of data] min^{-1}
[Valid data range] 0 to 99999

When the spindle speed fluctuation detection function is used, set an allowable fluctuation width (i) for not issuing an alarm.

4914	Time (p) from the change of a specified speed until spindle speed fluctuation detection is started

[Input type] Parameter input
[Data type] 2-word spindle
[Unit of data] msec
[Valid data range] 0 to 999999

When the spindle speed fluctuation detection function is used, set a time (p) from the change of a specified speed until spindle speed fluctuation detection is started. In other words, spindle speed fluctuation detection is not performed until a set time has elapsed after a specified speed is changed. However, when the actual spindle speed is assumed to have reached a specified value within a set time (p), spindle speed fluctuation detection is started.

4921	Allowable speed ratio (dq) used to assume that the spindle has reached a specified speed (at power-on)

[Input type] Parameter input
[Data type] Word spindle
[Unit of data] 1%, 0.1%
[Valid data range] 1 to 100, 1 to 1000

When the spindle speed fluctuation detection function is used, set an allowable speed ratio (dq) used to assume that the spindle has reached a specified speed. To validate this parameter, it is necessary to set bit 6 (UDPs) of parameter No.4900 to 1. Then, at power-on, parameter No.4911 (q) is invalid, and parameter No.4921 (dq) is valid.

> **NOTE**
> 1 If address Q is specified in the G26 block after power-on, parameter No.4921 (dq) becomes invalid, and parameter No.4911 (q) becomes valid. If address Q is not specified in the G26 block after power-on, parameter No.4921 (dq) is still valid. Also, When alarm PS1305 is issued because specified address Q value is out of valid data range, parameter No.4921 (dq) is still valid.
> 2 The unit of data is determined by bit 0 (FLR) of parameter No.4900.

4922	Spindle speed fluctuation ratio (dr) for not issuing a spindle speed fluctuation detection alarm (at power-on)

[Input type] Parameter input
[Data type] Word spindle
[Unit of data] 1%, 0.1%
[Valid data range] 1 to 100, 1 to 1000

When the spindle speed fluctuation detection function is used, set a spindle speed fluctuation ratio (dr) for not issuing an alarm. To validate this parameter, it is necessary to set bit 6 (UDPs) of parameter No.4900 to 1. Then, at power-on, parameter No.4912 (r) is invalid, and parameter No.4922 (dr) is valid.

> **NOTE**
> 1 If address R is specified in the G26 block after power-on, parameter No.4922 (dr) becomes invalid, and parameter No.4912 (r) becomes valid. If address R is not specified in the G26 block after power-on, parameter No.4922 (dr) is still valid. Also, When alarm PS1305 is issued because specified address R value is out of valid data range, parameter No.4922 (dr) is still valid.
> 2 The unit of data is determined by bit 0 (FLR) of parameter No.4900.

4923	Spindle speed fluctuation width (di) for not issuing a spindle speed fluctuation detection alarm (at power-on)

[Input type] Parameter input
[Data type] 2-word spindle
[Unit of data] min^{-1}
[Valid data range] 0 to 99999

When the spindle speed fluctuation detection function is used, set an allowable fluctuation width (di) for not issuing an alarm. To validate this parameter, it is necessary to set bit 6 (UDPs) of parameter No.4900 to 1. Then, at power-on or cleared state, parameter No.4913 (i) is invalid, and parameter No.4923 (di) is valid.

> **NOTE**
> If address I is specified in the G26 block after power-on, parameter No.4923 (di) becomes invalid, and parameter No.4913 (i) becomes valid. If address I is not specified in the G26 block after power-on, parameter No.4923 (di) is still valid. Also, When alarm PS1305 is issued because specified address I value is out of valid data range, parameter No.4923 (di) is still valid.

4924	Time (dp) from the change of a specified speed until spindle speed fluctuation detection is started (at power-on)

[Input type] Parameter input
[Data type] 2-word spindle
[Unit of data] msec
[Valid data range] 0 to 999999

When the spindle speed fluctuation detection function is used, set a time (dp) from the change of a specified speed until spindle speed fluctuation detection is started. In other words, spindle speed fluctuation detection is not performed until a set time has elapsed after a specified speed is changed. However, when the actual spindle speed is assumed to have reached a specified value within a set time (dp), spindle speed fluctuation detection is started. To validate this parameter, it is necessary to set bit 6 (UDPs) of parameter No.4900 to 1. Then, at power-on, parameter No.4914 (p) is invalid, and parameter No.4924 (dp) is valid.

NOTE
If address P is specified in the G26 block after power-on, parameter No.4924 (dp) becomes invalid, and parameter No.4914 (p) becomes valid. If address P is not specified in the G26 block after power-on, parameter No.4924 (dp) is still valid. Also, When alarm PS1305 is issued because specified address P value is out of valid data range, parameter No.4924 (dp) is still valid.

Diagnosis data

1590	The index number of the spindle axis that is subjected to spindle speed fluctuation detection

[Data type] 2-word path

The index number of the spindle axis that is subjected to spindle speed fluctuation detection is indicated.

1591	Allowable speed ratio used to assume that the spindle has reached a specified speed

[Data type] Word path
[Unit of data] 1%, 0.1%
[Valid data range] 1 to 100, 1 to 1000

When the spindle speed fluctuation detection function is used, allowable speed ratio used to assume that the spindle has reached a specified speed is indicated.

NOTE
The unit of data is determined by bit 0 (FLR) of parameter No. 4900.

1592	Spindle speed fluctuation ratio for not issuing a spindle speed fluctuation detection alarm

[Data type] Word path
[Unit of data] 1%, 0.1%
[Valid data range] 1 to 100, 1 to 1000

When the spindle speed fluctuation detection function is used, spindle speed fluctuation ratio for not issuing an alarm is indicated.

> **NOTE**
> The unit of data is determined by bit 0 (FLR) of parameter No. 4900.

1593	Spindle speed fluctuation width for not issuing a spindle speed fluctuation detection alarm

[Data type] 2-word path
[Unit of data] min^{-1}
[Valid data range] 0 to 99999

When the spindle speed fluctuation detection function is used, allowable fluctuation width for not issuing an alarm is indicated.

1594	Time from the change of a specified speed until spindle speed fluctuation detection is started

[Data type] 2-word path
[Unit of data] msec
[Valid data range] 0 to 999999

When the spindle speed fluctuation detection function is used, time from the change of a specified speed until spindle speed fluctuation detection is started is indicated. In other words, spindle speed fluctuation detection is not performed until a set time has elapsed after a specified speed is changed. However, when the actual spindle speed is assumed to have reached a specified value within a set time, spindle speed fluctuation detection is started.

> **NOTE**
> Diagnosis data Nos.1590 to 1594 are "0" when spindle speed fluctuation detection function is disabled as follows.
> - G25 mode
> - There is no spindle selected with the spindle speed fluctuation detection
> - The specified spindle speed is 0 min^{-1}.
> - A search by program restart is in progress.
> - Spindle is under other than velocity control

Alarm and message

Number	Message	Description
OH0704	OVERHEAT:SPINDLE	Spindle is overheated by the spindle speed fluctuation detection function. <1> For heavy cutting, ease the cutting conditions. <2> Check whether the cutter has been blunted. <3> Check whether the spindle amplifier is malfunctioning.

Number	Message	Description
PS5305	ILLEGAL SPINDLE NUMBER	In a spindle select function by address P for a multiple-spindle control, 1) Address P is not specified. 2) Parameter No. 3781 is not specified to the spindle to be selected. 3) An illegal G code which cannot be commanded with an S_P_; command is specified. 4) The multi-spindle control cannot be used because the bit 1 (EMS) of parameter No. 3702 is 1. 5) The spindle amplifier number of each spindle is not set in parameter No. 3717. 6) A prohibited command for a spindle was issued (parameter No. 11090). 7) An invalid value is set in parameter No. 11090.

Note

NOTE

1 Even if the conditions to start the spindle speed fluctuation detection function are satisfied, the spindle speed fluctuation detection function is not performed under the following conditions:
- The specified spindle speed is 0 min^{-1}.
- A search by program restart is in progress.

2 If the spindle stop signal *SSTP<Gn029.6> is set to “0”, detection is not performed.

3 If any of the spindle stop signals *SSTP1 to *SSTP4<Gn027.3, Gn027.4, Gn027.5, Gn026.6> is set to “0”, detection is not performed on the corresponding spindle.

4 If alarm OH0704 "OVERHEAT:SPINDLE" is raised, a single-block stop occurs in automatic operation. The spindle overheat alarm is displayed on the screen. In addition, the spindle speed fluctuation detection alarm signal SPAL is output (the signal is set to “1” in the alarm state).
This signal is cleared to “0” by a reset.

5 If the cause of alarm OH0704 is not eliminated by a reset, the alarm will be raised again.

6 Alarm OH0704 can be suppressed across an allowable variation width specified in parameter No.4913. If the actual spindle speed continues to be 0 min^{-1} for one second or longer, however, an alarm will be raised.

7 The raising of alarm OH0704 does not automatically cause the spindle to stop.

8 G25 and G26 must be specified in a predetermined format. Avoid specifying the preparatory function, auxiliary functions, and the like together with G25 or G26.

9 A serial spindle signal that can affect the actual spindle speed should be manipulated in the G25 mode.

10 If a spindle is under velocity control, spindle speed fluctuation detection is carried out.

11 Avoid making a spindle orientation operation while the spindle speed fluctuation detection function is enabled.

12 If address P is used to select a spindle while the multi-spindle control is carried out, avoid specifying S_P_; together with G26. If this is attempted, alarm PS5305 will be raised.

NOTE

13 For a serial spindle, carefully check the gear count selection statuses of clutch/gear signals (CTH1, CTH2) and gear selection signals (GR3O, GR2O, GR1O (type M)/GR1, GR2(type T). The spindle speed fluctuation detection function does not normally work if the gear count statuses of the two types of signals are different.

CNC system							Serial spindle side	
Lathe system、Machining center system			Machining center system					
GR2	GR1	Selected gear	GR3O	GR2O	GR1O	Selected gear	CTH1	CTH2
0	0	1st stage	0	0	1	1st stage	0	0
0	1	2nd stage	0	1	0	2nd stage	0	1
1	0	3rd stage	1	0	0	3rd stage	1	0
1	1	4th stage					1	1

FANUC AC SPINDLE MOTOR α*i* series PARAMETER MANUAL (B-65280EN)

10.20 SPINDLE CONTROL WITH SERVO MOTOR

Overview

Servo motors can be controlled by spindle functions like spindle rotation commands or rigid tapping.

(1) Spindle control with servo motor
Rotation commands (S command) can be used to control the speed of spindles by regarding servo motors as spindles (live tools). No reference position return is necessary to switch between rotation and positioning commands.

(2) Spindle indexing
There are two types of spindle indexing. The first type allows the next-block command to be executed before spindle indexing is finished. The second type allows the next block to be executed only after spindle indexing is completed.
With the first type, it is possible to issue commands to axes other than the axis for which a spindle indexing command has been issued, before the next command is issued to the axis. The next command can be issued only after it is confirmed that spindle indexing is completed. Using this function can reduce the wait time. In addition, an axis can be stopped at a specified point by issuing a spindle indexing command to the axis when the spindle is rotating.

(3) Rigid tapping with servo motor
Rigid tapping can be carried out by regarding a servo motor as a rotation axis.

(4) Threading, feed per revolution, and constant surface speed control
Threading, feed per revolution, and constant surface speed control can be carried out by regarding a servo motor as a spindle.

(5) Spindle output control with PMC
Spindle output control with PMC can be carried out by regarding a servo motor as a spindle controlled axis.

Notes

(1) Enable the spindle serial output (bit 5 (SSN) of parameter No,8133 is 0) and multi-spindle control (bit 3 (MSP) of parameter No,8133 is 1).
If this function is used under the conditions below, the multi-spindle control option is not enabled.
- Two or more spindles are not used on any path.

- The spindle gear type is T.
- No G code (G96.1, G96.2, G96.3, or G96.4) commands are used.
- Spindle indexing is not used.

(2) This function handles a servo motor used as a spindle controlled axis as one of controlled spindles and one of controlled axes.
(3) When carrying out rigid tapping with servo motor, enable the rigid tapping (bit 3 (NRG) of parameter No,8135 is 0) and the canned cycle (bit 4 (NCD) of parameter No,8137 is 0).
(4) When carrying out constant surface speed control, enable the constant surface speed control (bit 0 (SSC) of parameter No,8133 is 1).

Multi-spindle control	○	○
Rigid tapping	○	○
Spindle output control with PMC	○	○
Actual spindle speed output (T series)	○	○
Spindle indexing	×	○

NOTE
Servo motor can be used as tool rotation axis. (*1)

10.20.1 Spindle Control with Servo Motor

Specification

- Command with a program

This function supports two modes; SV speed control mode (a spindle rotation command (S command) is enabled for the servo motor-controlled rotation axis) and position control mode (ordinary positioning is enabled). Controlling servo motor rotation requires issuing an SV speed control mode ON command (G96.4). Once the command is issued, the S command for the servo motor remains enabled until the mode is canceled. No positioning command is usable if the SV speed control mode is ON.
Performing positioning requires canceling the SV speed control mode. Canceling the SV speed control mode (setting the position control mode to ON) requires issuing a spindle indexing command (G96.1 or G96.2). In the position control mode, the S command is disabled as in the ordinary servo axis state. However, information about the S command is preserved. So, when the SV speed control mode becomes ON, the motor starts rotating at the speed already specified.

- Command with a signal

The SV speed control mode signal <Gn521> can also be used to specify whether to turn ON or OFF the SV speed control mode.
If the SV speed control mode is turned ON using the signal and then OFF using a program command, turning it ON again requires re-entering the signal or re-issuing the G96.4 command.

The SV speed control mode in-progress signal <Fn521> can be used to check whether the SV speed control mode is in effect.
Turning the SV speed control mode signal OFF during rotation performs spindle indexing and then turns the SV speed control mode OFF. Spindle indexing is executed with R0 (absolute position 0).
Specify an M code not involved in buffering as an M code to be used as a command for switching the SV speed control mode (parameters Nos. 3411 to 3420 and 11290 to 11299).

Format

G96.4 P_ ;	SV speed control mode ON
M03 (M04) S_ P_ ;	Rotation command

S: Spindle speed [min^{-1}] (numeric value of up to five digits)
P: Spindle selection with multi-spindle control

Using G96.4 and a spindle selection command P can turn the SV speed control mode ON for each axis separately. Likewise, using a spindle indexing command (G96.1/G96.2) and a spindle selection command P can cancel the SV speed control mode, that is, turn on the position control mode ON, for each axis separately.
To specify “G96.4 P_ ;”, use an independent block.
However, it is possible to specify "G96.4 P_ S_ ;".

Explanation

- Command

(1) Spindle speed command output
Set up the spindle speed command in the same way as for the ordinary speed command (S command). However, turn the SV speed control mode ON before issuing the rotation command (S command). When performing positioning, cancel the SV speed control mode, and select the position control mode.
The sequence by the following input signals is unnecessary.
*ESPA, MRDYA, and SFRA

(2) Condition for stopping spindle speed output
Commands once output to a spindle become 0 if *SSTP becomes 0 or if a command (such as S0) that makes the spindle speed command output 0 is issued. Also, issuing a spindle indexing command (G96.1/G96.2) makes the spindle speed command output 0. In addition, an emergency stop condition and servo alarm bring the spindle to a stop.
With M05, the CNC does not make the command output to the spindle 0.

(3) Stopping rotation by spindle indexing
Issuing a command that specifies a position enables the rotating axis to stop at the specified position. For details, see Subsection of "Spindle Indexing Function."

(4) Maximum speed
The maximum speed that can be specified is usually 2777 min^{-1}.
However, setting bit 3 (IRC) of parameter No. 1408 to 1 may be able to increase the limit to about 27770 min^{-1} depending on the performance of the related motor and detector. (when IS-B is used.)

Depending on the increment system, the maximum speed is as below.

Increment system	Bit 7 (IESP) of parameter No. 1013 = 0	Bit 7 (IESP) of parameter No. 1013 = 1
IS-B	27750min^{-1}	27750min^{-1}
IS-C	2777min^{-1}	27750min^{-1}

It is assumed that bit 3 (IRC) of parameter No. 1408 is set to 1 in all cases.

Example command for switching between rotation control and position control

Spindle name	Spindle select P code (parameter No. 3781)	Servo motor axis address
S1	P1	C

Command with a program (SV speed control mode in-progress signal (Fn521))

Program command	SV speed control mode ON/OFF	Operation
G96.4 P1 ;	ON (SV speed control mode in-progress signal (C) =1)	SV speed control mode ON (C).
M03 S100 P1 ;	ON	The servo motor rotation axis C rotates in the normal direction at 100 [min^{-1}].
:	:	:
G96.1 P1 R0 ;	OFF (SV speed control mode in-progress signal (C) = 0)	The servo motor rotation axis C stops at C = 0 (spindle indexing).
G00 C180.0 ;	OFF (SV speed control mode in-progress signal (C) = 0)	Positioning at C = 180 degrees.
M03 S200 P1 ;	OFF (SV speed control mode in-progress signal (C) = 0)	M03 S200 is stored without causing the servo motor to rotate.
G96.4 P1 ;	ON (SV speed control mode in-progress signal (C) = 1)	The servo motor rotation axis C rotates in the normal direction at 200[min^{-1}]. SV speed control mode ON (C).

Signal-controlled mode switching

Program command	SV speed control mode ON/OFF	Operation
M15 ;	ON (SV speed control mode in-progress signal (C) = 1)	SV speed control mode is turned ON (C) with M code.
M03 S100 P1 ;	ON (SV speed control mode in-progress signal (C) =1)	Servo motor rotation axis C rotates in normal direction at 100 [min^{-1}].
:	:	:
G96.1 P1 R0 ;	OFF (SV speed control mode in-progress signal (C)=0)	Servo motor rotation axis C stops at C = 0 (spindle indexing).
G00 C180. ;	OFF (SV speed control mode in-progress signal (C)=0)	Positioning at C = 180 degrees.
M15 ;	ON (SV speed control mode in-progress signal (C)=1)	SV speed control mode is turned ON (C) with M code.
M03 S100 P1 ;	ON	Servo motor rotation axis C rotates in normal direction at 100 [min^{-1}].

- Multi-spindle control and commands from another path

Controlling the rotation of a spindle in a path that has another spindle (such as a servo motor used as a live tool) requires the multi-spindle control. The path spindle control function can handle commands from another path. The address P-based spindle select function for multi-spindle control can be used to select spindles in another path.

Example of program commands are as follows.

Example 1: (Spindle selection with address P)

Bit 3 (MPP) of parameter No. 3703 = 1: A spindle is selected with address P.

Spindle configuration (S1 = first spindle and S2 = second spindle)

Path 1	Path 2
S1 (spindle axis)	S3 (spindle axis)
S2 (servo axis)	S4 (servo axis)

Setting address P for spindle selection in multi-spindle control

Parameter	Path 1	Path 2
3781	11 (S1)	21 (S3)
	12 (S2)	22 (S4)

Program example

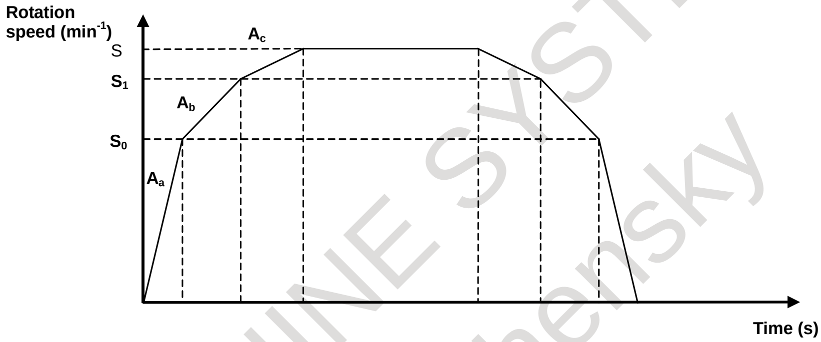
Command issuing path	Program	Operation
1	M03 S1000 P12 ;	S2 rotates in normal direction at 1000 min^{-1}.
1	M03 S1500 P22 ;	S4 rotates in normal direction at 1500 min^{-1}.
2	M04 S1500 P11 ;	S1 rotates in reverse direction at 1500 min^{-1}.

- Operation (automatic/manual) of spindle control with servo motor axis

Once a spindle control with servo motor axis has returned to its reference position, it can operate in the same manner as in the ordinary servo axis or spindle rotation control mode. To operate the a spindle control with servo motor axis manually, keep the SV speed control mode OFF.

- Acceleration/deceleration (time constant)

It is possible to change the spindle acceleration/deceleration specified in a rotation command according to the speed of the spindle.
Acceleration/deceleration can be switched at two points of speed, using parameters S0 and S1 (switching speed). In addition, parameters Aa, Ab, and Ac are available to set up three acceleration/deceleration spans.



S_0	Setting of parameter No. 11020 (acceleration/deceleration is switched at rotation speed S0 (min^{-1})).
S_1	Setting of parameter No. 11021 (acceleration/deceleration is switched at rotation speed S1 (min^{-1})).
S	Specified rotation speed (min^{-1}).
Aa	Setting of parameter No. 11030 (acceleration/deceleration (min^{-1}/s) used between rotation speeds 0 and S0).
Ab	Setting of parameter No. 11031 (acceleration/deceleration (min^{-1}/s) used between rotation speeds S0 and S1).
Ac	Setting of parameter No. 11032 (acceleration/deceleration (min^{-1}/s) used between rotation speeds S1 and motor's maximum).

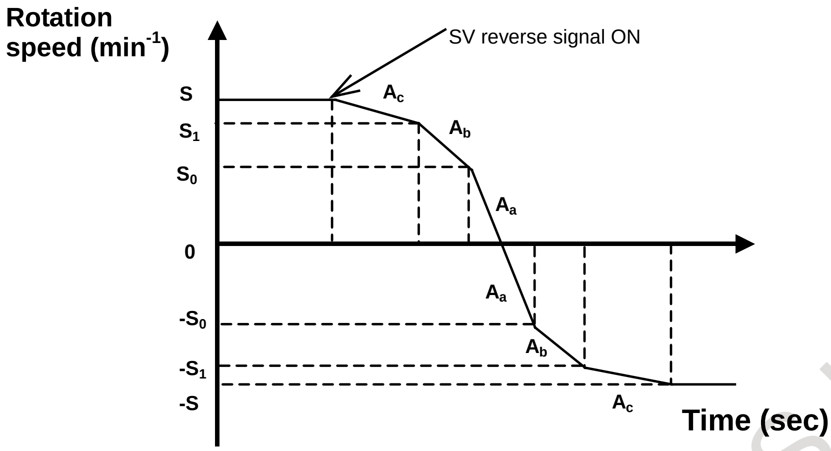
Determine the setting of each parameter according to the torque characteristic of the motor.

- Acceleration/deceleration after interpolation

Acceleration/deceleration after interpolation is available in the SV speed control mode. Bit 1 (TCR) of parameter No. 11001 can be used to select a time constant type, that is, parameter No. 1622
(Time constant of acceleration/deceleration in cutting feed for each axis) or parameter No. 11016 (Time constant of acceleration/ deceleration in SV speed control mode for each axis).

- Direction of rotation

It is possible to change the polarity of the spindle speed output voltage, using bits 6 (CWM) and 7 (TCM) of parameter No. 3706.
It is also possible to reverse the direction of spindle rotation, using the SV reverse signal <Gn523>.
These functions are usable in the rotation mode and during rigid tapping. Changing the signal to 1/0 during rotation causes the spindle to decelerate, reverse, and then accelerate.



- Reference position return

Before issuing the first command, be sure to make a reference position return.

- Display

Bit 3 (NDF) of parameter No. 3115 can be used to specify whether to display the actual speed. In addition, bits 0 (NDP) and 1 (NDA) of parameter No. 3115 can be used to specify whether to display, respectively, the current position and the remaining amount of movement.

- Setting of a rotation axis with a servo motor

(1) Axis setting
For the servo axis number of the axis to be set as a rotation axis with a servo motor (parameter No. 1023), set a value as a servo motor as usual. Specify which servo motor to use as a spindle controlled axis, using bit 7 (SRV) of parameter No. 11000. Specify which spindle to use as the spindle controlled axis with the servo motor, by setting the spindle number in parameter No. 11010. For the selected spindle, reset the spindle amplifier number (parameter No. 3717) to 0.
In multi-spindle control, set bit 3 (MPP) of parameter No. 3703 to 1 to specify that program commands be used to select a spindle.
Also set parameter No. 3781 with the P code for selecting a spindle.

(2) Using a command to specify a spindle speed requires adjusting the following parameters.

Parameter No. 11013:	Positioning deviation limit in movement
Parameter No. 11014:	Positioning deviation limit in the stop state
Parameter No. 11015:	Maximum motor speed

(3) Rotation axis setting
Using bits 0 (ROTx) and 1 (ROSx) of parameter No. 1006, select rotation axis type A.
Using the rollover function, round the absolute coordinate values to be displayed to an amount of movement per rotation specified in parameter No. 1260 in order to prevent rotation axis coordinate overflow. Also round the relative coordinate values to be displayed to an amount of movement per rotation by setting bit 2 (RRLx) of parameter No. 1008 to 1.
The rollover function is enabled by setting bit 0 (ROAx) of parameter No. 1008 to 1 (for the rotation axis).

(4) Extension of maximum speed
When using spindle control with servo motor, set 1 to bit 3 (FEX) of parameter No.8003.

- Example of parameter setting

The following examples show typical parameter settings. These typical parameter settings should be used unless otherwise stated.

(1) Spindle controlled axis setting
Let the fourth axis of the CNC be the C axis. Assuming that the fourth axis is connected to the second spindle, let us use the second spindle as a spindle controlled axis (servo motor).
No.11000#7 (C) = 1

No.11010 (C) = 2 (a spindle number is specified for a controlled axis assigned to the spindle controlled axis.)

(Set up No. 3717 (S2) = 0.)

Given below are the least command increment, detection unit, and the amount of movement per rotation for the C axis.

Least command increment = $\frac{L \times CMR}{Q \times DMR}$

Detection unit = $\frac{\text{Least command increment}}{CMR} = \frac{L}{Q \times DMR}$

Amount of movement per tool axis rotation =

$\frac{360}{\text{Least command increment}}$

where

L: Amount of tool movement per motor rotation (360 × speed increment ratio) [deg]
For example, if the servo motor is connected directly to the spindle (live tool), L = 360. For example, if the speed must be increased by twice, L = 720.

Q: Number of pulses per pulse coder rotation
(For the serial pulse coder, Q = 1000000.)
The least command increment mentioned above is specific to the C axis and is determined independently of bits 0 (IS-A) and 1 (IS-C) of parameter No 1013.
Reset both bits 0 (IS-A) and (IS-C) of parameter No 1013 to 0 to select IS-B.
If the servo motor is connected directly to the spindle (live tool):

Least command increment= $\frac{360 \times 1}{1000000 \times 36/100} = 0.001$ [deg]

Detection unit = 0.001 [deg]

Amount of movement per tool axis rotation =360.0 [deg]

So, the required parameter setting must be:

Parameter No. 11011 (C) = 360.000 (amount of movement per spindle controlled axis rotation)

In addition, the acceleration/deceleration values for rotation control must be specified in parameters Nos. 11020 to 11032.

Let us assume that the axis parameters be specified for the fourth axis, as follows:

(2) Servo parameter setting

Let us assume: CMR = 1 and DMR = 36/100

(The capacity of the reference counter will be 360000.)

No.1820 (C) = 2	(CMR)
No.1821 (C) = 360000	(Reference counter capacity)
No.2084 (C) = 36	(DMR numerator)
No.2085 (C) = 100	(DMR denominator)

If the tool axis-to-motor gear ratio is 1:1:

No.11015(C) = 5000	(Maximum motor speed)
No.3741(S2) = 5000	(Maximum speed for gear 1)

For the other servo parameters, use the respective typical settings.

(3) Full closed system setting

When using spindle control in a full closed system, set bit 1 (FSR) of parameter No. 11000 to 1.

Signal

SV speed control mode signals SRVON1 to SRVON8<Gn521>

[Classification] Input signal

[Function] These signal switch the respective axes to the SV speed control mode.

[Operation] Setting these signals to 1 cause the respective axes to enter the SV speed control mode.
Resetting these signals to 0 cause the respective axes to exit the SV speed control mode.
Resetting the signals to 0 during axis rotation causes the respective axes to start spindle indexing, to stop at the origin (R0), and to exit the SV rotation mode.

> **NOTE**
> 1 Even if these signals are 1, the spindle control function remains disabled when a program command turns the SV speed control mode OFF (the SV speed control mode in-progress signal Fn521 becomes 0). To enable it, re-set these signals to 1.
> 2 Specify an M code not involved in buffering as an M code to be used as a command for switching the SV speed control mode (parameters Nos. 3411 to 3420 and 11290 to 11299).

SV reverse signals SVRVS1 to SVRVS8<Gn523>

[Classification] Input signal

[Function] These signals cause the respective axes to reverse their rotation direction in the SV speed control mode.

[Operation] Setting these signals to 1 cause the respective axes to reverse their rotation direction.
Resetting these signals to 0 cause the respective axes to resume their normal rotation direction.

> **NOTE**
> These signals are effective even in rigid tapping.

SV speed control mode in-progress signals SVREV1 to SVREV8<Fn521>

[Classification] Output signal

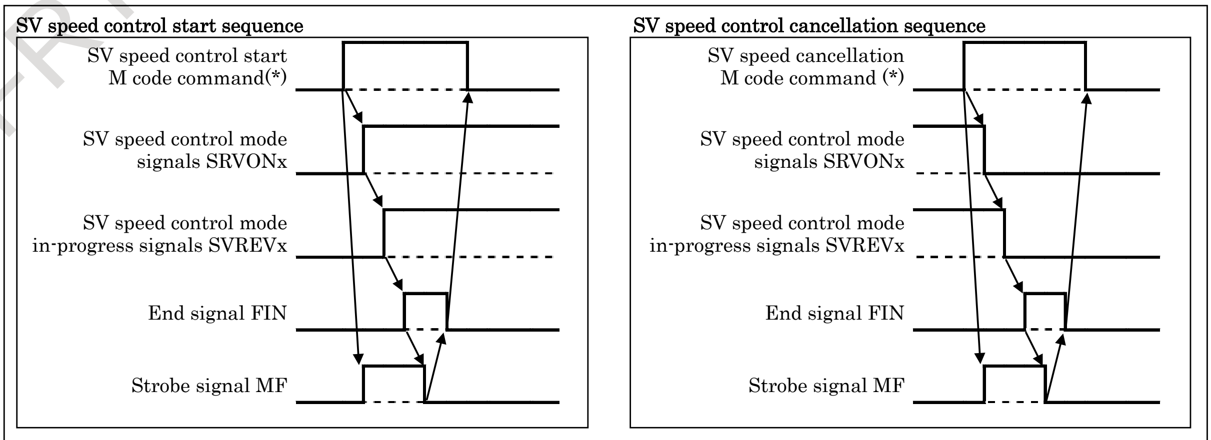
[Function] These signals inform that the respective axes are in the SV speed control mode.

[Output cond.] These signals are 1 if:

- The respective axes are in the SV speed control mode.

These signals are 0 if:

- The respective axes are in the SV speed control mode, or
- The respective axes are in the position control mode.



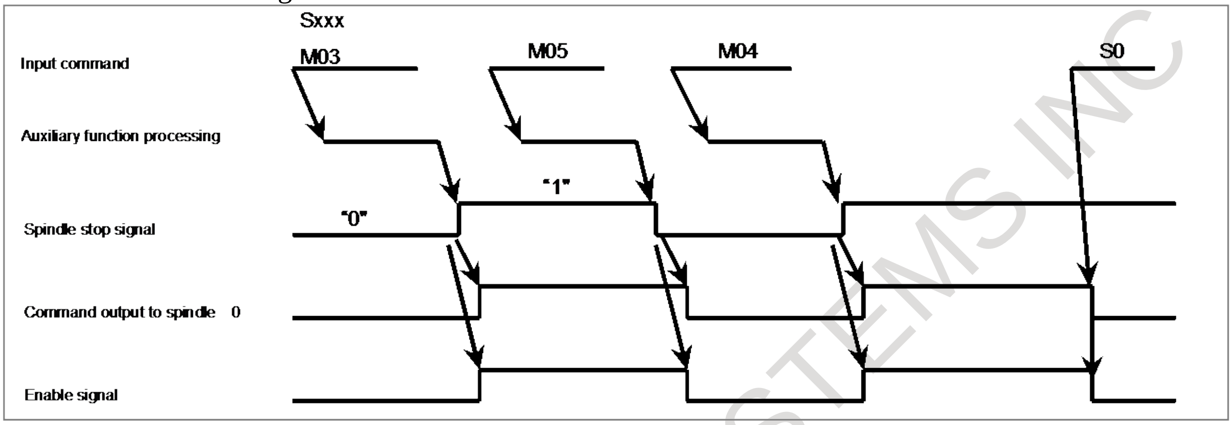
(*) Specify an M code not involved in buffering as an M code to be used as a command for switching the SV speed control mode.

Spindle stop signal *SSTP<Gn029.6>

[Classification] Input signal

[Function] This signal stops the command output to the spindle.

[Operation] When this signal becomes 0, the command output to the spindle becomes 0, resulting in the enable signal becoming 0. So, M05 is not output. When this signal becomes 1, the command output to the spindle resumes its previous value, resulting in the enable signal becoming 1.



The timing chart above is illustrative only. To be more precise, follow a timing chart that meets the specification of the speed control unit for the spindle motor in use.

- Keep this signal set to 1 unless it is used.
- The CNC uses the commands M03, M04, and M05 to send only code and strobe signals.

Individual spindle stop signals
*SSTP1<Gn027.3> *SSTP2<Gn027.4> *SSTP3<Gn027.5> *SSTP4<Gn026.6>

[Classification] Input signal

[Function] These signals are usable only during multi-spindle control.
They cause the respective spindles to stop.

*SSTP1 1: Does not make the output to the first spindle 0 min^{-1}.
0: Makes the output to the first spindle 0 min^{-1}.

*SSTP2 1: Does not make the output to the second spindle 0 min^{-1}.
0: Makes the output to the second spindle 0 min^{-1}.

*SSTP3 1: Does not make the output to the third spindle 0 min^{-1}.
0: Makes the output to the third spindle 0 min^{-1}.

*SSTP4 1: Does not make the output to the fourth spindle 0 min^{-1}.
0: Makes the output to the fourth spindle 0 min^{-1}.

Spindle speed override signals SOV0 to SOV7<Gn030>

[Classification] Input signal

[Function] These signals enable an override of 0% to 254% of the S command value sent to the CNC to be applied to the spindle in 1% increments.

[Operation] Specify an override value in binary, using the 8 bits SOV0 to SOV7.
The spindle speed override specified with these signals becomes disabled, and an override of 100% is applied to the spindle speed during:

- Tapping cycle (for the M series, G84 and G74 or, for the T series, G84 and G88)
- Threading mode (for the M series, G33 or, for the T series, G32, G92, and G76)
  → Specify an override of 100% unless this function is used.
  (An override of 0% is applied, preventing spindle rotation.)

Spindle enable signals ENB<Fn001.4> ENB2<Fn038.2> ENB3<Fn038.3> ENB4<Fn039.1>

[Classification] Output signal

[Function] These signals inform whether there is an output to the second, third, or fourth spindle if the multi-spindle control is available.
The signals can be used as a condition for stopping the analog spindle and in PMC ladder sequences related to rigid tapping.
(See Subsection, "Rigid Tapping.")

[Output cond.]

ENB 1 if the output to the first spindle control unit is not 0.
0 if the output to the first spindle control unit is 0.

ENB2 1 if the output to the second spindle control unit is not 0.
0 if the output to the second spindle control unit is 0.

ENB3 1 if the output to the third spindle control unit is not 0.
0 if the output to the third spindle control unit is 0.

ENB4 1 if the output to the fourth spindle control unit is not 0.
0 if the output to the fourth spindle control unit is 0.

Multi-spindle address P signals MSP00 to MSP15<Fn160.0 to Fn161.7>

[Classification] Output signal

[Function] These signals output the P value most recently specified by the S_ P_ ; command.

[Output cond.] If the address P-based multi-spindle control is enabled (bit 3 (MPP) of parameter No. 3703 =1), the P value specified by the S_ P_ ; command is output. If no S_ P_ ; has been issued since application of the power, the initial P value specified in parameter No. 3775 is output.

Notes

- Unlike spindle motors, servo motors stop if a servo alarm, emergency stop, or machine lock condition occurs.
- Specify an M code not involved in buffering as an M code to be used as a command for switching the SV speed control mode (parameters Nos. 3411 to 3420 and 11290 to 11299).
- M code for switching the SV speed control mode must be specified in an independent block.
  When using multiple M commands in a single block, the M code must be specified as the first M command.
- G96.1, G96.2, G96.3, G96.4, and M code for switching the SV speed control mode must be specified in the path to which the spindle of interest belongs.
- The actual maximum motor speed is determined by applying a feed gear factor to the maximum motor speed specified in parameter No. 11015.
- If bit 3 (IRC) of parameter No. 1408 is 0, the malfunction prevent function may work at a rotation speed of about 2778 min-1. To allow the motor to run at 2778min-1 or faster, set bit 3 (IRC) of parameter No. 1408 to 1. If the bit is set to 1, the command can specify a rotation speed of up to about 27778 min^{-1}.
- This function must be set for type T gears.
- G96.1, G96.2, G96.3, G96.4 cannot be commanded for settings other than multi-spindle control type P.
- Feed axis synchronous control or synchronous control cannot be performed on an axis that is in SV rotation control mode.
- As for the axis used for spindle control with a servo motor, disable the setting of bit 7 (ALGx) of parameter No. 1814, which adjusts the loop gain in Cs contour control mode to the loop gain of the Cs contour control axis, and the setting of parameter No. 3900 and after, which sets the loop gain of the axis to interpolate with the Cs contour control axis. Otherwise, the loop gain of the servo axis will change suddenly if the system enters Cs contour control mode during rotation control.
- When using spindle control with servo motor, set 1 to bit 3 (FEX) of parameter No.8003.

Parameter

The major related parameters are described below.

	#7	#6	#5	#4	#3	#2	#1	#0
1006							ROSx	ROTx

[Input type] Parameter input
[Data type] Bit axis

> **NOTE**
> When at least one of these parameters is set, the power must be turned off before operation is continued.

#0 ROTx Setting linear or rotation axis.
#1 ROSx

ROSx	ROTx	Meaning
0	0	Linear axis (1) Inch/metric conversion is done. (2) All coordinate values are linear axis type. (Is not rounded in 0 to 360°) (3) Stored pitch error compensation is linear axis type (Refer to parameter No. 3624)

ROSx	ROTx	Meaning
0	1	Rotary axis (A type) (1) Inch/metric conversion is not done. (2) Machine coordinate values are rounded in 0 to 360°. Absolute coordinate values are rounded or not rounded by bits 0 (ROAx) and 2 (RRLx) of parameter No. 1008. (3) Stored pitch error compensation is the rotation type. (Refer to parameter No. 3624) (4) Automatic reference position return (G28, G30) is done in the reference position return direction and the move amount does not exceed one rotation.
1	1	Rotary axis (B type) (1) Inch/metric conversion is not done. (2) Machine coordinate values, absolute coordinate values and relative coordinate values are linear axis type. (Is not rounded in 0 to 360°). (3) Stored pitch error compensation is linear axis type (Refer to parameter No. 3624) (4) Cannot be used with the rotary axis roll-over function and the index table indexing function (M series)
Except for the above.		Setting is invalid (unused)

1022	Setting of each axis in the basic coordinate system

[Input type] Parameter input
[Data type] Byte axis
[Valid data range] 0 to 7

To determine a plane for circular interpolation, cutter compensation, and so forth (G17: Xp-Yp plane, G18: Zp-Xp plane, G19: Yp-Zp plane) specify which of the basic three axes (X, Y, and Z) is used for each control axis, or a parallel axis of which basic axis is used for each control axis.
A basic axis (X, Y, or Z) can be specified only for one control axis.
Two or more control axes can be set as parallel axes for the same basic axis.

Setting	Meaning
0	Rotary axis (Neither the basic three axes nor a parallel axis)
1	X axis of the basic three axes
2	Y axis of the basic three axes
3	Z axis of the basic three axes
5	Axis parallel to the X axis
6	Axis parallel to the Y axis
7	Axis parallel to the Z axis

In general, the increment system and diameter/radius specification of an axis set as a parallel axis are to be set in the same way as for the basic three axes.

1023	Number of the servo axis for each axis

NOTE
When this parameter is set, the power must be turned off before operation is continued.

[Input type] Parameter input
[Data type] Byte axis
[Valid data range] 0 to 80

This parameter associates each control axis with a specific servo axis. Specify values 1+8n, 2+8n, 3+8n, 4+8n, 5+8n, and 6+8n (n = 0, 1, 2, …, 9) like 1, 2, 3, 4, 5, …, 77, and 78.

The control axis number is the order number that is used for setting the axis-type parameters or axis-type machine signals

- With an axis for which Cs contour control/spindle positioning is to be performed, set -(spindle number) as the servo axis number.
  Example)
  When exercising Cs contour control on the fourth controlled axis by using the first spindle, set -1.
- For tandem controlled axes or electronic gear box (EGB) controlled axes, two axes need to be specified as one pair. So, make a setting as described below.
  Tandem axis: For a master axis, set an odd (1, 3, 5, 7, 9, ...) servo axis number. For a slave axis to be paired, set a value obtained by adding 1 to the value set for the master axis.
  EGB axis: For a slave axis, set an odd (1, 3, 5, 7, 9, ...) servo axis number. For a dummy axis to be paired, set a value obtained by adding 1 to the value set for the slave axis.

1260	The shift amount per one rotation of a rotary axis

NOTE
When this parameter is set, the power must be turned off before operation is continued.

[Input type] Parameter input
[Data type] Real axis
[Unit of data] deg
[Min. unit of data] Depend on the increment system of the applied axis
[Valid data range] 0 or positive 9 digit of minimum unit of data (refer to the standard parameter setting table (B))
(When the increment system is IS-B, 0.0 to +999999.999)

Set the shift amount per one rotation of a rotary axis.
For the rotary axis used for cylindrical interpolation, set the standard value.

	#7	#6	#5	#4	#3	#2	#1	#0
1408					IRCx			

[Input type] Parameter input
[Data type] Bit axis

#3 IRCx The least input increment of the maximum cutting feedrates set in parameters Nos. 1430 and 1432 is:
0: Not multiplied by ten.
1: Multiplied by ten.

Set this parameter for the following axes, which are operated by the following functions:
- Spindle control axis by servo motor
- Tool rotary axis in the polygon turning function (T series)

If a rotation speed of 1000 (1/min) (=360000 (deg/min)) is to be used when this parameter is set to 1, set 36000.0 in parameter No. 1430/1432.

1430	Maximum cutting feedrate for each axis

[Input type] Parameter input
[Data type] Real axis
[Unit of data] mm/min, inch/min, deg/min (machine unit)
[Min. unit of data] Depend on the increment system of the applied axis
[Valid data range] Refer to the standard parameter setting table (C)
(When the increment system is IS-B, 0.0 to +999000.0)
Specify the maximum cutting feedrate for each axis.

1432	Maximum cutting feedrate for all axes in the acceleration/deceleration before interpolation

[Input type] Parameter input
[Data type] Real axis
[Unit of data] mm/min, inch/min, deg/min (machine unit)
[Min. unit of data] Depend on the increment system of the applied axis
[Valid data range] Refer to the standard parameter setting table (C)
(When the increment system is IS-B, 0.0 to +999000.0)
Set a maximum cutting feedrate for each axis in the look-ahead acceleration/deceleration before interpolation mode such as AI contour control. When this parameter is set to 0 or the look-ahead acceleration/deceleration before interpolation mode is not set, the maximum cutting feedrate set in parameter No. 1430 is used.

1825	Servo loop gain for each axis

[Input type] Parameter input
[Data type] Word axis
[Unit of data] 0.01/sec
[Valid data range] 1 to 32767
Set the loop gain for position control for each axis.
When the machine performs linear and circular interpolation (cutting), the same value must be set for all axes. When the machine requires positioning only, the values set for the axes may differ from one another. As the loop gain increases, the response by position control is improved. A too large loop gain, however, makes the servo system unstable.
The relationship between the positioning deviation (the number of pulses counted by the error counter) and the feedrate is expressed as follows:

Positioning deviation = Feedrate / (60 × Loop gain)
Unit : Positioning deviation mm, inch or deg
Feedrate mm/min, inch/min, or deg/min
Loop gain 1/sec

1826	In-position width for each axis

[Input type] Parameter input
[Data type] 2-word axis
[Unit of data] Detection unit
[Valid data range] 0 to 99999999
The in-position width is set for each axis.
When the deviation of the machine position from the specified position (the absolute value of the positioning deviation) is smaller than the in-position width, the machine is assumed to have reached the specified position. (The machine is in the in-position state.)

1827	In-position width in cutting feed for each axis

[Input type] Parameter input

[Data type] 2-word axis
[Unit of data] Detection unit
[Valid data range] 0 to 99999999

Set an in-position width for each axis in cutting feed. This parameter is used when bit 4 (CCI) of parameter No. 1801=1.

1828	Positioning deviation limit for each axis in movement

[Input type] Parameter input
[Data type] 2-word axis
[Unit of data] Detection unit
[Valid data range] 0 to 99999999

Set the positioning deviation limit in movement for each axis.
If the positioning deviation exceeds the positioning deviation limit during movement, a servo alarm SV0411, "EXCESS ERROR (MOVING)" is generated, and operation is stopped immediately (as in emergency stop).
Generally, set the positioning deviation for rapid traverse plus some margin in this parameter. Refer to the following set value.

$$\textbf{Setting value} = \frac{\textbf{Rapid traverse rate}^{(\textbf{Note 1})}}{\textbf{60} \times \textbf{Servo loop gain}^{(\textbf{Note 2})}} \times \frac{1}{\textbf{Detection unit}} \times 1.2 \textbf{ to } 1.5$$

> ⚠ **CAUTION**
> If this parameter is not set correctly, machine or workpiece can be damaged.

> **NOTE**
> 1 Usually, this value is parameter No.1420. When the maximal feedrate of each axis exceeds parameter No.1420 according to the command and override, the value is the maximal feedrate of the each axis.
> 2 Usually, this value is parameter No.1825. When the servo loop gains other than parameter No.1825 is effective, the value is actual servo loop gains.

1829	Positioning deviation limit for each axis in the stopped state

[Input type] Parameter input
[Data type] 2-word axis
[Unit of data] Detection unit
[Valid data range] 0 to 99999999

Set the positioning deviation limit in the stopped state for each axis.
If, in the stopped state, the positioning deviation exceeds the positioning deviation limit set for stopped state, a servo alarm SV0410 is generated, and operation is stopped immediately (as in emergency stop).

	#7	#6	#5	#4	#3	#2	#1	#0
3702							EMS	

[Input type] Parameter input
[Data type] Bit path

#1 EMS The multi-spindle control is:
0: Used.

1: Not used.

	#7	#6	#5	#4	#3	#2	#1	#0
3703					MPP	MPM		2P2

[Input type] Parameter input
[Data type] Bit

> **NOTE**
> When at least one of these parameters is set, the power must be turned off before operation is continued.

#0 2P2 When a multi-path system is used, inter-path spindle control allows:
0: Configuration where the spindle that belongs to one path only is shared between path 1 and path 2.
1: Configuration where the spindles that belong to path 1 and 2 are shared between the two paths.
When the spindle that belongs to an arbitrary path is shared between arbitrary paths, set bit 2 (MPM) of parameter No. 3703. (The meanings of signals used vary, so that ladder program modifications need to be made.)

#2 MPM When a multi-path system is used, the configuration allowed by inter-path spindle control:
0: Follows the setting of bit 0 (2P2) of parameter No. 3703.
1: Allows the sharing of the spindle that belongs to a path between arbitrary paths.

#3 MPP In multi-spindle control, a spindle selection using a programmed command instead of using the signals (SWS1 to SWS4<Gn027.0 to 2, Gn026.3>) is:
0: Not made.
1: Made.

> **NOTE**
> When this parameter is set to 1, set parameter No. 3781 at the same time.

	#7	#6	#5	#4	#3	#2	#1	#0
3706	TCW	CWM						

[Input type] Parameter input
[Data type] Bit path

#6 CWM
#7 TCW Set voltage polarity when the spindle speed is output from the following table

TCW	CWM	Voltage polarity
0	0	Both M03 and M04 positive
0	1	Both M03 and M04 negative
1	0	M03 positive, M04 negative
1	1	M03 negative, M04 positive

3717	Spindle amplifier number to each spindle

> **NOTE**
> When this parameter is set, the power must be turned off before operation is continued.

[Input type] Parameter input
[Data type] Byte spindle
[Valid data range] 0 to Maximum number of controlled axes

Set a spindle amplifier number to be assigned to each spindle.
0: No spindle amplifier is connected.
1: Spindle motor connected to amplifier number 1 is used.
2: Spindle motor connected to amplifier number 2 is used.
to
n: Spindle motor connected to amplifier number n is used.

3718	Subscript for display of a serial spindle (main spindle) or analog spindle

[Input type] Parameter input
[Data type] Byte spindle
[Valid data range] 0 to 122

Set a subscript to be added to spindle speed display on a screen such as the position display screen.
Used when the spindle switching function is not used, or used for the main spindle when the spindle switching function is used.

> **NOTE**
> This parameter is invalid when an extended spindle name is used.

3719	Subscript for display of a serial spindle (sub-spindle)

[Input type] Parameter input
[Data type] Byte spindle
[Valid data range] 0 to 122

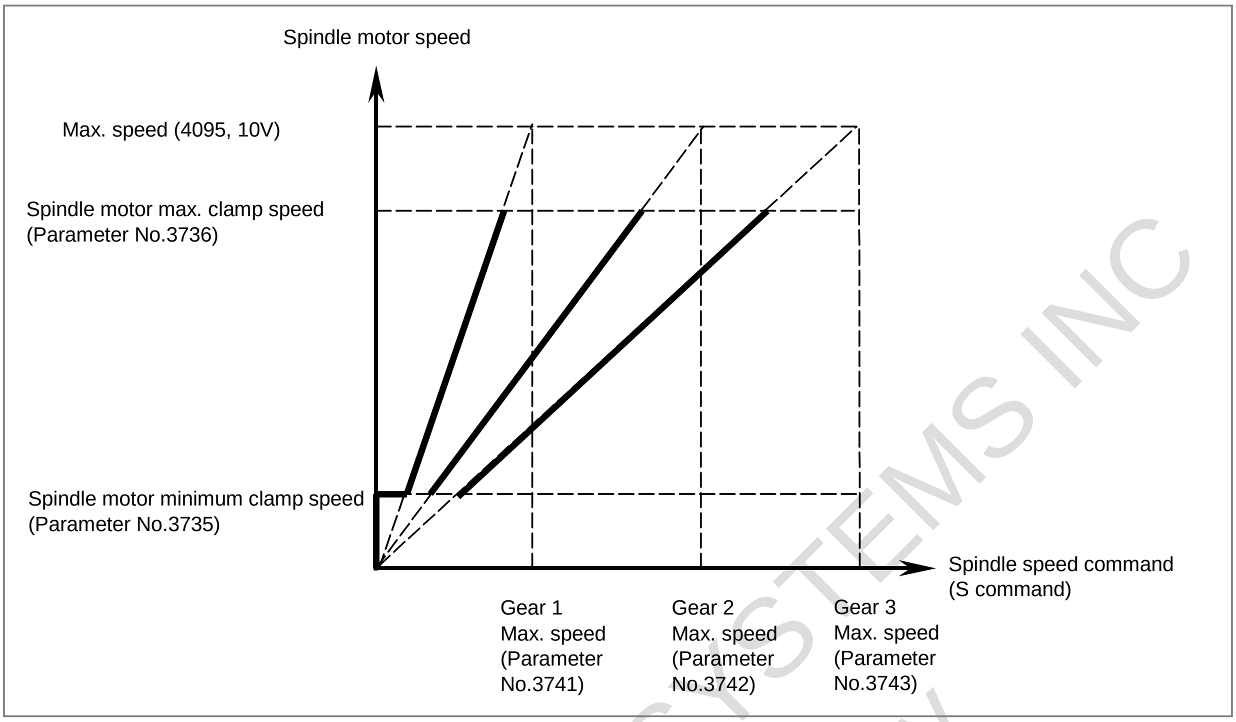
Set a subscript to be added to spindle speed display on a screen such as the position display screen.
Used for the sub-spindle when the spindle switching function is used.

> **NOTE**
> This parameter is invalid when an extended spindle name is used.

3741	Maximum spindle speed for gear 1
3742	Maximum spindle speed for gear 2
3743	Maximum spindle speed for gear 3
3744	Maximum spindle speed for gear 4

[Input type] Parameter input
[Data type] 2-word spindle
[Unit of data] min^{-1}
[Valid data range] 0 to 99999999

Set the maximum spindle speed corresponding to each gear.



3772	Maximum spindle speed

[Input type] Parameter input
[Data type] 2-word spindle
[Unit of data] min^{-1}
[Valid data range] 0 to 99999999

This parameter sets the maximum spindle speed.

When a command specifying a speed exceeding the maximum speed of the spindle is specified , or the speed of the spindle exceeds the maximum speed because of the spindle speed override function, the spindle speed is clamped at the maximum speed set in the parameter.

> ⚠ **CAUTION**
> 1 When 0 is set in this parameter, the speed of the spindle is not clamped.
> 2 When spindle speed command control is applied using the PMC, this parameter has no effect, and the spindle speed is not clamped.

3775	Default P command value for spindle selection in multi-spindle control

> **NOTE**
> When this parameter is set, the power must be turned off before operation is continued.

[Input type] Parameter input
[Data type] Word path
[Valid data range] 0 to 32767

When bit 3 (MPP) of parameter No. 3703 is set to 1 and bit 2 (MPA) of parameter No. 3706 is set to 1 in multi-spindle control, set a default P command value applicable if S_P_ is not specified even once after power-up.

3781	P code for selecting the spindle in multi-spindle control

[Input type] Parameter input
[Data type] Word spindle
[Valid data range] 0 to 32767

If bit 3 (MPP) of parameter No. 3703 is set to 1, set the P code to select each spindle under multi-spindle control. Specify the P code in a block containing the S command.

[Example] If the P code value for selecting the second spindle is set to 3,
S1000 P3;
causes the second spindle to rotate at S1000.

> **NOTE**
> 1 This parameter is valid if bit 3 (MPP) of parameter No. 3703 is set to 1.
> 2 If this parameter is set to 0, the corresponding spindle cannot be selected by a P code.
> 3 Under multi-path control, the P code specified here is valid for each path.
> For instance, if the P code to select the first spindle of path 2 is set to 21, specifying S1000 P21; in path 1 causes the first spindle of path 2 to be rotated at S1000.
> 4 Identical P code values cannot be used for different spindles. (Identical P code values cannot be used even if the paths are different.)
> 5 When this parameter is used (when bit 3 (MPP) of parameter No. 3703 is set to 1), the spindle command selection signal is invalid.
> 6 To use this parameter, enable the multi-spindle control (bit 3 (MSP) of parameter No,8133 is 1).

	#7	#6	#5	#4	#3	#2	#1	#0
8003					FEX			

[Input type] Parameter input
[Data type] Bit axis

> **NOTE**
> When this parameter bit is set, the power must be turned off before operation is continued.

#3 FEX The maximum feedrate that can be achieved by the machine during cutting feed or continuous feed in PMC axis control, or spindle control with servo motor is:
0: Not extended.
1: Extended.

Restrictions
- Parameters for setting the time constants for linear acceleration/deceleration after interpolation and bell-shaped acceleration/deceleration after interpolation
When as the acceleration/deceleration type, linear acceleration/ deceleration after interpolation or bell-shaped acceleration/ deceleration after interpolation is used for each of rapid traverse, cutting feed, and manual feed, the maximum allowable time constant is a half of the maximum value that can be set conventionally.

The time constant parameters used are as follows:

Parameter No.	Meaning
1620	Time constant (T) used for linear acceleration/deceleration in rapid traverse for each axis, or time constant (T1) used for bell-shaped acceleration/deceleration in rapid traverse for each axis
1621	Time constant (T2) used for bell-shaped acceleration/deceleration in rapid traverse for each axis
1622	Time constant for acceleration/deceleration in cutting feed for each axis
1624	Time constant for acceleration/deceleration in jog feed for each axis
1626	Time constant for acceleration/deceleration in threading cycles for each axis
1769	Time constant for acceleration/deceleration after cutting feed interpolation in the mode of look-ahead acceleration/deceleration before interpolation
5271 to 5274	Time constant for acceleration/deceleration in rigid tapping extraction (first to fourth gears)
5365 to 5368	Time constant for bell-shaped acceleration/deceleration in rigid tapping (first to fourth gears)

- The waveform display function of VCMD on the SERVO GUIDE or the SERVO GUIDE Mate.
  As the feedrate increases, more data is acquired for VCMD waveform display, which can prevent waveforms from being displayed correctly.

> ⚠ **CAUTION**
> When this function is enabled, the feedrate is extended to the maximum value that can be specified for cutting feed or continuous feed in PMC axis control if CMR is 1. If CMR is greater than 1, the feedrate is limited to a value smaller than the maximum value that can be specified.
> Note that the maximum motor speed may be exceeded depending on the feedrate specified.

	#7	#6	#5	#4	#3	#2	#1	#0
11000	SRV						FSR	

[Input type] Parameter input
[Data type] Bit axis

> **NOTE**
> When at least one of these parameters is set, the power must be turned off before operation is continued.

#1 FSR The axis to be subjected to servo motor-based spindle control is of a:
0: Semi-closed system.
1: Full-closed system.

#7 SRV Spindle control with servo motor are:
0: Not performed.
1: Performed

> **NOTE**
> When spindle control with servo motor are used for an axis, parameter No. 11010 must also be set for the axis.

	#7	#6	#5	#4	#3	#2	#1	#0
11001							TCR	

[Input type] Parameter input
[Data type] Bit axis

#1 TCR In SV speed control mode, time constant of acceleration/deceleration after interpolation for spindle control with servo motor is:
0: The parameter No. 1622.
(Time constant of acceleration/deceleration in cutting feed for each axis)
1: The parameter No. 11016.
(Time constant of acceleration/deceleration in SV speed control mode for each axis)
Set this parameter for the axis to be placed under spindle control with servo motor.

11010	Spindle number used by spindle control with servo motor or spindle control with Cs contour control

> **NOTE**
> When this parameter is set, the power must be turned off before operation is continued.

[Input type] Parameter input
[Data type] Byte axis
[Valid data range] 0 to maximum number of controlled spindles
This parameter sets a spindle number for a servo axis for which spindle control with servo motor is performed.

> **NOTE**
> Set a spindle number for the axes set in bits 6 and 7 of parameter No. 11000. For axes for which spindle control with servo motor is not performed, set 0.

11011	Movement of spindle control with servo motor axis per revolution

> **NOTE**
> When this parameter is set, the power must be turned off before operation is continued.

[Input type] Parameter input
[Data type] Real axis
[Unit of data] deg
[Min. unit of data] Depend on the increment system of the applied axis
[Valid data range] 0 or positive 9 digit of minimum unit of data (refer to the standard parameter setting table (B))
(When the increment system is IS-B, 0.0 to +999999.999)
This parameter sets a movement of axis per revolution for which spindle control with servo motor is performed.

11012	Spindle indexing speed for each axis

[Input type] Parameter input
[Data type] 2-word axis
[Unit of data] min^{-1}
[Valid data range] 0 to 99999999

In spindle control with servo motor, set the spindle indexing speed for each axis.
If 0 is set, the spindle indexing speed is assumed to be the setting of parameter No. 11020 (speed (S_0) for switching acceleration/ deceleration for each axis).

11013	Positioning deviation limit for each axis in movement

[Input type] Parameter input
[Data type] 2-word axis
[Unit of data] Detection unit
[Valid data range] 0 to 99999999

This parameter sets the limit of positional deviation for each axis during movement in spindle control with servo motor.

11014	Positioning deviation limit for each axis in the stopped state

[Input type] Parameter input
[Data type] 2-word axis
[Unit of data] Detection unit
[Valid data range] 0 to 99999999

This parameter sets the limit of positional deviation at stop for each axis in spindle control with servo motor.

11015	Maximum motor speed

[Input type] Parameter input
[Data type] 2-word axis
[Unit of data] min^{-1}
[Valid data range] 0 to 99999999

This parameter sets the maximum motor speed applicable when spindle control with servo motor is performed.

11016	Time constant of acceleration/deceleration in SV speed control mode for each axis

[Input type] Parameter input
[Data type] Word axis
[Unit of data] msec
[Valid data range] 0 to 4000

In spindle control with servo motor, set the time constant of acceleration/deceleration after interpolation in cutting feed for SV speed control mode. Set this parameter for the target axis for spindle control with servo motor. Set the time constant used for exponential acceleration/deceleration in cutting feed, bell-shaped acceleration/deceleration after interpolation or linear acceleration/deceleration after interpolation in cutting feed for each axis. Type of acceleration/deceleration is applied by bits 0 (CTLx) and 1 (CTBx) of parameter No. 1610.

11017	FL rate of exponential acceleration/deceleration in SV speed control mode for each axis

[Input type] Parameter input
[Data type] Real axis
[Unit of data] mm/min, inch/min, deg/min (machine unit)
[Min. unit of data] Depend on the increment system of the applied axis
[Valid data range] Refer to the standard parameter setting table (C)
(When the increment system is IS-B, 0.0 to +999000.0)

In spindle control with servo motor, this parameter sets the lowest feedrate (FL rate) in exponential acceleration/deceleration for velocity control.

Set this parameter for the target axis for spindle control with servo motor.

11020	Acceleration/deceleration switching speed (S_0) for each axis

[Input type] Parameter input
[Data type] 2-word axis
[Unit of data] min^{-1}
[Valid data range] 0 to 99999999

In spindle control with servo motor, this parameter sets the speed at which acceleration/ deceleration is changed to perform rotation control. (First step)

11021	Acceleration/deceleration switching speed (S_1) for each axis

[Input type] Parameter input
[Data type] 2-word axis
[Unit of data] min^{-1}
[Valid data range] 0 to 99999999

In spindle control with servo motor, this parameter sets the speed at which acceleration/ deceleration is changed to perform rotation control. (Second step)

11030	Individual acceleration / deceleration 1 (Leg 1)

[Input type] Parameter input
[Data type] 2-word axis
[Unit of data] min^{-1}/s
[Valid data range] 0 to 100000

In spindle control with servo motor, this parameter sets acceleration/deceleration to be applied to perform rotation control. When the speed ranges from 0 to acceleration switching speed 1, acceleration/deceleration 1 is applied. Acceleration switching speed 1 is the speed set in parameter No. 11020.

11031	Individual acceleration / deceleration 2 (Leg 2)

[Input type] Parameter input
[Data type] 2-word axis
[Unit of data] min^{-1}/s
[Valid data range] 0 to 100000

In spindle control with servo motor, this parameter sets acceleration/deceleration to be applied to perform rotation control. When the speed ranges from acceleration switching speed 1 to acceleration switching speed 2, acceleration/ deceleration 2 is applied. Acceleration switching speed 1 and acceleration switching speed 2 are the speeds set in parameters Nos. 11020 and 11021, respectively.

11032	Individual acceleration / deceleration 3 (Leg 3)

[Input type] Parameter input
[Data type] 2-word axis
[Unit of data] min^{-1}/s
[Valid data range] 0 to 100000

In spindle control with servo motor, this parameter sets acceleration/deceleration to be applied to perform rotation control. When the speed ranges from acceleration switching speed 2 to the maximum speed, acceleration/deceleration 3 is applied. Acceleration switching speed 2 is the speed set in parameter No. 11021.

10.20.2 Spindle Indexing Function

Format

G96.1 P_ R_ ;	After spindle indexing is completed, the operation of the next block is started.
G96.2 P_ R_ ;	Before spindle indexing is completed, the operation of the next block is started.
G96.3 P_ ;	After it is confirmed that spindle indexing is completed, the operation of the next block is started.

P: Spindle selection with multi-spindle control
R: Stoppage angle [deg] (0 to (parameter No. 1260))

To specify address P, use parameter No. 3781 (P code for selecting a spindle in multi-spindle control).
To turn the position control mode ON without performing spindle indexing, do so after canceling the SV speed control mode by issuing G96.1 command with no R specified when the motor is at a halt.
When the motor is rotating, issuing a G96.1 (or G96.2) command with no R specified results in the motor coming to a halt by behaving in the same manner as for R0.

NOTE
1 When using G96.2, issue G96.3 before another spindle move command, to make sure that the spindle is at a complete halt.
2 To issue G96.1, G96.2, or G96.3, use an independent block.

Spindle indexing command

- Move command

(1) Command waiting for spindle indexing to be completed
If G96.1 is issued, the next block is executed after spindle indexing is completed.
(2) Command not waiting for spindle indexing to be completed
If G96.2 is issued, the next block can be executed before spindle indexing is completed.

- Movement completion check command

G96.3 is used to check to see if spindle indexing is completed. If it has not been completed, the next block waits for spindle indexing to be completed. If it is completed, the next block is executed.

- SV speed control mode cancellation

If G96.1 is used to perform spindle indexing, the SV speed control mode is canceled when spindle indexing is completed.
If G96.2 is used to perform spindle indexing, G96.3 can be used to check to see if spindle indexing is completed and, if completed, cancel the SV speed control mode. Issuing G96.2 not followed by G96.3 cannot cancel the SV speed control mode even if spindle indexing is completed.
If SV speed control mode cancel, it is necessary to be commanded in the path to which the live tool axis belongs.

- Spindle indexing command during spindle rotation

Issuing G96.1 or G96.2 with a position specified during spindle rotation causes the spindle to stop at the specified position.
Example)
M03 S1000 ;...........................Rotation at S1000
G96.1 P1 R180.0 ;..................Stoppage of rotation at the 180° position

- Spindle indexing speed

Issuing G96.1 or G96.2 causes a move speed to be dedicated to spindle indexing. Specify the move speed for spindle indexing, using parameter No. 11012.

- Spindle indexing acceleration/deceleration

Fig. 10.20.2 (a) is the acceleration/deceleration specified by G96.1/G96.2.

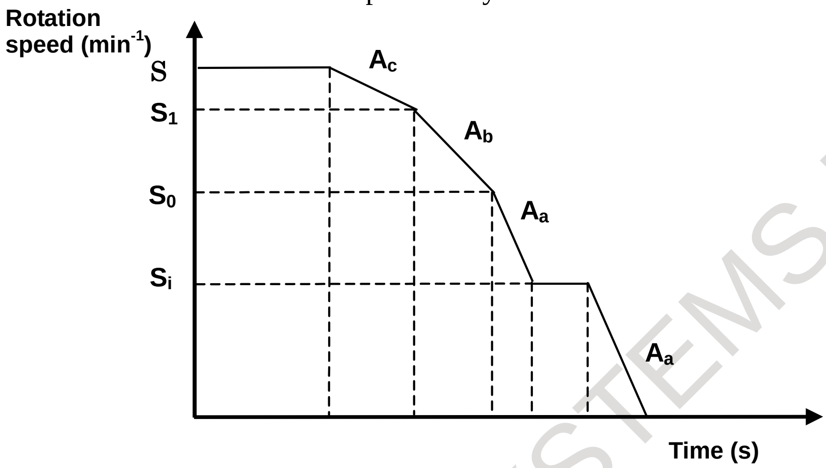


Fig. 10.20.2 (a)

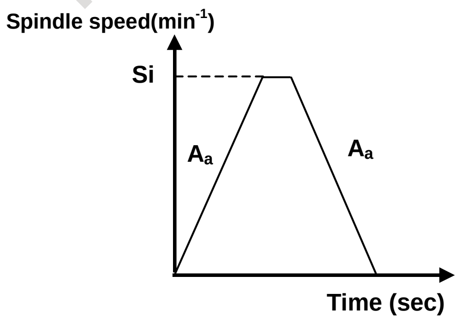
S_0	Parameter No. 11020 setting (acceleration/deceleration is switched at a rotation speed of S_0 (min^{-1}).)
S_1	Parameter No. 11021 setting (acceleration/deceleration is switched at a rotation speed of S_1 (min^{-1}).)
S	Command-specified rotation speed (min^{-1})
Si	Spindle indexing speed (min^{-1}) parameter No. 11012
Aa	Parameter No. 11030 setting (acceleration/deceleration (min^{-1}/s) used between rotation speeds 0 and S_0 (span 1))
A_b	Parameter No. 11031 setting (acceleration/deceleration (min^{-1}/s) used between rotation speeds S_0 and S_1 (span 2))
Ac	Parameter No. 11032 setting (acceleration/deceleration (min^{-1}/s) used between rotation speeds S_1 and the maximum motor speed S (span 3))

Spindle indexing speed during a stop

If spindle indexing is executed (G96.1) while the rotation tool axis is stopped (with SV rotation control mode being ON), indexing is performed within one rotation, so that the spindle indexing speed (No. 11012) may not be attained.



Spindle indexing command (absolute coordinate/machine coordinate)

Using bit 0 (SIC) of parameter No. 11005 can select which coordinate system, absolute or machine, is to be used in spindle indexing.

Example:

If the difference between the machine and absolute coordinates (machine coordinate – absolute coordinate) is 100.000:

- Spindle indexing performed by turning the SV speed control mode signal SRVON<Gn521> OFF (“1” to “0”) or issuing a spindle indexing
  G code (with no R specified)
  1. If bit 0 (SIC) of parameter No. 11005 = 0:
     Spindle indexing is performed with a machine coordinate of 100.000 and an absolute coordinate of 0.000.
  2. If bit 0 (SIC) of parameter No. 11005 = 1:
     Spindle indexing is performed with a machine coordinate of 0.000 and an absolute coordinate of 260.000.
- G code-based spindle indexing (with R specified)
  Assuming that spindle indexing is specified with R100.000:
  1. If bit 0 (SIC) of parameter No. 11005 = 0:
     Spindle indexing is performed with a machine coordinate of 200.000 and an absolute coordinate of 100.000.
  2. If bit 0 (SIC) of parameter No. 11005 = 1:
     Spindle indexing is performed with a machine coordinate of 100.000 and an absolute coordinate of 0.000.

- Example program commands

1. A move command is issued to the spindle, using G96.2. The spindle starts moving, and the execution of the next block begins.
   The spindle keeps moving even when any other block is being executed.
   (The spindle indexing signal SPP<Fn522> is “1” during spindle indexing.)
2. When another command is issued to the spindle, G96.3 is used to heck in advance whether the spindle has finished moving.
   If the spindle is still moving (the spindle indexing signal is on), the CNC enters a wait state. If the spindle has finished moving, the command is issued to cause the spindle to start moving.

Example: Command not waiting for spindle indexing to finish and command checking whether spindle indexing has finished (parameter No. 3781 (S1) = 1)

Program command	Operation
G96.2 P1 R270.0 ;	Command not waiting for spindle indexing to finish. The first spindle S1 moves to 270.0.
G01 X10.0 Y20.0 F1000.0 ;	Starts cutting feed. No wait for spindle indexing to finish.
G02 X50.0 Y100.0 R50.0 ;	Starts circular interpolation. No wait for spindle indexing to finish.
G96.3 P1 ;	Checks whether spindle indexing has finished.
M29 S100 P1 ;	Starts rigid tapping if the spindle indexing signal is 0.
G84 X10.0 Y 20.0 R-5.0 Z-20.0	Waits for rigid tapping command if the spindle indexing signal is 1.

Notes

1. Spindle speed override signals and spindle stop signal are invalid from the cancellation of SV speed control mode to the completion of spindle indexing.
   - 1st spindle speed override signal SOV0 to SOV7<Gn030>
   - 2nd spindle speed override signal SOV20 to SOV27<Gn376>
   - 3rd spindle speed override signal SOV30 to SOV37<Gn377>
   - 4th spindle speed override signal SOV40 to SOV47<Gn378>
   - Spindle stop signal *SSTP<Gn029.6>

- Individual spindle stop signals *SSTP1, *SSTP2, *SSTP3, *SSTP4<Gn027.3, Gn027.4, Gn027.5>, <Gn026.6>

2. When the SV speed control mode is canceled, the spindle speed clamp is valid to the spindle speed command clamp (Function to spindle speed clamp by value set to internal relay address (R) of PMC specified by parameter No. 3773). Even if internal relay address (R) of PMC is changed from the cancellation of SV speed control mode to the completion of spindle indexing, the spindle speed clamp is not changed.
3. Specify an M code not involved in buffering as an M code to be used as a command for switching the SV speed control mode (parameters Nos. 3411 to 3420 and 11290 to 11299).
4. M code for switching the SV speed control mode must be specified in an independent block. When using multiple M commands in a single block, the M code must be specified as the first M command.
5. G96.1, G96.2, G96.3, G96.4, and M code for switching the SV speed control mode must be specified in the path to which the spindle of interest belongs.
6. After G96.2 command, command G96.3 before commanding move command such as rapid traverse (G00) or cutting feed (G01) to rotation axis. Move command is specified without commanding G96.3, alarm PS0445 “ILLEGAL AXIS OPERATION” is issued.
7. If G96.3 is not commanded after G96.2 command, SV speed control mode is not canceled. For example, reset before G96.2 command. Cancel the mode before issuing the axis move command.
8. If the spindle stops rotating because of G96.1, G96.2, the spindle speed command output becomes 0. To cause the spindle to restart rotating, place the spindle in the SV speed control mode, and then, issue an S command.
9. Spindle indexing is enabled only in the SV speed control mode. In any mode other than the SV speed control mode, use ordinary positioning.
10. If the specified spindle indexing speed is 0, the acceleration/deceleration switching rotation speed (stage 1) (parameter No. 11020) is used as the actual spindle indexing speed.
11. G96.1, G96.2, G96.3, G96.4 cannot be commanded for settings other than multi-spindle control type P.

Signal

Spindle indexing signal for each axis SPP1 to SPP8<Fn522>

[Classification] Output signal
[Function] These signals inform that spindle indexing for the respective axes is in progress.
[Output cond.] The signals are “1” if:
- Spindle indexing for the respective axes has not finished.

The signals are “0” if:
- Spindle indexing for the respective axes has finished.

11012	Spindle indexing speed for each axis

[Input type] Parameter input
[Data type] 2-word axis
[Unit of data] min^{-1}
[Valid data range] 0 to 99999999

In spindle control with servo motor, set the spindle indexing speed for each axis.
If 0 is set, the spindle indexing speed is assumed to be the setting of parameter No. 11020 (speed (S_0) for switching acceleration/ deceleration for each axis).

10.20.3 Speed-up of Spindle Indexing Function

Overview

In conventional spindle indexing, spindle indexing to the specified position after the speed was accelerated or was decelerated up to the spindle indexing speed was executed.
In this function, the spindle indexing is executed directly to the specified position. The spindle indexing time can be reduced.

Explanation

When bit 1 (HSP) of parameter No. 11002 is set to 1, spindle indexing when the spindle rotates is sped up.
When the spindle has stopped, the spindle indexing is the same as the conventional the spindle indexing.

Format

The command format for this type of the spindle indexing is the same as for the conventional type of the spindle indexing.
For details, see “Spindle Indexing” of the conventional type.

Speed-up of Spindle Indexing Function

In the following cases, the spindle indexing speed up is executed.
- G96.1(G96.2) is specified during spindle rotation
- SV speed control mode signals SRVON<Gn521> is set to ”0” during spindle rotation

In the following, the above-mentioned operation is described, "SV speed control mode off".

- Allowable spindle speed of spindle indexing (Parameter(No.11019))

Set the allowable spindle speed of the spindle indexing in parameter No. 11019.

(1) When the SV speed control mode is canceled, the spindle speed is higher than the allowable spindle speed. Decelerates from the spindle speed when the SV speed control mode is canceled, and the spindle indexing is executed to the specified position.

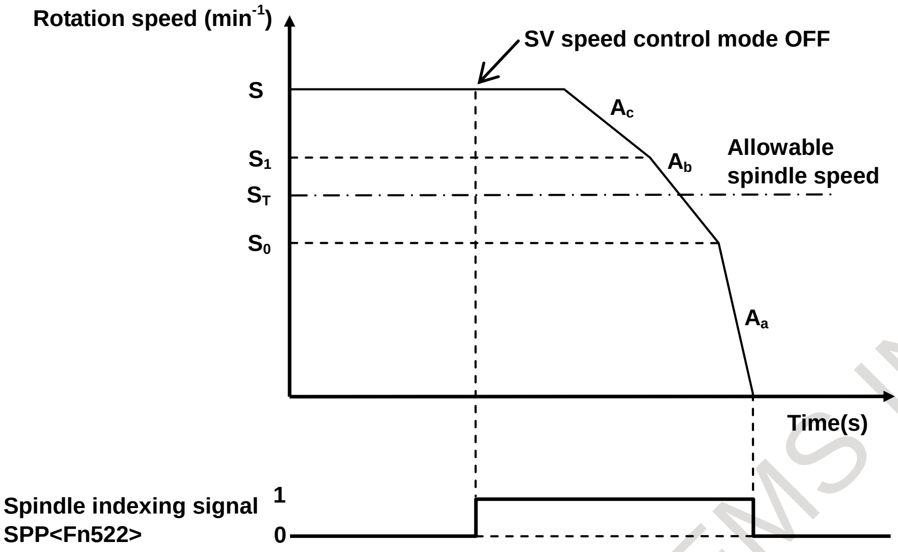

Fig. 10.20.3 (a) Spindle speed is higher than the allowable spindle speed

(2) When the SV speed control mode is canceled, the spindle speed is lower than the allowable spindle speed. The spindle accelerates once, and the spindle indexing is executed to the specified position.

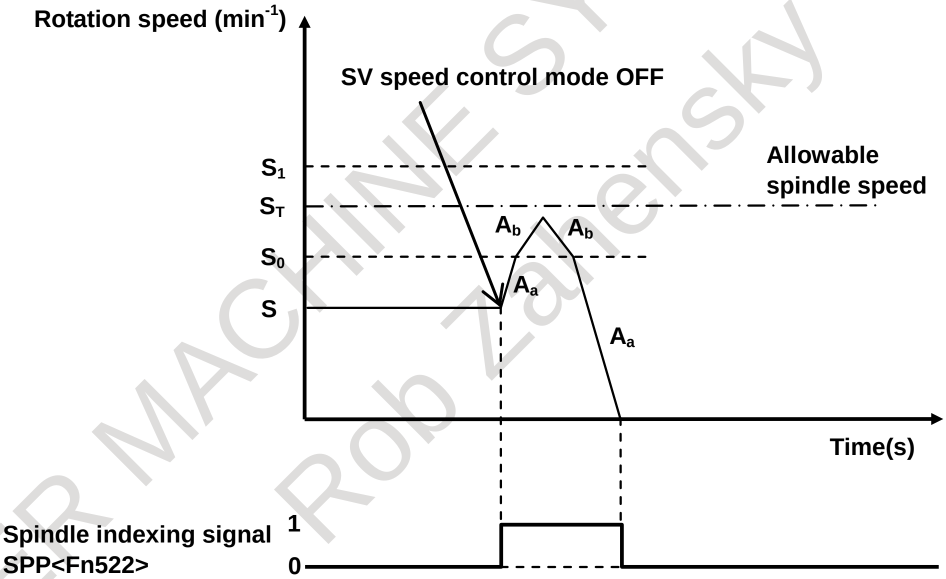

Fig. 10.20.3 (b) Spindle speed is lower than the allowable spindle speed

When accelerating during spindle indexing, the spindle speed is clamped at the lowest spindle speed among the following spindle speed.

- Parameter(No.11019) : Allowable spindle speed of spindle indexing
- Parameter(No.3772) : Maximum spindle speed
- Parameter(No.3741 to 3744) : Maximum spindle speed (Gear 1 to Gear 4)
- Spindle speed set to internal relay address (R signal) of PMC specified by parameter(No. 3773)

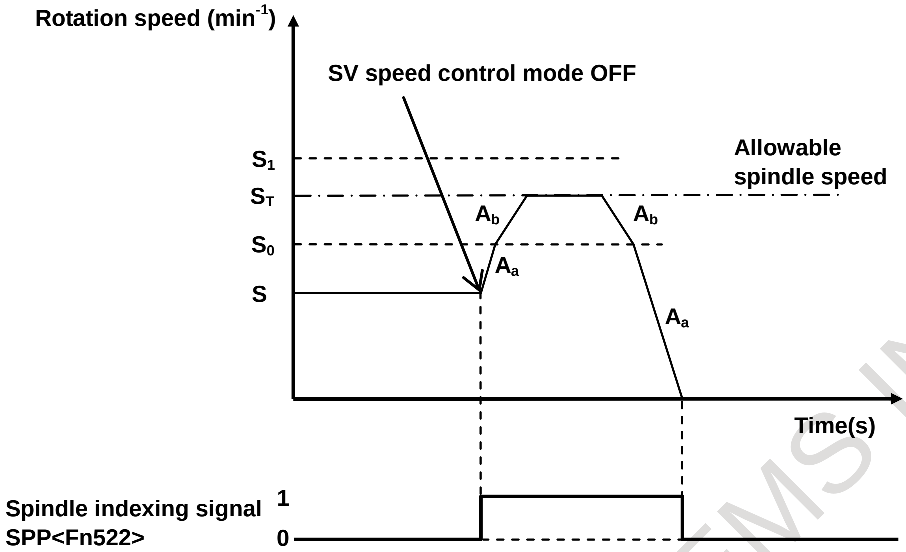

Fig. 10.20.3 (c) Clamped by allowable spindle speed

The spindle doesn't accelerate when the parameter (No.11019) is 0. The spindle decelerates from the spindle speed when the SV speed control mode is canceled, and the spindle indexing is executed to the specified position.

- Spindle indexing acceleration/deceleration

As for the spindle speed of the acceleration/deceleration switching and the acceleration after the SV speed control mode is canceled, the parameter in Table 10.20.3 is applied as shown in Fig. 10.20.3 (a) to Fig. 10.20.3 (c).

Table 10.20.3 Parameters for acceleration during spindle indexing

S_0	Acceleration switching speed (S_0) [min^{-1}] (parameter No.11020)
S_1	Acceleration switching speed (S_1) [min^{-1}] (parameter No.11021)
S	Specified rotation speed[min^{-1}]
S_T	Allowable spindle speed of spindle indexing[min^{-1}] (parameter No.11019)
A_a	Acceleration 1 [min^{-1}/s] (parameter No.11030)
A_b	Acceleration 2 [min^{-1}/s] (parameter No.11031)
A_c	Acceleration 3 [min^{-1}/s] (parameter No.11032)

- Spindle indexing signal for each axis

The spindle indexing signal SPP<Fn522> is “1” form Fig. 10.20.3 (a) to Fig. 10.20.3 (c) during spindle indexing until the spindle decelerates and stops after the SV speed control mode is canceled

Notes

1. Spindle speed override signals and spindle stop signal are invalid from the cancellation of SV speed control mode to the completion of spindle indexing.
   - 1st spindle speed override signal SOV0 to SOV7<Gn030>
   - 2nd spindle speed override signal SOV20 to SOV27<Gn376>
   - 3rd spindle speed override signal SOV30 to SOV37<Gn377>
   - 4th spindle speed override signal SOV40 to SOV47<Gn378>
   - Spindle stop signal *SSTP<Gn029.6>
   - Individual spindle stop signals *SSTP1, *SSTP2, *SSTP3, *SSTP4<Gn027.3, Gn027.4, Gn027.5>, <Gn026.6>
2. When the SV speed control mode is canceled, the spindle speed clamp is valid to the spindle speed command clamp (Function to spindle speed clamp by value set to internal relay address (R) of PMC specified by parameter No. 3773). Even if internal relay address (R) of PMC is changed from the

cancellation of SV speed control mode to the completion of spindle indexing, the spindle speed clamp is not changed.

3. Specify an M code not involved in buffering as an M code to be used as a command for switching the SV speed control mode (parameters Nos. 3411 to 3420 and 11290 to 11299).
4. M code for switching the SV speed control mode must be specified in an independent block. When using multiple M commands in a single block, the M code must be specified as the first M command.
5. G96.1, G96.2, G96.3, G96.4, and M code for switching the SV speed control mode must be specified in the path to which the spindle of interest belongs.
6. After G96.2 command, command G96.3 before commanding move command such as rapid traverse (G00) or cutting feed (G01) to rotation axis. Move command is specified without commanding G96.3, alarm PS0445 “ILLEGAL AXIS OPERATION” is issued.
7. If G96.3 is not commanded after G96.2 command, SV speed control mode is not canceled. For example, reset before G96.2 command. Cancel the mode before issuing the axis move command.
8. If the spindle stops rotating because of G96.1, G96.2, the spindle speed command output becomes 0. To cause the spindle to restart rotating, place the spindle in the SV speed control mode, and then, issue an S command.
9. Spindle indexing is enabled only in the SV speed control mode. In any mode other than the SV speed control mode, use ordinary positioning.
10. G96.1, G96.2, G96.3, G96.4 cannot be commanded for settings other than multi-spindle control type P.

Signal

Spindle indexing signal for each axis SPP1 to SPP8<Fn522>

[Classification] Output signal

[Function] These signals inform that spindle indexing for the respective axes is in progress.

[Output cond.] The signals are “1” if:

- Spindle indexing for the respective axes has not finished.

The signals are “0” if:

- Spindle indexing for the respective axes has finished.

Signal address

	#7	#6	#5	#4	#3	#2	#1	#0
Fn522	SPP8	SPP7	SPP6	SPP5	SPP4	SPP3	SPP2	SPP1

Parameter

	#7	#6	#5	#4	#3	#2	#1	#0
11002							HSP	

[Input type] Parameter input

[Data type] Bit axis

#1 HSP Speed-up of Spindle indexing is:

0: Disabled.

1: Enabled.

> **NOTE**
> This parameter is Automatic setting parameter. For details, refer to the appendix "Automatic setting / Initial setting parameter" in this manual.

11019	Allowable spindle speed of spindle indexing

[Input type] Parameter input
[Data type] 2-word axis
[Unit of data] min^{-1}
[Valid data range] 0 to 99999999

When bit 1 (HSP) of parameter No. 11002 is 1, allowable spindle speed of speed-up spindle indexing is set.
When the SV speed control mode is canceled, the spindle speed is lower than the this parameter setting value, the spindle accelerates to this parameter setting value
The spindle doesn't accelerate when this parameter is 0. The spindle decelerates from the spindle speed when the SV speed control mode is canceled, and the spindle indexing is executed to the specified position.

10.20.4 Rigid Tapping with Servo Motor

Format

The command format for this type of rigid tapping is the same as for the conventional type of rigid tapping.
For details, see “Rigid Tapping” of the conventional type.

> **NOTE**
> Using rigid tapping commands requires putting the rotation axis servo motor in the position control mode in advance. If the servo motor is rotating, cause it to exit the SV speed control mode by issuing G96.1/G96.2. The SV speed control mode in-progress signal SVREV<Fn521> can be used to check what mode the servo motor rotation axis is in.

Rigid tapping specification

- **Feedrate**

For rigid tapping, the feedrate of a drilling axis is one specified in an F command, and that of the spindle is S × the amount of movement per live tool axis rotation (parameter No. 11011) [deg/min].
Feed per minute and feed per revolution are detailed later.
During rigid tapping, the spindle speed is limited by a parameter for specifying the maximum cutting feedrate for the axis used as a live tool axis, that is, parameter No. 1430 (or No. 1432 if look-ahead acceleration/ deceleration before interpolation is enabled).
Usually, the upper end of the maximum cutting feed range that can be specified by parameter No. 1430 or No. 1432 is 999999.999[deg/min] (equivalent to S2778 [min^{-1}]). For live tool axes specified for use in rigid tapping (bit 3 (IRC) of parameter No. 1408 = 1), the actual spindle speed is limited to within 10 times the setting of the maximum cutting feedrate parameter.
Example:
Maximum cutting feedrate parameter No. 1430 = 360000
Limit to the maximum spindle speed 360000×10 = 3600000 [deg/min] (S10000 [min^{-1}])

> ⚠ **CAUTION**
> Make the tapper thread pitch equal to one specified by the program (F, S). Otherwise, the tool or workpiece may be damaged.

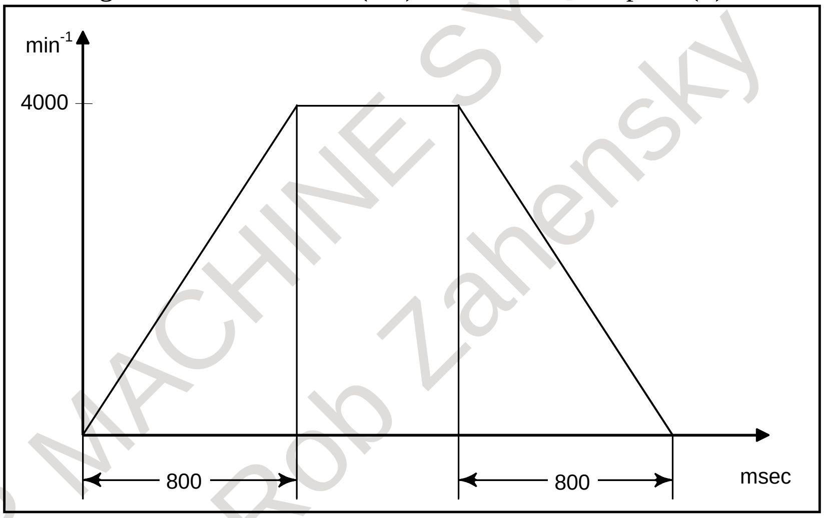
Acceleration/deceleration control

- Acceleration/deceleration after interpolation

In rigid tapping with servo motor, unlike the conventional type of rigid tapping, it is possible to apply linear acceleration/deceleration of constant acceleration/deceleration time type and bell-shape acceleration/deceleration.
Resetting bit 0 (SRBx) of parameter No. 11001 to 0 makes it possible to apply linear acceleration/deceleration after interpolation of constant acceleration time type. Setting the bit to 1 makes it possible to apply bell-shape acceleration/deceleration after interpolation of constant acceleration time type.
The time constant for each gear is specified in parameters Nos. 11060 to 11063. If bit 2 (TDR) of parameter No. 5201 = 1, the tool extraction time constant for each gear is specified in parameter Nos. 11065 to 11068. Specify each of these parameters for the live tool axis used in rigid tapping.
The acceleration/deceleration types and time constants used for drilling axes are set to the same values as for live tool axes.

NOTE
Time constants specified for rigid tapping with servo motor are different from those for the conventional type of rigid tapping.

Example: Parameter settings are: Time constant (TC) = 800 msec and speed (S) = 4000 min^{-1}



- Acceleration/deceleration before interpolation

If AI contour control I or II can be used in rigid tapping with servo motor, issuing a rigid tapping command in the "acceleration/deceleration before look-ahead interpolation" mode makes it possible to apply acceleration/deceleration before look-ahead interpolation to this type of rigid tapping. Acceleration/deceleration before look-head interpolation is effective when the AI contour control mode is ON. For details, see the Subsection of "AI Contour Control I and AI Contour Control II."
Parameter No. 11050 is used to specify the maximum allowable acceleration value for acceleration/deceleration interpolation used in rigid tapping. Parameter No. 11051 is used to specify the acceleration change time for look-ahead bell-shape acceleration/deceleration before interpolation. As for look-ahead acceleration/deceleration before interpolation used in rigid tapping, the maximum allowable acceleration value is 100000 (deg/s^2).
It is possible to change a speed of up to S1000 (min^{-1}) (equivalent to 360000 (deg/min) in 60 (ms).
The time constant (parameter No. 11052) for cutting feed acceleration/deceleration after interpolation usable in the "look-ahead acceleration/deceleration before interpolation" mode is a constant-time type.

> **NOTE**
> Specify the same time constant for both drilling and live tool axes. Otherwise, it is likely that the machine may malfunction.

- Feedrate clamp by parameter No.8465

In AI contour control, the maximum allowable feedrate is set by parameter No.8465. The maximum allowable feedrate of rigid tapping with servo motor during AI contour control is also set by parameter No.8465. If bit 0 (NCL) of parameter No.11003 is set to 1, the maximum allowable feedrate of rigid tapping with servo motor during AI contour control is not clamped by parameter No.8465. However, maximum allowable feedrate set by parameter No.1432 is available regardless of bit 0 (NCL) of parameter No.11003.

- Ignoring feedrate commands

When AI contour control II is enabled and bit 7 (NOF) of parameter No.8451 is set to 1, all feedrate commands are ignored and feedrate is specified by parameter No.8465. If bit 1 (FEN) of parameter No.11003 is set to 1, feedrate of rigid tapping with servo motor can be specified by machining program. But feedrate is limited by maximum allowable feedrate of parameter No.1432.

Reference position return

With this function, it is impossible to perform spindle orientation at the start of rigid tapping. Before issuing a rigid tapping command, perform spindle indexing or positioning at a point where drilling should begin. For details, see Subsection of "Spindle Indexing Function."

Diagnosis data

Also in rigid tapping with servo motor, information about rigid tapping is displayed on the diagnosis display screen. See Subsection of “Diagnosis Display” for what information is displayed.

Notes

If the pitch is very small or the amount of travel along the drilling axis is large, the amount of travel along the rotation axis becomes large, possibly resulting in alarm PS0003, “TOO MANY DIGITS”.

Parameter

1430	Maximum cutting feedrate for each axis

[Input type] Parameter input
[Data type] Real axis
[Unit of data] mm/min, inch/min, deg/min (machine unit)
[Min. unit of data] Depend on the increment system of the applied axis
[Valid data range] Refer to the standard parameter setting table (C)
(When the increment system is IS-B, 0.0 to +999000.0)
Specify the maximum cutting feedrate for each axis.

1432	Maximum cutting feedrate for all axes in the acceleration/deceleration before interpolation

[Input type] Parameter input
[Data type] Real axis
[Unit of data] mm/min, inch/min, deg/min (machine unit)
[Min. unit of data] Depend on the increment system of the applied axis
[Valid data range] Refer to the standard parameter setting table (C)
(When the increment system is IS-B, 0.0 to +999000.0)

Set a maximum cutting feedrate for each axis in the look-ahead acceleration/deceleration before interpolation mode such as AI contour control. When this parameter is set to 0 or the look-ahead acceleration/deceleration before interpolation mode is not set, the maximum cutting feedrate set in parameter No. 1430 is used.

	#7	#6	#5	#4	#3	#2	#1	#0
8451	NOF							

[Input type] Setting input
[Data type] Bit path

#7 NOF In AI contour control, an F command is:
0: Not ignored.
1: Ignored.
When this parameter is set to 1, the specification of the maximum allowable feedrate set in parameter No. 8465 is assumed.

8465	Maximum allowable feedrate for AI contour control

[Input type] Setting input
[Data type] Real path
[Unit of data] mm/min, inch/min, deg/min (input unit)
[Min. unit of data] Depend on the increment system of the reference axis
[Valid data range] Refer to the standard parameter setting table (C)
(When the increment system is IS-B, 0.0 to +999000.0)
This parameter sets the maximum allowable feedrate for contour control.
If a feedrate higher than the setting of this parameter is specified in the AI contour control mode, the feedrate is clamped to that set in this parameter.
If this parameter is set to 0, no clamping is performed.
When bit 7 (NOF) of parameter No. 8451 is set to 1, the tool moves, assuming that the feedrate set in this parameter is specified. If 0 is set in this parameter at this time, a movement is made at the specified feedrate.

	#7	#6	#5	#4	#3	#2	#1	#0
11001								SRBx

[Input type] Parameter input
[Data type] Bit axis

#0 SRBx Acceleration/deceleration after interpolation in cutting feed during rigid tapping with servo motor is:
0: Linear acceleration/deceleration.
1: Bell-shaped acceleration/deceleration.

	#7	#6	#5	#4	#3	#2	#1	#0
11003							FEN	NCL

[Input type] Parameter input
[Data type] Bit path

#0 NCL In AI contour control, feedrate of rigid tapping with servo motor is:
0: limited by maximum allowable feedrate of parameter No.8465.
1: not limited by maximum allowable feedrate of parameter No.8465.
Maximum allowable feedrate of parameter No.1432 is enabled regardless of this parameter.

#1 FEN When ignoring feedrate commands is enabled (bit 7 (NOF) of parameter No.8451 is 1), feedrate of rigid tapping with servo motor is specified by:

0: parameter No.8465.

1: machining program.

Maximum allowable feedrate of parameter No.1432 is enabled regardless of this parameter.

11050	Maximum allowable acceleration rate in acceleration/deceleration before interpolation for each axis in rigid tapping

[Input type] Parameter input
[Data type] Real axis
[Unit of data] mm/sec^2, inch/sec^2, deg/sec^2 (machine unit)
[Min. unit of data] Depend on the increment system of the applied axis
[Valid data range] Refer to the standard parameter setting table (D)
(When the machine system is metric system, 0.0 to +100000.0. When the machine system is inch system, 0.0 to +10000.0)

Set a maximum allowable acceleration rate in look-ahead acceleration/ deceleration before interpolation for each axis.

If a value greater than 100000.0 is set, the value is clamped to 100000.0. If 0 is set, the specification of 100000.0 is assumed. If 0 is set for all axes, however, look-ahead acceleration/deceleration before interpolation is not performed.

11051	Acceleration change time of bell-shaped acceleration/deceleration before interpolation in rigid tapping

[Input type] Parameter input
[Data type] 2-word path
[Unit of data] msec
[Valid data range] 0 to 200

Set an acceleration change time of look-ahead bell-shaped acceleration/ deceleration before interpolation (time for changing from the state of constant federate (A) to the state of constant acceleration/deceleration (C) at the acceleration rate calculated from the acceleration rate set in parameter No. 11050: time of (B) in the Fig. 10.20.4 (d)).

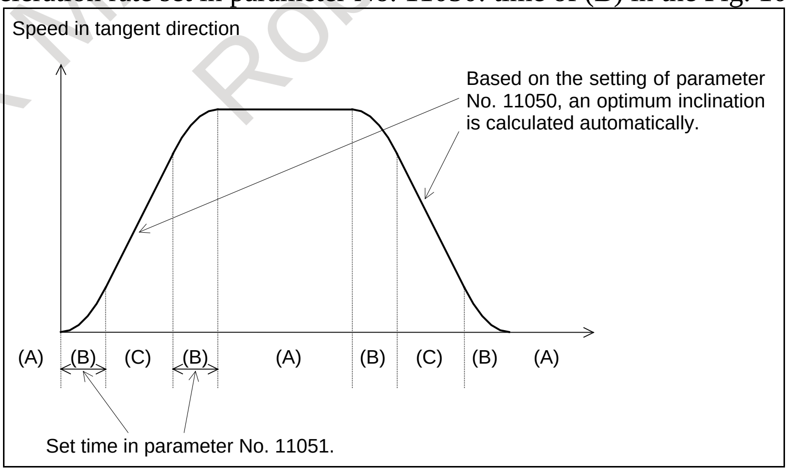


Fig. 10.20.4

11052	Time constant for acceleration/deceleration after cutting feed interpolation in the acceleration/deceleration before interpolation mode in rigid tapping

[Input type] Parameter input
[Data type] Word axis
[Unit of data] msec

[Valid data range] 0 to 4000

In the look-ahead acceleration/deceleration before interpolation mode as in AI contour control, not the ordinary time constant (parameter No. 1622) but the value of this parameter is used.

Be sure to specify the same time constant value for all axes except for a special application.

If different values are set, correct linear and circular figures cannot be obtained.

11060	**Time constant for acceleration/deceleration after cutting feed interpolation in rigid tapping (first gear)**
11061	**Time constant for acceleration/deceleration after cutting feed interpolation in rigid tapping (second gear)**
11062	**Time constant for acceleration/deceleration after cutting feed interpolation in rigid tapping (third gear)**
11063	**Time constant for acceleration/deceleration after cutting feed interpolation in rigid tapping (fourth gear)**

[Input type] Parameter input
[Data type] Word axis
[Unit of data] msec
[Valid data range] 0 to 4000

For the time constants in rigid tapping with servo motors, parameters Nos. 11060 to 11063 are used, not parameters Nos. 5261 to 5264.

Set these parameters with a live tool axis in rigid tapping.

11065	**Time constant for acceleration/deceleration after cutting feed interpolation in rigid tapping extraction (first gear)**
11066	**Time constant for acceleration/deceleration after cutting feed interpolation in rigid tapping extraction (second gear)**
11067	**Time constant for acceleration/deceleration after cutting feed interpolation in rigid tapping extraction (third gear)**
11068	**Time constant for acceleration/deceleration after cutting feed interpolation in rigid tapping extraction (fourth gear)**

[Input type] Parameter input
[Data type] Word axis
[Unit of data] msec
[Valid data range] 0 to 4000

If bit 2 (TDR) of parameter No. 5201 is set to 1, for the time constants in rigid tapping extraction with servo motors, parameters Nos. 11065 to 11068 are used, not parameters Nos. 5271 to 5274.

Set these parameters with a live tool axis in rigid tapping.

10.20.5 Threading, Feed per Revolution, and Constant Surface Speed Control

Overview

The following are supported in spindle control with servo motor:
- Feed per revolution
- Threading
- Constant surface speed control

- Feed per revolution

The feedrate for feed per revolution is obtained from the separate detector linked to the spindle. If the detector incorporated in the servo motor is used, the feedrate is calculated from the servo motor rotation speed and gear ratio.
Which detector to use is specified by bit 1 (OPTx) of parameter No. 1815.
See Subsection of "Feed Per Revolution/Manual Feed Per Revolution," for explanations about feed per revolution.

- Threading

Threading can be performed by reading the one-rotation signal from a separate detector linked to the spindle.
In a configuration in which the spindle and motor are linked at a specific gear ratio, a detector linked to the spindle at a gear ratio of 1:1 is necessary.
See Section of “THREADING,” for explanations about threading.

- Constant surface speed control

Using the S code (value following the letter S) to specify a surface speed (m/min or feet/min) enables the speed of the spindle to be controlled so that the surface speed is kept constant with regard to any change in the tool position.
As for gear change, use T type gear change.
See Section of “CONSTANT SURFACE SPEED CONTROL,” for explanations about constant surface speed control.

- Multi-spindle control

If the machine is equipped with a spindle controlled axis and spindle with servo motor, using rotation commands requires the multi-spindle control.
As for gear change, use T type gear change.
See Section of “MULTI-SPINDLE CONTROL,” for explanations about multi-spindle control.

Format

- Feed per revolution, threading, and constant surface speed control

The command format for feed per revolution, threading, and constant surface speed control explained above is the same as for the ordinary types of feed per revolution, threading, and constant surface speed control.

Examples

The following are examples in which the second spindle (C axis) is used for servo motor rotation control and position control.
(The G code system A in lathe system is selected.)

- Feed per revolution

Program command	Operation
M*** ;	The C axis rotation control mode is turned ON.
M03 S100 P2 ;	The C axis rotates at 100 min^{-1}.
G99 G01 Z-100. F10. ;	The Z axis moves at a feed-per-revolution speed of 1000 mm/min.
:	:
M*** ;	The C axis position control mode is set to ON (rotation control mode OFF). The spindle stops with C = 0.000.

- Threading

Program command	Operation
M*** ;	The C axis rotation control mode is set to ON.
M03 S100 P2 ;	The C axis rotates at 100 min^{-1}.
G32 Z-100.0 F1.0 ;	The Z-axis moves at a threading speed of 100 mm/min with a pitch of 1.000 mm.
:	:
M*** ;	The C axis position control mode is set to ON (rotation control mode OFF). The axis stops with C = 0.000.

- Constant surface speed control

Program command	Operation
M*** ;	The C axis rotation control mode is set to ON.
M03 S100 P2 ;	The C axis rotates at 100 min^{-1}.
G96 S12 P2.0 ;	The constant surface speed control mode is set to ON. The C axis rotates at 12 m/min.
G01 X100.0 Z20.0 ;	The tool moves in the constant surface speed control mode.
:	:
G97 S100 P2.0 ;	The constant surface speed control mode is set to OFF. The C axis rotates at 100 min^{-1}.
M*** ;	The C axis position control mode is set to ON (rotation control mode OFF). The axis stops with C = 0.000.

Parameters

	#7	#6	#5	#4	#3	#2	#1	#0
1815							OPTx	

[Input type] Parameter input
[Data type] Bit axis

> **NOTE**
> When this parameter is set, the power must be turned off before operation is continued.

#1 OPTx The separate position detector is:
0: Not to be used (semi-closed system)
1: To be used (full-closed system)

> **NOTE**
> In case of using the absolute position detector (bit 5 (APCx) of parameter No.1815 is set to 1), please set the following parameters that correspond to the absolute position detector which is actually used.
> - parameter No.1815#6, No.1815#0, No.1817#3, No.1868, No.2275#1, No.2394
>
> If these parameters are not set correctly, the machine coordinates are not correctly established at power-on.

2455	Integral part (α) of the number of pulses for one rotation

[Data type] Word axis
[Valid data range] 0 to 32767
If 0 is specified, no threading counter is output.
If the specified range is exceeded, an invalid parameter alarm SV0417 is issued.
(Detail number of diagnosis data No. 0352: 4553)

2456	Exponential part (β) of the number of pulses for one rotation

[Data type] Word axis
[Valid data range] 0 to 12
If the specified range is exceeded, an invalid parameter alarm SV0417 is issued.
(Detail number of diagnosis data No. 0352: 4563)

Number of pulses per detector rotation (Np) = $\alpha \times 2^{\beta}$
Determine α and β so that the above expression is satisfied.
For a closed system is in use, specify a value that corresponds to separate detector pulses.

Setting examples

System	Np(pulse/rev)	No.2455	No.2456	Remarks
αi Pulsecoder	Np=1,000,000	16384	7	
AB phase (12000p/rev)	Np=12,000	12000	0	
Serial output type rotary encoder (million pulses/rev)	Np=1,000,000	16384	7	
Serial output type rotary encoder (RCN223,723,220)	Np=8,000,000	16384	10	No.2275#0 No.2394 must be set.
5000λ/rev detector +High-resolution serial output circuit C or H	Np=5000×512 =5000×2^{9}	5000	9	No.2274#0=1 must be set.
18000λ/rev detector +High-resolution serial output circuit C or H	Np=18000×512 =18000×2^{9}	18000	9	No.2274#0=1 must be set.
36000λ/rev detector +High-resolution serial output circuit C or H	Np=36000×512 =18000×2^{10}	18000	10	No.2274#0=1 must be set.
5000λ/rev detector + analog SDU	Np=5000×512 =5000×2^{9}	5000	9	
18000λ/rev detector + analog SDU	Np=36000×512 =18000×2^{10}	18000	10	
36000λ/rev detector + analog SDU	Np=36000×512 =18000×2^{10}	18000	10	
2048λ/rev detector + Synchronous built-in servo motor position detection circuit	Np= 2,000,000	16384	8	

	#7	#6	#5	#4	#3	#2	#1	#0
11001						DDMx		

[Input type] Parameter input
[Data type] Bit axis

#2 DDMx The motor used for spindle control with servo motor is:
0: Not a DD motor.
1: A DD motor.

Notes

When using the functions explained above, enable the constant surface speed control (bit 0 (SSC) of parameter No,8133 is 1), spindle serial output (bit 5 (SSN) of parameter No,8133 is 0), and multi-spindle control (bit 3 (MSP) of parameter No,8133 is 1).

To use a DD motor, set bit 2 (DDMx) of parameter No. 11001 to 1.
Also needed are the CNC software and servo software supporting the functions.

10.20.6 Spindle Output Control with PMC

Overview

The “spindle control with servo motor” function enables the PMC to be sued for spindle output control.

How to specify

Once the SV speed control mode has been turned ON, spindle output control with PMC can be specified using the same commands as for ordinary spindle control.
Refer to Section of “SPINDLE OUTPUT CONTROL BY THE PMC,” of the connection manual for detailed descriptions.

NOTE
1 For the “spindle control with servo motor” function, the maximum motor speed is one specified in parameter No. 11015.
2 Even if using spindle output control by the PMC, specify parameters Nos. 3741 to 3744.

10.20.7 Speed Arrival Signals and Speed Zero Signals

Overview

In the function of spindle control with a servo motor, output signals equivalent to the speed arrival signals SARx and the speed zero signals SSTx for serial spindles are added. In the past, to determine whether the rotation axis with a servo motor reached at the specified speed, it was necessary to read the speed by using the real spindle speed output (T series) or PMC window function. By adding the speed arrival signals and the speed zero signals equivalent to those for serial spindles, the need is eliminated to create a new PMC ladder program for reading the servo motor speed and determining whether it has reached the specified speed. This makes it easy to replace the spindle (rotary tool) using a spindle motor with a servo motor.

Signal

speed arrival signals SVSAR1 to SVSAR8<Fn377>

[Classification] Output signal

[Function] In connection with the speed command in spindle control with a servo motor, these signals notify that the actual rotation speed of the servo motor has reached the previously set range.

[Output cond.] These signals are set to “1” in the following cases:

- In SV rotation control mode, the difference between the motor speed and the specified speed goes below the speed arrival detection level.
- The system enters position control mode.
- Spindle indexing is executed.
- Rigid tapping with a servo motor is executed.

These signals are set to “0” in the following cases:

- In SV rotation control mode, the difference between the motor speed and the specified speed goes above the speed arrival detection level.
- An emergency stop occurs. (Note)
- The system enters the servo off state.

> **NOTE**
> At the point when the servo software recognizes an emergency stop, SVSARx is set to “0”. Even if a condition for speed arrival is met, SVSARx is not set to “1”.

Speed zero signals SVSST1 to SVSST8<Fn376>

[Classification] Output signal

[Function] These signals notify that the rotation speed of the servo motor used for spindle control with a servo motor has become equal to or less than the speed detection level.

[Output cond.] These signals are set to 1 in the following case:

- The motor speed goes below the speed zero detection level.

These signals are set to 0 in the following case:

- The motor speed goes above the speed zero detection level.

Signal address

	#7	#6	#5	#4	#3	#2	#1	#0
Fn376	SVSST8	SVSST7	SVSST6	SVSST5	SVSST4	SVSST3	SVSST2	SVSST1
Fn377	SVSAR8	SVSAR7	SVSAR6	SVSAR5	SVSAR4	SVSAR3	SVSAR2	SVSAR1

Parameter

2482	Speed arrival detection level

[Input type] Parameter input

[Data type] Word axis

[Unit of data] 0.1%

[Valid data range] 0 to 1000

[Recommended value] 0 (15%)

This parameter sets the detection range for the speed arrival signal SVSARx as a percentage of the specified speed. The actual detection level used is the setting of this parameter plus an offset of 50/min.

If the difference between the motor speed and the specified speed reaches the speed arrival detection level, the speed arrival signal SVSARx is set to 1.

2483	Speed zero detection level

[Input type] Parameter input
[Data type] Word axis
[Unit of data] min^{-1}
[Valid data range] 0 to 32767
[Recommended value] 0 (45/min)

This parameter sets the detection range for the speed zero signal SVSSTx.
If the motor speed becomes equal to or less than the speed zero detection level, the speed zero signal SVSSTx is set to 1.

Note

- This function does not support composite control.
- Servo software supporting this function is required.

10.20.8 Using Speed Control to Improve Spindle Control with Servo Motor

Overview

Conventionally, spindle control with servo motor has used position control for the SV rotation control mode. This function enables speed control to be used.

Specification

Setting bit 0 (SPCx) of parameter No. 11000 to 1 enables speed control to be used for the SV rotation control mode. (If bit 0 (SPCx) of parameter No. 11000 is 0, position control is used for the SV rotation control mode.)

To turn the SV rotation control mode ON, use a G code (G96.4) or the signal SRVON (Gn521) = 1 in the same manner as conventional.
To turn the SV rotation control mode OFF, use a G code (G96.1) or the signal SRVON (Gn521) = 0.

If speed control is used for the SV rotation control mode, issuing G96.1 during rotation outputs S0, causing the SV rotation control mode to be turned OFF after rotation stops. In this case, however, spindle indexing does not operate.

When using SRVON (Gn521) = 0 to turn the SV rotation control mode OFF, previously stop rotation by issuing S0 or resetting the spindle stop signal (SSTP (Gn029.6) or SSTPx (Gn027.3, 4, 5, Gn026.6)) to 0. Resetting the signal SRVON (Gn521) to 0 during rotation cannot turn the SV rotation control mode OFF.

If speed control is used for the SV rotation control mode, it is impossible to use spindle indexing (G96.1/G96.2/G96.3). When positioning the spindle at a specified location, previously turn the SV rotation control mode OFF.

Even when this function is used, positional information is updated during rotation. The current position managed by the CNC is updated by follow-up. The value of position error displayed at diagnosis data No.300 etc. is the difference between actual machine position and current position updated by follow-up.

NOTE

Status output signals in servo rotation control mode (SV rotation control mode) are as follows.

Status output signals in servo rotation control mode

Status output signals	Position control (Bit 0 (SPC) of parameter No.11000 is 0)	Speed control (Bit 0 (SPC) of parameter No.11000 is 1)	
		Bit 1 (VCSx) of parameter No.11004 is 0	Bit 1 (VCSx) of parameter No.11004 is 1
Axis moving signals MV1 to MV8<Fn102>	Spindle rotation : “1” Spindle stop : “0”	“0” at all times	Velocity command 0 : “0” Velocity command except for 0 : “1”
Axis moving direction signals MVD1 to MVD8<Fn106>	Spindle forward rotation : “0” Spindle reverse rotation : “1”	The status when servo rotation control mode is changed is maintained.	Positive velocity command : “0” Negative velocity command : “1”
In-position signals INP1 to INP8<Fn104>	In-position : “1” Not in-position : “0”	“1” at all times	“0” at all times

Parameter

	#7	#6	#5	#4	#3	#2	#1	#0
11000	**SRVx**							**SPCx**

[Input type] Parameter input
[Data type] Bit axis

NOTE

When at least one of these parameters is set, the power must be turned off before operation is continued.

#0 SPCx In spindle control with servo motor, the SV rotation control mode uses:
0: Position control.
1: Speed control.

#7 SRVx Spindle control with servo motor are:
0: Not performed.
1: Performed

	#7	#6	#5	#4	#3	#2	#1	#0
11004							**VCSx**	

[Input type] Parameter input
[Data type] Bit axis

#1 VCSx When SV rotation control mode of spindle control with servo motor is speed control (bit 0 (SPCx) of parameter No.11000 is 1), improvement of status output signals is:
0: Disabled.
1: Enabled.

Specifications of status output signals are as follows.

Status output signals	Bit 1 (VCSx) of parameter No.11004 is 0	Bit 1 (VCSx) of parameter No.11004 is 1
Axis moving signals MV1 to MV8<Fn102>	"0" at all times	Velocity command 0: "0" Velocity command except for 0: "1"
Axis moving direction signals MVD1 to MVD8<Fn106>	The status when servo rotation control mode is changed is maintained.	Positive velocity command: "0" Negative velocity command: "1"
In-position signals INP1 to INP8<Fn104>	"1" at all times	"0" at all times

10.20.9 Spindle Synchronous Control for Spindle Control with Servo Motor

Overview

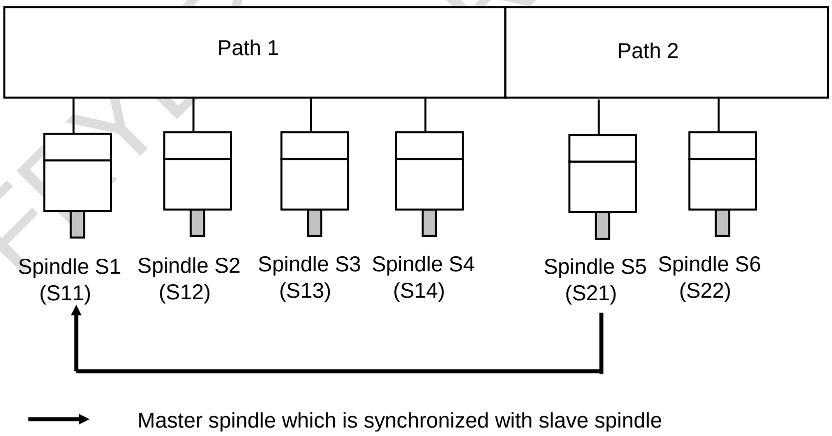
This function enables control spindles synchronously in spindle control using servo motor. It also enables the control of the rotation phase of a spindle, a polygon-bar as well as a round-bar can be exchanged between two spindles. A combination of a master spindle and slave spindle in spindle synchronous control can be selected arbitrarily.
This function can be used with servo motors in the state of SV speed control mode.

Specification

Synchronous-spindle configuration

In spindle synchronous control, the spindle which is issued S command is called the master spindle. A spindle which ignores any S command that is issued for it, and instead rotates synchronously with the master spindle, is called the slave spindle.
Example :
Combining spindles of different paths for spindle synchronization
Parameter setting
Bit 4 (SSS) of parameter No.3704 (PATH1)=1, (PATH2)=1
Parameter No.4831(ALL) =0
Parameter No.4832(S1) =0, (S2) =0,(S3) =0,(S4) =0,(S5) =1,(S6) =0

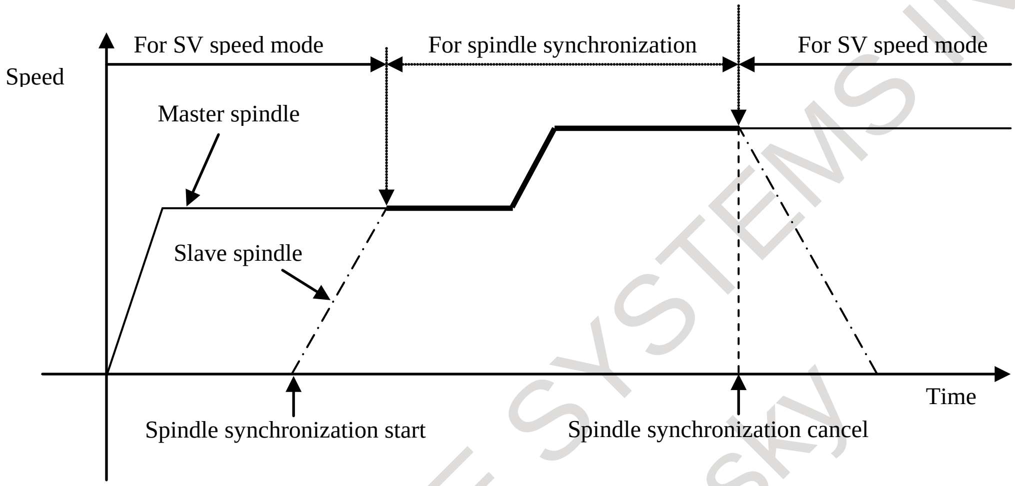
Master spindle	Slave spindle
First spindle of path 1(S11)	First spindle of path 2(S21)



Acceleration/deceleration

As for the acceleration/deceleration when the slave axis synchronizes with the master axis, the parameters Nos.11020 to 11021 and Nos.11030 to 11032 at the acceleration/deceleration of spindle control function with servo motor or the parameters Nos.11070 to 11071 and Nos.11080 to 11082 at the acceleration of spindle synchronous control for spindle control with servo motor becomes effective. In case of bit 6 (DCSx) of parameter No.11001 for the acceleration/deceleration is set to 1, the parameter(Nos.25720 to 25721 and Nos.25730 to 25732) at the deceleration of spindle synchronous control for spindle control becomes effective.

Ex.) In case of bit 6 (CSA) of parameter No.11005 =1:



Speed synchronization

When the spindle synchronous control signal is set to 1, the spindle synchronous control mode is set. When spindle synchronous control is specified, slave spindle is accelerated or decelerated to a specified speed of master spindle then enters the synchronous control state.
The spindle synchronous speed control completion signal is output when the two spindles have reached the speed matching a specified spindle synchronous speed and the speed difference between the two spindles is
within the value set in parameter No.11042.
The S command to the master spindle is clamped by the maximum speed of the slave spindle if S command is more than the maximum speed of the slave spindle(No.3741-No.3744).

Phase matching

Spindle phase synchronization is executed by setting the spindle phase synchronization control signal to set to 1 in the spindle synchronous control mode (after the output of the spindle synchronous speed control completion signal). The synchronous state between the two axes is not maintained during spindle phase synchronization operation (until the spindle phase synchronization control completion signal is set to 1).
The spindle phase synchronization completion signal is output when the error difference between the two spindles lies within the allowable number of pulses set in the CNC parameter No.4810. When the two spindles hold a workpiece, do not specify spindle phase synchronization.
When spindle phase synchronization control is executed, the speed fluctuation of slave spindle can be reduced. When parameter No.11040 is 0, the speed fluctuation of the slave spindle increases because the amount of the movement of the slave spindle is output at a time and the position deflection increases rapidly. The phase match can be executed smoothly because the amount of the movement of the slave spindle is divided by the number of pulses of parameters No.11040 of each 8msec.
When spindle phase synchronization control is specified, phase matching is executed by movement of slave spindle. The operation of the master spindle is not influenced. Therefore, you can command spindle phase synchronization control at the same time by each slave spindle.

Speed command

In the spindle synchronous control mode, the speed command for the master spindle is valid.
In the spindle synchronous control mode, a speed for the master spindle can be command in the same way as for an ordinary S command.
When 0 is set in the parameter corresponding to a selected gear, the spindle does not make a synchronous rotation.
A S command for a master spindle before the spindle synchronous control mode is set are valid even in the spindle synchronous control mode. A speed command for a master spindle during spindle synchronous control is also valid as a command for the master spindle after spindle synchronous control is canceled.

Command by PMC DI signals

Spindle synchronous control can be commanded by the DI signal of PMC.

- Spindle synchronous control mode ON

Spindle synchronous control is executed when spindle synchronous control signal of each spindle SPSYCs<Gn288.0~3> is set to 1. Phase match is executed when spindle phase synchronization control signal of each spindle SPPHSs<Gn289.0~3> is set to 1.

- Spindle synchronous control mode OFF

Spindle synchronous control is released when spindle synchronous control signal of each spindle SPSYCs<Gn288.0~3> is set to 0.

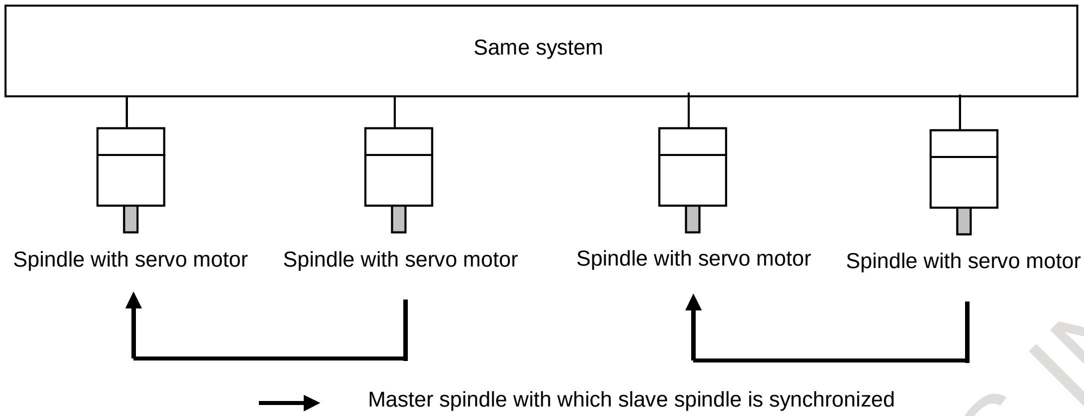
Supplement

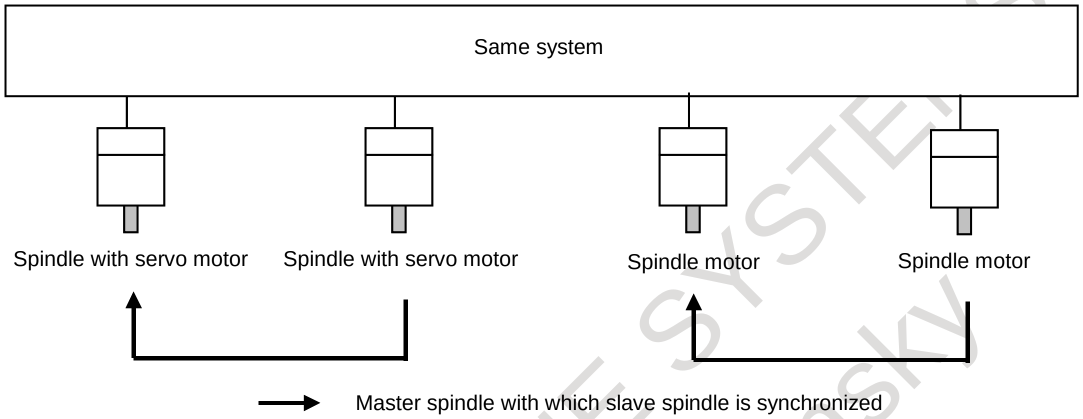
To monitor an error mutually between two spindles in the spindle synchronous control mode, the phase error monitor signal SYCAL<Fn044.4>(SYCAL1 to SYCAL4<Fn043.0> to <Fn043.3>) is available. A synchronization error between two spindles is always monitored. When a synchronization error exceeding the value (absolute number of error pulses) set in parameter No.4811 is detected, this signal is set to “1”. When the synchronization error does not exceed the value set in parameter No.4811, the signal is set to “0”.
Even when two spindles hold a workpiece in the synchronous control state, constant surface speed control can be performed. Even if the speed of a spindle changes, however, the synchronous speed changes within the parameter-set range (acceleration/deceleration time constant in spindle synchronous control).
In spindle synchronous control, the spindle speed offset value (parameter No.3731) is invalid.
The slave axis moves whenever instructing in the spindle phase synchronization.

Limitation

When both a master spindle and a slave spindle are SV speed control mode, you can command to change spindle synchronous mode.
For spindles during the spindle synchronous control mode, commands for rigid tapping, simple synchronous control, and so on cannot be specified.
The ratio of the gear of the master axis and the slave axis should be the same.
If SV speed control mode of spindle control with servo motor is velocity control type (bit 0 (SPCx) of parameter No.11000 =1), this function cannot be used.

The example that can be used is shown as follows. The pair that can be used is shown in the example. if each pair is like a pair of “synchronization with spindle control with servo motor or a pair of the usual synchronization with spindle control”, two or more pairs of the synchronization can be specified.





Diagnosis data (Spindle synchronous control)

300	Position deviation of each servo motor

The position deviation of each servo motor is indicated.

425	Synchronization error of each spindle

The absolute value of the synchronization error of each spindle in spindle synchronization is indicated. A synchronization error is indicated with a slave spindle.

Signal

Spindle synchronous control signal of each spindle
SPSYC1 to SPSYC4<Gn288.0 to Gn288.3>

[Classification] Input signal

[Function] These signals turn on the spindle synchronous control mode.

[Operation] When each of these signals is set to “1”, the spindle synchronous control mode with a spindle set as a slave spindle is set.
When each of these signals is set to “0”, the spindle synchronous control mode with a spindle set as a slave spindle is canceled. When SPSYCs is set to “1”, spindle synchronization with a spindle set as a slave spindle is performed. These signals are valid only when bit 4 (SSS) of parameter No.3704 is set to 1 and bit 5 (SCB) of parameter No.4800 is set to 0.
Which spindle is synchronized with which spindle is set using parameter No.4831 or No.4832.

Spindle phase synchronization control signal of each spindle
SPPHS1 to SPPHS4 <Gn289.0 to Gn289.3>

[Classification] Input signal

[Function] These signals turn on the spindle phase synchronization control mode (phase matching) for each spindle.

[Operation] When each of these signals is set to “1”, spindle phase matching is performed in the spindle synchronous control mode with a spindle set as a slave spindle. These signals are valid when the spindle synchronous control signal SPSYCs for each spindle is set to “1”. Specify each of these signals after the spindle synchronous speed control completion signal FSPSYs for each spindle is set to “1”.
A spindle phase synchronization control operation is started on the rising edge of each of these signals. So, phase matching once performed is not lost when each of these signals is set to “0”. These signals are valid only when bit 4 (SSS) of parameter No.3704 is set to 1 and bit 5 (SCB) of parameter No.4800 is set to 0. Set a phase shift amount in parameter No.11041.

> **NOTE**
> Before specifying these signals, ensure that the spindle synchronous speed control completion signal FSPSYs is set to “1”. When the spindle synchronous speed control completion signal FSPSYs is set to “0”, phase matching operation is not performed.

Spindle synchronous speed control completion signal for each spindle
FSPSY1 to FSPSY4<Fn288.0 to Fn288.3>

[Classification] Output signal

[Function] These signals show that spindle synchronous control (speed synchronization) with each spindle set as a slave spindle is completed.

[Output cond.] This signal is set to “1” in the following case:

- This signal is output when two spindles have reached the speed equivalent to a specified spindle synchronous speed and the speed difference between the two spindles is equal to or less than the value set in parameter No.11042 in the spindle synchronous control mode.

This signal is set to “0” in the following cases:

- In the spindle synchronous control mode, two spindles have not reached the speed equivalent to a specified spindle synchronous speed.
- In the spindle synchronous control mode, the speed difference between two spindles is greater than the value set in parameter No.11042.
- The spindle synchronization control mode is not set.
  These signals are valid only when bit 4 (SSS) of parameter No.3704 is set to 1 and bit 5 (SCB) of parameter No.4800 is set to 0.

> **NOTE**
> Even if this signal is once set to “1”, this signal is set to “0” when the speed difference exceeds the value set in parameter No.11042 for a cause such as cutting load fluctuation.

Spindle phase synchronization control completion signal of each spindle
FSPPH1 to FSPPH4<Fn289.0 to Fn289.3>

[Classification] Output signal

[Function] These signals show that spindle phase synchronization control (phase matching) with each spindle set as a slave spindle is completed.

[Output cond.] This signal is set to “1” in the following case:

- This signal is output when phase matching is completed with the spindle phase synchronization control signal (when the error pulse difference between the two spindles is equal to or less than the value set in parameter No.4810) after the two spindles have reached the speed equivalent to a specified spindle synchronous speed in the spindle synchronous control mode.

This signal is set to “0” in the following cases:

- In the spindle synchronous control mode, the phase matching of two spindles is not completed.
- In the spindle synchronous control mode, the error pulse difference between two spindles is greater than the value set in parameter No. 4810.
- The spindle synchronous control mode is not set.
- The spindle phase synchronization control mode is not set.

  These signals are valid only when bit 4 (SSS) of parameter No.3704 is set to1 and bit 5 (SCB) of parameter No.4800 is set to 0.

> **NOTE**
> Even if this signal is once set to “1”, this signal is set to “0” when the speed difference exceeds the value set in parameter No.4810 for a cause such as cutting load fluctuation.

Spindle phase error monitor signal for each spindle
SYCAL1 to SYCAL4<Fn043.0 to Fn043.3>

[Classification] Output signal

[Function] These signals show that in the spindle synchronous control mode with each spindle set as a slave spindle, the error pulse difference between two spindles is greater than a parameter-set value.

[Output cond.] This signal is set to “1” in the following case:

- In the spindle synchronous control mode, the error pulse difference between two spindles is greater than the value set in parameter No.4811 after spindle synchronous control is completed.

This signal is set to “0” in the following cases:

- The spindle synchronous control mode is not set.
- In the spindle synchronous control mode, the error pulse difference between two spindles is equal to or less than the value set in parameter No.4811.

  These signals are valid only when bit 4 (SSS) of parameter No.3704 is set to 1 and bit 5 (SCB) of parameter No.4800 is set to 0.

Parameter

Parameters which are used for this function are as follows.

	#7	#6	#5	#4	#3	#2	#1	#0
11000								SPCx

[Input type] Parameter input
[Data type] Bit axis

> **NOTE**
> When at least one of these parameters is set, the power must be turned off before operation is continued.

#0 SPCx SV speed control mode of spindle control with servo motor is:
0: Position control type.
1: Velocity control type.

> **NOTE**
> Spindle synchronous control for spindle control with servo motor (bit 3 (SSY) of parameter No.11005=1) is only available with this parameter setting 0.

	#7	#6	#5	#4	#3	#2	#1	#0
11001		DCSx						

[Input type] Parameter input
[Data type] Bit axis

#6 DCSx Acceleration/deceleration for deceleration is:
0: Disabled.
1: Enabled.

	#7	#6	#5	#4	#3	#2	#1	#0
11005		CSA			SSY		CSC	

[Input type] Parameter input
[Data type] Bit

#1 CSC The coordinate of spindle phase synchronization control servo motor is:
0: Absolute coordinate.
1: Machine coordinate.

#3 SSY Spindle synchronous control with servo motor is:
0: Disabled.
1: Enabled.

> **NOTE**
> This function is only available with the parameter setting of bit 0 (SPCx) of parameter No.11000=0.

#6 CSA Acceleration/deceleration for spindle synchronous control with servo motor is:
0: Acceleration/deceleration for speed control.
1: Acceleration/deceleration for spindle synchronous control.

11040	Spindle phase synchronization with servo motor compensation data

[Input type] Parameter input
[Data type] 2-word spindle
[Unit of data] pulse
[Valid data range] 0 to 359999

This parameter reduces speed fluctuations in case of aligning phase of spindle in spindle phase synchronization control.
When this parameter is 0, since the phase alignment amount is output at a time, the position deviation quickly becomes large, and there are large speed fluctuation on phase alignment.
It is possible to perform smooth phase alignments as phase alignment amounts is separated by the number of 8 msec pulses set in this parameter.

11041	Shift amount for spindle phase synchronization control with servo motor

[Input type] Parameter input
[Data type] Real spindle
[Unit of data] deg
[Min. unit of data] Depend on the increment system of the applied axis
[Valid data range] 0 to 359.999

Sets the shift amount of slave spindle from master spindle at spindle phase synchronization control with servo motor.

11042	Detection level for spindle synchronization with servo motor completion signal

[Input type] Parameter input
[Data type] Word spindle
[Unit of data] min^{-1}
[Valid data range] 0 to 32767

For the synchronization speed command at synchronization control with servo motor, if the deviations of the respective spindle motor speeds are within the setting level, the spindle synchronization control complete signal(FSPSY) becomes 1.

11070	Acceleration/deceleration switching speed (S_0) of spindle synchronous

[Input type] Parameter input
[Data type] 2-word axis
[Unit of data] min^{-1}
[Valid data range] 0 to 999999999

Set the acceleration/deceleration switching points S_0 for spindle synchronous control with servo motor.

11071	Acceleration/deceleration switching speed (S_1) of spindle synchronous

[Input type] Parameter input
[Data type] 2-word axis
[Unit of data] min^{-1}
[Valid data range] 0 to 999999999

Set the acceleration/deceleration switching points S_1 for spindle synchronous control with servo motor.

11080	Individual acceleration / deceleration 1 of spindle synchronous (Leg 1)

[Input type] Parameter input

[Data type] 2-word axis
[Unit of data] min^{-1}/s
[Valid data range] 0 to 100000

In spindle control with servo motor, this parameter sets acceleration/deceleration to be applied to perform spindle synchronous control. When the speed ranges from 0 to acceleration switching speed 1, acceleration/deceleration 1 is applied. Acceleration switching speed 1 is the speed set in parameter No. 11070.

11081	Individual acceleration / deceleration 2 of spindle synchronous (Leg 2)

[Input type] Parameter input
[Data type] 2-word axis
[Unit of data] min^{-1}/s
[Valid data range] 0 to 100000

In spindle control with servo motor, this parameter sets acceleration/deceleration to be applied to perform spindle synchronous control. When the speed ranges from acceleration switching speed 1 to acceleration switching speed 2, acceleration/ deceleration 2 is applied. Acceleration switching speed 1 and acceleration switching speed 2 are the speeds set in parameter Nos. 11070 and 11071, respectively.

11082	Individual acceleration / deceleration 3 of spindle synchronous (Leg 3)

[Input type] Parameter input
[Data type] 2-word axis
[Unit of data] min^{-1}/s
[Valid data range] 0 to 100000

In spindle control with servo motor, this parameter sets acceleration/deceleration to be applied to perform spindle synchronous control. When the speed ranges from acceleration switching speed 2 to the maximum speed, Acceleration/deceleration 3 is applied. Acceleration switching speed 2 is the speed set in parameter No. 11071.

25720	Acceleration/deceleration switching speed (S_{10}) of spindle synchronous for deceleration

[Input type] Parameter input
[Data type] 2-word axis
[Unit of data] min^{-1}
[Valid data range] 0 to 999999999

Set the acceleration/deceleration switching points of spindle synchronous control with servo motor for deceleration S_{10} .

> **NOTE**
> When bit 6 (DCSx) of parameter No.11001 and bit 6 (CSA) of parameter No.11005 are set to 1, this parameter becomes effective.

25721	Acceleration/deceleration switching speed (S_{11}) of spindle synchronous for deceleration

[Input type] Parameter input
[Data type] 2-word axis
[Unit of data] min^{-1}
[Valid data range] 0 to 999999999

Set the acceleration/deceleration switching points of spindle synchronous control with servo motor for deceleration S_{11}.

> **NOTE**
> When bit 6 (DCSx) of parameter No.11001 and bit 6 (CSA) of parameter No.11005 are set to 1, this parameter becomes effective.

25730	Individual acceleration / deceleration of spindle synchronous for deceleration (0 to S_{10})

[Input type] Parameter input
[Data type] 2-word axis
[Unit of data] min^{-1}/s
[Valid data range] 0 to 100000

Set the acceleration/deceleration of spindle synchronous control with servo motor for deceleration of Leg 1 (0 to S_{10}).
Acceleration switching speed 1 is the speed set in parameter No. 25720.

> **NOTE**
> When bit 6 (DCSx) of parameter No.11001 and bit 6 (CSA) of parameter No.11005 are set to 1, this parameter becomes effective.

25731	Individual acceleration / deceleration of spindle synchronous for deceleration (S_{10} to S_{11})

[Input type] Parameter input
[Data type] 2-word axis
[Unit of data] min^{-1}/s
[Valid data range] 0 to 100000

Set the acceleration/deceleration of spindle synchronous control with servo motor for deceleration of Leg 2 (S10 to S11). Acceleration switching speed 1 and acceleration switching speed 2 are the speeds set in parameter Nos. 25720 and 25721, respectively.

> **NOTE**
> When bit 6 (DCSx) of parameter No.11001 and bit 6 (CSA) of parameter No.11005 are set to 1, this parameter becomes effective.

25732	Individual acceleration / deceleration of spindle synchronous for deceleration (S_{11} to Maximum speed)

[Input type] Parameter input
[Data type] 2-word axis
[Unit of data] min^{-1}/s
[Valid data range] 0 to 100000

Set the acceleration/deceleration of spindle synchronous control with servo motor for deceleration of Leg 3 (S11 to Maximum speed). Acceleration switching speed 2 and acceleration switching speed 3 are the speeds set in parameter Nos. 25721 and 25722, respectively.

> **NOTE**
> When bit 6 (DCSx) of parameter No.11001 and bit 6 (CSA) of parameter No.11005 are set to 1, this parameter becomes effective.

	#7	#6	#5	#4	#3	#2	#1	#0
3704				SSS				

[Input type] Parameter input
[Data type] Bit path

> **NOTE**
> When this parameter is set, the power must be turned off Before operation is continued.

#4 SSS Synchronous spindle control by each spindle is:
0: Not performed.
1: performed.
This master axis and slave axis of synchronous spindle control can be selected from the arbitrary spindles.
The target spindle of synchronous spindle control is specified in parameter No.4831.
In addition, the following signals affect the control.
Synchronous spindle signals of each spindle SPSYCs
Signals of synchronous control of the spindle phase for each spindle SPPHSs

<u>For this function, set 1.</u>

	#7	#6	#5	#4	#3	#2	#1	#0
4800			SCB					

[Input type] Parameter input
[Data type] Bit

> **NOTE**
> When this parameter is set, the power must be turned off Before operation is continued.

#5 SCB The combination of a master spindle and slave spindle for spindle synchronization depends on:
0: Setting of bit 4 (SSS) of parameter No.3704.
When bit 4 (SSS) of parameter No.3704 is set to 0
The first spindle and second spindle of each path can be selected as the master spindle and slave spindle, respectively, for spindle synchronization.
When bit 4 (SSS) of parameter No.3704 is set to 1 a combination of arbitrary spindles of each path can be selected for spindle synchronization.
Set a master spindle for each slave spindle in parameter No. 831.
Set a spindle number of each path. By setting a spindle number common to the system in parameter No.4832, an arbitrary spindle that belongs to a different path can be selected as a master spindle for spindle synchronization.
Set a spindle number common to the system. Set parameter No.4831 to 0.
Spindle synchronization based on arbitrary spindles must be enabled for the path to which a slave spindle belongs and for the path to which a master spindle belongs.

1: Conventional 16TT system compatible specifications.
The first spindle of path 1 and the first spindle of path 2 can be selected as the master spindle and slave spindle, respectively, for spindle synchronization.
As control signals, the signal interface of the 16TT system compatible specifications can be used.
For this function, set 0.

	#7	#6	#5	#4	#3	#2	#1	#0
4801								SNDs

[Input type] Parameter input
[Data type] Bit spindle

> **NOTE**
> When this parameter is set, the power must be turned off Before operation is continued.

#0 SNDs During spindle synchronization control, the rotation direction of each spindle motor is:
0: Same as the specified sign.
1: Opposite to the specified sign.

4810	Error pulse between two spindles when synchronizing phases in the spindle synchronization control mode

[Input type] Parameter input
[Data type] Word spindle
[Unit of data] Detection unit
[Valid data range] 0 to 255

Set an allowable error pulse value between two spindles at phase synchronization time in the spindle synchronization control mode.
This parameter is used to check the completion of phase synchronization performed in the spindle synchronization control mode and to check the phase difference during spindle synchronization control. When the error pulse value between two spindles become equal to or less than the value set in this parameter, the spindle phase synchronization control completion signals FSPPH<Fn044.3> and FSPPH1 to 4 <Fn289.0 to 3> are set to “1”.

4811	Error pulse between two spindles when synchronizing phases in the spindle synchronization control mode

[Input type] Parameter input
[Data type] Word spindle
[Unit of data] Detection unit
[Valid data range] 0 to 32767

Set the allowable error count for the error pulses between two spindles in the spindle synchronization control mode. This parameter is used to check a spindle synchronization error phase difference.
When a spindle synchronization error equal to or greater than the value set in this parameter is detected, the phase error monitor signals SYCAL<F044#4> and SYCAL1 to 4<F043#0 to 3> are set to 1.

4832	Master spindle of each slave spindle under spindle synchronization control (spindle number common to the system)

[Input type] Parameter input

[Data type] Byte spindle
[Valid data range] 0 to Maximum number of controlled axes (common to the system)

> **NOTE**
> When this parameter is set, the power must be turned off Before operation is continued.

When a spindle is set as a slave spindle in spindle synchronization control on each spindle, set which spindle (master spindle) the slave spindle is to be synchronized with.

> **NOTE**
> 1 This parameter is valid if bit 4 (SSS) of parameter No. 3704 is set to 1 (to enable spindle synchronization based on arbitrary spindles) for the path to which a slave spindle belongs and for the path to which a master spindle belongs.
> 2 The setting of a slave spindle as a master spindle is invalid. Be sure to set 0 for a spindle that is to function as a master spindle.
> 3 In this parameter, set a spindle number common to the system. When this parameter is used, parameter No.4831 is set to 0.

Notes

> **NOTE**
> 1 Output signal SYCAL<Fn044.4> is used for monitoring a phase shift in synchronous control. Whether the processing is performed when a phase shift is detected depends on the specifications determined by the machine tool builder.
> 2 A gear ratio of 1 : 1 only is allowed between the spindle and position coder.
> 3 A CNC system restriction is imposed on the maximum number of spindles.
> 4 If the speed at the spindle synchronous mode exceeds maximum speed of slave spindle, an alarm PS0447 “ILLEGAL SETTING DATA” occurs.
> 5 Master spindle and slave spindle stop rotating due to a servo alarm, emergency stop, machine lock, etc.
> 6 When using this function, enable the spindle synchronous control function (bit 4 (SYC) of parameter No,8133 is 1).

10.20.10 Improvement of Spindle Stop Motion for Spindle Control with Servo Motor

Overview

If SV speed control mode is canceled during spindle rotation, spindle indexing is executed and spindle is stopped at specified position so far. When bit 0 (NSP) of parameter No.11002 is set to 1, If SV speed control mode is canceled during spindle rotation, spindle indexing is not executed and spindle is decelerated and stopped. When spindle indexing is unnecessary, machining cycle time can be reduced.

Format

When bit 0 (NSP) of parameter No.11002 is set to 1:

G96.1 P_ ; **The operation of the next block is started after deceleration stop of spindle.**

G96.2 P_ ; **The operation of the next block is started before deceleration stop of spindle.**

G96.1 P_ R_ ; **The operation of the next block is started after completing spindle indexing.**

G96.2 P_ R_ ; **The operation of the next block is started before completing spindle indexing.**

G96.3 P_ ; **The operation of the next block is started after confirming completion of spindle indexing.**

P : Spindle selection with multi-spindle control
R : Stoppage angle [deg] (0 to (parameter No.1260))

NOTE
1. When using G96.2, issue G96.3 before another spindle move command, to make sure that the spindle is at a complete halt.
2. To issue G96.1, G96.2, or G96.3, use an independent block.

Explanation

When bit 0 (NSP) of parameter No.11002 is set to 1, if SV speed is canceled during spindle rotation, spindle indexing is not executed and spindle is decelerated and stopped.

Command with a program

When R address is not commanded at G96.1 block, spindle indexing is not executed and spindle is decelerated and stopped. SV speed control mode in-progress signal SVREV<Fn521> becomes “0” after deceleration stop of spindle, and SV speed control mode is canceled. Then, the next block is started. When also R address is not commanded at G96.2 block as well, spindle indexing is not executed and spindle is decelerated and stopped. If G96.2 is commanded, the next block is started without waiting deceleration stop of spindle. If G96.3 is commanded, SV speed control mode in-progress signal SVREV<Fn521> becomes “0”, and SV speed control mode is canceled. When R address is commanded at G96.1 or G96.2 block, spindle indexing is executed and spindle is stopped at specified position.

Command with a signal

When SV speed control mode signal SRVON<Gn521> is set to “0”, spindle indexing is not executed and spindle is decelerated and stopped. SV speed control mode in-progress signal SVREV<Fn521> becomes “0” after deceleration stop of spindle, and SV speed control mode is canceled.

Acceleration up to deceleration stop of spindle

When SV speed control mode is canceled, parameter (No.11020, No.11021, No.11030, No.11031, No.11032) is applied to deceleration stop of spindle as well as acceleration of spindle.

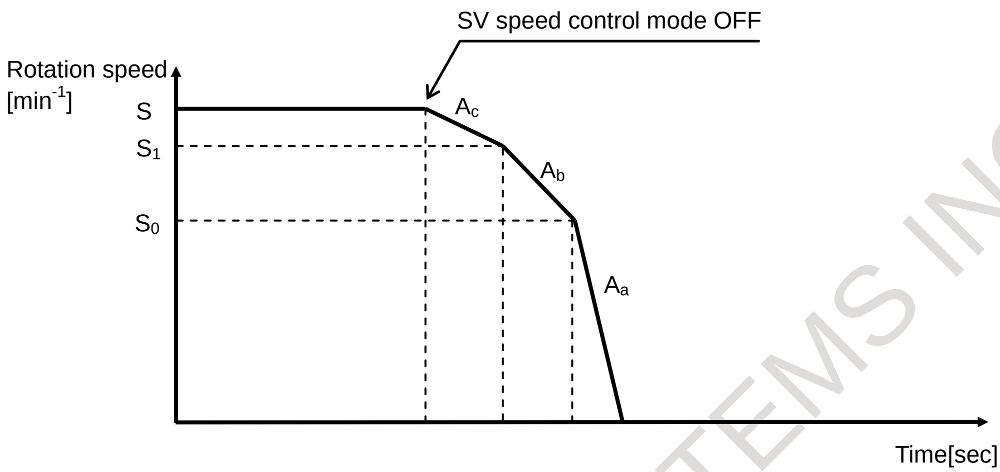

Fig. 10.20.10 Acceleration up to deceleration stop

Table 10.20.10 Parameters for acceleration up to deceleration stop

S	Specified rotation speed[min^{-1}]
S_0	Acceleration switching speed (S_0) [min^{-1}] (parameter No.11020)
S_1	Acceleration switching speed (S_1) [min^{-1}] (parameter No.11021)
A_a	Acceleration 1 [min^{-1}/s] (parameter No.11030)
A_b	Acceleration 2 [min^{-1}/s] (parameter No.11031)
A_c	Acceleration 3 [min^{-1}/s] (parameter No.11032)

Notes

- Specify an M code not involved in buffering as an M code to be used as a command for switching the SV speed control mode (parameters Nos.3411 to 3420 and 11290 to 11299).
- M code for switching the SV speed control mode must be specified in an independent block. When using multiple M commands in a single block, the M code must be specified as the first M command.
- G96.1, G96.2, G96.3, G96.4, and M code for switching the SV speed control mode must be specified in the path to which the spindle of interest belongs.
- After G96.2 command, command G96.3 before commanding move command such as rapid traverse (G00) or cutting feed (G01) to rotation axis. Move command is specified without commanding G96.3, alarm PS0445 “ILLEGAL AXIS OPERATION” is issued.
- If G96.3 is not commanded after G96.2 command, SV speed control mode is not canceled. For example, reset before G96.2 command.
- G96.1, G96.2 G96.3, G96.4 cannot be commanded for settings other than multi-spindle control type P.

Parameter

	#7	#6	#5	#4	#3	#2	#1	#0
11002								**NSP**

[Input type] Parameter input
[Data type] Bit axis

#0 NSP When SV speed control mode is canceled, spindle indexing is:
0: executed.
1: not executed.

10.20.11 Alarm and Message

Number	Message	Description
PS0003	TOO MANY DIGIT	Data entered with more digits than permitted in the NC instruction word. The number of permissible digits varies according to the function and the word.
PS0445	ILLEGAL AXIS OPERATION	The positioning command was issued in the speed control mode. Check the SV speed control mode signal.
PS0446	ILLEGAL COMMAND IN G96.1/G96.2/G96.3/G96.4	G96.1, G96.2, G96.3, and G96.4 are specified in the block that includes other commands. Modify the program.
PS0447	ILLEGAL SETTING DATA	The spindle controlled axis is incorrectly set. Check the parameter for the live tool control function by a servo motor.
PS0601	ILLEGAL AXIS COMMAND FOR SERVO MOTOR SPINDLE	The move command was executed to the servo axes for spindle use of the spindle control with servo motor. Modify the program.
SV0410	EXCESS ERROR (STOP)	The amount of positional deviation during stopping exceeded the parameter No. 1829 setting value.
SV0411	EXCESS ERROR (MOVING)	The amount of positional deviation during traveling became excessive than the parameter setting value.
SV0417	ILL DGTL SERVO PARAMETER	A digital serve parameter setting is incorrect.
DS2003	ILLEGAL USE FOR SERVO MOTOR SPINDLE	The servo axes for spindle use of the spindle control with servo motor was used by the following functions. - PMC axis control - Chopping
PW0036	ILLEGAL SETTING FOR SERVO MOTOR SPINDLE	The parameter setting for the servo axes for spindle use of the spindle control with servo motor is illegal. - The servo axes number for spindle use has exceeded 4 axes. - Servo axes number for spindle use are fewer than the axes number of designation of servo axes for spindle use. - The servo axes for spindle use is not set as a spindle control with servo motor axis. - The servo axes for spindle use is not set as a rotation axis.. - The servo axis number (parameter No.1023) is a negative value.

10.21 SPINDLE REVOLUTION NUMBER HISTORY FUNCTION

Overview

This function counts the spindle revolution number and displays the total revolution number as diagnosis data.
Total revolution number data as diagnosis data can be read with the PMC window function, and can be used for spindle unit life management on the PMC ladder.

Explanation

This function is enabled by setting bit 5 (SSH) of parameter No. 3799, to 1.

Two total revolution number displays are provided, which are shown as diagnosis data Nos. 1520 and 1521, respectively.

Total revolution number data as diagnosis data can be read with the PMC window function.

For details, refer to "Reading diagnosis data (function code 33) in Chapter 5, "Window Functions", in the PMC Programming Manual (B-64513EN).

As for total revolution number display data, the total revolution number data for a specified diagnosis data number can be cleared for a specific spindle, using the signals below.

- Using the total spindle revolution number reset selection signal SSRS <Gn533.4>, select the diagnosis data number of the total revolution number data to be cleared.
- Using an appropriate total spindle revolution number reset signals SSR1 to SSR4 <Gn533.0 to Gn533.3>, clear the total revolution number data for a specific spindle.

NOTE

1. When using this function, enable the spindle serial output (bit 5 (SSN) of parameter No,8133 is 0).
2. Storage of spindle revolution number data in data-retention memory is performed at intervals of about one second. If the power is turned off while a spindle is revolving, revolution number data is not stored for about one second before the power is turned off.
3. This function is effective to a built-in spindle motor and to a spindle configuration in which a spindle and a spindle motor is connected together at a gear ratio of 1:1.
4. If the spindle switching function (a configuration in which one set of main/sub-spindle motors are connected to a single spindle amplifier) is used, total revolution number data is counted as an integrated value of two spindles.

Signal

Total spindle revolution number reset signals SSR1 to SSR4 <Gn533.0 to Gn533.3>

[Classification] Input signal

[Function] Each of these signals resets the total revolution number for its corresponding spindle, returning diagnosis data No. 1520, total revolution number display, to zero.
If SSRS is “1”, each of these signals resets diagnosis data No. 1521, total revolution number display, returning it to zero.

[Operation] When set to “1”, each signal performs the operation below.

- Reset the total revolution number for its corresponding spindle. SSR1 corresponds to the first spindle, SSR2 the second spindle, SSR3 the third, and SSR4 the fourth.

Total spindle revolution number reset selection signal SSRS <Gn533.4>

[Classification] Input signal

[Function] Used to select between diagnosis data Nos. 1520 and 1521; the total spindle revolution number for the selected item No. will be reset.

[Operation] When set to “1”, it performs the operation below.

- The total spindle revolution number for diagnosis data No. 1521 can be reset.

When set to “0”, it performs the operation below.

- The total spindle revolution number for diagnosis data No. 1520 can be reset.

Signal address

	#7	#6	#5	#4	#3	#2	#1	#0
Gn533				SSRS	SSR4	SSR3	SSR2	SSR1

Parameter

	#7	#6	#5	#4	#3	#2	#1	#0
3799			SSH					

[Input type] Parameter input
[Data type] Bit spindle

#5 SSH On the diagnosis screen, total spindle speed data is:
0: Not displayed.
1: Displayed.

Diagnosis data

1520	Total spindle revolution number 1

[Data type] 2-word spindle
[Unit of data] 1000 min^{-1}
[Valid data range] 0 to 999999999
The spindle revolution number is counted, and the total revolution number is displayed.

1521	Total spindle revolution number 2

[Data type] 2-word spindle
[Unit of data] 1000 min^{-1}
[Valid data range] 0 to 999999999
The spindle revolution number is counted, and the total revolution number is displayed.

10.22 SERVO/SPINDLE SYNCHRONOUS CONTROL

10.22.1 Servo/Spindle Synchronous Control

Overview

This function provides the following functions to use a servo motor as a spindle:

(a) Servo motor spindle control
Can rotate the servo motor at the rotation speed specified with an input signal.

(b) Servo motor spindle synchronization
Can rotate the servo motor in synchronization with the feedback pulses from the position coder of the spindle.

(c) Differential speed synchronization
(i) Can superimpose a command from the CNC on the servo motor in servo motor spindle synchronization.
(ii) Can superimpose the rotation speed specified with an input signal on the servo motor in servo motor spindle synchronization.

NOTE
When using this function, enable the spindle synchronous control (bit 4 (SYC) of parameter No,8133 is 1).

Explanation

- Connection

Input feedback pulses from the position coder to the pulse module.
To make effective the feedback pulses input to the pulse module, set parameters Nos. 24096 to 24103.
This causes the spindle (position coder) and the servo motor to synchronize with each other.

Example) Connection example

Parameter No. 24096 = 1: Uses connector number 1 (JF101).

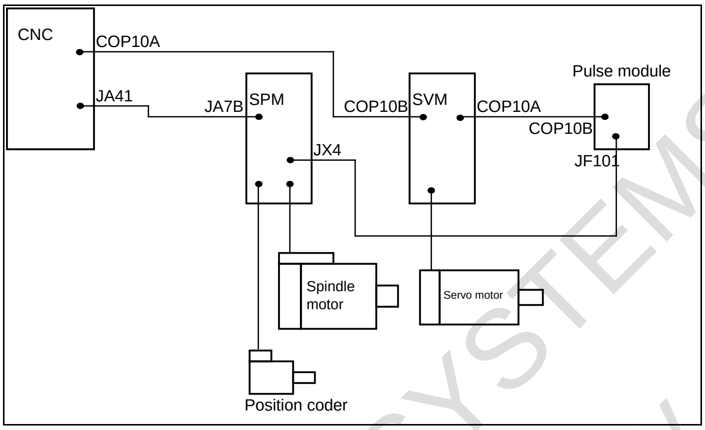

Fig. 10.22.1 (a) Connection example for servo/spindle synchronous control

> **NOTE**
> During operation, the combination of spindle and servo motor to synchronize cannot be changed.

- Configuration

To use this function, the detection unit must be specified by setting the flexible feed gear (M/N) (parameter No.2084 and 2085) in such a way that the number of pulses per rotation of the spindle will be 4096. Thus, it is necessary to select a servo motor-to-spindle gear ratio a:b so that the M and N values of the flexible feed gear as determined from the expression below will be equal to or less than 32767.

$$\frac{M}{N} = \frac{a}{b} \times \frac{4,096}{1,000,000}$$

To perform servo motor and spindle synchronous control, set a magnification (integral multiple or R) so that the number of feedback pulses from the position coder will be 4096 per rotation of the spindle. That is, the gear ratio of the position coder to the spindle must be one to an integer.

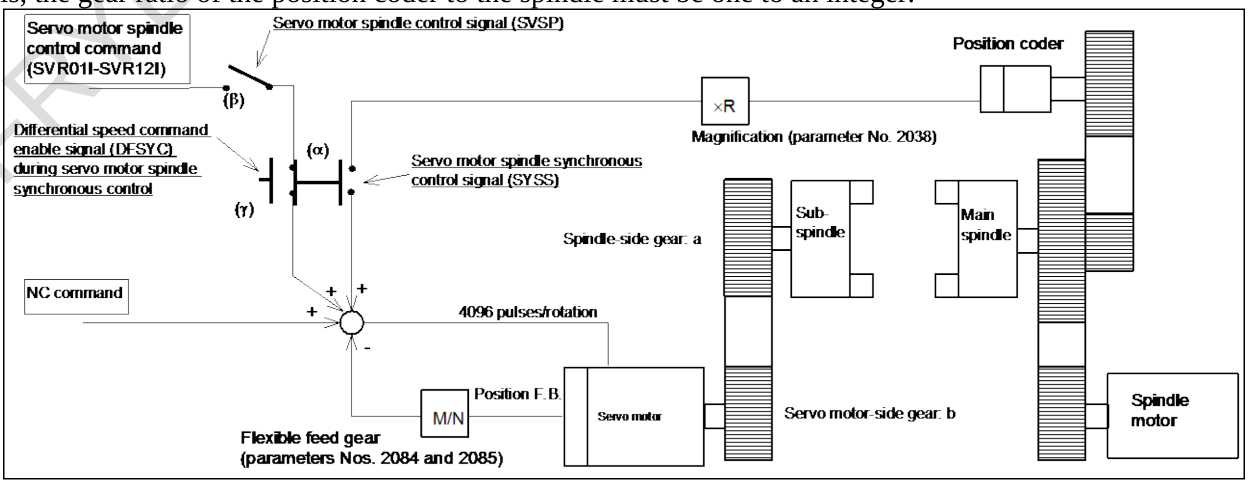

Fig. 10.22.1 (b) System configuration example

- Setting example

If using the A-axis (rotation axis) of the servo motor as the sub-spindle

Conditions

Detector	:	1,000,000 (pulses/rotation)
Spindle-side gear	:	8,000
Servo motor-side gear	:	3,600
CMR	:	1 (setting: 2)

Gear ratio of the position coder to the main-spindle: 1 to 2

The flexible feed gear can be determined from the formula below.

$$\frac{M}{N}=\frac{a}{b}\times\frac{4{,}096}{1{,}000{,}000}=\frac{8{,}000}{3{,}600}\times\frac{4{,}096}{1{,}000{,}000}=\frac{256}{28{,}125}$$

If these settings are made, a normal move command for the A-axis will be A4.096 per rotation of the spindle, and the speed command will be a feed per minute command per rpm, F4.096.

The magnification (R) for servo motor and spindle synchronous control will be set to 2 because the gear ratio of the position coder to the main-spindle is 1:2.

- Servo motor spindle control

Can rotate the servo motor at the rotation speed specified with an input signal.

- Servo motor spindle control mode

By setting the servo motor spindle switching signal SVSP <Gn022.7> to "1", the system enters servo motor spindle control mode, so that the servo motor can be rotated at the rotation speed specified with a signal.
In servo motor spindle control mode, the servo motor spindle control mode signal SVSPM <Fn090.7> is set to "1".
By setting SVSP to "0", servo motor spindle control mode is canceled. If this occurs, SVSPM is set to "0".

NOTE

1. In servo motor spindle control mode, coordinates will not be updated. Thus, the relationships between coordinates and actual machine position will be lost.
2. If a move command is commanded from the CNC on the servo motor in servo motor spindle control mode, alarm PS5211 "ILLEGAL AXIS OPERATION" is issued.

- Specifying a motor rotation speed

The rotation speed of the servo motor in servo motor spindle control mode can be specified with the servo motor rotation speed specification signals SVR01I to SVR12I <Gn021.0 to Gn022.3>. Set the setting determined from the formula below, in binary notation.

$$Setting=\frac{\text{Speed of spindle motor}}{\text{Maximum speed of spindle motor(parameter No.3842)}}\times 4095$$

The rotation direction of the motor can be specified with the servo motor rotation polarity specification signal SVGN <Gn022.5>.

- Acceleration/deceleration

If servo motor spindle control mode is turned on or off or if the rotation speed specified with SVR01I to SVR12I changes, acceleration/deceleration is performed with the time constant set in parameter No. 3843.
When a steady state is attained after the completion of acceleration/deceleration, the servo motor spindle control mode acceleration/deceleration completion signal SVAR <Fn090.6> is set to "1".

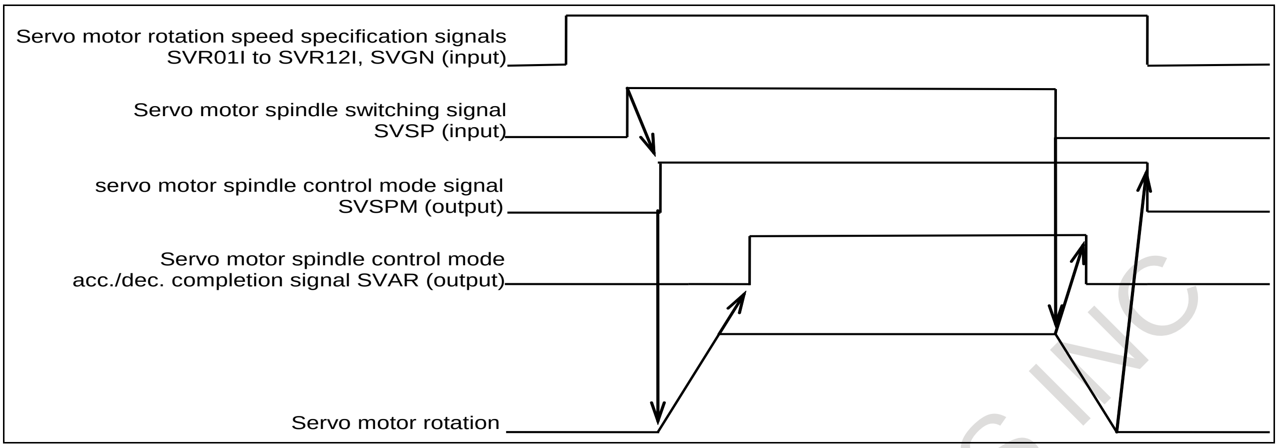

Fig. 10.22.1 (c) Timing chart of signals during servo motor spindle control

- Servo motor spindle synchronization

Can rotate the servo motor in synchronization with the feedback pulses from the position coder of the main-spindle.

- Servo motor spindle synchronization mode

By setting the servo motor spindle synchronization start signal SYSS <Gn061.2> to “1”, the system enters servo motor spindle synchronization mode. When the system enters servo motor spindle synchronization mode, the servo motor accelerates or decelerates to the rotation speed of the main-spindle that is specified with parameter No. 3844. If a move command is commanded from the CNC in acceleration/deceleration, alarm PS5211 “ILLEGAL AXIS OPERATION” is issued. Upon completion of acceleration/deceleration, the servo motor spindle synchronization mode acceleration/deceleration completion signal SYAR <Fn090.4> is set to “1”. Then the servo motor rotates in synchronization with the feedback pulses from the position coder.

When the system enters servo motor spindle synchronization mode, the servo motor spindle synchronization mode signal SYSSM <Fn090.5> is set to “1”.

By setting SYSS to “0”, servo motor spindle synchronization mode is canceled. If a rotation command is being executed with servo motor spindle control, the sub-spindle accelerates or decelerates to the speed specified at that point. Upon completion of the cancellation of servo motor spindle synchronization, SYSSM is set to “0”.

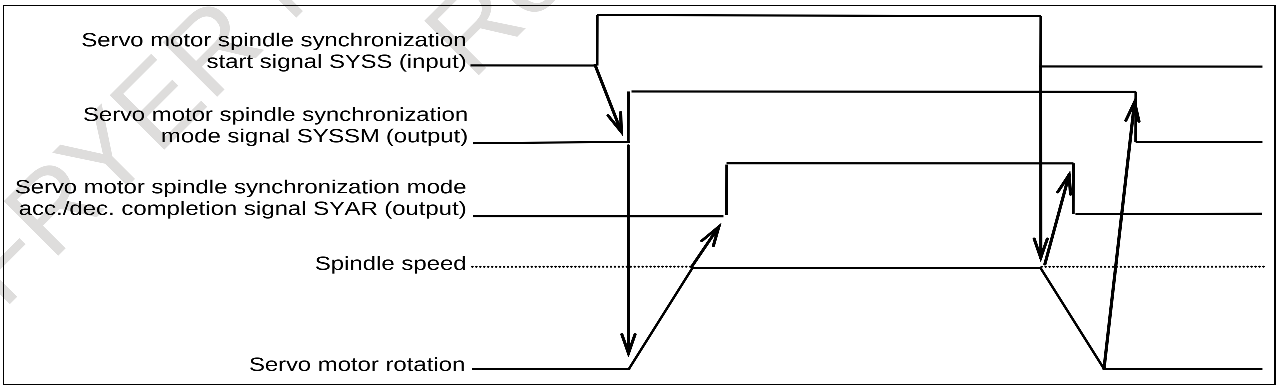

Fig. 10.22.1 (d) Timing chart of signals during servo motor spindle synchronization

> **NOTE**
> 1 In servo motor spindle synchronization mode, coordinates will not be updated. Thus, the relationships between coordinates and actual machine position will be lost. That is, the updating of coordinates with NC commands in servo motor spindle synchronization mode does not represent the actual movements of the machine.

> **NOTE**
> 2 At the start or end of servo motor spindle synchronization mode, all servo axes except sub-spindles must be stopped.
> 3 To start or cancel servo motor spindle synchronization mode during automatic operation, be sure to specify an M code that does not perform buffering before and after switching modes.
> 4 In servo motor spindle synchronization mode, nano interpolation is disabled on sub-spindles.
> 5 In servo motor spindle synchronization mode, do not use the torque control or speed control of PMC axis control on sub-spindles.

- Relationships with servo motor spindle control mode

In servo motor spindle synchronization mode, rotation commands due to servo motor spindle control commands are disabled. By setting SYSS to 0, servo motor spindle control commands are enabled.

- Differential speed synchronization

Can superimpose a move command from the CNC or the rotation speed specified with an input signal on the servo motor in servo motor spindle synchronization mode. It cannot superimpose both of them at the same time.

- Superimposition of a move command

If a move command is executed on the servo axis in servo motor spindle synchronization mode, the move command is superimposed on the synchronization speed.

- Superimposition of the rotation speed from an input signal

By setting the differential speed synchronization command signal DFSYC <Gn022.4> and the servo motor spindle switching signal SVSP to “1” in servo motor spindle synchronization mode, SVR01I to SVR12I and SVGN become effective, so that the servo motor rotates at the speed resulting from synthesizing the speed specified with SVR01I to SVR12I and the speed at which to synchronize with the feedback from the position coder.

If a move command is commanded from the CNC on the servo motor in servo motor spindle synchronization mode when DFSYC and SVSP signals set to “1”, alarm PS5211 “ILLEGAL AXIS OPERATION” is issued.

- Relationships with Servo motor spindle control and Servo motor synchronous control

In servo motor spindle synchronization mode, rotation commands due to servo motor spindle control commands are disabled. (When servo motor synchronous control is performed during servo motor spindle control mode, servo motor spindle control mode is canceled).

By one of the followings, servo motor spindle control commands are enabled again.

- Differential speed synchronization mode is enabled (Change DFSYC from "0" to "1")
- Servo motor synchronous control is canceled (Change SYSS from "1" to "0")

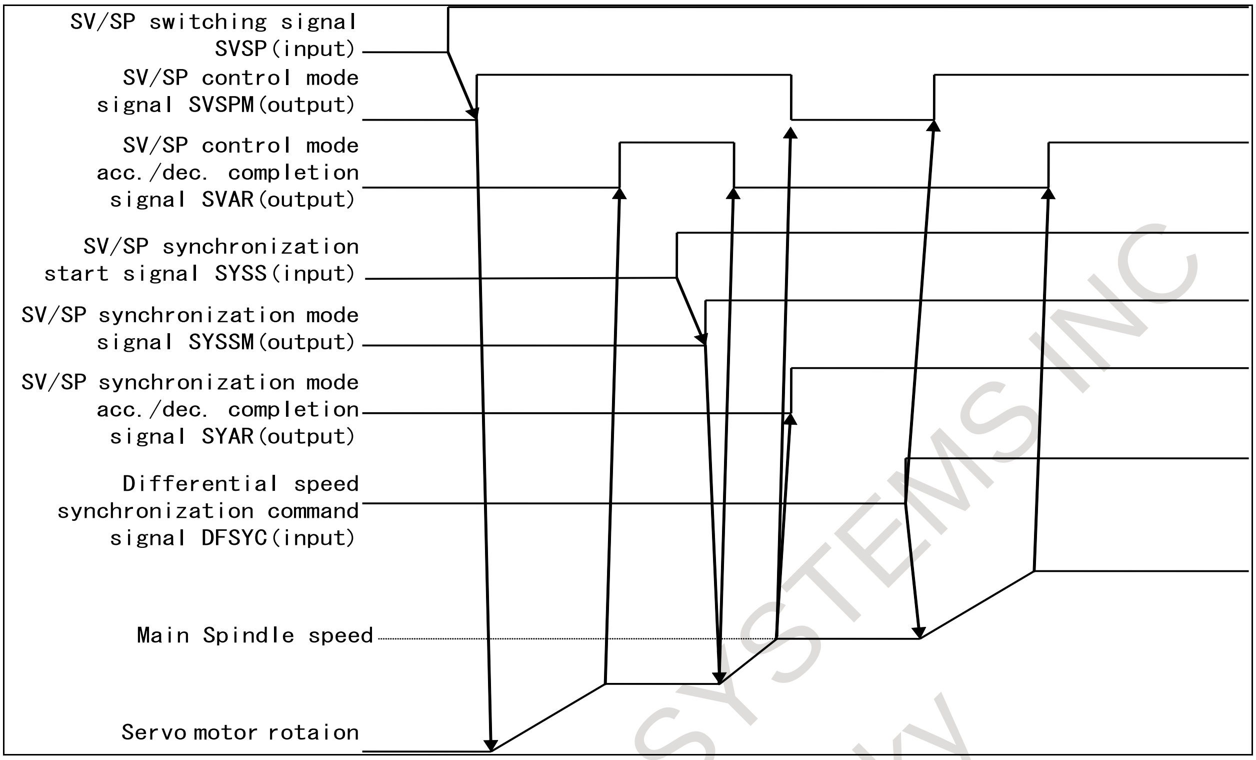

Fig.10.22.1 (e) Timing chart of signals related to servo motor spindle control

Feed forward

During servo spindle control and servo spindle synchronization, the function of feed forward with a servo motor can be enabled. Enabling the feed forward function has the effect of preventing delays due to servo errors when differential speed commands are issued.

Signal

Servo motor spindle control switching signal SVSP <Gn022.7>

[Classification] Input signal

[Function] By setting SVSP to "1", the system enters servo motor spindle control mode, so that a command is executed on the servo motor at the rotation speed previously set in the 12 bits of SVR1I to SVR12I. If this occurs, SVSPM is set to "1".
By setting SVSP to "0", servo motor spindle control mode is canceled. If this occurs, SVSPM is set to "0".

> **NOTE**
> In servo motor spindle control mode, coordinates will not be updated. Thus, the relationships between coordinates and actual machine position will be lost.

Servo motor spindle control mode signal SVSPM <Fn090.7>

[Classification] Output signal

[Function] This signal notifies that the system is in servo motor spindle control mode.

[Output cond.] This signal is set to "1" when the system enters servo motor spindle control mode.

Servo motor rotation speed specification signals SVR01I to SVR12I <Gn021.0 to Gn022.3>

[Classification] Input signal

[Function] These signals enable specification of the rotation speed of the servo motor during servo motor spindle control by setting the setting determined from the formula below, in binary notation.

$$Setting = \frac{\text{Speed of spindle motor}}{\text{Maximum speed of spindle motor(parameter No.3842)}} \times 4095$$

Servo motor rotation polarity specification signal SVGN <Gn022.5>

[Classification] Input signal

[Function] This signal specifies the rotation direction of the servo motor.

0: The polarity is plus.

1: The polarity is minus.

Servo motor spindle control mode acceleration/deceleration completion signal SVAR <Fn090.6>

[Classification] Output signal

[Function] This signal notifies that servo motor acceleration/deceleration has ended in servo motor spindle control.

[Output cond.] This signal is set to “1” at the end of acceleration/deceleration in servo motor spindle control mode.

Servo motor spindle synchronization start signal SYSS <Gn061.2>

[Classification] Input signal

[Function] By setting SYSS to “1”, the system enters servo motor spindle synchronization mode. If this occurs, SYSSM is set to “1”.

When the system enters servo motor spindle synchronization mode, the sub-spindle accelerates or decelerates to the rotation speed of the main spindle. Then, the sub-spindle rotates in synchronization with the feedback pulses from the position coder of the main spindle.

By setting SYSS to “0”, servo motor spindle synchronization mode is canceled. If a rotation command is being executed with servo motor spindle control, the sub-spindle accelerates or decelerates to the speed specified at that point. Upon completion of the cancellation of servo motor spindle synchronization, SYSSM is set to “0”.

In servo motor spindle synchronization mode, rotation commands due to servo motor spindle control commands are disabled. By setting SYSS to “0”, servo motor spindle control commands are enabled.

> **NOTE**
> In servo motor spindle synchronization mode, coordinates will not be updated. Thus, the relationships between coordinates and actual machine position will be lost. That is, the updating of coordinates with NC commands in servo motor spindle synchronization mode does not represent the actual movements of the machine.

Servo motor spindle synchronization mode signal SYSSM <Fn090.5>

[Classification] Output signal

[Function] This signal notifies that the system is in servo motor spindle synchronization mode.

[Output cond.] This signal is set to “1” when the system enters servo motor spindle synchronization mode.

Servo motor spindle synchronization mode acceleration/deceleration completion signal SYAR <Fn090.4>

[Classification] Output signal

[Function] This signal notifies that servo motor acceleration/deceleration has ended in servo motor spindle synchronization.

[Output cond.] This signal is set to “1” at the end of acceleration/deceleration in servo motor spindle synchronization mode.

Differential speed synchronization command signal DFSYC <Gn022.4>

[Classification] Input signal

[Function] This signal enables superimposing of rotation commands due to servo motor spindle control in servo motor spindle synchronization mode.

Parameter

3841	Servo motor spindle control axis number

[Data type] Word

[Valid data range] 1 to 24

This parameter sets the axis number of an axis to be subject to servo motor spindle control or servo motor spindle synchronization.
Setting the parameter to 0 disables servo motor spindle control and servo motor spindle synchronization.
For servo motor spindle synchronization, you have to set bit 4 (SPSx) of parameter No. 2016.

3842	Maximum speed for servo motor spindle control

[Data type] 2-word

[Unit of data] min^{-1}

[Valid data range] 0 to 9999

This parameter sets the maximum speed of the spindle to be subject to servo motor spindle control.

3843	Time constant for acceleration/deceleration under servo motor spindle control

[Data type] Word

[Unit of data] msec

[Valid data range] 0 to 4000

This parameter sets the time constant for acceleration/deceleration under servo motor spindle control and servo motor spindle synchronization.
The type of acceleration/deceleration is linear acceleration/deceleration.
Set the parameter to the time to be taken for the spindle speed to reach 1000 (min^{-1}).

3844	Master spindle number

[Data type] Word

[Valid data range] 0 to 104

Set the number of the spindle (position coder) to be subject to servo motor spindle synchronization.
The hundreds and tens digits represent a path; the units digit represents the number of the position coder in the path.
To synchronize the servo axis in the second path and the second position coder in the first path under dual-path control, for example, set this parameter for the second path to 12.
When the hundreds and tens digits are both 0, the local path is assumed.
When a value of 0 is specified, the first position coder in the local path is assumed.

> ⚠ **WARNING**
> 1 The combination of the position coder and servo motor to be synchronized with each other is determined by wire connection. Even though you change the setting of this parameter, therefore, you cannot change the combination of the position coder and servo motor to be synchronized with each other.
> 2 This parameter is used for acceleration or deceleration to be performed when the synchronization mode is turned on/off.
> 3 It is dangerous to set a value not matching the actually wire-connected combination as it prevents correct acceleration/deceleration. Be sure to set a value matching the actual wire connection.

	#7	#6	#5	#4	#3	#2	#1	#0
2003					PIENx			

[Data type] Bit axis

#3 PIENx PI control is:
0: Disabled.
1: Enabled.

> **NOTE**
> This bit must be set to use the feed forward function.

[Data type] Bit axis

#4 SPSx Servo motor spindle synchronization is:

0: Disabled.

1: Enabled.

> **NOTE**
> Be sure to set this bit to perform servo spindle synchronization.

2038	Spindle feedback magnification (R)

[Data type] Word
[Valid data range] ±32737

Set a magnification so that the number of feedback pulses from the position coder of the main spindle during servo motor spindle synchronization will be 4096 per rotation of the spindle.

$$\text{Setting} = \frac{\text{Gear of spindle}}{\text{Gear of position coder}}$$

If the setting is 0, synchronous control is not performed.
The rotation direction of the servo motor changes with the sign of the setting.

2068	Feed forward coefficient

[Data type] Word
[Valid data range] 0 to 10000

Setting = α x 100

> **NOTE**
> To use the feed forward function, this parameter must be set.

2069	Velocity feed forward coefficient

[Data type] Word
[Valid data range] 50 to 200

This parameter adjusts follow-up capability if it is poor.

NOTE
To use the feed forward function, this parameter must be set.

2084	Flexible feed gear (numerator) (M)
2085	Flexible feed gear (denominator) (N)

[Data type] Word axis
[Valid data range] 0 to 32767
Set the flexible feed gear so that the command per rotation of the spindle will be 4096.

24096	Connector number for the first or ninth separate detector interface unit
24097	Connector number for the second or tenth separate detector interface unit
24098	Connector number for the third or eleventh separate detector interface unit
24099	Connector number for the fourth or twelfth separate detector interface unit
24100	Connector number for the fifth separate detector interface unit
24101	Connector number for the sixth separate detector interface unit
24102	Connector number for the seventh separate detector interface unit
24103	Connector number for the eighth separate detector interface unit

NOTE
When these parameters are set, the power must be turned off before operation is continued.

[Input type] Parameter input
[Data type] Byte axis
[Valid data range] 0 to 8
Set a connector number for the connector to which a separate detector interface unit is attached if the separate detector interface unit is to be used. The following table lists the necessary settings. Be sure to specify 0 for connectors not in use.

Correspondence between connectors and connector numbers

Connector	Connector number
JF101	1
JF102	2
JF103	3
JF104	4
JF105	5
JF106	6
JF107	7
JF108	8

(Setting example)

C2	–	–	–	JF103	0	0	0	3

NOTE

1 Specify these parameters when separate detector interface units are used.

2 Parameters Nos. 24096 to 24103 are specified automatically when data is entered on the FSSB setting screen if the FSSB setting mode in use is the automatic setting mode (bit 0 (FMD) of parameter No. 1902 = 0). If the manual setting 2 mode (bit 0 (FMD) of parameter No. 1902) = 1), specify the parameters directly.

Alarm and message

Number	Message	Description
PS5211	ILLEGAL AXIS OPERATION	- A move command is commanded from the CNC on the servo motor in servo motor spindle control mode. - A move command is commanded from the CNC on the servo motor in acceleration/deceleration of servo motor spindle synchronization mode. - A move command is commanded from the CNC on the servo motor in servo motor spindle synchronization mode when differential speed synchronization command signal DFSYC and the servo motor spindle switching signal SVSP set to “1”.

Notes

Servo/Spindle synchronous control (FSSB type)

The separate detector interface unit becomes unnecessary by the FSSB communication between a CNC and a spindle amplifier.

However, if the separate detector interface unit is used, do not set the setting (the parameters FHRSV (bit 2 of No.2429) and FHESP (bit 2 of No.4549) of Servo/Spindle synchronous control (FSSB type).

Refer to "11.22.2 Servo/Spindle synchronous control (FSSB type)" for details.

Servo alarm

If a servo alarm occurs, servo spindle control and servo spindle synchronization mode are canceled. If this occurs, SVSPM, SYSSM, SVAR, and SYAR (<Fn090> signals) are all cleared.

After the servo alarm is canceled, servo spindle control and servo spindle synchronization will be enabled again.

Servo off

If follow-up is performed (bit 0 (FUPx) of parameter No. 1819 = 0), servo spindle control and servo spindle synchronization mode are canceled. If this occurs, SVSPM, SYSSM, SVAR, and SYAR (<Fn090> signals) are all cleared.

If follow-up is not performed (bit 0 (FUPx) of parameter No. 1819 = 1), servo spindle control and servo spindle synchronization mode are not canceled. Commands are accumulated as servo errors.

Emergency stop

In the event of an emergency stop, servo spindle control and servo spindle synchronization mode are canceled. If this occurs, SVSPM, SYSSM, SVAR, and SYAR (<Fn090> signals) are all cleared.
After the emergency stop is canceled, servo spindle control and servo spindle synchronization will be enabled again.

Multi-path

- Number of axes

Only a single servo axis per path can be used with this function.

- Signal address

If the servo motor on the second path is used, the addresses of all control signals are the original ones plus 1000.
Similarly, for the third path, the addresses are the original ones plus 2000.

- Synchronization between paths

It is possible to synchronize between paths. To do this, input the signal for the path to which the servo axis belongs.
For example, to synchronize the spindle on path 1 with the servo axis on path 2, input the signal on path 2 (G1000 to G1999).

- Synchronization of multiple axes

It is possible to synchronize multiple servo axes to a single main-spindle. To do this, input the signals on the multiple paths to which the servo axes belong.
It is necessary to connect multiple position coders to the same main-spindle and input them to the connectors of the respective pulse modules.

10.22.2 Servo/Spindle Synchronous Control (FSSB Type)

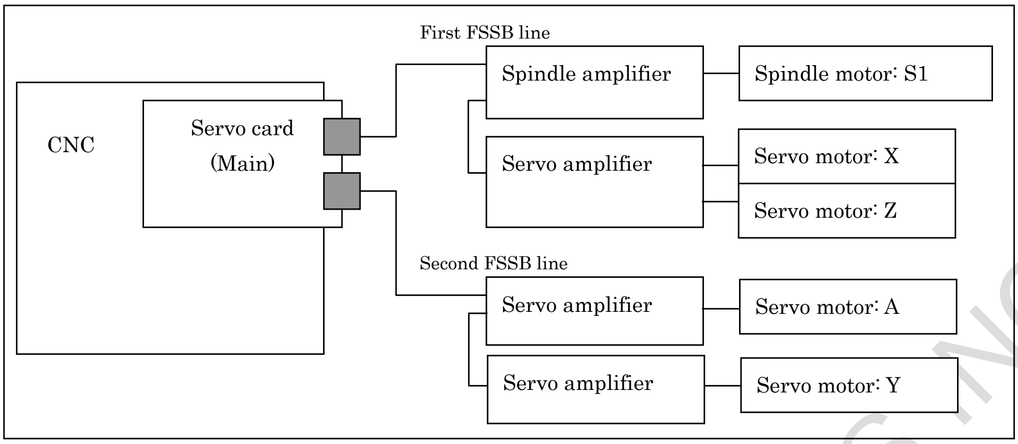
Outline

By the FSSB communication between a CNC and a spindle amplifier, rotational position information of a spindle can be transmitted from a spindle amplifier to a servo control on CNC. Servo/Spindle synchronous control (FSSB type) is a function that a servo axis follows a spindle axis by utilizing this FSSB communication. And it is a feature of this function that the separate detector interface unit becomes unnecessary compared with the ordinary function.

Explanation

The amplifier of main-spindle (spindle motor) and the amplifier of sub-spindle (servo motor) used for Servo/Spindle synchronous control (FSSB type) need to be connected to the main servo card. The spindle amplifier and the servo amplifier used for Servo/Spindle synchronous control (FSSB type) can be connected to both the first FSSB line and the second FSSB line. (This function can be executed between two motors connected to another line.)

Ex.1) Servo/Spindle synchronous control (FSSB type) with A axis and S1 spindle axis in the one path system.
[Example of connection of FSSB]

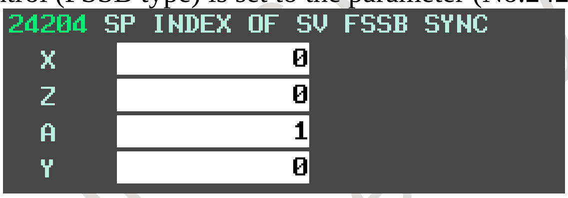


[Example of parameter setting]

The following setting are necessary in addition to setting of existing parameters related to Servo/Spindle synchronous control.

When the parameter FHR (Bit 0 of No.24203) is set to 1, position data transmission by FSSB is enabled.

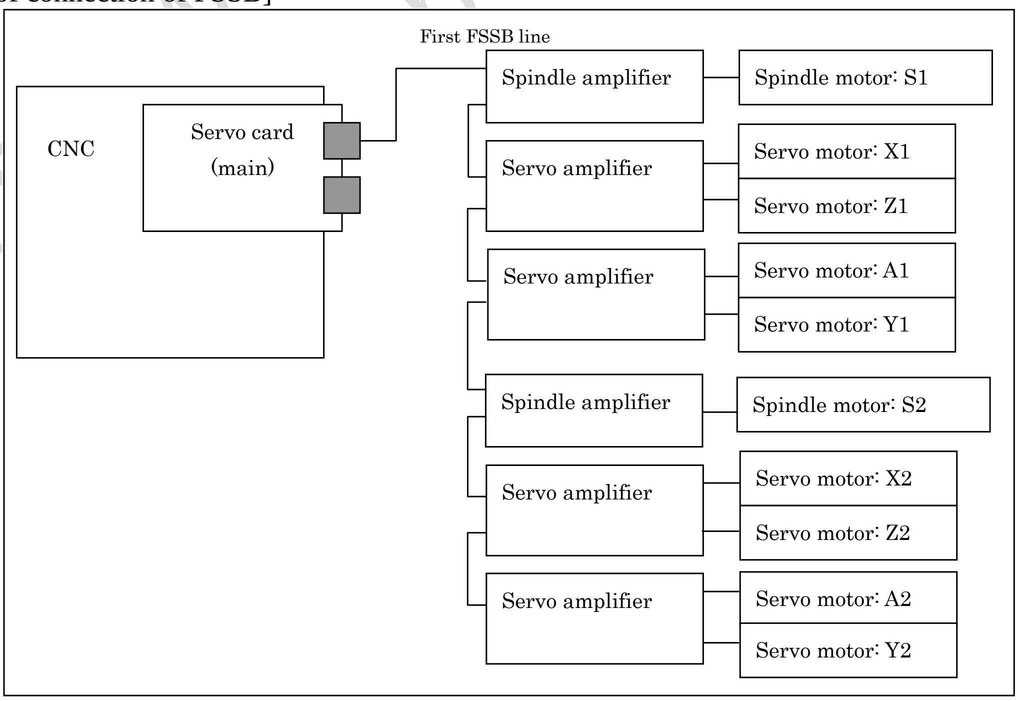
And, the index number of the spindle axis (S1) that synchronizes with the servo axis (A) used by Servo/Spindle synchronous control (FSSB type) is set to the parameter (No.24204) as follows.



In addition, set the parameter FSBSYN (bit2 of No.2429) of A axis and the parameter FHESP (bit2 of No.4549) of S1 spindle axis to 1.

Ex.2) Servo/Spindle synchronous control (FSSB type) with A1 - S1 and A2 - S2 in two path system.

[Example of connection of FSSB]

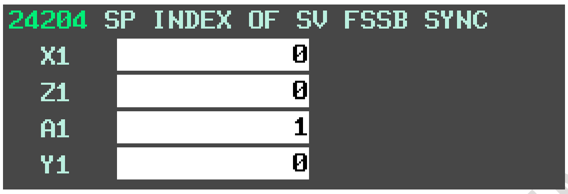


[Example of parameter setting]

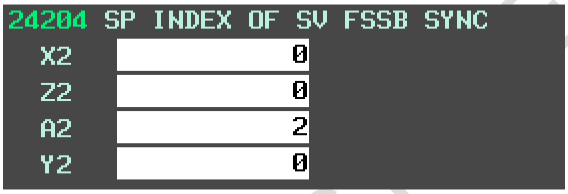
The following setting are necessary in addition to setting of existing parameters related to Servo/Spindle synchronous control.

When the parameter FHR (Bit 0 of No.24203) is set to 1, position data transmission by FSSB is enabled.
And, the index number of the spindle axes (S1, S2) that synchronizes with the servo axes (A1, A2) used by Servo/Spindle synchronous control (FSSB type) is set to the parameter (No.24204) as follows.

Path1



Path2



In addition, set the parameter FSBSYN (bit2 of No.2429) of A1 and A2 axes and the parameter FHESP (bit2 of No.4549) of S1 and S2 spindle axes to 1.

Eight or less index numbers of the spindle axis can be set in all system. If nine or more index numbers of the spindle axis or illegal index number of spindle axis is set, the alarm (PW0037) "SV/SP COMBINATION ERROR" is issued.

NOTE

1. When the parameter is changed, the power must be turned off before an operation is continued.
2. Servo/Spindle synchronous control (FSSB type) cannot be used with analog spindle or the spindle control with servo motor. If the above setting is set the parameter No.24204, the alarm (PW0037) “SV/SP COMBINATION ERROR” is issued.
3. The setting of the arbitrary gear ratio (DMR function) for main-spindle (spindle motor) cannot be used.
4. With sub-spindle (servo motor) used by Servo/Spindle synchronous control (FSSB type), the following servo software functions cannot be used.
   - FSSB high-speed rigid tapping
   - Electronic Gear Box
   - Full-closed control

   If these functions are used, the alarm SV0417, “ILL DGTL SERVO PARAMETER” is issued.
5. Others follow notes of Servo/Spindle synchronous control.

> 2 In the spindle axis, in which this parameter is 1, FSSB high-speed rigid tapping cannot be used. If using with FSSB high-speed rigid tapping, the alarm (SP9068) “ILLEGAL SPINDLE PARAMETER” is issued.

Alarm and message

Number	Message	Description
PW0037	SV/SP COMBINATION ERROR	- The servo axis has dummy axis setting. Please check parameters (No.1023, bit 0 of No.2009, and bit 4 of No.11802). - The setting for the function for spindle axis number to synchronize with servo axis is illegal. Please check parameters (bit 0 of No.3716, No.3717, and No.24204).
SV0417	ILLEGAL SERVO PARAMETER	- The setting for the function, which is not available with Servo/Spindle synchronous control (FSSB type) together, is done. Please turn it off.
SP9068	ILLEGAL SPINDLE PARAMETER	- Servo/Spindle synchronous control (FSSB type) and FSSB high-speed rigid tapping cannot be used together. Please check the parameter (bit 1 and bit2 of No.4549). - In the case of Servo/Spindle synchronous control (FSSB type) using, please turn off FSSB high-speed rigid tapping.

Diagnose

1612	The index number of the spindle axis that synchronizes with each servo axis

[Data Type] Byte axis

The index number of the spindle axis that can use direct communication between a spindle amplifier and a servo amplifier on FSSB connection is displayed.

10.22.3 Phase Synchronization for Servo/Spindle Synchronous Control

Outline

There are three functions on Servo/Spindle synchronous control.

(a) Servo motor spindle control
Can rotate the servo motor at the rotation speed specified with an input signal.

(b) Servo motor spindle synchronization
Can rotate the servo motor in synchronization with the feedback pulses from the spindle sensor.

(c) Differential speed synchronization
  (i) Can superimpose a command from the CNC on the servo motor in servo motor spindle synchronization.
  (ii) Can superimpose the rotation speed specified with an input signal on the servo motor in servo motor spindle synchronization.

By this function, the phase of sub-spindle (the servo motor machine coordinate zero point in the status of reference position establishment) can match the phase of main-spindle (the spindle sensor position determined by the one-rotation signal) on (b) Servo motor spindle synchronization.
Addition, the phase can be shifted by the parameter.

Refer to the manual CONNECTION MANUAL (FUNCTION) (B-64693EN-1) "11.22.1 Servo/Spindle synchronous control" for the basic specification of Servo/Spindle synchronous control.

It is necessary to set Servo/Spindle synchronous control (FSSB type). Refer to the manual CONNECTION MANUAL (FUNCTION) (B-64693EN-1) "11.22.2 Servo/Spindle synchronous control (FSSB type)" for details.

Enable spindle synchronous control (bit 4 (SYC) of parameter No.8133 is 1) for this function.

Explanation

The phase of sub-spindle (the servo motor machine coordinate zero point in the status of reference position establishment) can match the phase of main-spindle (the spindle sensor position determined by the one-rotation signal). Addition, the phase can be shifted by the parameter No.3845.
The method of phase synchronization is shown as follows.

(1) Establish the reference position of sub-spindle (servo motor) by Reference position establishment. (Reference position establishment signals ZRFx <Fn120.x> is "1")
(2) Execute spindle orientation of main-spindle (spindle motor).
(3) When Servo motor spindle synchronization start signal SYSS <Gn061.2> is set "1", it becomes servo motor spindle synchronization mode.
(4) When it becomes servo motor spindle synchronization mode, Servo motor spindle synchronization mode signal SYSSM <Fn090.5> becomes "1".
(5) When it becomes servo motor spindle synchronization mode, sub-spindle accelerates or decelerates to the rotation speed of main-spindle.
(6) When the acceleration/deceleration of sub-spindle is completed, Servo motor spindle synchronization mode acceleration/deceleration completion signal SYAR <Fn090.4> becomes "1".

(7) When Phase synchronization for Servo/Spindle synchronous start signal SYPST <Gn517.7> is set "1" after the acceleration/deceleration of sub-spindle is completed, phase synchronization starts.
(8) The shift value between main-spindle and sub-spindle can be set by parameter No.3845.
(9) It accelerates or decelerates from the current spindle motor speed to the setting speed of parameter No.3846 by Linear acceleration/deceleration with the acceleration rate based on parameter No.3843.
(10) When the synchronization error pulse value become small value more than allowable error pulse value set by parameter No.3847, Phase synchronization for Servo/Spindle synchronous finished signal SYPFN <Fn527.6> becomes "1".
(11) After Phase synchronization for Servo/Spindle synchronous finished signal SYPFN <Fn527.6> becomes "1", set "0" to Phase synchronization for Servo/Spindle synchronous start signal SYPST <Gn517.7>.
(12) When Servo motor spindle synchronization start signal SYSS <Gn061.2> is set "0", servo motor spindle synchronization mode is canceled.
(13) Servo motor spindle synchronization mode acceleration/deceleration completion signal SYAR <Fn090.4> and Phase synchronization for Servo/Spindle synchronous finished signal SYPFN <Fn527.6> become "0".
(14) Sub-spindle decelerates and stops.
(15) When the acceleration/deceleration of sub-spindle is completed, Servo motor spindle synchronization mode signal SYSSM <Fn090.5> becomes "0".

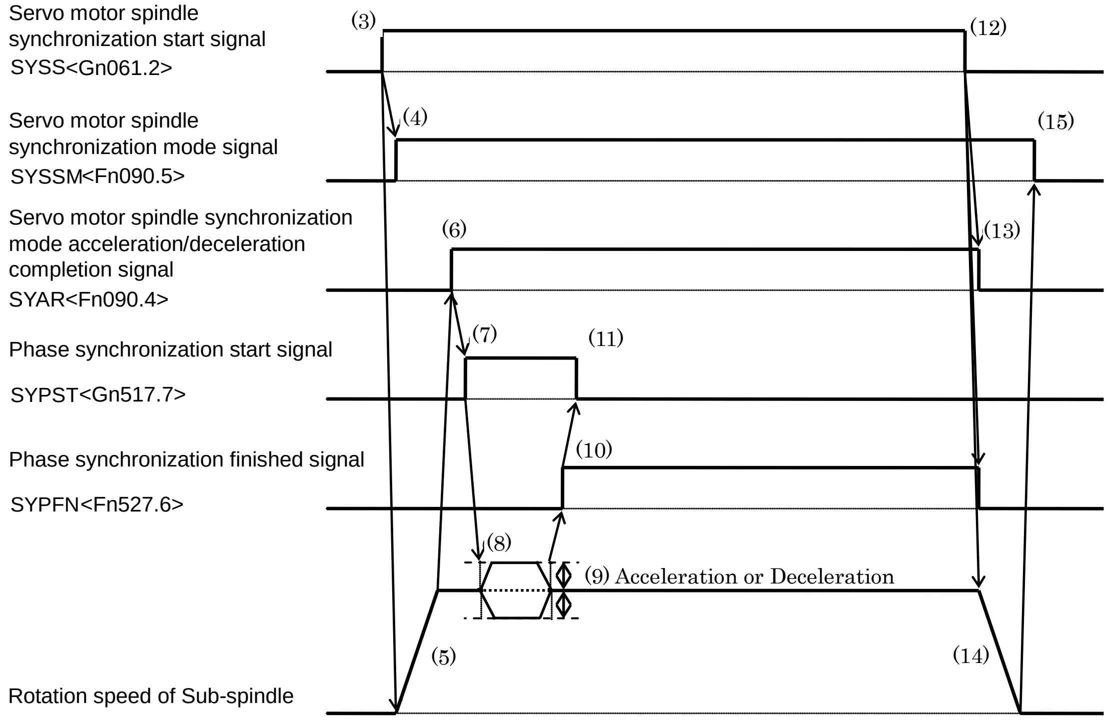

Fig. 10.22.3 Signal sequence of phase synchronization on Servo/Spindle synchronous control

NOTE

NOTE

1 Phase synchronization cannot be executed in superimposition by differential speed synchronization or motion command. Addition, if differential speed synchronization or motion command is specified in phase synchronization, phase synchronization is canceled and differential speed synchronization or motion command is executed. In this case, Phase synchronization for Servo/Spindle synchronous error signal SYPER <Fn527.7> becomes "1".

2 Phase synchronization cannot be executed while canceling Servo/Spindle synchronous control.
In addition, If Servo/Spindle synchronous control is canceled during execution phase synchronization, phase synchronization is canceled.

3 If the servo software or the spindle software doesn’t correspond to this function, Phase synchronization for Servo/Spindle synchronous error signal SYPER <Fn527.7> becomes "1" when Phase synchronization for Servo/Spindle synchronous start signal SYPST <Gn517.7> is set "1".

4 Depending on the mechanical rigidity or the servo response, the synchronization error might occur in high-speed rotation or acceleration/deceleration. Therefore, set big value more than the synchronization error to allowable error pulse value on phase synchronization (parameter No.3847).
Addition, using together with "Soft start/stop function" of spindle motor is effective for a decrease in synchronization error at acceleration/deceleration. Refer to Spindle motor parameter manual (B-65280EN) for details.

5 On phase synchronization, the setting of gear rate is as following.
- Main-spindle (spindle motor)
  The gear ratio between main-spindle and spindle sensor can be used only 1:1.
  On the system that the arbitrary gear ratio between motor sensor and spindle (parameter Nos.4171-4174) or the arbitrary gear ratio between spindle sensor and spindle (parameter Nos.4500-4503) is used, phase synchronization cannot be used.
- Sub-spindle (servo motor)
  The gear rate between sub-spindle and servo motor can be set n:m.

6 Always use Feed-forward function of sub-spindle (servo motor). It is recommended to set 100% to feed-forward coefficient. Refer to "Feed-forward Function" of Servo motor parameter manual (B-65270EN).

7 It is necessary to set Servo/Spindle synchronous control (FSSB type) for this function. Refer to the manual CONNECTION MANUAL (FUNCTION) (B-64693EN-1) "11.22.2 Servo/Spindle synchronous control (FSSB type)" for details.

8 It is necessary to establish the reference position (Reference position establishment signals ZRFx <Fn120.x> is "1") of sub-spindle (servo motor) before phase synchronization start from power supply turning on.
However, if the combination between main-spindle (spindle motor) and sub-spindle (servo motor) is not changed, the reference position establishment since the second times is unnecessary.

9 Set rotary axis A type (bit 0 (ROT) of parameter No.1006 is set 1 and bit 1 (ROS) of parameter No.1006 is set 0) to sub-spindle (servo motor).

NOTE

10 When Servo/Spindle synchronous control is executed, the relationships between coordinates and actual machine position of sub-spindle (servo motor). Thus, the base phase of sub-spindle (servo motor) is the machine coordinate zero point in the status of reference position establishment.

11 Other notes follow notes of Servo/Spindle synchronous control written in the following manual.
- CONNECTION MANUAL (FUNCTION) (B-64693EN-1) "11.22.1 Servo/Spindle synchronous control"

⚠ **CAUTION**

1 Set "0" to Phase synchronization for Servo/Spindle synchronous start signal SYPST <Gn517.7>, after Phase synchronization for Servo/Spindle synchronous finished signal SYPFN <Fn527.6> becomes "1".

2 Phase synchronization cannot execute when Phase synchronization for Servo/Spindle synchronous error signal SYPER <Fn527.7> is "1". Phase synchronization for Servo/Spindle synchronous error signal SYPER <Fn527.7> becomes "0", when Phase synchronization for Servo/Spindle synchronous start signal SYPST <Gn517.7> is set "0".

3 When a motor excitation is cut (Emergency stop, Servo/Spindle alarm is issued, or etc...), set "0" to Phase synchronization for Servo/Spindle synchronous start signal SYPST <Gn517.7>.

4 Set a multiple of 4.096 to the shift amount per one rotation (parameter No.1260) of sub-spindle (servo motor).

5 If the gear ratio for sub-spindle and servo motor is not integer and these connect is semi-closed system, the phase of sub-spindle when the power supply is turned on again will not be guaranteed.

Signal

Phase synchronization for Servo/Spindle synchronous start signal SYPST <Gn517.7>

[Classification] Input signal

[Function] This signal starts phase synchronization for Servo/Spindle synchronous.

[Operation] On Servo/Spindle synchronous, when this signal set “1” from “0”, phase synchronization starts.

Phase synchronization for Servo/Spindle synchronous finished signal SYPFN <Fn527.6>

[Classification] Output signal

[Function] This signal notifies that Phase synchronization for Servo/Spindle synchronous completed.

[Operation] This signal becomes “1” in the following case:
- When the synchronization error pulse value become small value more than allowable error pulse value after phase synchronization was executed.

This signal becomes “0” in the following cases:
- When Servo/Spindle synchronous mode is off.
- When the synchronization error pulse value become big value more than allowable error pulse value in Servo/Spindle synchronous mode.
- When Phase synchronization for Servo/Spindle synchronous error signal SYPER becomes “1”.

Phase synchronization for Servo/Spindle synchronous error signal SYPER <Fn527.7>

[Classification] Output signal

[Function] This signal notifies that Phase synchronization for Servo/Spindle synchronous cannot complete.

[Operation] This signal becomes “1” in the following cases:
- When the setting of phase synchronization for Servo/Spindle synchronous is incorrect.
- When phase synchronization cannot start though Phase synchronization for Servo/Spindle synchronous start signal SYPST is set “1”. (When the feedrate during phase synchronization (parameter No.3846) is 0, when the base position of phase synchronization is not detected, or etc…)
- When phase synchronization is interrupted in execution of phase synchronization. (When differential speed synchronization is specified in execution of phase synchronization, or etc…)
- When Phase synchronization for Servo/Spindle synchronous start signal SYPST is set “1” in execution of differential speed synchronization.
- When the servo software or the spindle software doesn’t correspond to this function.

This signal becomes “0” in the following cases:
- When Servo/Spindle synchronous is mode off.
- When Phase synchronization for Servo/Spindle synchronous start signal SYPST is set “0”.

	#7	#6	#5	#4	#3	#2	#1	#0
Fn527	SYPER	SYPFN						

Parameter

3845	Shift value of phase synchronization for Servo/Spindle synchronous control

[Input type] Parameter input
[Data type] Word path
[Unit of data] Detection unit
[Valid data range] 0 to 4095

Set a shift value of phase synchronization for Servo/Spindle synchronous control to this parameter. One rotation of spindle is 4096 pulses.

Example) If the sub-spindle should be at a quarter rotation position from main-spindle, set 1024 to this parameter.

3846	Feedrate during phase synchronization for Servo/Spindle synchronous control

[Input type] Parameter input
[Data type] Real path
[Unit of data] deg/min (machine unit)
[Valid data range] Refer to standard parameter setting table (C)
(When the increment system is IS-B, 0.0 to +999000.0)

Set a feedrate during phase synchronization for Servo/Spindle synchronous control to this parameter.

It accelerates or decelerates from the current spindle motor speed for this parameter by linear acceleration/deceleration with the acceleration rate based on parameter No.3843.

Example) When the increment system IS-B and CMR (parameter No.1820) is 1, the amount of movement will be 4.096[deg] per rotation of the spindle. Therefore, if speed during phase synchronization will be 10[min^{-1}], set 40.96[deg/min] to this parameter.

> **NOTE**
> Set this parameter when Phase synchronization start signal SYPST is "0".
> This parameter setting is reflected when Phase synchronization start signal SYPST become "1" from "0".

3847	Allowable error pulse value on phase synchronization for Servo/Spindle synchronous control

[Input type] Parameter input
[Data type] Word path
[Unit of data] Detection unit
[Valid data range] 0 to 4095

On phase synchronization for Servo/Spindle synchronous control, when the synchronization error pulse value between main-spindle and sub-spindle become small value more than this parameter, Phase synchronization finished signal SYPFN become "1".

> **NOTE**
> Depending on the mechanical rigidity or the servo response, the synchronization error might occur in high-speed rotation or acceleration/deceleration. Therefore, set big value more than the synchronization error to this parameter.

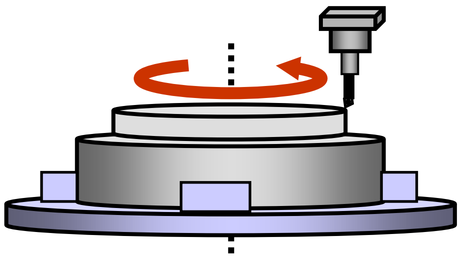
10.23 HIGH-PRECISION SPINDLE SPEED CONTROL

Overview

A large-scale machine cuts a large-diameter workpiece by turning it. Conventional spindle commands (S code commands) cannot specify a surface speed (cutting speed) for large-diameter workpieces in detail because they specify the spindle speed using an integer value. This function uses numbers having decimal points, thus enabling the cutting speed to be specified in detail.

Cutting a large-diameter workpiece by turning it



Explanation

Setting bit 3 (SDP) of parameter No. 3798 to 1 enables high-precision spindle speed control. (Resetting bit 3 (SDP) of parameter No. 3798 to 0 enables conventional spindle commands using integers.) When high-precision spindle control is in use, spindle speed commands (S code commands, a command for maximum spindle speed clamping (G50), and a constant-surface speed control command (G96)) can be issued in units of 0.1 min^{-1} (for constant-surface speed control, 0.1 m/min).

<Command format >
S code command:
M03 S3.5 (Making the spindle rotate at 3.5 [min^{-1}])
Example)
Using high-precision spindle speed control enables the following surface speeds to be selected for a workpiece 4 meters in diameter.

Spindle command	Spindle speed[min^{-1}]	Surface speed [m/min]
S3 M03 ;	3	37.7
S3.2 M03 ;	3.2	40.2
S3.5 M03 ;	3.5	44.0
S3.8 M03 ;	3.8	47.8
S4 M03 ;	4	50.3

Command for maximum spindle speed clamping (G50):
G50 S3.5 (Clamping the spindle speed at 3.5 [min^{-1}])

Constant surface speed control (G96) :
G96 S44.5 (Making the spindle rotate at a surface speed of 44.5 [m/min])
Example)
Using high-precision spindle speed control makes the spindle rotate at the speeds listed below when the specified surface speed is 44.5 [m/min] or 45 [m/min].

Reference-axis position	Surface speed 44.5[m/min]	Surface speed 45[m/min]
	Spindle speed [min^{-1}]	
X=0.1[m];	70.8	71.6
X=0.5[m];	14.2	14.3
X=1.0[m];	7.1	7.2
X=1.5[m];	4.7	4.8
X=2.0[m];	3.5	3.6

The range of speeds specified with axis rotation commands (S code commands) is as follows:

- For serial spindle
  0.0 to 1000.0[min^{-1}]
- For analog spindle
  0.0 to 400.0[min^{-1}]
- For servo motor (using spindle control with servo motor)
  0.0 to 1000.0[min^{-1}]

> **NOTE**
> Using spindle rotation of a speed control type (bit 0 (SPCx) of parameter No. 11000 = 1) requires a servo motor/spindle configuration having a servo motor-to-spindle speed reduction ratio of not higher than 1/40.

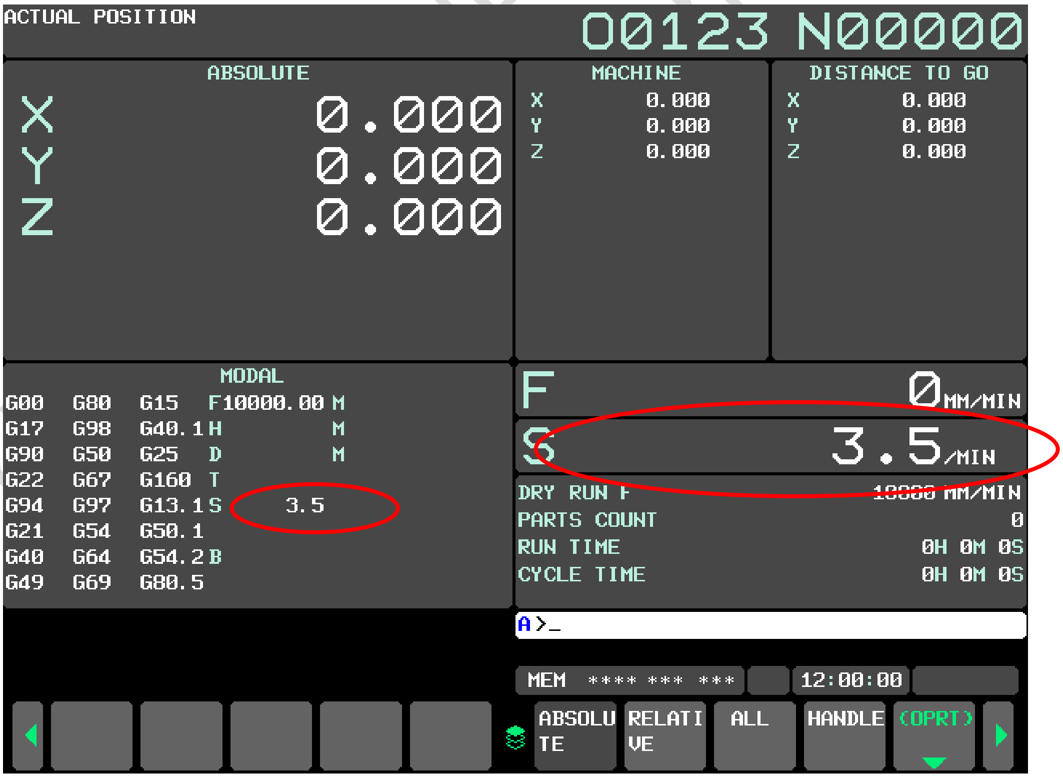
An integer command is assumed if the command specifies a value having no decimal point. For example, if S55 is issued, S55.0 is assumed.

Enabling high-precision spindle speed control makes changes to the following parameter settings and the increment system of data as follows:

- The settings of parameter No. 3771 (minimum spindle speed in the constant-surface speed control mode (G96)) and parameter No. 3772 (upper limit to the rotation speed of individual spindles) are integer data in units of 0.1 min^{-1}.
- The setting of parameter No. 3732 (spindle speed in spindle orientation or spindle motor speed in spindle gear shifting) is integer data in units of 0.1 min^{-1}.
- Data related to spindle speeds in spindle speed signals and values in spindle function code signals are in units of 0.1 min^{-1}.
- Actual spindle speeds read by applications (such as macros, C Language Executor, and FOCAS2) are integer data in units of 0.1 min^{-1}.

Actual spindle speed and S code command displays

If high-precision spindle speed control is enabled, the actual spindle speed and S code commands are displayed using a decimal point.



NOTE

1. When high-precision spindle speed control is enabled, ******.* is displayed if the actual spindle speed or an S command exceeds a maximum allowable display digits.
2. The following screens do not support a display with a decimal point for the actual spindle speed and the S code commands. If high-precision spindle speed control is enabled, the fractional part is rounded off.
   - Operating monitor screen
   - Dynamic graphic (tool path screen)
   - Dynamic graphic (animation drawing screen)

Parameter

	#7	#6	#5	#4	#3	#2	#1	#0
3798				SSI	SDP			

[Input type] Parameter input
[Data type] Bit

#3 SDP High-precision spindle speed control is:
0: Not used.
1: Used.

NOTE
When at least one of these parameters is set, the power must be turned off before operation is continued.

#4 SSI The resolution enabled for the spindle speed command is:
0: Maximum spindle speed/4095 [min^{-1}].
1: Maximum spindle speed/16383 [min^{-1}].

NOTE
When at least one of these parameters is set, the power must be turned off before operation is continued.

	#7	#6	#5	#4	#3	#2	#1	#0
4809								NSY

[Input type] Parameter input
[Data type] Bit

T

#0 NSY When the spindle speed changes during spindle synchronization control, resolution improvement is:
0: Disabled. (Speed change in units of about 3.7 [min^{-1}])
1: Enabled. (Speed change in units of about 0.03 [min^{-1}] at minimum but not higher than maximum spindle speed/4095 [min^{-1}])

This parameter is valid when spindle synchronization control or spindle-spindle polygon turning is used.
Using high-precision spindle speed control and spindle synchronization control simultaneously requires setting the parameter to 1.

NOTE
1 When this parameter is set, the power must be turned off before operation is continued.
2 Using this function requires the serial spindle software that supports it.

M

#0 NSY When the spindle speed changes during spindle synchronization control, resolution improvement is:
0: Disabled. (Speed change in units of about 3.7 [min^{-1}])
1: Enabled. (Speed change in units of about 0.03 [min^{-1}] at minimum but not higher than maximum spindle speed/4095 [min^{-1}])

This parameter is valid when spindle synchronization control is used.
Using high-precision spindle speed control and spindle synchronization control simultaneously requires setting the parameter to 1.

NOTE
1 When this parameter is set, the power must be turned off before operation is continued.
2 Using this function requires the serial spindle software that supports it.

	#7	#6	#5	#4	#3	#2	#1	#0
11000								SPCx

[Input type] Parameter input
[Data type] Bit axis

NOTE
When this parameter is set, the power must be turned off before operation is continued.

#0 SPCx SV speed control mode of spindle control with servo motor is:
0: Position control type.
1: Velocity control type.

Notes

- The speed of the feed axis may vary during feed per revolution at a rotation speed of 1 min^{-1} or lower depending on the detection unit used for the feedback data (4096 (pulse/rev)) from the position coder.
- Changing bit 3 (SDP) of parameter No. 3798 enables this function only after the power is turned off and on again.
- If a decimal point is omitted, the desktop calculator decimal point setting is assumed regardless of the setting of bit 0 (DPI) of parameter No. 3401.
  Example: If S123 is issued, S123.0 is assumed.
- If a command with two or more digits after the decimal point specified is issued, the specified value is rounded off to one digit after the decimal point.
  Example: If S123.45 is issued, S123.5 is assumed.
- In S commands that call a subprogram using an S code, the number of digits after the decimal point is not a target with respect to the number of permissible S code digits (parameter No. 3031).

Limitation

- If an analog spindle motor is used, the spindle may fail to rotate at a specified speed depending on the type of the spindle motor and the resolution of the spindle motor drive amplifier with respect to the speed command voltage, and the spindle motor-to-spindle speed reduction ratio.
- High-precision spindle speed control is invalid for rigid tapping S commands. If a command with a decimal point is issued, the command is assumed to specify an integer (with the fraction rounded off).
- The M type gear selection method is unusable.
- The Manual Guide *i* is unusable.

10.24 SIMPLE SPINDLE ELECTRONIC GEAR BOX

Overview

This function executes spindle synchronous control between two serial spindles based on input signals so that one spindle (slave spindle) follows the other spindle (master spindle). It uses a method of referencing directly feedback pulses to enable the slave spindle to follow fluctuations in the master spindle speed with a small error, thereby achieving high-precision spindle synchronous control.

An example of using the function might be rotary guide bush control where two spindles are used.

An electronic gear box (hereafter called EGB) for the spindle is used to make the two spindles synchronize with each other.

Using the function requires enabling the spindle serial output (bit 5 (SSN) of parameter No.8133 is 0) and the Cs contour control (bit 2 (SCS) of parameter No.8133 is 1).

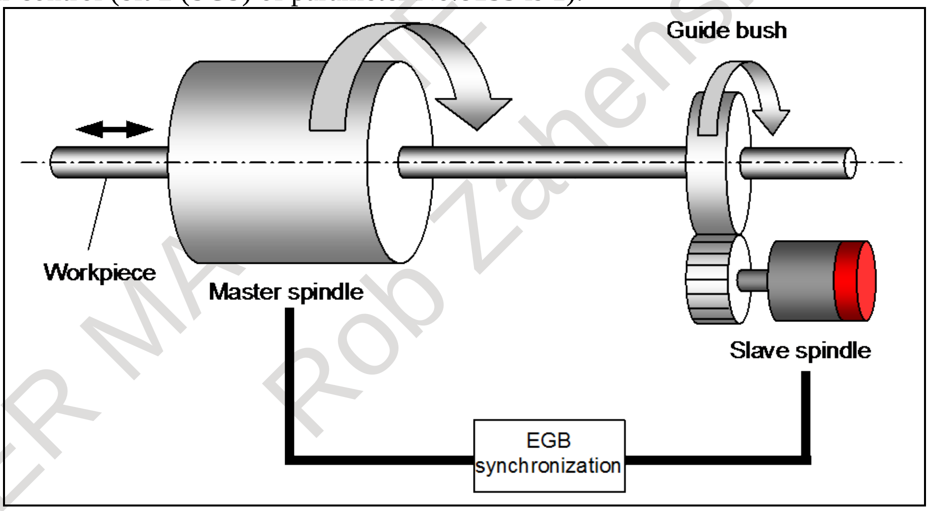


Fig. 10.24 (a) Application example

Specification

With the spindle EGB, the synchronous pulse is produced from the feedback pulse output by the position detector attached to the master axis, and the slave axis rotates according to the synchronous pulse. The feedback pulse sent from master spindle to the slave spindle is forwarded by communication between spindle amplifiers.

This function uses the PMC input signal to turn the simple spindle EGB mode ON/OFF.

Turning on the simple spindle EGB mode ON does not impose any limitation to the spindle control mode for the master spindle. However, the slave spindle must be in the Cs contour control mode.

During the simple spindle EGB mode, the coordinates of the slave spindle are not updated even if the slave spindle moves in synchronization with the master spindle.

The simple spindle EGB needs the same spindle system configuration (motor, amplifier, and sensor) as the spindle EGB. For details, see the Item, “Spindle EGB (spindle electronic gear box)” in the FANUC

AC SPINDLE MOTOR α*i* series, FANUC AC SPINDLE MOTOR β*i* series, FANUC BUILT-IN SPINDLE MOTOR bi series PARAMETER MANUAL (B-65280EN).

Differences between the simple spindle EGB and the spindle EGB

The following table lists the differences between the simple spindle EGB and the spindle EGB.

Table 10.24 Differences between the simple spindle EGB and the spindle EGB

	Simple spindle electronic gear box	Spindle electronic gear box
Feature	- PMC input signal is used to turn synchronization ON/OFF. - No positional control is performed during the synchronization mode.	- G code command is used to turn synchronization ON/OFF. - Positional control is performed during the synchronization mode. - Gear processing functions such as helical gear compensation and retract are usable.
Major use	For rotary guide bush, which requires only simple spindle synchronization rather than positional control	For gear processing, which requires positional control as well as retract operations

Signal

Simple spindle EGB signals

SSEGB1<Gn351.0>: First spindle
SSEGB2<Gn351.1>: Second spindle
SSEGB3<Gn351.2>: Third spindle
SSEGB4<Gn351.3>: Fourth spindle

[Classification] Input signal

[Function] Select the simple spindle EGB.

[Operation] When each signal becomes "1", the simple spindle EGB mode is turned ON with the respective serial spindles selected as a slave.
When each signal becomes "0", the simple spindle EGB mode is turned OFF for the respective serial spindles being used as a slave.

> **NOTE**
> 1 These signals are valid when the bit 0 (SEGs) of parameter No. 7705 is 1.
> 2 If the simple spindle EGB mode is turned ON or OFF when both the master and slave spindles are not at halt, the slave spindle accelerates or decelerates abruptly. When turning the simple spindle EGB mode ON or OFF, be sure to previously put both the master and the slave spindles at halt.
> 3 During the simple spindle EGB mode, keep the slave spindle in the Cs contour control mode.

Simple spindle EGB mode signals

SSEGBM1<Fn351.0>: First spindle
SSEGBM2<Fn351.1>: Second spindle
SSEGBM3<Fn351.2>: Third spindle
SSEGBM4<Fn351.3>: Fourth spindle

[Classification] Output signal

[Function] These signals indicate whether the simple spindle EGB mode is ON for the respective spindles selected as a slave spindle.

[Output cond.] Each signal becomes "1" when:

- The simple spindle EGB mode is ON for the respective spindles selected as a slave spindle.

Each signal becomes "0" when:

- The simple spindle EGB mode is OFF for the respective spindles selected as a slave spindle.

Signal address

	#7	#6	#5	#4	#3	#2	#1	#0
Gn351					SSEGB4	SSEGB3	SSEGB2	SSEGB1

	#7	#6	#5	#4	#3	#2	#1	#0
Fn351					SSEGBM4	SSEGBM3	SSEGBM2	SSEGBM1

Sequence

- Simple spindle EGB mode ON

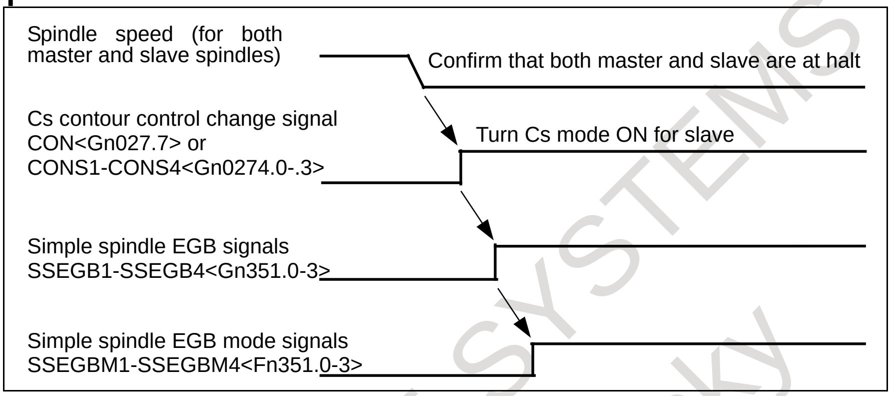

Fig. 10.24 (b) Simple spindle EGB mode ON

- Simple spindle EGB mode OFF

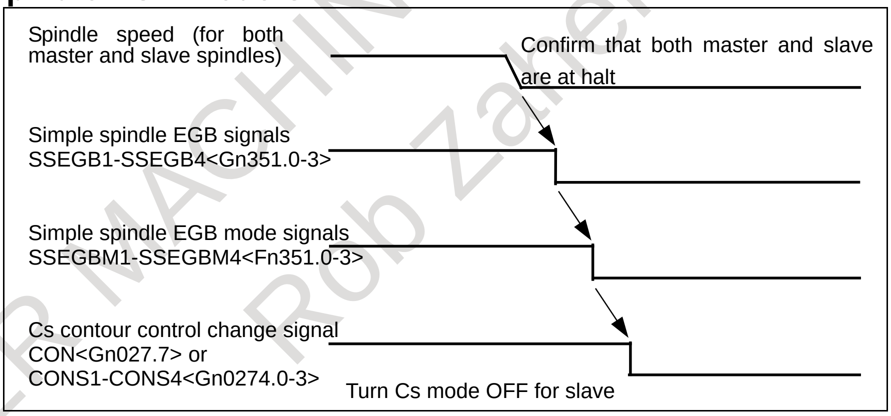

Fig. 10.24 (c) Simple spindle EGB mode OFF

NOTE

1. When turning the simple spindle EGB mode ON or OFF, keep both the master and slave spindles at halt.
2. During the simple spindle EGB mode, the positional deviation of the Cs axis for the slave spindle from the master spindle is returned to the slave spindle. For the slave spindle in the simple spindle EGB mode, checks are constantly made for any excess error value during movement.

NOTE

3 During the simple spindle EGB mode, the coordinates of the Cs axis for the slave spindle are not updated even if the slave spindle is synchronized with the master spindle.
4 During the simple spindle EGB mode, it is impossible to make a reference point return for the Cs axis for the slave spindle.
5 During the simple spindle EGB mode, it is impossible to perform composite control for the Cs axis for the slave spindle.
6 The simple spindle EGB needs the same spindle system configuration (motor, amplifier, and sensor) as the spindle EGB.
7 The synchronization mode is canceled if a servo alarm or spindle alarm condition is detected.
8 Making a request for an emergency stop during synchronization causes both the master and slave spindles decelerate to stop while they are kept in synchronization. However, they may not stay in synchronization once they stop. Release the slave spindle from the simple EGB mode and Cs mode after an emergency stop.

Parameter

	#7	#6	#5	#4	#3	#2	#1	#0
7705								SEGs

[Input type] Parameter input

10.25 SPINDLE SPEED COMMAND CLAMP

Overview

By using this function, spindle speed can be clamped to the maximum speed by setting on internal relay (R signal) data.

Explanation

The internal relay addresses (R signal) is specified with parameter No.3773 for each spindle. Four bytes starting at the setting are used for each spindle. Spindle speed is clamped to the maximum speed by setting on internal relay (R signal) data.

For example, this function can be used to change maximum speed depending on selected tool as following procedure.

1. On the PMC side, the maximum speed depending on the selected tool is set on the internal relay addresses (R signal) specified with the parameter. (The PMC program is created by machine tool builders)
2. The CNC reads maximum speed from PMC internal relay (R signal). The CNC clamp spindle speed to maximum speed immediately if the spindle speed exceeds the maximum speed.

Figure 11.26(a) show the processing of the spindle speed clamp when a command is specified after the tool change.

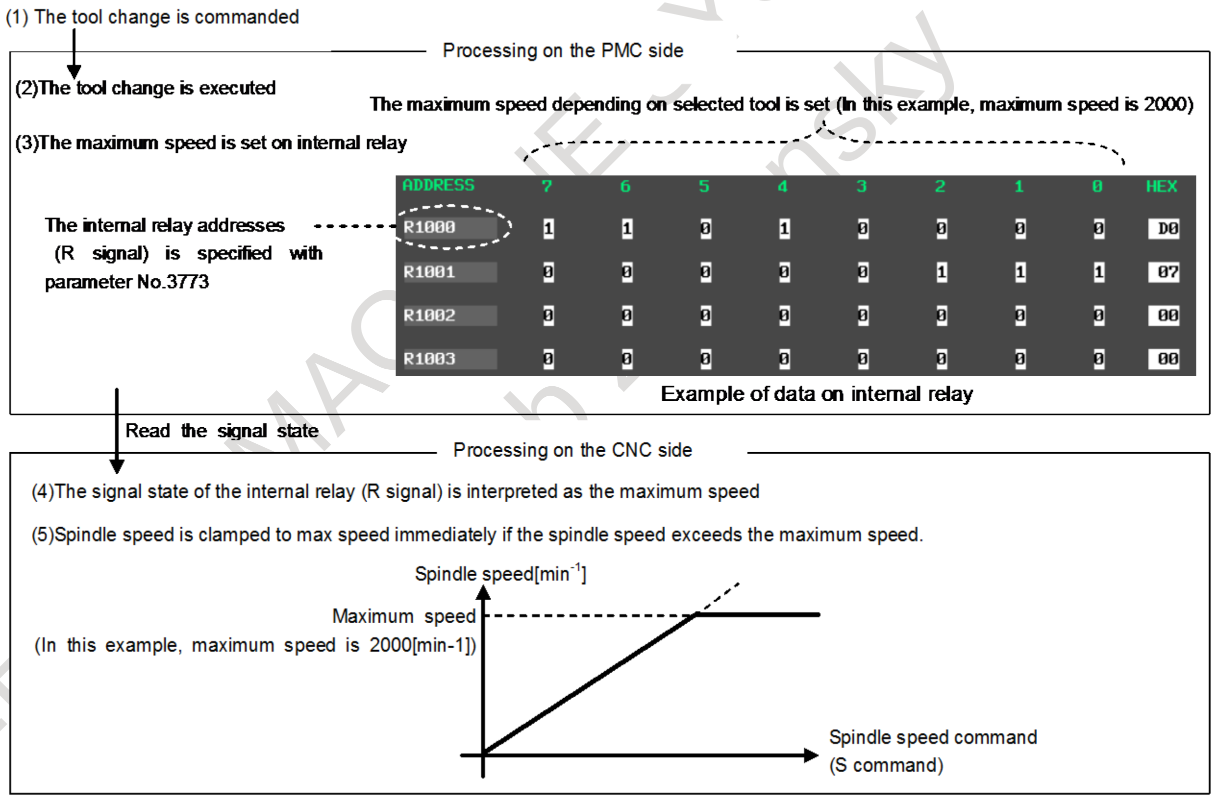

Fig.10.25 (a) processing of this function

> **NOTE**
> 1 This function only effects for a spindle speed command (including spindle override, constant surface speed control), it doesn't effect except spindle speed command (spindle orientation, rigid tapping and so on).
> 2 When spindle speed command control is applied using the PMC, this function has no effect, and the spindle speed is not clamped.

NOTE

3 When the spindle synchronous control is executed, spindle speed of the master and the slave are clamped to the lower value of master's maximum speed and slave's maximum speed.
4 When the M type gear selection method is used, this function has effect even if minimum clamp speed of the spindle motor (parameter No.3735) is larger than the max speed specified on PMC internal relay (R signal).
5 The maximum speed can be set within the range of 0 to 99999999 [min^{-1}]
6 This function has effect for unselected spindle by address P or spindle selection signals SWS1 to SWS4 <Gn027.0 to Gn027.2 and Gn026.3>
7 Depending on bit 3 (SDP) of parameter No. 3798, which is related to High-precision spindle speed control, the maximum speed is changed as following table.

SDP = 0	The signal state of the internal relay (R signal) is interpreted as the maximum speed. The maximum speed can be set within the range of 0 to 99999999 [min^{-1}]
SDP = 1	1/10 of the signal state of the internal relay (R signal) is interpreted as the maximum speed. The maximum speed can be set within the range of 0 to 9999999.9 [min^{-1}]

Parameter

3773	Start address of the R signal specifying maximum speed

NOTE

When this parameter is set, the power must be turned off before operation is continued.

[Input type] Parameter input
[Data type] 2-word spindle
[Valid data range] 0 to maximum address (multiple of 4. 0, 4, 8, ...)

This parameter sets the start address of the R signal specifying maximum speed.
Four bytes starting at the setting are used for each spindle.

NOTE

1 As for the setting of parameter
<1> Set a value that is a multiple of 4 (0, 4, 8, etc.).
<2> The range of the R address differs depending on the PMC kind and the memory size. Check the specifications of the PMC, and set a value within the valid range. (Example: R addresses in the range from R0 to R7999 if memory B of the first PMC is used. Thus, values which can be set are 4, 8, 12, 16, …7992, 7996 in this case)
If any setting other than the above items (<1>, <2>) is made, alarm PW5390, "R-ADDRESS SETTING IS ILLEGAL" is issued.
2 When value of parameter No. 3773 is zero, this function has no effect.

> ⚠ **WARNING**
> If an internal relay of the set address in this parameter is used by another usage, it may cause an unexpected machine behavior. Be careful enough that you must prevent the competition of the used internal relay.

Alarm and message

Number	Massage	Description
PW5390	R-ADDRESS SETTING IS ILLEGAL	One of the R address range of the PMC set by parameters No. 3773, No. 13541 and No. 13542 or the first address of the range is invalid.

10.26 IMPROVEMENT OF SPINDLE FEEDBACK PULSES

Overview

Feedback pulses of the spindle which is used at the feed per revolution, threading and spindle speed display becomes able to be changed by setting of parameter.
By this function, the fluctuation of axis speed at the feed per revolution and threading is reduced, and a smoother axis moving becomes possible.

Specification

It is usually, feedback pulses of the spindle is 4096 pulses per one rotation of the spindle. However, the setting of feedback pulses of the spindle can be changed by the bit 7 (FBP) of parameter No.3716 and No.3720.

- Feedback pulses per one rotation of the spindle can be chosen from 4096 pulses or $4096 \times 2^{\wedge 14}$ pulses in serial spindle.
- Feedback pulses per one rotation of the spindle can be chosen from 4096 pulses or $4096 \times 2^{\wedge 14}$ pulses in spindle control with servo motor.
- Feedback pulses per one rotation of the spindle can be chosen from 4096 to 400000 pulses in analog spindle.

The changing of feedback pulses of the spindle becomes effective by the setting of bit 7 (FBP) of parameter No.3716. And number of feedback pulses is set by parameter No.3720. However, when bit 7 (FBP) of parameter No.3716 is set to 1, it is not necessary to set parameter No.3720 because parameter No.3720 is set automatically in serial spindle and spindle control with servo motor.

> **NOTE**
> 1 When feedback pulses in analog spindle are not 4096pulse/rev, alarm SP1255, "CAN NOT CHANGE SPINDLE MODE" occurs if rigid tapping or spindle positioning is specified. (This alarm not occurs when serial spindle.)
> 2 The effect of this function depends on the resolution of detector.
> (In serial spindle, the resolution of each detector is as follows. This function is not effective in αi position coder.
>
> | | |
> |---|---|
> | αiBZ sensor | 360000pulse/rev |
> | αiCZ sensor | 3600000pulse/rev |
> | αi position coder | 4096pulse/rev |
>
> In spindle control with servo motor, this function is not effective as long as the resolution of detector is not small larger than 4096 pulses per one rotation.)
> Moreover, the accuracy is not assured by the above values because they are indicated as the resolution of detector. Select the detector with enough accuracy for machining accuracy.

> **NOTE**
> 3 Maximum spindle speed becomes as follows when this function is effective.
> In serial spindle or spindle control with servo motor, maximum spindle speed is 99999 min^{-1}.
> However, maximum spindle speed depends on the specification of spindle motor, spindle amplifier and detector too.
> In analog spindle, maximum spindle speed depends on the time rules of interface of position coder.
> Refer “Analog spindle connection material” (A-65618EN) about the time rules of interface of position coder.
> About the applicable pulse number of position coder and upper limit of spindle speed, the influence such as the machine vibrations is considered, calculate the number in which the margin is given for "time rules" satisfy without fail in any case.

Parameter

	#7	#6	#5	#4	#3	#2	#1	#0
3716	FBP							

> **NOTE**
> When this parameter is set, the power must be turned off before operation is continued.

[Input type] Parameter input
[Data type] Bit spindle

#7 FBP Changing the number of spindle position coder pulses is
0: Not executed.
1: Executed.

3720	Number of position coder pulses

> **NOTE**
> When this parameter is set, the power must be turned off before operation is continued.

[Input type] Parameter input
[Data type] 2-word spindle
[Unit of data] Number of pulses
[Valid data range] Serial spindle
: 0, 4096 When bit 7 (FBP) of parameter No.3716 is set to 1: 4096×2^{14}
Spindle control with servo motor
: 0, 4096 When bit 7 (FBP) of parameter No.3716 is set to 1: 4096×2^{14}
Analog spindle
: 0, 4096 When bit 7 (FBP) of parameter No.3716 is set to 1: from 0 to 400000

Set the number of position coder pulses.
In analog spindle, 4096 is set to parameter automatically if parameter No.3720 is set to 0 or less.
In serial spindle or spindle control with servo motor, the setting method is changed by setting of the bit 7 (FBP) of parameter No.3716.

- When the bit 7 (FBP) of parameter No.3716 is set to 0:
  4096 is set to parameter automatically if parameter No.3720 is set to 0 or less.
- When the bit 7 (FBP) of parameter No.3716 is set to 1:
  $4096 \times 2^{\wedge 14}$ is set to parameter automatically.

Alarm and message

Number	Message	Description
SP1255	CAN NOT CHANGE SPINDLE MODE	In the analog spindle control, rigid tapping and spindle positioning can not be used except when the number of pulses output from the position coder of the spindle is 4096pulse/rev.

10.27 RESOLUTION OF SPINDLE SPEED COMMAND

Overview

By this function, the resolution of spindle speed commands and related signals is improved, and high accuracy spindle speed command is achieved.
This function is effective on serial spindle.

Explanation

When bit 0(SSE) of parameter No.3791 is set to 1, spindle speed command resolution of serial spindle is improved.
The resolution is decided on parameters of Table 10.27 (a).

Table 10.27 (a)

Resolution	Bit 0(SSE) of parameter No.3791	Bit 4(SSI) of parameter No.3798
4096	0	0
16383	0	1
1048575	1	0
1048575	1	1

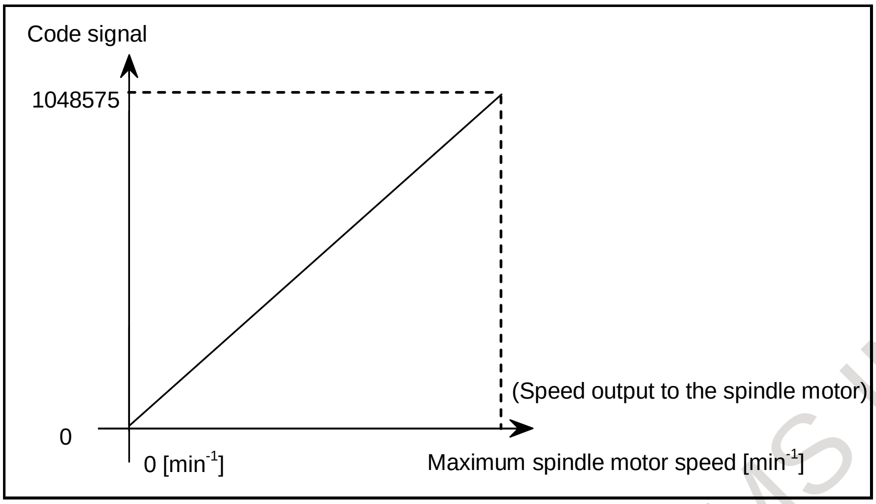
And then, the following signals become high resolution.

- Spindle speed command output

The commanded spindled speed by machining program is calculated through the gear change processing. Refer to chapter of “SPINDLE SPEED CONTROL” in Connection manual (function) (B-64693EN-1) for detail.

When bit 0(SSE) of parameter No.3791 is set to 1, the calculated speed command is outputted by the S32-bit code signals RE01O to RE32O<Fn708 to Fn711> from 0 to 1048575. Then, S12-bit code signals R01O to R12O <Fn036.0 to Fn037.3> are not effective.

$$\text{32-bit code signals output value} = \frac{\text{Spindle motor speed}[\text{min}^{-1}]}{\begin{array}{c}\text{Maximum spindle motor speed}[\text{min}^{-1}]\\ \text{(parameter No.4020)}\end{array}} \times 1048575$$



- Multi spindle control

When Multi spindle control is effective, the speed commands output signals of each spindle are depended the parameter setting in Table 10.27 (b).

Table 10.27 (b)

		Bit 0(SSE) of parameter No.3791 is set to 1
Effective output signals	1st spindle	RE01O to RE32O<Fn708 to Fn711>
	2nd spindle	RE01O2 to RE32O2<Fn712 to Fn715>
	3rd spindle	RE01O3 to RE32O3<Fn716 to Fn719>
	4th spindle	RE01O4 to RE32O4<Fn720 to Fn723>

		Bit 0(SSE) of parameter No.3791 is set to 0	
		BIT 3(MRS) of parameter No.3709 is set to 0	BIT 3(MRS) of parameter No.3709 is set to 1
Effective output signals	1st spindle	R01O to R12O <Fn036.0 to Fn037.3>	R01O to R12O<Fn036.0 to Fn037.3>
	2nd spindle		R01O2 to R12O2<Fn200.0 to Fn201.3>
	3rd spindle		R01O3 to R12O3<Fn204.0 to Fn205.3>
	4th spindle		R01O4 to R12O4<Fn270.0 to Fn271.3>

Refer to Chapter of “Multi spindle control” in “Connection manual (function)” (B-64693EN-1) for detail of spindle select.

NOTE
1. RE01Os to RE32Os are 32-bit, but effective signals are 20-bit.
2. When SSE is set to 1 for a spindle in system, even if common signals setting are set (SSE is 0 and MRS is 0), each spindle signals (R01Os to R12Os) are effective.

- SPINDLE OUTPUT CONTROL BY THE PMC

When bit 0 (SSE) of parameter No.3791 is set to 1, if spindle motor speed is specified from PMC, set signals as follow.

- Switching the controller from the CNC to the PMC, by issuing a signal used to select the spindle motor speed command SINDs
- Setting the spindle motor speed data, calculated by the PMC, in spindle control signals RE01Is toRE12Is. Then, the spindle motor speed command signals R01Is to R12Is is not effective.

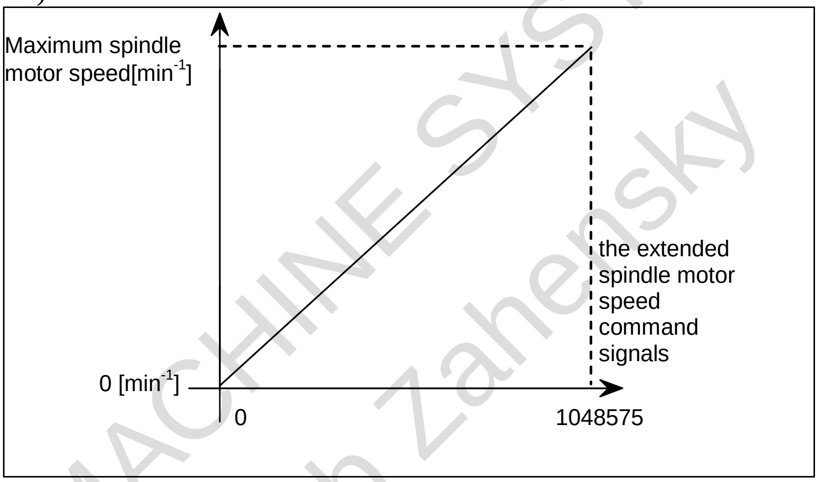
Table 10.27 (c)

		Bit 0(SSE) of parameter No.3791 is set to 0	Bit 0(SSE) of parameter No.3791 is set to 1
Effective spindle motor Speed command signals	**1st spindle**	R01I to R12I<Gn032.0 to Gn033.3>	RE01I to RE32I<Gn708 to Gn711>
	2nd spindle	R01I2 to R12I2<Gn034.0 to Gn035.3>	RE01I2 to RE32I2<Gn712 to Gn715>
	3rd spindle	R01I3 to R12I3<Gn036.0 to Gn037.3>	RE01I3 to RE32I3<Gn716 to Gn719>
	4th spindle	R01I4 to R12I4<Gn272.0 to Gn273.3>	RE01I4 to RE32I4<Gn720 to Gn723>

When bit 0(SSE) of parameter No.3791 is set to 1, a spindle motor speed is set to the data by a following calculating method.

$$\text{Setting value of the extended spindle motor speed command signals} = \frac{\text{Spindle motor speed}[\mathrm{min}^{-1}]}{\begin{array}{c}\text{Maximum spindle motor speed}[\mathrm{min}^{-1}] \\ \text{(parameter No.4020)}\end{array}} \times 1048575$$

(Spindle motor speed)



Following signal that doesn't depend on bit 0(SSE) of parameter No.3791 setting is used on same signals.

Table 10.27 (d)

1st spindle	SIND,SSIN,SGN,<Gn033.7,.6,.5>
2nd spindle	SIND2,SSIN2,SGN2,<Gn035.7,.6,.5>
3rd spindle	SIND3,SSIN3,SGN3,<Gn037.7,.6,.5>
4th spindle	SIND4,SSIN4,SGN4,<Gn273.7,.6,.5>

Refer to Chapter of "Spindle output control by the PMC" in "Connection manual (function)" (B-64693EN-1) for detail of the SINDs, SSINs and SGNs.

- For multi spindle control

When multi spindle control is effective and TYPE-A is selected (bit 2(MSI) of parameter No.3709 is set to 0), the signals for the second to forth spindles RE01I2,3,4 to RE32I2,3,4 are not effective.
Even when multi-spindle control is not effective, the signals for the second to forth spindles RE01I2,3,4 to RE32I2,3,4 can used.

NOTE

Extended spindle motor speed command signals RE01Is to RE32Is are 32-bit, but effective signals are 20-bit.

- Command output to the spindle control unit

The speed command output decided into CNC is commanded to the spindle control unit of serial spindle at digital data following the resolution of Table 10.27 (a).
When bit 0 (SSE) of No.3791 is set to 1, the resolution of digital data is 0 to ±1048575

T

- Actual spindle speed output

When bit 0 (SSE) of No.3791 is set to 1, extended actual spindle speed signals ARE00 to ARE15 <Fn580 to Fn583> can read actual spindle speed.
However, then signals AR00 to AR15<Fn040, Fn041>,AR002 to AR152< Fn202, Fn203>,AR003 to AR153< Fn206, Fn207>,AR004 to AR154< Fn272, Fn273> are not effective.

- For multi spindle control

When the multi spindle control is effective, a actual speed of each spindle is depended on parameter of Table 10.27 (e).

Table 10.27 (e)

		Bit 0(SSE) of parameter No.3791 is set to 0	Bit 0(SSE) of parameter No.3791 is set to 1
Effective Actual spindle speed Output signals	1st spindle	AR00 to AR15<Fn040, Fn041>	ARE00 to ARE31<Fn580 to Fn583>
	2nd spindle	AR002 to AR152< Fn202, Fn203>	ARE002 to ARE312<Fn584 to Fn587>
	3rd spindle	AR003 to AR153< Fn206, Fn207>	ARE003 to ARE313<Fn588 to Fn591>
	4th spindle	AR004 to AR154< Fn272, Fn273>	ARE004 to ARE314<Fn592 to Fn595>

Refer to Chapter of "Multi spindle control" in "Connection manual (function)" (B-64693EN-1) for detail of spindle select.

High-precision spindle speed control

If high-precision spindle speed control is enable (bit 3 (SDP) of parameter No.3798 is set to 1), spindle speed commands (S code commands, a command for maximum spindle speed clamping (G50), and a constant-surface speed control command (G96)) can be issued in units of 0.1 min^{-1} (for constant-surface speed control, 0.1 m/min).Actual spindle speed signals are in units of 0.1 min^{-1}.
Refer to Chapter of "High-precision spindle speed control" in "Connection manual (function)" (B-64693EN-1).

Notes

- The supported serial spindle software is required to this function.
- When signals of multi spindle relation are used, enable multi spindle control function(bit 3 (MSP) of parameter No.8133 is 1) separately.

Limitations

- Analog spindle control

This function is not effective in "Analog spindle control".

- Spindle control with servo motor

This function is not effective in "Spindle control with servo motor".

- Spindle synchronous control / Spindle command synchronous control / Polygon turning with two spindles

Set the same setting at the bit 0 (SSE) of parameter No.3791 when "Spindle synchronous control", "Spindle command synchronous control" or "Polygon turning with two spindles" is used on each spindle.

If the setting is different, the alarm SP1257,” ILLEGAL PARAMETER (No.3791#0)” occurs.

Signal

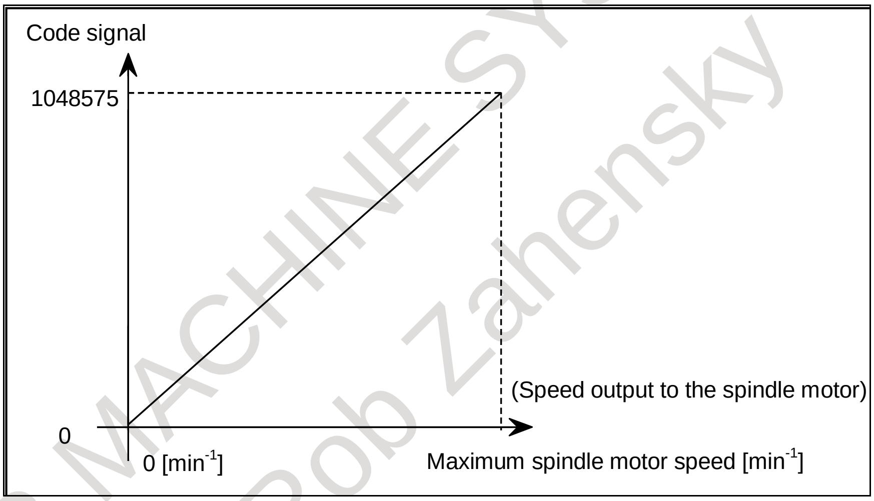
S 32-bit code signals

RE01O to RE32O<Fn708 to Fn711>: for 1st spindle
RE01O2 to RE32O2<Fn712 to Fn715>: for 2nd spindle
RE01O3 to RE32O3<Fn716 to Fn719>: for 3rd spindle
RE01O4 to RE32O4<Fn720 to Fn723>: for 4th spindle

[Classification] Output signal

[Function] When bit 0(SSE) of parameter No.3791 is set to 1, CNC is outputted the speed command output of calculated spindle motor to PMC as the S32-bit code signals RE01Os to RE32Os. Then, S12-bit code signals R01O to R12O<Fn036.0 to Fn037.3> are not effective.
When Multi spindle control is effective and bit 3 (MRS) of parameter No.3709 is set to 1, spindle motor of each spindle speed command are outputted to S32-bit code signals RE01Os to RE32Os. Then, R01Os to R12Os <Fn200.0 to Fn201.3>, <Fn204.0 to Fn205.3>, <Fn270.0 to Fn271.3> are not effective.

[Output cond.] The relationship between the spindle speed command value (calculated by the CNC) and the value output by this signal is as shown below.



> **NOTE**
> S32-bit code signals RE01Os to RE32Os are 32-bit, but effective signals are 20-bit.

Extended spindle motor speed command signals

RE01I to RE32I<Gn708 to Gn711>: for 1st spindle
RE01I2 to RE32I2<Gn712 to Gn715>: for 2nd spindle
RE01I3 to RE32I3<Gn716 to Gn719>: for 3rd spindle
RE01I4 to RE32I4<Gn720 to Gn723>: for 4th spindle

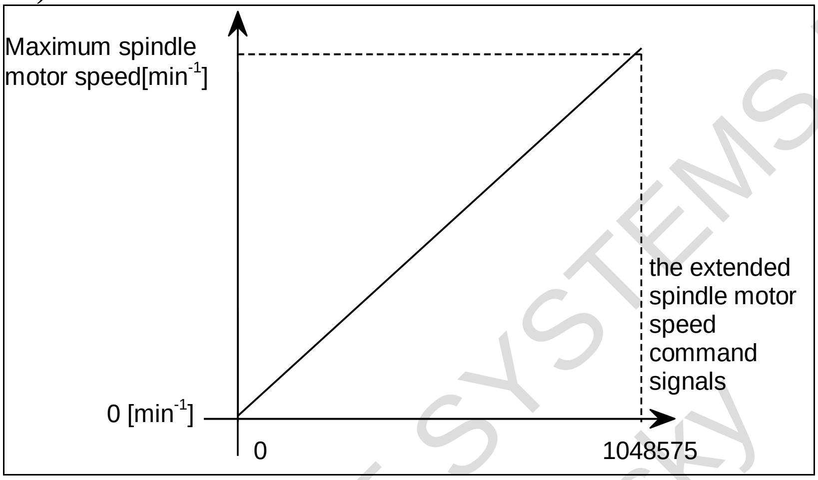
[Classification] Input signal

[Function] When bit 0(SSE) of parameter No.3791 is set to 1, the speed command is possible to the each spindle motor by RE01I to RE32Ix. Then, R01Ix to R12Ix<Gn032.0 to Gn033.3>,<Gn034.0 to Gn035.3>,<Gn036.0 to Gn037.3> , <Gn272.0 to Gn273.3> is not effective.
However, when multi spindle control is effective and TYPE-A is selected (bit 2(MSI) of parameter No.3709 is set to 0), the signals for the second to forth spindles RE01I2,3,4 to RE32I2,3,4 are not effective.

[Operation] If the PMC is being used to control the spindle motor speed command, specify, in binary format, the value obtained using the following expression.

$$\text{Value to be specified by extended spindle motor speed command signals} = \frac{\text{Spindle motor speed}[\min^{-1}]}{\text{Maximum spindle motor speed}[\min^{-1}] \text{ (parameter No.4020)}} \times 1048575$$

(Spindle motor speed)



> **NOTE**
> Extended spindle motor speed command signals RE01Is to RE32Is are 32-bit, but effective signals are 20-bit.

T

Extended actual spindle speed signals

ARE00 to ARE31<Fn580 to Fn583>: for 1st spindle
ARE002 to ARE312<Fn584 to Fn587>: for 2nd spindle
ARE003 to ARE313<Fn588 to Fn591>: for 3rd spindle
ARE004 to ARE314<Fn592 to Fn595>: for 4th spindle

[Classification] Output signal

[Function] When bit 0(SSE) of parameter No.3791 is set to 1, ARE00x to ARE31x can read the actual spindle speed obtained by feedback pulses from the position coder mounted on the spindle. Then, AR00Ox to AR15Ox <Fn202,Fn203>,<Fn206,Fn272>, <Fn202,Fn273> is not effective.
When bit 3 (SDP) of parameter No.3798 is set to 1, Extended actual spindle speed signals are in units of 0.1 $\min^{-1}$. (When bit 3 (SDP) of parameter No.3798 is 0, there are in units of 1 $\min^{-1}$)

[Output cond.] When bit 0(SSE) of parameter No.3791 is set to 1, these 32-bit binary code signals are always output. The actual spindle speed and the signals have the following relationship:

$$Spindle\quad speed = \sum_{i=0}^{31} \left\{ 2^i \times V_i \right\} \times D \min^{-1}$$

Where Vi=0 when AREi is 0
and Vi=1 when AREi is 1
and D=1 when bit 3 (SDP) of parameter No.3798 is 0
and D=0.1 when bit 3 (SDP) of parameter No.3798 is 1

Note

NOTE

When bit 0(SSE) of parameter No.3791 is set to 1, following signals are not effective.

- Spindle motor speed command signals	R01I to R12I, R01I2 to R12I2, R01I3 to R12I3, R01I4 to R12I4
- S12-bit code signals	R01O to R12O, R01O2 to R12O2, R01O3 to R12O3, R01O4 to R12O4
- Actual spindle speed signals	AR00 to AR15, AR002 to AR152, AR003 to AR153, AR004 to AR154

Parameter

	#7	#6	#5	#4	#3	#2	#1	#0
3791								SSE

[Input type] Parameter input
[Data type] Bit spindle

#0 SSE The resolution enabled for the spindle speed command:
0: depend to the bit 4(SSI) of parameter No.3798.
1: is a maximum spindle speed/1048575 [min^{-1}].

> **NOTE**
> 1 When this parameter is set, the power must be turned off before operation is continued.
> 2 When bit 0 (SSE) of parameter No.3791 is set to 1, bit 4 (SSI) of parameter No.3798 is not effective.

	#7	#6	#5	#4	#3	#2	#1	#0
3798				SSI	SDP			

[Input type] Parameter input
[Data type] Bit

> **NOTE**
> When this parameter is set, the power must be turned off before operation is continued.

#3 SDP High-precision spindle speed control is:
0: Not used.
1: Used.

#4 SSI The resolution enabled for the spindle speed command is:
0: Maximum spindle speed/4095 [min^{-1}].
1: Maximum spindle speed/16383 [min^{-1}].

	#7	#6	#5	#4	#3	#2	#1	#0
3709					MRS	MSI		

[Input type] Parameter input
[Data type] Bit path

#2 MSI In multi-spindle control, the Spindle motor speed command selection signal SINDs signal is valid
0: Only when the first spindle is valid (Spindle motor speed command selection signal SINDs for the 2nd, 3rd spindle becomes ineffective) (TYPE-A)
1: For each spindle irrespective of whether the spindle is selected (Each spindle has its own Spindle motor speed command selection signal SINDs). (TYPE-B)

#3 MRS When the actual spindle speed signals and S 12-bit code signals are output in multi-spindle control:
0: The signals common to the first spindle and second spindle are used, and the signals for the spindle selected by the spindle selection signal are output.
1: The signals for the first spindle and the signals for the second spindle are output separately.

Alarm and message

Number	Message	Description

SP1257	ILLEGAL PARAMETER (No.3791#0)	Bit 0(SSE) of parameter No.3791 is illegal setting.
		Causes of the alarm are as follows.
		- The setting of bit 0 (SSE) of parameter No.3791 is different because of the master and slave. Please change the following function to the same setting.
		  - Spindle synchronous control
		  - Spindle command synchronous control
		  - Polygon turning with two spindles
		- The bit 0 (SSE) of parameter No.3791 is set to 1 the spindle control software that does not support this function. Please set 0 to bit 0 (SSE) of parameter No.3791.

Diagnosis data

- When bit 0 (SSE) of No.3791 is set to 1, the spindle motor speed is displayed to the diagnosis data No.1547. And then, the diagnosis No.411 is displayed 0.

1547	Spindle motor speed data (2 word)

[Data type] 2 word spindle
[Unit] min^{-1}

- When this function is effective, bit 0 of diagnosis data No.1570 is set to 1.

	#7	#6	#5	#4	#3	#2	#1	#0
1570								S2W

S2W A spindle speed command is the resolution of maximum spindle speed/1048575 [min^{-1}].

10.28 SPINDLE CONTROL MODE CHANGING BY PROGRAM COMMAND

Overview

Spindle control mode can be changed by commanding M code which is set to parameter. The following spindle control modes can be changed.

- Spindle orientation
- Cs contour control

Programming PMC ladder for changing the spindle mode is unnecessary.

Explanation

- Spindle orientation

Set M code for spindle orientation ON to parameter No.25800, and set M code for spindle orientation OFF to parameter No.25801. If spindle orientation by program command is not available, set 0 to parameters No.25800, and No.25801 of the spindle.
If spindle selection by address P of Multi-spindle control is enabled (bit 3 (MPP) of parameter No.3703 is 1), spindle executing spindle orientation can be selected by address P. Spindles executing spindle orientation by program command use the same M code for spindle orientation ON, and the same M code

for spindle orientation OFF. Set the same M code to parameter of spindle executing spindle orientation (refer to Example (2)).

When M code for spindle orientation ON or M code for spindle orientation OFF is commanded, auxiliary function code signals M00 to M31<Fn010 to Fn013> and auxiliary function strobe signal MF<Fn007.0> are not output.

DI signals for spindle orientation are available even if M code for spindle orientation ON and M code for spindle orientation OFF are available. However, DI signals are not available from commanding M code for spindle orientation ON to canceling spindle orientation. If M code for spindle orientation ON or M code for spindle orientation OFF is commanded when spindle orientation command signal ORCMA<Gn070.6> (first spindle), ORCMB<Gn074.6> (second spindle), ORCMC<Gn204.6> (third spindle), ORCMD<Gn266.6> (fourth spindle) is "1", alarm PS0553, "SP-MODE CHANGE IMPOSSIBLE" is issued.

There are two methods for specifying stop position of spindle orientation.

- Orientation with the fixed stop position (bit 0 (ORT) of parameter No.3729 is 0)
  Stop position of spindle orientation can be set to parameters No.4031 (MAIN spindle) and No.4204 (SUB spindle).
- Orientation with the stop position set externally (bit 0 (ORT) of parameter No.3729 is 1)
  Stop position of spindle orientation can be commanded by address R. Increment system of address R is that of reference axis (parameter No.1031). Least input increment for stop position of spindle orientation is 360°/4096=0.088° when bit 0 (ORPUNT) of parameter No.4542 is 0 or 360°/32768=0.011° when ORPUNT is 1. If address R is not commanded, stop position of spindle orientation is 0°. If M code for spindle orientation ON is commanded again after commanding M code for spindle orientation ON, spindle is moved to the stop position newly commanded. Spindle took a shortcut and move angle is within ±180° at this time.

Format

M_ (P_) (R_) ; Spindle orientation ON

M : M code for spindle orientation ON (parameter No.25800)
P : Spindle selection of Multi-spindle control
R : Stop position of spindle orientation (when bit 0 (ORT) of parameter No.3729 is 1)

M_ (P_) ; Spindle orientation OFF

M : M code for spindle orientation OFF (parameter No.25801)
P : Spindle selection of Multi-spindle control

Example (1) Spindle orientation of first spindle and second spindle by program command

Table 10.28 (a) Example of parameter setting

	Parameter		
	No.25800	**No.25801**	**No.3729#0**
First spindle	19	18	1
Second spindle	119	118	1
Third spindle	0	0	0

:	
:	
:	

If M code for spindle orientation ON is commanded, spindle speed command is set to 0 in order not to rotate the spindle when spindle orientation is canceled. Therefore, S code has to be newly commanded for rotating the spindle after spindle orientation OFF. In Multi-spindle control, if spindle selection method by spindle selection signals SWS1 to SWS4 <Gn027.0, Gn027.1, Gn027.2>, <Gn026.3> is used, select spindle by spindle selection signals before commanding S code. If S code has not been commanded in the path from which M code for spindle orientation ON is commanded and only M03/M04 is commanded, alarm PS0554, "S-CODE IS NOT COMMANDED" is issued in order not to start machining without spindle rotation. If only M code except for M03/M04 is commanded, alarm PS0554 is not issued. If M code except for M03/M04 is used for spindle rotation, be sure to command S code in order not to start machining without spindle rotation.

Example (3) example of alarm PS0554 by only M03/M04 command

Example of machining program

O1003 ;	
:	
N10 M03 S100 P1 ;	First spindle rotates at a speed of 100[min^{-1}].
:	
N20 M19 P1 ;	Spindle orientation of first spindle is executed.
:	
N30 M18 P1 ;	Spindle orientation of first spindle is canceled. First spindle does not rotate until S code is newly commanded.
:	
:	
:	
N40 M03 ;	Alarm PS0554, "S-CODE IS NOT COMMANDED" is issued because S code has not been commanded.
:	
:	
:	

NOTE

1 G code using address P, address Q, or address R and M code for spindle orientation ON or M code for spindle orientation OFF cannot be commanded in the same block. When spindle selection by address P is available, if machine coordinate system select command (G53) is commanded, alarm PS0552, "SP-MODE CHANGE COMMAND ERROR" is issued.
When spindle selection by address P is available and the addition of workpiece coordinate system 48 pairs or 300 pairs is available, if selecting a workpiece coordinate system (G54) is commanded, alarm PS0552, “SP-MODE CHANGE COMMAND ERROR” is issued.

2 Spindle orientation by program command is not canceled by emergency stop, reset. However, if emergency stop or reset is executed during M code for spindle orientation ON, spindle orientation is canceled.

3 S code has to be newly commanded for rotating the spindle after canceling spindle orientation by program command. If S code has not been commanded in the path from which M code for spindle orientation ON is commanded and only M03/M04 is commanded, alarm PS0554, "S-CODE IS NOT COMMANDED" is issued. If only M code except for M03/M04 is commanded, alarm PS0554 is not issued. Be sure to command S code if M code except for M03/M04 is used for spindle rotation in order not to start machining without spindle rotation.

4 Multiple M commands in a single block cannot be used. Don’t command other M codes with M code for spindle orientation ON or M code for spindle orientation OFF in the same block.

5 Spindle orientation by program command cannot be used if spindle orientation by a magnetic sensor is used.

6 Enabling spindle serial output (bit 5 (SSN) of parameter No.8133 is 0) and spindle orientation (bit 4 (NOR) of parameter No.8135 is 0) is required in order to use this function.

- Cs contour control

Set M code for Cs contour control ON to parameter No.25802, and set M code for Cs contour control OFF to parameter No.25803. If Cs contour control by program command is not available, set 0 to parameters No.25802 and No.25803 of the spindle.
If spindle selection by address P of Multi-spindle control is enabled (bit 3 (MPP) of parameter No.3703 is 1), spindle changing Cs contour control mode can be selected by address P. Spindles changing Cs contour control mode by program command use the same M code for Cs contour control ON, and the same M code for Cs contour control OFF. Set the same M code to parameter of spindle changing Cs contour control mode (refer to Example (5)).

When M code for Cs contour control ON or M code for Cs contour control OFF is commanded, auxiliary function code signals M00 to M31<Fn010 to Fn013> and auxiliary function strobe signal MF<Fn007.0> are not output.

Cs contour control axis coordinate establishment is available when bit 2 (CSF) of parameter No.3712 is 1 and bit 5 (CSPTRE) of parameter No.4353 is 1. If "Q1" is commanded with M code for Cs contour control ON in the same block, coordinate of Cs contour control axis is established after changing Cs contour control.

Cs contour control change signal CON<Gn027.7>, Cs contour control change signals in each axis CONS1 to CONS4<Gn274.0 to Gn274.3>, or Cs axis coordinate establishment request signals CSFI1 to CSFI4<Gn274.4 to Gn274.7> are available even if M code for Cs contour control ON or M code for Cs contour control OFF are available. However, DI signals are not available from commanding M code for Cs contour control ON to canceling Cs contour control. If M code for Cs contour control ON or M code for Cs contour control OFF is commanded when Cs contour control change signal or Cs contour control change signal in each axis is "1", alarm PS0553, "SP-MODE CHANGE IMPOSSIBLE" is issued.

Format

M_ (P_) (Q1) ; Cs contour control ON

M : M code for Cs contour control ON (parameter No.25802)
P : Spindle selection of Multi-spindle control
Q1 : Cs contour control axis coordinate establishment

M_ (P_) ; Cs contour control OFF

M : M code for Cs contour control OFF (parameter No.25803)
P : Spindle selection of Multi-spindle control

Example (4) Cs contour control of first spindle and second spindle by program command

Table 10.28 (c) Example of parameter setting

	Parameter			
	No.25802	No.25803	No.4353#5	No.3712#2

   :
```

If M code for Cs contour control ON is commanded, spindle speed command is set to 0 in order not to rotate the spindle when Cs contour control is canceled. Therefore, S code has to be newly commanded for rotating the spindle after Cs contour control OFF. In Multi-spindle control, if spindle selection method by spindle selection signals SWS1 to SWS4 <Gn027.0, Gn027.1, Gn027.2>, <Gn026.3> is used, select spindle by spindle selection signals before commanding S code. If S code has not been commanded in the path from which M code for Cs contour control ON is commanded and only M03/M04 is commanded, alarm PS0554, "S-CODE IS NOT COMMANDED" is issued in order not to start machining without spindle rotation. If only M code except for M03/M04 is commanded, alarm PS0554 is not issued. If M code except for M03/M04 is used for spindle rotation, be sure to command S code in order not to start machining without spindle rotation.

Example (6) example of alarm PS0554 by only M03/M04 command

Example of machining program

Program	Description
O1006 ;	
:	
N10 M05 ;	First spindle stops.
:	
N20 M50 P1 ;	First spindle changes to Cs contour control.
:	
N30 M51 P1 ;	First spindle changes to spindle rotation control.
:	
N40 M03 ;	Alarm PS0554, "S-CODE IS NOT COMMANDED" is issued because S code has not been commanded.
:	
:	
:	

If M code for spindle orientation ON is commanded after Cs contour control ON by program command, Cs contour control is canceled, and spindle orientation is executed.

Example (7)
M code command for spindle orientation ON after Cs contour control ON by program command

Example of machining program

Program	Description
O1007 ;	
:	
N10 M50 P1 ;	First spindle changes to Cs contour control.
:	
N20 M19 R270.0 P1 ;	First spindle changes to spindle rotation control, then executes spindle orientation. Stop position of the spindle is 270°.
:	
:	
:	

Similarly, if M code for Cs contour control ON is commanded during spindle orientation ON by program command, spindle orientation is canceled, and the spindle changes to Cs contour control.

Example (8)
M code command for Cs contour control ON during spindle orientation ON by program command

Example of machining program

Program	Description
O1008 ;	
:	
N10 M19 P1 ;	Spindle orientation of first spindle is executed. Stop position of the spindle is 0°.
:	
:	
N20 M50 P1 ;	First spindle cancels spindle orientation, then changes Cs contour control.
:	
:	
:	

NOTE

1 G code using address P, address Q, or address R and M code for Cs contour control ON or M code for Cs contour control OFF cannot be commanded in the same block. When spindle selection by address P is available, if machine coordinate system select command (G53) is commanded, alarm PS0552, "SP-MODE CHANGE COMMAND ERROR" is issued.
When spindle selection by address P is available and the addition of workpiece coordinate system 48 pairs or 300 pairs is available, if selecting a workpiece coordinate system (G54) is commanded, alarm PS0552, "SP-MODE CHANGE COMMAND ERROR" is issued.

2 Cs contour control by program command is not canceled by emergency stop, reset. However, if emergency stop or reset is executed during M code for Cs contour control ON, Cs contour control is canceled.

3 In changing Cs contour control, if CW command signals SFR or CCW command signals SRV has to be changed by PMC ladder, Cs contour control change completion signal FSCSL<Fn044.1> or Cs contour control change completion signal in each axis FCSS1 to FCSS4<Fn274.0 to Fn274.4> is available (bit 3 (NCS) of parameter No.3729 has to be set to 1 (switching to Cs contour control is completed even when the spindle activating current is off)).

4 S code has to be newly commanded for rotating the spindle after canceling Cs contour control by program command. If S code has not been commanded in the path from which M code for Cs contour control ON is commanded and only M03/M04 is commanded, alarm PS0554, "S-CODE IS NOT COMMANDED" is issued. If only M code except for M03/M04 is commanded, alarm PS0554 is not issued. Be sure to command S code if M code except for M03/M04 is used for spindle rotation in order not to start machining without spindle rotation.

5 Multiple M commands in a single block cannot be used. Don't command other M codes with M code for Cs contour control ON or M code for Cs contour control OFF in the same block.

6 Enabling spindle serial output (bit 5 (SSN) of parameter No.8133 is 0) and Cs contour control (bit 2 (SCS) of parameter No.8133 is 1) is required in order to use this function.

- Spindle control mode OFF

Spindle orientation by program command or Cs contour control by program command can be canceled by M codes which are set to parameter No.25804, No.25805, and No.25806. The spindle whose parameters (No.25804, No.25805, and No.25806) are set to 0 cannot use M codes for spindle control mode OFF.

If spindle selection by address P of Multi-spindle control is enabled (bit 3 (MPP) of parameter No.3703 is 1), spindle canceling spindle control mode can be selected by address P. Spindles canceling spindle control mode by program command use the same M code for spindle control mode OFF. Set the same M code to parameter of spindle canceling spindle control mode (refer to Example (10)).

When M code for spindle control mode OFF (parameter No.25804, No.25805, and No.25806) is commanded, auxiliary function code signals M00 to M31<Fn010 to Fn013> and auxiliary function strobe signal MF<Fn007.0> are output.

Format

M_ (P_) ;   Spindle control mode OFF

M : M code for spindle control mode OFF (parameter No.25804, No.25805, and No.25806)

P : Spindle selection of Multi-spindle control

Example (9) Spindle rotation after spindle control mode OFF

:	
:	
N40 M04 S200 P2 ;	Second spindle changes to spindle rotation control. Second spindle rotates at a speed of 200[min^{-1}].
:	
:	
:	

NOTE

1 G code using address P, address Q, or address R and M code for spindle control mode OFF cannot be commanded in the same block. When spindle selection by address P is available, if machine coordinate system select command (G53) is commanded, alarm PS0552, "SP-MODE CHANGE COMMAND ERROR" is issued.
When spindle selection by address P is available and the addition of workpiece coordinate system 48 pairs or 300 pairs is available, if selecting a workpiece coordinate system (G54) is commanded, alarm PS0552, "SP-MODE CHANGE COMMAND ERROR" is issued.

2 S code has to be newly commanded for rotating the spindle after canceling spindle control mode by M code. If S code has not been commanded and only M03/M04 is commanded, alarm PS0554, "S-CODE IS NOT COMMANDED" is issued. If only M code except for M03/M04 is commanded, alarm PS0554 is not issued. Be sure to command S code if M code except for M03/M04 is used for spindle rotation in order not to start machining without spindle rotation.

3 If M03/M04 is set as M code for spindle control mode OFF, S code has to be command with M03/M04 in the same block. If S code is not commanded, alarm PS0554 is issued.

4 If Multiple M commands in a single block is used, command M code for spindle control mode OFF as the first M code.

- Spindle control mode OFF by signal

Spindle orientation by program command or Cs contour control by program command can be canceled by spindle control mode off signals MDOFF1 to MDOFF4<Gn586.4 to Gn586.7>. If you want to cancel spindle orientation or Cs contour control by emergency stop, reset, and so on, spindle control mode can be canceled by spindle control mode off signals MDOFF1 to MDOFF4<Gn586.4 to Gn586.7>. If spindle control mode off signal MDOFF1 to MDOFF4<Gn586.4 to Gn586.7> is set to "1", spindle control mode is canceled. If spindle orientation is canceled, spindle orientation completion signal ORARA to ORARD<Fn045.7, Fn049.7, Fn168.7, Fn266.7> is set to "0". Then, set "0" to spindle control mode off signals MDOFF1 to MDOFF4<Gn586.4 to Gn586.7>. If Cs contour control is canceled, Cs contour control change completion signal FSCSL<Fn044.1> or Cs contour control change completion signal in each axis FCSS1 to FCSS4<Fn274.0 to Fn274.3> is set to "0". Then, set "0" to spindle control mode off signals MDOFF1 to MDOFF4<Gn586.4 to Gn586.7>.

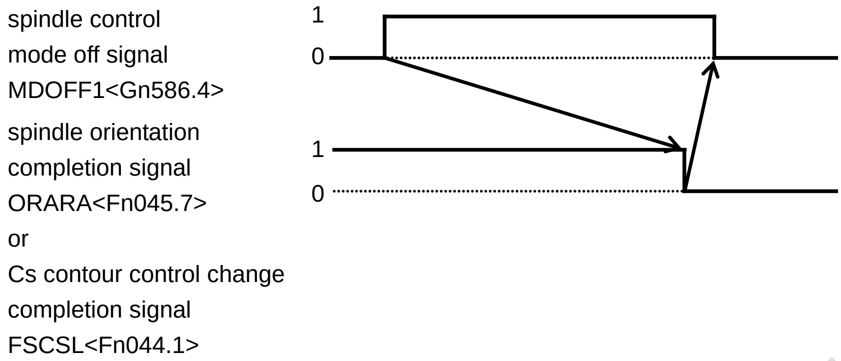

Fig. 10.28 (a) Spindle control mode OFF by signal

Spindle orientation by orientation command signal ORCMA to ORCMD<Gn070.6, Gn074.6, Gn204.6, Gn266.6> cannot be canceled by spindle mode off signals MDOFF1 to MDOFF4<Gn586.4 to Gn586.7>. Similarly, Cs contour control by Cs contour control change signal CON<Gn027.7> or Cs contour control change signals in each axis CONS1 to CONS4<Gn274.0 to Gn274.3> cannot be canceled by spindle mode off signals MDOFF1 to MDOFF4<Gn586.4 to Gn586.7>.
When spindle control mode off signal MDOFF1 to MDOFF4<Gn586.4 to Gn586.7> is "1", if M code for spindle orientation ON set to parameter No.25800 or M code for Cs contour control ON set to parameter No.25802 is commanded, alarm PS0553, "SP-MODE CHANGE IMPOSSIBLE" is issued.

- Multi-spindle address P signals

If bit 0 (ADP) of parameter No.25807 is set to 1, the value of address P which is commanded to select mode changing spindle is output to multi-spindle address P signals MSP00 to MSP15<Fn160.0 to Fn161.7>.

Limitation

- Command with a signal

M code for spindle control mode changing is not output to MDI program by auxiliary function output in program restart function.

- Auxiliary function output in moving axis

If M code for spindle control mode changing is commanded in G50.9 block, alarm PS5330 "G50.9 FORMAT ERROR" is issued.

- Hypothetical Cs axis

Spindle control mode changing by program command is not available for hypothetical Cs axis. Set 0 to parameters Nos.25800 to 25806.

- Spindle control with servo motor

Spindle control mode changing by program command is not available for spindle controlled with servo motor. Set 0 to parameter Nos.25800 to 25806.

M

- Canned cycle for drilling

In Fine boring cycle (G76) and Back boring cycle (G87), M19 is output in order to execute spindle orientation during canned cycle. If M19 is set as M code for spindle orientation by program command, M19 in Fine boring cycle (G76) and Back boring cycle (G87) does not execute spindle orientation by program command, auxiliary function code signals M00 to M31<Fn010 to Fn013> and auxiliary function strobe signal MF<Fn007.0> are output. Spindle orientation M19 in Fine boring cycle (G76) and Back boring cycle (G87) has to execute by PMC ladder.

Signal

Spindle control mode off signals MDOFF1 to MDOFF4 <Gn586.4 to Gn586.7>

[Classification] Input signal

[Function] In spindle control mode changing by program command, spindle orientation by program command or Cs contour control by program command is canceled.

[Operation] If spindle control mode off signal MDOFF1 to MDOFF4<Gn586.4 to Gn586.7> is set to "1", spindle orientation by program command or Cs contour control by program command is canceled. If spindle orientation completion signal ORARA to ORARD<Fn045.7, Fn049.7, Fn168.7, Fn266.7>, or Cs contour control change completion signal FSCSL<Fn044.1> (Cs contour control change completion signal in each axis FCSS1 to FCSS4<Fn274.0 to Fn274.3>) is set to "0", set "0" to spindle control mode off signals MDOFF1 to MDOFF4<Gn586.4 to Gn586.7>.

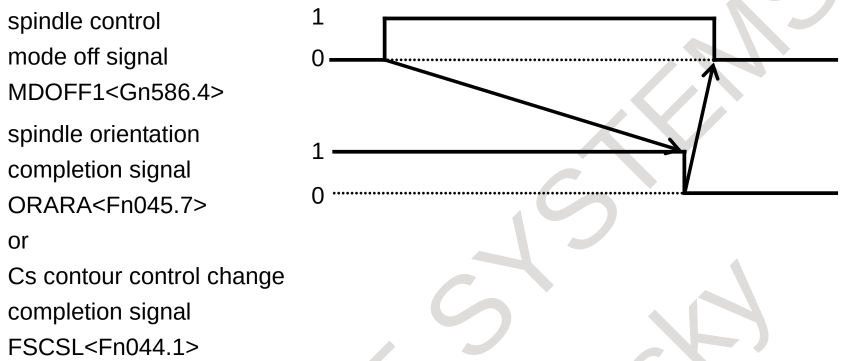

Fig. 10.28 (b) Spindle control mode OFF by signal

Multi-spindle address P signals MSP00 to MSP15 <Fn160.0 to Fn161.7>

[Classification] Output signal

[Function] The P value specified last by the S_P_; command is output.
When extended spindle names are used, the value in parameter No. 3781 corresponding to the spindle number of the spindle name specified last is output.

[Output cond.] When multi-spindle control by using address P is enabled (bit 3 (MPP) of parameter No. 3703 is 1), the P value specified in the S_P_; command is output. When no S_P_; command has been specified even once since power-up, the initial P value set in parameter No. 3775 is output.
When extended spindle names are used, the value in parameter No. 3781 corresponding to the spindle number of the spindle name specified last is output. When no spindle name has been specified even once, the value set in parameter No. 3775 is output.

Parameter

25800	M code for spindle orientation ON

> **NOTE**
> 1 When this parameter is set, the power must be turned off before operation is continued.
> 2 Don’t set M code used for any other function.
> 3 The M code set in this parameter prevents buffering.
> 4 Auxiliary function code signals M00 to M31<Fn010 to Fn013> and auxiliary function strobe signal MF<Fn007.0> are not output.
> 5 If this parameter is set to 0, the spindle cannot use spindle orientation by program command.

[Input type] Parameter input
[Data type] 2-word spindle
[Valid data range] 0 to 99999999

Set M code for spindle orientation ON.

25801	M code for spindle orientation OFF

> **NOTE**
> 1 When this parameter is set, the power must be turned off before operation is continued.
> 2 Don’t set M code used for any other function.
> 3 Auxiliary function code signals M00 to M31<Fn010 to Fn013> and auxiliary function strobe signal MF<Fn007.0> are not output.
> 4 If this parameter is set to 0, the spindle cannot use spindle orientation by program command.

[Input type] Parameter input
[Data type] 2-word spindle
[Valid data range] 0 to 99999999

Set M code for spindle orientation OFF.

25802	M code for Cs contour control ON

> **NOTE**
> 1 When this parameter is set, the power must be turned off before operation is continued.
> 2 Don’t set M code used for any other function.
> 3 The M code set in this parameter prevents buffering.
> 4 Auxiliary function code signals M00 to M31<Fn010 to Fn013> and auxiliary function strobe signal MF<Fn007.0> are not output.
> 5 If this parameter is set to 0, the spindle cannot use Cs contour control by program command.

[Input type] Parameter input
[Data type] 2-word spindle
[Valid data range] 0 to 99999999

Set M code for Cs contour control ON.

25803	M code for Cs contour control OFF

NOTE
1 When this parameter is set, the power must be turned off before operation is continued.
2 Don't set M code used for any other function.
3 Auxiliary function code signals M00 to M31<Fn010 to Fn013> and auxiliary function strobe signal MF<Fn007.0> are not output.
4 If this parameter is set to 0, the spindle cannot use Cs contour control by program command.

[Input type] Parameter input
[Data type] 2-word spindle
[Valid data range] 0 to 99999999
Set M code for Cs contour control OFF.

25804	M code for spindle control mode OFF 1
25805	M code for spindle control mode OFF 2
25806	M code for spindle control mode OFF 3

NOTE
1 When this parameter is set, the power must be turned off before operation is continued.
2 Don't set M code used for any other function.
3 If this parameter is set to 0, the spindle cannot use M code for spindle control mode OFF.

[Input type] Parameter input
[Data type] 2-word spindle
[Valid data range] 0 to 99999999
Set M code for spindle control mode OFF.

	#7	#6	#5	#4	#3	#2	#1	#0
25807								ADP

[Input type] Parameter input
[Data type] Bit

NOTE
When this parameter is set, the power must be turned off before operation is continued.

#0 ADP In Spindle control mode changing by program command, when spindle selection by address P of Multi-spindle control is enabled, multi-spindle address P signals MSP00 to MSP15<Fn160.0 to Fn161.7> (the value is address P commanded with M code for spindle control mode changing) is:
0: Not output.
1: Output.

	#7	#6	#5	#4	#3	#2	#1	#0
3703					MPP			

[Input type] Parameter input
[Data type] Bit

> **NOTE**
> When this parameter is set, the power must be turned off before operation is continued.

#3 MPP In multi-spindle control, a spindle selection using a programmed command instead of using the signals (SWS1 to SWS4<Gn027.0 to Gn027.2, Gn026.3>) is:
0: Not made.
1: Made.

> **NOTE**
> When this parameter is set to 1, set parameter No.3781 at the same time.

	#7	#6	#5	#4	#3	#2	#1	#0
3712						CSF		

[Input type] Parameter input
[Data type] Bit

#2 CSF In the Cs contour control mode, the function for setting machine coordinates and absolute coordinates based on the machine position of the spindle if the origin is already set up is:
0: Disabled.
1: Enabled.

	#7	#6	#5	#4	#3	#2	#1	#0
3729					NCSs			ORTs

[Input type] Parameter input
[Data type] Bit spindle

#0 ORTs When a serial spindle is used, the spindle orientation function of stop position external setting type based on the position coder is:
0: Not performed.
1: Performed.

> **NOTE**
> When bit 0 (ORPUNT) of No.4542 is set to 1, if bit 0 (ORTs) of parameter No.3729 is changed, the power must be turned off before operation is continued.

#3 NCSs When the Cs contour control mode is set:
0: Switching to Cs contour control is completed when the spindle activating current is on (the spindle amplifier is ready for operation in the Cs contour control mode).
1: Switching to Cs contour control is completed even when the spindle activating current is off (the spindle amplifier is not ready for operation in the Cs contour control mode).

If this parameter is set to 1, the Cs contour control switch end signal is output without waiting for the spindle to decelerate to a stop.

3781	P code for selecting the spindle in multi-spindle control

[Input type] Parameter input
[Data type] Word spindle
[Valid data range] 0 to 32767

If bit 3 (MPP) of parameter No. 3703 is set to 1, set the P code to select each spindle under multi-spindle control. Specify the P code in a block containing the S command.

[Example] If the P code value for selecting the second spindle is set to 2,
S1000 P2;
Causes the second spindle to rotate at S1000.

NOTE

1. This parameter is valid if bit 3 (MPP) of parameter No. 3703 is set to 1.
2. If this parameter is set to 0, the corresponding spindle cannot be selected by a P code.
3. Under multi-path control, the P code specified here is valid for each path.
   For instance, if the P code to select the first spindle of path 2 is set to 21, specifying S1000 P21; in path 1 causes the first spindle of path 2 to be rotated at S1000.
4. Identical P code values cannot be used for different spindles. (Identical P code values cannot be used even if the paths are different.)
5. When this parameter is used (when bit 3 (MPP) of parameter No. 3703 is set to 1), the spindle command selection signal is invalid.
6. To use this parameter, enabling the multi-spindle control (bit 3 (MSP) of parameter No.8133 is 1) is needed.

4031	Stop position in orientation by a position coder (MAIN spindle)

4204	Stop position in orientation by a position coder (SUB spindle)

[Input type] Parameter input
[Data type] Word spindle
[Unit of data] Detection unit
[Valid data range] Depend on the bit 0 (ORPUNT) of No.4542 setting (Refer to the table below)

Bit 0 (ORPUNT) of No.4542	Least input increment	Valid data range
0	360/4096= 0.08789	0 to 4095
1	360/32768= 0.01098	0 to 32767

Each of these parameters specifies a stop position in orientation by a position coder.
These parameters are valid when bit 0 (ORT) of parameter No.3729 is set to 0.

4075	Orientation completion signal detection level (limits of in-position)（MAIN spindle）

4226	Orientation completion signal detection level (limits of in-position)（SUB spindle）

[Input type] Parameter input

[Data type] Word spindle
[Unit of data] Detection unit
[Valid data range] Depend on the bit 0 (ORPUNT) of No.4542 setting (Refer to the table below)

Bit 0 (ORPUNT) of No.4542	Least input increment	Valid data range
0	360/4096= 0.08789	0 to 100
1	360/32768= 0.01098	0 to 1000

This data is used to set the detecting level of orientation completion signal (ORARA). ORARA is assumed to be 1 if the position error is within the setting.

4077	Stop position shift amount in orientation by a position coder(MAIN spindle)

4228	Stop position shift amount in orientation by a position coder(SUB spindle)

[Input type] Parameter input
[Data type] Word spindle
[Unit of data] Detection unit
[Valid data range] Depend on the bit 0 (ORPUNT) of No.4542 setting (Refer to the table below)

Bit 0 (ORPUNT) of No.4542	Least input increment	Valid data range
0	360/4096= 0.08789	-4095 to 4095
1	360/32768= 0.01098	-32767 to 32767

Each of these parameters specifies a stop position shift amount in orientation by a position coder.
This parameter is valid no matter what the setting of bit 0 (ORT) of parameter No.3729 is.

	#7	#6	#5	#4	#3	#2	#1	#0
4353			CSPTRE					

[Input type] Parameter input
[Data type] Bit spindle

#5 CSPTRE Specifies whether to enable Cs axis positional data transfer, as follows:
0: Disable.
1: Enable.

To use this function, reset bit 7 (RFCHK3) of parameter No. 4016 to 0.

	#7	#6	#5	#4	#3	#2	#1	#0
4542								ORPUNT

[Input type] Parameter input
[Data type] Bit spindle

#0 ORPUNT Least input increment for Stop position of spindle orientation, Stop position shift amount, In-position width
0: 360/4096 = 0.08789 [deg]
1: 360/32768 = 0.01098 [deg]

⚠ **CAUTION**

In the αi position coder, the effect is not achieved by the fine resolution application of stop position because the sensor resolution is 4096p/rev.

NOTE

To use this function, the corresponding serial spindle software is required.

Alarm and message

Number	Message	Description
PS0552	SP-MODE CHANGE COMMAND ERROR	Spindle control mode changing command is illegal. Causes of the alarm are as follows. - Spindle control mode changing is commanded for disabling spindle. - Multiple M commands are commanded in spindle orientation ON/OFF command or Cs contour control ON/OFF command. - Illegal G code (G53, G54) is commanded at spindle control mode changing block.
PS0553	SP-MODE CHANGE IMPOSSIBLE	Spindle control mode changing command cannot execute. Causes of the alarm are as follows. - Spindle control mode changing by program command is commanded during spindle orientation or Cs contour control by DI signal. - During spindle control mode changing, spindle control mode changing is commanded from the other path. - Spindle control mode changing is commanded when spindle control mode off signal MDOFF1 to MDOFF4<Gn586.4 to Gn586.7> is "1".
PS0554	S-CODE IS NOT COMMANDED	M03/M04 is commanded alone without S code.
PW0053	SP-MODE CHANGE SETTING ERROR	The setting of parameters Nos.25800 to 25806 is illegal. Causes of the alarm are as follows. - The setting value is out of range. - The same value is set when spindle selection by address P is not used. - The same value is not set to all spindles when spindle selection by address P is used. - The value except for 0 is set when spindle orientation or Cs contour control is not enabled (bit 4 (NOR) of parameter No.8135 is 1 or bit 2 (SCS) of parameter No.8133 is 0). - One of M code of spindle orientation ON/OFF is set. - One of M code of Cs contour control ON/OFF is set.

11 TOOL FUNCTIONS

11.1 TOOL FUNCTIONS OF LATHE SYSTEM

T

Overview

When address T followed by a numeric value is specified, the code signal and strobe signal are sent to the machine and are used to select a tool on the machine side. Just one T code can be specified in a block.

When a move command and T code are specified within the same block, these commands are executed in one of the following two ways:

(1) The move command and tool function command are started at the same time.

(2) After the move command ends, the tool function command is started.

Explanation

A numeric value following the T code specifies selection of a tool. Part of the numeric value is also used as a tool offset number for specifying an offset value such as a tool offset value. Tools are selected according to the specification method and parameter setting as Table 11.1 (a):

Table 11.1 (a)

Meaning of T code (Note 1) Bit 1 (LGN) of parameter No. 5002 =0	Meaning of T code (Note 1) Bit 1 (LGN) of parameter No. 5002 =1	Parameter setting and offset No. specification method (Note 2)
T XXXXXXX X ↑ ↑ Tool selection / Tool geometry/ tool wear offset	T XXXXXXX X ↑ ↑ Tool selection / Tool wear offset Tool geometry offset	Tool wear offset No. is specified by lowest 1 digit of T code. When parameter No. 5028 is set to 1
T XXXXXX XX ↑ ↑ Tool selection / Tool geometry/ tool wear offset	T XXXXXX XX ↑ ↑ Tool selection / Tool wear offset Tool geometry offset	Tool wear offset No. is specified by lowest 2 digits of T code. When parameter No. 5028 is set to 2
T XXXXX XXX ↑ ↑ Tool selection / Tool geometry/ tool wear offset	T XXXXX XXX ↑ ↑ Tool selection / Tool wear offset Tool geometry offset	Tool wear offset No. is specified by lowest 3 digits of T code When parameter No. 5028 is set to 3

NOTE

1 The maximum number of digits of the T code can be specified in parameter No. 3032. (1 to 8 digits)

2 If 0 is set in parameter No. 5028, the length of the offset number specified in the T code depends on the number of tool offsets.

Example: When the number of tool offsets ranges from 1 to 9: Lowest 1 digit
When the number of tool offsets ranges from 10 to 99: Lowest 2 digits
When the number of tool offsets ranges from 100 to 999: Lowest 3 digits

11.1.1 Tool Offset

T

Overview

Tool offset is used to compensate for the difference when the tool actually used differs from the imagined tool used in programming (usually, standard tool).Tool nose moves on the programmed path by this compensation.

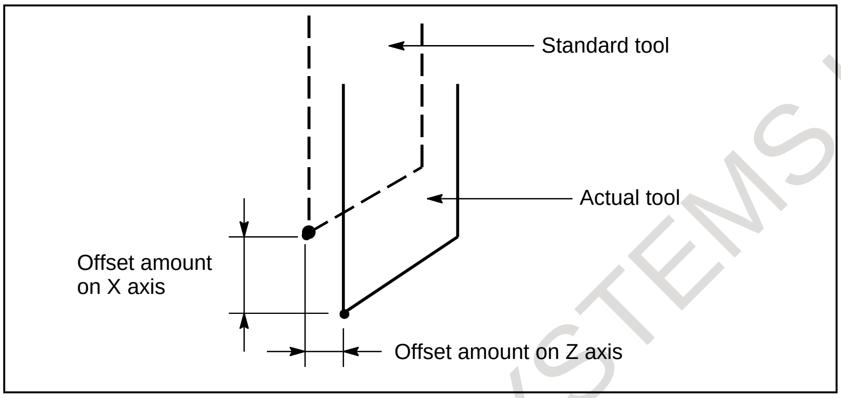

Fig. 11.1.1 (a) Tool offset

11.1.2 Tool Geometry Offset and Tool Wear Offset

T

Overview

Tool geometry offset and tool wear offset are possible to divide the tool offset to the tool geometry offset for compensating the tool shape or tool mounting position and the tool wear offset for compensating the tool nose wear. When these values are not distinguished from each other, the total of the values is set as the tool offset value.
By setting the bit 0 (WOF) of parameter No.3290, the modification of tool wear offset values or tool position offset values by MDI key input can be disabled.
By setting the bit 1 (GOF) of parameter No.3290, the modification of tool geometry offset values by MDI key input can be disabled. In order to permit an operator only to modify tool wear offset values, set the bit 1 (GOF) of parameter No.3290 to 1.

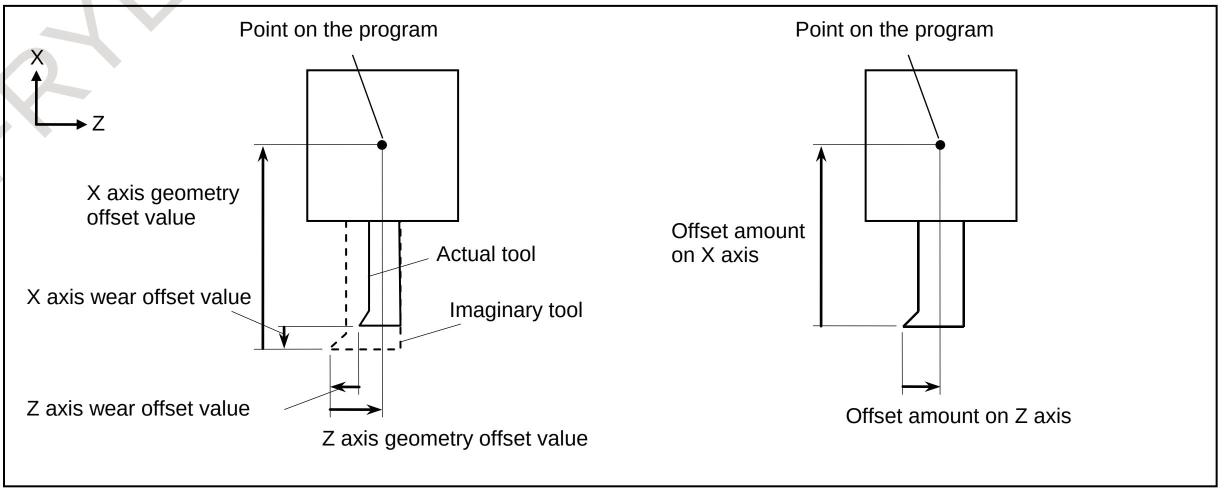

Fig. 11.1.2 (a) If tool geometry compensation and tool wear compensation are distinguished from each other (left) and if they are not (right)

Set the distance from tool nose to the point on the program (tool nose of standard tool, or tool mounting position) to a tool geometry offset value.

Generally, a sign of tool wear offset value is the opposite to a sign of tool geometry offset value. In the example of the above figure, the geometry offset value is a positive and the wear offset value is a negative.

11.1.3 Offset

T

Explanation

- Compensation methods

Two methods are available to geometry compensation and wear compensation, compensation with tool movement and compensation with coordinate shift. Which compensation method to select can be specified with bits 2 (LWT) and 4 (LGT) of parameter No. 5002. When the tool geometry/wear compensation is not enabled (bit 6 (NGW) of parameter No. 8136 is set to 1), however, compensation with tool movement is assumed unconditionally.

Table 11.1.3 (a)

Tool geometry and wear compensation NGW(No.8136#6)	Compensation element	Parameter			
		LWT=0 LGT=0	LWT=1 LGT=0	LWT=0 LGT=1	LWT=1 LGT=1
Disable (NGW=1)	Wear and geometry not distinguished	Tool movement			
Enable (NGW=0)	Wear compensation	Tool movement	Coordinate shift	Tool movement	Coordinate shift
	Geometry compensation	Coordinate shift	Coordinate shift	Tool movement	Tool movement

- Compensation with tool movement

The tool path is offset by the X, Y, and Z tool offset values for the programmed path. The tool offset distance corresponding to the number specified by the T code is added to or subtracted from the end position of each programmed block.

The vector with tool offset X, Y, and Z is called the offset vector. Compensation is the same as the offset vector.

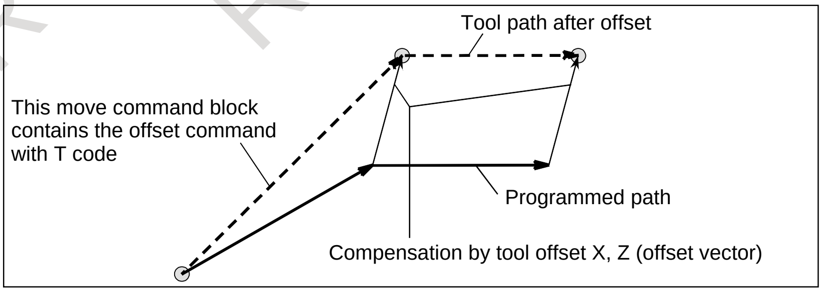

Fig. 11.1.3 (a) Offset operation with tool movement

NOTE

1 When G50 X_Z_T_ ; is specified, the tool is not moved.
The coordinate system in which the coordinate value of the tool position is (X,Z) is set. The tool position is obtained by subtracting the offset value corresponding to the tool offset number specified in the T code.

2 The G codes in the 00 group other than G50 must not be specified in the same block as that containing a T code. If any one of G28, G29, G30, and G53 is specified in the same block together with a T code, alarm PS0245, "T-CODE NOT ALLOWED IN THIS BLOCK", is issued.

- Compensation with coordinate shift

The work coordinate system is shifted by the X, Y, and Z tool offset amounts. Namely, the offset amount corresponding to the number designated with the T code is added to or subtracted from the absolute coordinates.

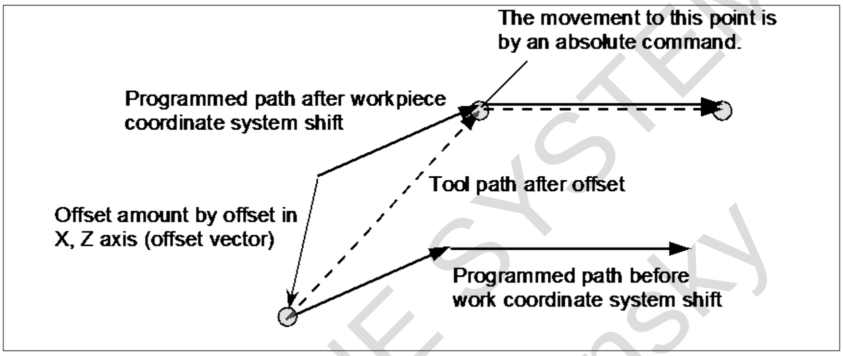

Fig. 11.1.3 (b) Offset operation with coordinate shift

- Starting and canceling offset by specifying a T code

Specifying a tool offset number with a T code means to select the tool offset value corresponding to it and to start offset. Specifying 0 as a tool offset number means to cancel offset.
For offset with tool movement, whether to start or cancel the offset can be specified with bit 6 (LWN) of parameter No. 5002.
For compensation with coordinate shift, the offset is started and canceled when a T code is specified. For the cancellation of geometry compensation, its operation can be selected with bit 5 (LGC) of parameter No. 5002.

Table 11.1.3 (b)

Compensation method	Bit 6 (LWN) of parameter No. 5002=0	Bit 6 (LWN) of parameter No. 5002=1
Tool movement	When a T code is specified	When an axial movement is specified
Coordinate shift	When a T code is specified (Note that geometry compensation can be canceled only if bit 5 (LGC) of parameter No. 5002 = 1.)	

- Canceling offset with reset

Tool offset is canceled under one of the following conditions:
<1> The power to the CNC is turned off and turned back on
<2> The reset button on the MDI unit is pressed
<3> A reset signal is input from the machine to the CNC
In cases <2> and <3> above, it is possible to select a cancel operation using bits 3 (LVC) of parameter No. 5006 and 7 (TGC) of parameter No. 5003.

Table 11.1.3 (c)

Compensation method		Parameter			
		LVC=0 TGC=0	**LVC=1 TGC=0**	**LVC=0 TGC=1**	**LVC=1 TGC=1**
Tool movement	Wear compensation	Not canceled.	Canceled. (When axial movement is specified)	Not canceled.	Canceled. (When axial movement is specified)
	Geometry compensation				
Coordinate shift	Wear compensation	Not canceled.	Canceled.	Not canceled.	Canceled.
	Geometry compensation	Not canceled.	Not canceled.	Canceled.	Canceled.

Notes and restrictions

- Helical interpolation (G02, G03)
  Tool position offset cannot be specified in a block in which helical interpolation is used.
- Coordinate system rotation (G68.1)
  Coordinate system rotation is executed on the command program first, followed by tool position offset.
- 3-dimensional coordinate conversion (G68.1)
  If tool position offset is used, tool position offset with coordinate shift cannot be used. Offset with tool movement must be specified inside a nest of 3-dimensional coordinate conversion. At the beginning block of the 3-dimensional coordinate conversion, tool does not move for a converted tool offset value.
  Example)

```
G68.1 ... ;
T0101;
  :
T0100;
G69.1 ... ;
```

- Workpiece coordinate system preset (G50.3)
  When the bit 7(WTC) of parameter No.1205 is 0, performing workpiece coordinate system preset causes tool position offset with tool movement to be canceled; this does not cause tool position offset with coordinate shift to be canceled.
  When the bit 7(WTC) of parameter No.1205 is 1, performing workpiece coordinate system preset does not cause neither tool position offset with tool movement nor tool position offset with coordinate shift to be canceled.
- Machine coordinate system setting (G53), reference position return (G28), second, third, and fourth reference position return (G30), and manual reference position return

Basically, before performing these commands or operations, cancel tool position offset. These operations do not cause tool position offset to be canceled. The actions in the Table 11.1.3 (d) take place:

Table 11.1.3 (d)

	When the command or operation is specified	When the next axial movement command is specified
Tool movement	The tool offset value is temporarily canceled.	The tool offset value is reflected.
Coordinate shift	Coordinates with the tool offset value reflected are assumed.	Coordinates with the tool offset value reflected are assumed.

- Arbitrary speed threading
  The alarm PS0528, “THREADING FORMAT ERROR” is issued when a T-code and the M-code for starting arbitrary speed threading are specified in the same block.

- Auxiliary function output in moving axis (G50.9)
  The alarm PS5330, “G50.9 FORMAT ERROR” is issued when a T-code and auxiliary function output in moving axis (G50.9) are specified in the same block.

- Programmable parameter input (G10)
  The alarm PS1144, “G10 FORMAT ERROR” is issued when a T-code is specified during programmable parameter input.

Parameter

	#7	#6	#5	#4	#3	#2	#1	#0
1205	WTC							

[Input type] Parameter input
[Data type] Bit path

#7 WTC When workpiece coordinate system preset is done, actual tool position offset by tool movement is :
0: Not considered.
1: Considered.

3032	Allowable number of digits for the T code

[Input type] Parameter input
[Data type] Byte path
[Valid data range] 1 to 8
Set the allowable numbers of digits for the T codes.
When 0 is set, the allowable number of digits is assumed to be 8.

	#7	#6	#5	#4	#3	#2	#1	#0
3129							DAP	DRP

[Input type] Parameter input
[Data type] Bit path

#0 DRP For relative coordinate display:
0: The actual position considering a tool offset (tool movement) is displayed.
1: The programmed position excluding a tool offset (tool movement) is displayed.

#1 DAP For absolute coordinate display:
0: The actual position considering a tool offset (tool movement) is displayed.
1: The programmed position excluding a tool offset (tool movement) is displayed.

	#7	#6	#5	#4	#3	#2	#1	#0
3290							GOF	WOF

[Input type] Parameter input
[Data type] Bit path

#0 WOF Setting the tool offset value (tool wear offset) by MDI key input is:
0: Not disabled.
1: Disabled. (With parameters Nos. 3294 and 3295, set the offset number range in which updating the setting is to be disabled.)

> **NOTE**
> When tool offset memory A is selected with the M series, the tool offset set in this parameter WOF is followed even if geometric compensation and wear compensation are disabled (bit 6 (NGW) of parameter No. 8136 is set to 1) with the T series.

#1 GOF Setting the tool geometry offset value by MDI key input is:
0: Not disabled.
1: Disabled. (With parameters Nos. 3294 and 3295, set the offset number range in which updating the setting is to be disabled.)

3294	Start number of tool offset values whose input by MDI is disabled

3295	Number of tool offset values (from the start number) whose input by MDI is disabled

[Input type] Parameter input
[Data type] Word path
[Valid data range] 0 to 999

When the modification of tool offset values by MDI key input is to be disabled using bits 0 (WOF) and 1 (GOF) of parameter No. 3290, parameters Nos. 3294 and 3295 are used to set the range where such modification is disabled. In parameter No. 3294, set the offset number of the start of tool offset values whose modification is disabled. In parameter No. 3295, set the number of such values. In the following cases, however, none of the tool offset values may be modified:
- When 0 or a negative value is set in parameter No. 3294
- When 0 or a negative value is set in parameter No. 3295
- When a value greater than the maximum tool offset number is set in parameter No. 3294

In the following case, a modification to the values ranging from the value set in parameter No. 3294 to the maximum tool offset number is disabled:
- When the value of parameter No. 3294 added to the value of parameter No. 3295 exceeds the maximum tool offset number

When the offset value of a prohibited number is input through the MDI panel, the warning "WRITE PROTECT" is issued.

[Example] When the following parameter settings are made, modifications to both of the tool geometry offset values and tool wear offset values corresponding to offset numbers 51 to 60 are disabled:
- Bit 1 (GOF) of parameter No. 3290 = 1 (to disable tool geometry offset value modification)
- Bit 0 (WOF) of parameter No. 3290 = 1 (to disable tool wear offset value modification)
- Parameter No. 3294 = 51
- Parameter No. 3295 = 10

If the setting of bit 0 (WOF) of parameter No. 3290 is set to 0 without modifying the other parameter settings above, tool geometry offset value modification only is disabled, and tool wear offset value modification is enabled.

	#7	#6	#5	#4	#3	#2	#1	#0
5002	WNP	LWM	LGC	LGT	ETC	LWT	LGN	

[Input type] Parameter input
[Data type] Bit path

#1 LGN Geometry offset number of tool offset :
0: Is the same as wear offset number
1: Specifies the geometry offset number by the tool selection number

> **NOTE**
> This parameter is valid when tool geometry/wear compensation is enabled (bit 6 (NGW) of parameter No.8136 is 0).

#2 LWT Tool wear compensation is performed by:
0: Moving the tool.
1: Shifting the coordinate system.

> **NOTE**
> This parameter is valid when tool geometry/wear compensation is enabled (bit 6 (NGW) of parameter No.8136 is 0).

#3 ETC When a T-code command is two digits or shorter, the T code is:
0: Not extended.
1: Extended.
When this parameter is 1, two-digit or shorter T-code commands are extended. (Three-digit or longer T-code commands are not extended.) The value after extension is determined by the setting of the number of digits in the offset number in T-code commands (parameter No. 5028).

Parameter No. 5028	Number of digits after extension	Sample extension
1	Extended to two digits	Before extension: T1 → After extension: T11
2	Extended to four digits	Before extension: T1 → After extension: T0101
3 or greater	Not extended	

[Example]
- Parameter No. 5028 : 2
- Parameter No. 3032 : 4 (Allowable number of digits in T code)

Before extension	→	After extension
T1	→	T0101 (1-digit command is extended to 4 digits.)
T12	→	T1212 (2-digit command is extended to 4 digits.)
T112	→	T112 (Not extended)
T1122	→	T1122 (Not extended)

> **NOTE**
> 1 The setting of the allowable number of digits in T code (parameter No. 3032) indicates the number of digits in a specified command (before being extended). If the number of digits in the command exceeds the allowable number of digits in T code, the alarm PS0003, “TOO MANY DIGIT” is issued.

> **NOTE**
> 2 This parameter is dedicated to the lathe system. Tool change is available with the turret type setting (bit 3 (TCT) of parameter No. 5040 = 0).
> 3 If the number of digits in the offset number in a T-code command (parameter No. 5028) is set to 0, the value after extension is determined by the number of digits in the number of tool compensation values (parameter No. 5024).
> 4 Common variable #149 for calling a T-code macro is set to the pre-extension value.

#4 LGT Tool geometry compensation is:
0: Compensated by the shift of the coordinate system
1: Compensated by the tool movement

> **NOTE**
> This parameter is valid when tool geometry/wear compensation is enabled (bit 6 (NGW) of parameter No.8136 is 0).

#5 LGC When tool geometry compensation is based on coordinate shifting, the tool geometry offset is:
0: Not canceled by a command with offset number 0.
1: Canceled by a command with offset number 0.

> **NOTE**
> This parameter is valid when tool geometry/wear compensation is enabled (bit 6 (NGW) of parameter No.8136 is 0).

#6 LWM Tool offset operation based on tool movement is performed:
0: In a block where a T code is specified.
1: Together with a command for movement along an axis.

#7 WNP Imaginary tool tip number used for tool nose radius compensation, when the tool geometry/wear compensation function is equipped, is the number specified by:
0: Geometry offset number
1: Wear offset number

	#7	#6	#5	#4	#3	#2	#1	#0
5003	TGC							

[Input type] Parameter input
[Data type] Bit path

#7 TGC A tool geometry offset based on a coordinate shift is:
0: Not canceled by reset.
1: Canceled by reset.

> **NOTE**
> This parameter is valid when tool geometry/wear compensation is enabled (bit 6 (NGW) of parameter No.8136 is 0).

	#7	#6	#5	#4	#3	#2	#1	#0
5004							ORC	

[Input type] Parameter input
[Data type] Bit path

#1 ORC The setting of a tool offset value is corrected as:
0: Diameter value
1: Radius value

NOTE
This parameter is valid only for an axis based on diameter specification. For an axis based on radius specification, specify a radius value, regardless of the setting of this parameter.

	#7	#6	#5	#4	#3	#2	#1	#0
5006					LVC		TGC	

[Input type] Parameter input
[Data type] Bit

#1 TGC If a T code is specified in a block where G50, G04, or G10 is specified:
0: No alarm is issued.
1: The alarm PS0245, “T-CODE NOT ALLOWED IN THIS BLOCK” is issued.

#3 LVC A tool offset (geometry/wear) based on a tool movement and wear offset based on a coordinate shift are:
0: Not canceled by reset.
1: Canceled by reset.

5013	Maximum value of tool wear compensation

[Input type] Parameter input
[Data type] Real path
[Unit of data] mm, inch (offset unit)
[Min. unit of data] The increment system of a tool offset value is followed.
[Valid data range] The settings of bits 3 to 0 (OFE, OFD, OFC, and OFA) of parameter No. 5042 are followed.

For metric input

OFE	OFD	OFC	OFA	Valid data range
0	0	0	1	0 to 9999.99mm
0	0	0	0	0 to 9999.999mm
0	0	1	0	0 to 9999.9999mm
0	1	0	0	0 to 9999.99999mm
1	0	0	0	0 to 999.999999mm

For inch input

OFE	OFD	OFC	OFA	Valid data range
0	0	0	1	0 to 999.999inch
0	0	0	0	0 to 999.9999inch
0	0	1	0	0 to 999.99999inch
0	1	0	0	0 to 999.999999inch
1	0	0	0	0 to 99.9999999inch

This parameter sets the maximum allowable tool wear compensation value. If an attempt is made to set a tool wear compensation value, the absolute value of which exceeds the value set in this parameter, the following alarm or warning is output:

Input from MDI	Warning: DATA IS OUT OF RANGE
Input by G10	Alarm PS0032: ILLEGAL OFFSET VALUE IN G10.

When 0 or a negative value is set, no maximum allowable value is applied.

[Example] When 30.000 is set
As a tool offset value, a value from -30.000 to +30.000 can be input.

5014 **Maximum value of incremental input for tool wear compensation**

[Input type] Parameter input
[Data type] Real path
[Unit of data] mm, inch (offset unit)
[Min. unit of data] The increment system of a tool offset value is followed.
[Valid data range] The settings of bits 3 to 0 (OFE, OFD, OFC, and OFA) of parameter No. 5042 are followed.

For metric input

OFE	OFD	OFC	OFA	Valid data range
0	0	0	1	0to9999.99mm
0	0	0	0	0to9999.999mm
0	0	1	0	0to9999.9999mm
0	1	0	0	0to9999.99999mm
1	0	0	0	0to999.999999mm

For inch input

OFE	OFD	OFC	OFA	Valid data range
0	0	0	1	0to999.999inch
0	0	0	0	0to999.9999inch
0	0	1	0	0to999.99999inch
0	1	0	0	0to999.999999inch
1	0	0	0	0to99.9999999inch

Set the maximum allowable value for the tool wear compensation value, input as an incremental value. If the incremental input value (absolute value) exceeds the set value, the following alarm or warning message is output:

Input from MDI	Warning: DATA IS OUT OF RANGE
Input by G10	Alarm PS0032: ILLEGAL OFFSET VALUE IN G10.

When 0 or a negative value is set, no maximum allowable value is applied.

5024 **Number of tool compensation values**

NOTE
When this parameter is set, the power must be turned off before operation is continued.

[Input type] Parameter input
[Data type] Word path
[Valid data range] 0 to 999
Set the maximum allowable number of tool compensation values used for each path.
Ensure that the total number of values set in parameter No. 5024 for the individual paths is within the number of compensation values usable in the entire system. The number of compensation values usable in the entire system depends on the option configuration.

If the total number of values set in parameter No. 5024 for the individual paths exceeds the number of compensation values usable in the entire system, or 0 is set in parameter No. 5024 for all paths, the number of compensation values usable for each path is a value obtained by dividing the number of compensation values usable in the entire system by the number of paths.
Tool compensation values as many as the number of compensation values used for each path are displayed on the screen. If tool compensation numbers more than the number of compensation values usable for each path are specified, alarm PS0115, "VARIABLE NO. OUT OF RANGE" is issued.
For example, 64 tool compensation sets are used, 20 sets may be allocated to path 1, 30 sets to path 2, and 14 sets to path 3. All of 64 sets need not be used.

5028	Number of digits of an offset number used with a T code command

[Input type] Parameter input
[Data type] Byte path
[Valid data range] 0 to 4

Specify the number of digits of a T code portion that is used for a tool offset number (wear offset number when the tool geometry/wear compensation function is used).
When 0 is set, the number of digits is determined by the number of tool compensation values.
When the number of tool compensation values is 1 to 9: Lower 1 digit
When the number of tool compensation values is 10 to 99: Lower 2 digits
When the number of tool compensation values is 100 to 999: Lower 3 digits

[Example] When an offset number is specified using the lower 2 digits of a T code, set 2 in parameter No. 5028.
Txxxxxx yy
xxxxxx : Tool selection
yy : Tool offset number

In tool management function, set 4 in this parameter to set 4-digit number in parameter No.13265.

> **NOTE**
> A value longer than the setting of parameter No. 3032 (allowable number of digits of a T code) cannot be set.

	#7	#6	#5	#4	#3	#2	#1	#0
5040								OWD

[Input type] Parameter input
[Data type] Bit path

#0 OWD In radius programming (bit 1 (ORC) of parameter No. 5004 is set to 1),
0: Tool offset values of both geometry compensation and wear compensation are specified by radius.
1: Tool offset value of geometry compensation is specified by radius and tool offset value of wear compensation is specified by diameter, for an axis of diameter programming.

> **NOTE**
> This parameter is valid when tool geometry/wear compensation is enabled (bit 6 (NGW) of parameter No.8136 is 0).

Alarm and message

Number	Message	Description
PS0245	T-CODE NOT ALLOWED IN THIS BLOCK	One of the G codes, G50, G10, G04, G28, G29, G30, and G53, which cannot be specified in the same block as a T code, was specified with a T code.

11.1.4 Extended Tool Selection Function

T

Overview

In lathe system machines, tools are changed mainly with the following two methods:

(1) With a turret holding multiple tools, tools are changed by turning the turret (T command).
(2) With an automatic tool changer (ATC), tools are changed by using both cartridge indexing (T command) and tool change (such as M06) commands.

To support the tool change method explained in (2) above, the following tool selection specifications apply to this function:
<1> Tool compensation by a T command is disabled. This means that the T command performs auxiliary functions only.
<2> Tool compensation is enabled by using a G code instead of the T command. In this case, the following types of tool compensation are enabled:
- Tool length compensation
- Tool offset (compensation equivalent to that of a T command in the case of turret rotation type)

Explanation

- Selecting a tool change method

Bit 3 (TCT) of parameter No. 5040 selects a tool change method.
This changes the way for specifying tool compensation.
This parameter setting has influence on the range in the Table 11.1.4 (a) :

Table 11.1.4 (a)

	Bit 3 (TCT) of parameter No. 5040 = 0 (Turret type)	Bit 3 (TCT) of parameter No. 5040 = 1 (ATC type)
Operation of T command	Auxiliary function (tool change) and tool compensation	Auxiliary function (tool indexing) only
Tool compensation	Specified with T code	Specified with G43.7 D_
Compensation No. of tool compensation	Specified with T code	Specified with D code
Compensation No. of tool-nose radius compensation	Specified with T code	Specified with D code
Command such as G43, etc. (group 23)	Disabled (alarm)	Enabled
Compensation number of G43, etc. (group 23)	-	Specified with D code

- T command operation

(1) When bit 3 (TCT) of parameter No. 5040 is 0
The T command performs an auxiliary function and tool compensation.
The code signal issued to the machine is the T command value except the last 1 to 3 digits.
For example, suppose that the following command is issued when 2 is set in parameter No. 5028 (the number of digits comprising the offset number in the T code command):
T0313 ;
The T code signal sent to the machine indicates 03.
The tool compensation number, indicated by the lowest 2 digits, is 13.

(2) When bit 3 (TCT) of parameter No. 5040 is 1
The T command performs an auxiliary function only.
In this case, the code signal issued to the machine is the T command value.
For example, suppose that the following is specified:
T0313 ;
The T code signal issued to the machine is 0313. The T code signal is not affected by the setting of parameter No. 5028 (the number of digits comprising the offset number in the T code command).
The tool compensation number is not affected by this command.

- Tool compensation

(1) When bit 3 (TCT) of parameter No. 5040 is 0
The T command performs tool compensation.

(2) When bit 3 (TCT) of parameter No. 5040 is 1
The T command does not perform tool compensation.
To provide tool compensation, specify G43.7 D_.
Tool compensation is performed in the same way as with the T command when bit 3 (TCT) of parameter No. 5040 is 0.

- Compensation number of tool compensation

(1) When bit 3 (TCT) of parameter No. 5040 is 0
The lowest 1 to 3 digits of the T command are used. The number of digits is set in parameter No. 5028.
When tool geometry/wear compensation is enabled (bit 6 (NGW) of parameter No.8136 is 0), tool geometry compensation and wear compensation may also be assigned different compensation values by setting bit 1 (LGN) of parameter No. 5002.
For details, see Section "TOOL FUNCTIONS OF LATHE SYSTEM".

(2) When bit 3 (TCT) of parameter No. 5040 is 1
Except that a compensation number is specified with a D command, the same operation as (1) above is performed.

- Compensation number of tool-nose radius compensation

Same as for tool compensation described above.

- Specification of G43, etc.

(1) When bit 3 (TCT) of parameter No. 5040 is 0
G codes of group 23 such as G43 cannot be specified.
Specifying such a G code results in an alarm PS0366, "IMPROPER G-CODE IN TURRET METHOD".

(2) When bit 3 (TCT) of parameter No. 5040 is 1
G codes of group 23 such as G43 can be specified. The following G codes can be specified:
G43/G44: Tool length compensation
G43.7: Tool compensation
Specify a compensation number with D_. The D code is specified in the same way as for tool compensation and tool-nose radius compensation.

The reverse meanings can be set for G43/G44 and G43.7 by setting bit 4 (TLG) of parameter No. 5040.

- Tool compensation memory

As the compensation amount used by the functions listed below, only the value set in Z on the tool compensation memory screen is used, Values such as values set for the X, R, and Y-axis offsets are ignored.

G43/G44: Tool length compensation

As the compensation amount used in the following function, the values set for the X, Z, and Y-axis offsets on the tool compensation memory screen are used:

G43.7: Tool compensation

Limitation

- Switching between tool compensation mode and another compensation mode

In the tool compensation (G43.7) mode, a command such as a tool length compensation command (G43/G44) cannot be specified. Similarly, in a mode such as the tool length compensation mode (G43/G44), tool compensation (G43.7) cannot be specified.
Specifying such a command results in the alarm PS0368, “OFFSET REMAIN AT OFFSET COMMAND”.
To switch between compensation types, specify G49 to cancel the current compensation mode before setting another compensation mode.

- Multiple repetitive canned cycle

When a multiple repetitive canned cycle is executed with bit 3 (TCT) of parameter No. 5040 set to 1, note the following:

> ⚠ **CAUTION**
>
> 1 When a G71 to G76 command is specified in the FS15 tape format, a value such as the depth of cut is specified with a D code. In this case, a D command specified after G71 to G76 is assumed to be the depth of cut. For example, suppose that the command shown below is specified. In this case, the D command <1> is assumed to be the tool compensation number, and the D command <2> is assumed to be the depth of cut.
>
> Example:
>
> <u>D10</u> G71 P_Q_ U_ W_ <u>D7000</u> F_ S_;
> <1> <2>
>
> 2 In the operation of G71 to G73, a G code such as G43 and a D command specified in the finish figure blocks (the portion enclosed by the sequence numbers specified with P_ and Q_) are ignored, and the compensation amount set when the G71 to G73 block is specified becomes valid.

- Changing bit 3 (TCT) of parameter No. 5040

> ⚠ **WARNING**
>
> Before changing the setting of bit 3 (TCT) of parameter No. 5040, cancel the offset. If the setting is changed while the offset is applied, the subsequent offset operation may not be performed correctly or an alarm PS0368 occurs.

Parameter

	#7	#6	#5	#4	#3	#2	#1	#0
5040				TLG	TCT			

[Input type] Parameter input
[Data type] Bit path

#3 TCT The tool change method is based on:

0: Turret rotation. (Tool change operation is performed with a T command only.)
With a T command, an auxiliary function and tool offset operation are performed.

1: Automatic tool changer (ATC).
(Tool change operation is performed with an M command (such as M06)).

With a T command, an auxiliary function only is performed.
This parameter is valid with a lathe system only.

> ⚠ **WARNING**
> Before changing the setting of this parameter, cancel the offset. If the setting is changed while the offset is applied, the subsequent offset operation may not be performed correctly or an alarm PS0368 occurs.

#4 TLG When tool change operation is performed with the automatic tool changer (when bit 3 (TCT) of parameter No. 5040 is set to 1), tool offset operation is specified by:

0: G43.7.
At this time, G43 and G44 function as G codes for tool length compensation.

1: G43.
At this time, G43.7 and G44.7 function as G codes for tool length compensation.

Alarm and message

Number	Message	Description
PS0366	IMPROPER G-CODE IN TURRET METHOD	When the turret change tools method was selected (bit 3 (TCT) of parameter No. 5040 = 0), G43, or G43.7 was commanded.
PS0368	OFFSET REMAIN AT OFFSET COMMAND	- When the ATC change tools method was selected (bit 3 (TCT) of parameter No. 5040 = 1) during G43 mode, G43.7 was commanded. Or, G43 was commanded during G43.7 mode. - After bit 3 (TCT) of parameter No. 5040 was changed in the state in which a tool offset remained, another tool offset was specified.

Manual name	Item name
OPERATOR'S MANUAL (For Lathe System) (B-64694EN-1)	Extended tool selection function

11.1.5 Automatic Alteration of Tool Position Compensation (T Function)

T

Overview

After cutting tools are changed manually, entering the tool number of a new tool enables the previous tool position compensation values (tool geometry and wear compensation) to be changed to those for the new tool.

Details

After changing cutting tools manually, place the CNC in the JOG or HNDL (INC), or REF mode, enter the tool number of a new tool as a manual tool compensation tool number signal MTLN <Gn068, Gn069> or MT8N <Gn525-Gn528> from the PMC, and set the compensation command signal MTLC <Gn067.0> to "1". The CNC will read the tool number and change the previous tool position compensation values to those for the specified tool. Upon completion of the compensation value change, the compensation completion signal MTLA <Fn061.5> is output.

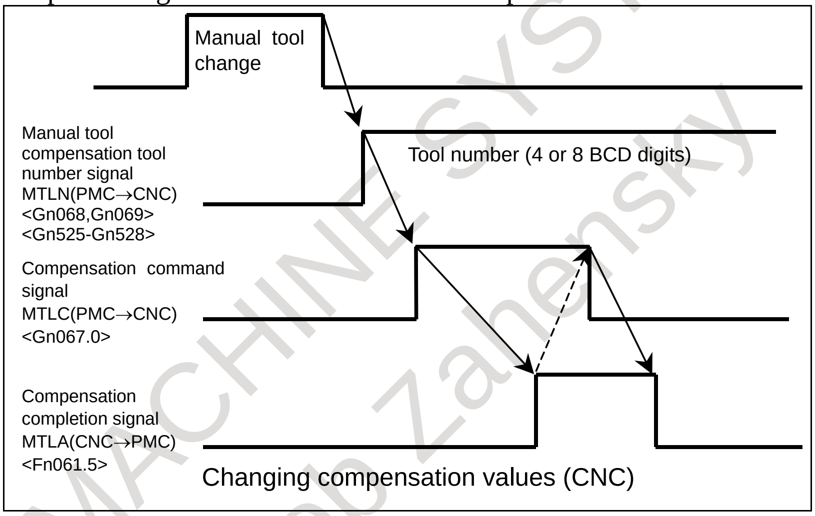

Fig. 11.1.5 (a)

Four BCD digits are used to specify the manual tool compensation tool number MTLN <Gn068, Gn069>. If it is necessary to specify the manual tool compensation tool number with a number exceeding 4 digits, use MT8N <Gn525-Gn528> to specify it with 8 BCD digits. Which size to use can be selected using bit 7 (MTL8D) of parameter No. 11400. The same rules as for the T code command in automatic operation are applied in specifying how many digits, 4 or 8, to use as the geometry or wear compensation numbers (parameter No. 5028).

This function is available only if the CNC is in the JOG, HNDL, or REF mode.

In any other operation mode, during automatic operation (running, pause, or stop), in the tool-nose radius compensation mode, (G41/G42 mode), setting the compensation command signal MTLC to "1" does not enable compensation.

If compensation is unavailable, the compensation completion signal MTLA does not become "1". Instead the compensation uncompleted signal MTLANG <Fn061.4> becomes "1". The reason for MTLANG = 1 can be known from diagnosis data No. 560.

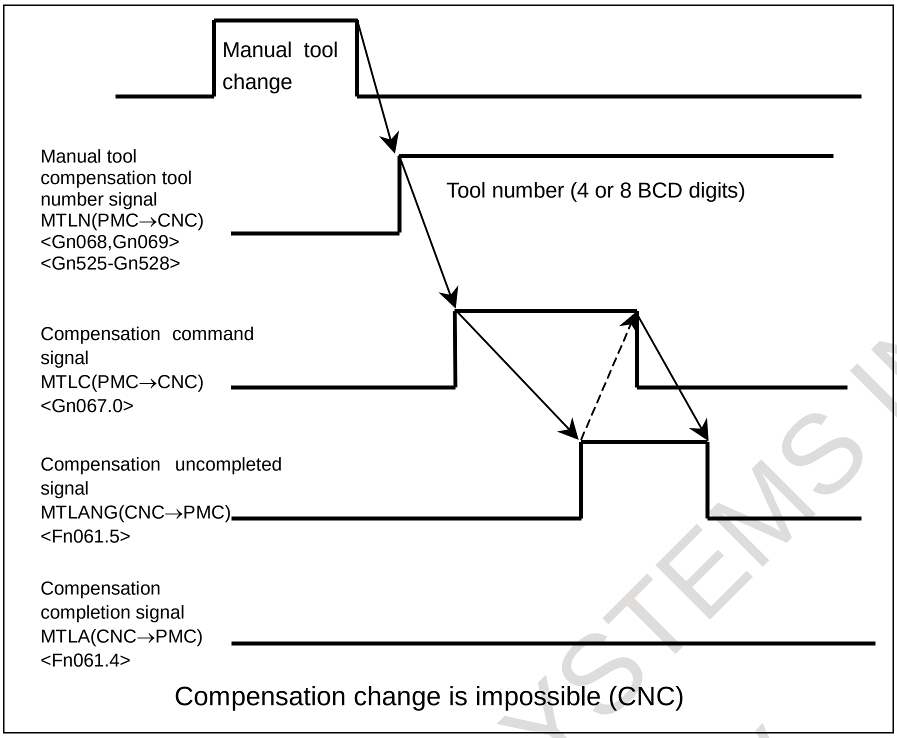

Fig. 11.1.5 (b)

Signal

Manual tool compensation tool number signal (4 digits) MTLN00 to MTLN15<Gn068, Gn069>

[Classification] Input signal

[Function] Specifies a tool number for manual tool compensation, using 4 BCD digits.

Manual tool compensation tool number signal (8 digits) MT8N00 to MT8N31<Gn525-Gn528>

[Classification] Input signal

[Function] Specifies a tool number for manual tool compensation, using 8 BCD digits.

Manual tool compensation command number MTLC<Gn067.0>

[Classification] Input signal

[Function] Requests to perform manual tool compensation. Setting this signal from "0" to "1" causes manual tool compensation to be performed. Re-set it to "0" when the compensation completion signal becomes = "1".

Manual tool compensation completion signal MTLA<Fn061.5>

[Classification] Output signal

[Function] Informs that manual tool compensation is completed. This signal becomes "1" when a compensation value is changed in manual tool compensation. It becomes "0" when the compensation command signal MTLC becomes "0".

Manual tool compensation uncompleted signal MTLANG<Fn061.4>

[Classification] Output signal

[Function] Informs that manual tool compensation is uncompleted. This signal becomes "1" if an attempt to perform manual tool compensation fails in changing a compensation value for any reason. It becomes "0" when the compensation command signal MTLC becomes "0". The reason for the failure of the attempt can be known from diagnosis data No. 560.

Signal address

	#7	#6	#5	#4	#3	#2	#1	#0
Gn068	MTLN07	MTLN06	MTLN05	MTLN04	MTLN03	MTLN02	MTLN01	MTLN00

Gn067								MTLC
Fn061			MTLA	MTLANG				

Diagnosis data

0560	Manual tool compensation status number

[Data type] Byte
[Unit of data] None
[Valid data range] 0 to 255

The following numbers are used to indicate whether compensation is completed or the reason for uncompleted compensation (if occur).

0: Manual tool compensation is completed normally.
1: The T code-specified data has exceeded the permissible range.
2: The offset value is out of range.
3: The offset number is out of range.
4: The CNC is undergoing automatic operation or axis movement.
5: The CNC is in the tool-nose radius compensation mode.
6: The CNC is in a mode other than the JOG, HNDL (INC), or REF mode.
7: A CNC parameter has specified an invalid number.

Parameter

	#7	#6	#5	#4	#3	#2	#1	#0
11400								MTL8D

[Input type] Parameter input
[Data type] Bit path

#0 MTL8D The number of digits in the T code used for automatic change of tool position compensation is specified as follows:

0: 4 digits (Existing DI signals <Gn068 and Gn069> are used.)
1: 8 digits (The DI signals <Gn525 to Gn528> are used.)

Notes

If the CNC is in the following conditions, setting the compensation command signal MTLC to “1” cannot change compensation values, and therefore, the compensation uncompleted signal MTLANG becomes “1”.

1) The CNC is in a mode other than the JOG, HNDL (INC), or REF mode.
2) The CNC is at an emergency stop.
3) The reset button on the MDI unit is held pressed.
4) A reset signal is input from the machine side.
5) The CNC is in an alarm condition.
6) The CNC is undergoing automatic operation (start, pause, or stop).
7) The CNC is in the tool-noose radius compensation mode (G41/G42 mode).

With this function, shifted coordinate systems are returned to the previous state by the first T code in the next session of automatic operation, and axis movement occurs by the amount of canceled shifting, thus resuming the position and coordinate systems of the inherent movement type.

Example:

If the amounts of wear compensation are: T1 = 0.1, T2 = 0.2, and T3 = 0.4

1) The state that T1 compensation is applied during automatic operation (compensation of 0.1 axis movement type):
2) The coordinate system is shifted by -0.1 (= T2 - T1) from the state mentioned in step 1 when tool T2 is selected in manual tool compensation.
3) When compensation T3 is applied again during automatic operation, the coordinate system is shifted by 0.2 (= T3 - T2), that is, totally by 0.3. The coordinate system, which has been shifted by -0.1 in step 2, is shifted back to the previous state.

Once the T3 compensation command has been executed, the same position and coordinate system as would be when the T3 compensation command is issued in the T1 compensation state are resumed.

When manual tool compensation ends properly, the T code modal changes to one where manual tool compensation was carried out (the tool function code signals T00 to T31<Fn026 to Fn029> also change).

11.1.6 Y Axis Offset

Overview

When the Y axis, one of the basic three axes, is used with a lathe system, this function performs Y axis offset.
When tool geometry/wear compensation is enabled (bit 6 (NGW) of parameter No.8136 is 0), both tool geometry offset and tool wear offset are effective to Y axis offset. This function is enabled when bit 1 (YOF) of parameter No. 8132 is set to 1.

Explanation

Y axis offset results in the same operation as tool offset. For an explanation of the operation, related parameters, and the like, refer to the item “Tool Offset.”

11.1.6.1 Support of arbitrary axes for Y axis offset

Overview

In a lath system, Y axis offset has been usable with the basic three axes only. This function enables Y axis offset to be used with arbitrary axes other than the Y axis, which is one of the basic three axes.

Parameter

5043	**Axis number for which Y-axis offset is used**

[Input type] Parameter input

[Data type] Byte path
[Valid data range] 0 to 24

Set the number of an axis for which Y-axis offset is used.
If 0 or a value beyond the valid data range is set, the Y-axis offset is applied to the Y-axis of the basic three axes. If setting is made for the X- or Z-axis of the basic three axes, the standard tool offset for the X- or Z-axis is not used, and only the Y-axis offset is used.

11.1.7 4th/5th Axis Offset

Overview

This function enables tool offset for the 4th axis and 5th axis following the basic three axes (X, Y, and Z axes). As with tool offsets based on the basic three axes (X, Y, and Z axes), 32 sets of 4th/5th axis tool offsets are available. When tool geometry/wear compensation is enabled (bit 6 (NGW) of parameter No.8136 is 0), tool geometry offset and tool wear offset are enabled. Moreover, the number of sets can be increased from 32 to 64, 99, 400, 999, or 2000.
A tool offset value can be applied to arbitrary axes by setting an axis number (1 to the maximum number of controlled axes) to be used for 4th axis offset in parameter No. 5044 and setting an axis number (1 to the maximum number of controlled axes) to be used for 5th axis offset in parameter No. 5045. By setting bit 1 (NO5) of parameter No. 11400 to 1, 5th axis offset is enabled.
If the same axis as used with the Y axis offset function is specified, however, a Y axis offset value is applied to the specified axis, and a 4th axis offset value or 5th axis offset value is invalidated.
Tool offset values can be input through an I/O device.

Explanation

The operation of 4th/5th axis offset is the same as the operation of tool offset. For the operation, see Section 12.1.1, "TOOL OFFSET".

Setting of tool offset values with the G10 command

By programming, 4th/5th axis offset values can be input.

Format

G10 P_ X_ Y_ Z_ R_ Q_ E_ F_ ;

or

G10 P_ U_ V_ W_ C_ Q_ E_ F_;

P : Offset number
- 0 : Specifies a workpiece coordinate system shift value.
- 1 to 999 : Specifies a tool wear offset value.
- 10000+(1 to 999) : Specifies a tool geometry offset value, with a number (1 to 999) representing an offset number.

X : X axis offset value (absolute)
Y : Y axis offset value (absolute)
Z : Z axis offset value (absolute)
U : X axis offset value (incremental)
V : Y axis offset value (incremental)
W : Z axis offset value (incremental)
R : Tool nose radius compensation value (absolute)
C : Tool nose radius compensation value (incremental)
Q : Virtual tool nose number
E : 4th axis offset value (absolute)
F : 5th axis offset value (absolute)

- Explanation

As in the G10 format above, address E for inputting a 4th axis offset value and address F for inputting a 5th axis offset value allow absolute values only to be input.

> **NOTE**
> 1 When compared with the conventional G10 format for changing tool offset values, address E for specifying a 4th axis offset value and address F for specifying a 5th axis offset value are newly added in the format above.
> 2 When a program based on the G10 format above is executed, only those offset values that correspond to programmed axis addresses and offset numbers are rewritten.

- Address name changing of format

When bit 2 (OFS) of parameter No.11403 is set to 1, the specification address in "Y-axis offset and 4th/5th axis offset" can use axis name 'A' or 'B' instead of default specification addresses 'Y', 'E' and 'F'.

Example) When the following parameters are set, the command address 'A' and 'B' are used for setting of a tool offset.

- Parameter No.5044 is set to 4 (4th axis offset is the 4th axis)
- Parameter No.5045 is set to 5 (5th axis offset is the 5th axis)
- Parameter No.1020 (4th axis ,5th axis) = 65, 66 (Address name of 4th /5th axis offset is 'A' and 'B')
- Bit 2 (OFN) of No.11403 is set to 1 (Address depend on parameter No.1020)

```
%
G10 P01 X_ Z_ A_ B_
G10 P02 X_ Z_ A_ B_
...
G10 P__ X_ Z_ A_ B_
%
```

A_ : Tool compensation data (4th axis offset value in the example).
B_ : Tool compensation data (5th axis offset value in the example).
The other addresses are the same as for the tool compensation amount.

> **NOTE**
> 1 The axis name that can be used as a specification address is only 'A', and 'B'. If 'A' or 'B' is used as the specification address in Y-axis offset, the address 'V' (incremental command of Y-axis offset) cannot be used.
> 2 If the either of following is set, the default specification addresses 'Y', 'E', and 'F' are used.
> - Parameter No.1020 is set to axis name other than 'A(65)' or 'B(66)'.
> - An extended axis name is used.
> 3 When bit 2 (OFN) of parameter No.11403 is set to 1, conventional offset data cannot be read. If conventional offset data is read, set 0 to bit 2 (OFN) of parameter No.11403.

Limitation

1. This function supports the common memory between each path.
2. This function does not support direct input/counter input of tool offset values measured.
3. This function does not support offset value writing using a custom macro variable.

4. This function does not support the PMC window function.
   However, this function supports writing/reading of 4th/5th axis offset values to and from the C Language Executor.
5. This function does not support external data input. So, no 4th/5th axis offset value can be modified with a PMC ladder.
6. This function does not support the second geometry tool offset function.
7. This function does not support the tool management function.
8. This function does not support the wrong operation prevention function.
9. This function does not support the program coordinate switch screen function and the offset memory switch function.

Parameter

5044	Axis number for which 4th-axis offset is used

> **NOTE**
> When this parameter is set, the power must be turned off before operation is continued.

[Input type] Parameter input
[Data type] Byte path
[Valid data range] 0, 1 to number of controlled axes

Set the number of an axis for which the 4th-axis offset is used.
When a value ranging from 1 to the number of controlled axes is set in this parameter, the 4th-axis offset is applied to the set axis number. If 0 or a value beyond the valid data range is set, the 4th-axis offset is not used. For the basic two axes X and Z, the standard tool offsets are used, so the 4th-axis offset cannot be used. When the axis set for the Y-axis offset function is set in this parameter, the Y-axis offset is used for the axis, and the 4th-axis offset is not used.

5045	Axis number for which 5th-axis offset is used

> **NOTE**
> When this parameter is set, the power must be turned off before operation is continued.

[Input type] Parameter input
[Data type] Byte path
[Valid data range] 0, 1 to number of controlled axes

Set the number of an axis for which the 5th-axis offset is used.
When a value ranging from 1 to the number of controlled axes is set in this parameter, the 5th-axis offset is applied to the set axis number. If 0 or a value beyond the valid data range is set, the 5th-axis offset is not used. For the basic two axes X and Z, the standard tool offsets are used, so the 5th-axis offset cannot be used. When the axis set for the Y-axis offset function is set in this parameter, the Y-axis offset is used for the axis, and the 4th-axis offset is not used.
When settings are made so that both the 5th-axis offset and 4th-axis offset apply to the same axis, only the 4th-axis offset is used, and the 5th-axis offset is not used.

	#7	#6	#5	#4	#3	#2	#1	#0
5040	NO4							

[Input type] Parameter input
[Data type] Bit path

#7 NO4 4th axis offset function is:
0: Used.
1: Not used.

	#7	#6	#5	#4	#3	#2	#1	#0
11400							NO5	

[Input type] Parameter input
[Data type] Bit path

#1 NO5 The fifth axis offset function is:
0: Not used.
1: Used.

11.2 TOOL FUNCTIONS OF MACHINING CENTER SYSTEM

M

Overview

Selection of tools can be done by commanding tool numbers with up to an 8-digit numeral after address T.

Signal

Refer to "AUXILIARY FUNCTION/2ND AUXILIARY FUNCTION"

Parameter

3032	Allowable number of digits for the T code

[Input type] Parameter input
[Data type] Byte path
[Valid data range] 1 to 8
Set the allowable numbers of digits for the T code.
When 0 is set, the allowable number of digits is assumed to be 8.

Note

NOTE
When a move command and a tool function are specified in the same block, the commands are executed in one of the following two ways:
(i) Simultaneous execution of the move command and tool function commands.
(ii) Executing tool function commands upon completion of move command execution.
The selection of either (i) or (ii) depends on the sequence program of PMC.

Reference item

Manual name	Item name

CONNECTION MANUAL (FUNCTION) (This manual)	Auxiliary function

11.2.1 Tool Compensation Memory

M

Overview

Tool compensation values include geometry compensation values and wear compensation values.
Tool compensation values can also be used without discriminating between geometry and wear compensation values.

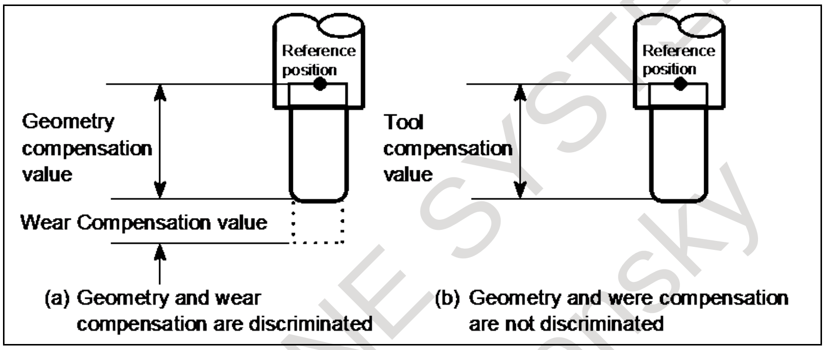

Fig. 11.2.1 (a) Geometric compensation and wear compensation

Tool compensation values can be entered into CNC memory from the MDI or from a program.
A tool compensation value is selected from the CNC memory when the corresponding code is specified after address H or D in a program.
The value is used for tool length compensation, cutter compensation, or the tool offset.

- Unit of range of tool compensation value

A tool offset unit and valid data range can be chosen from the following by setting the parameters:

Table 11.2.1 (a)
Unit of range of tool compensation value (metric input)

OFE	OFD	OFC	OFA	Unit	Range
0	0	0	1	0.01mm	±9999.99mm
0	0	0	0	0.001mm	±9999.999mm
0	0	1	0	0.0001mm	±9999.9999mm
0	1	0	0	0.00001mm	±9999.99999mm
1	0	0	0	0.000001mm	±999.999999mm

Unit of range of tool compensation value (inch input)

OFE	OFD	OFC	OFA	Unit	Range
0	0	0	1	0.001inch	±999.999inch
0	0	0	0	0.0001inch	±999.9999inch
0	0	1	0	0.00001inch	±999.99999inch
0	1	0	0	0.000001inch	±999.999999inch
1	0	0	0	0.0000001inch	±99.9999999inch

- Tool compensation memory

One of the tool compensation memory A/C can be selected according to the configuration of offset amount.

(1) Tool compensation memory A
There is no difference between geometry compensation memory and wear compensation memory in tool compensation memory A. Therefore, amount of geometry offset and wear offset together is set as the offset memory. There is also no differences between cutter compensation (D code) and tool length compensation (H code).

(2) Tool compensation memory C
Memory for geometry compensation and wear compensation is separate in tool compensation memory C. Geometry compensation and wear compensation can thus be set separately. Separate memories are prepared for cutter compensation (for D code) and for tool length compensation (for H code).

The above description is summarized as follows:

Table 11.2.1 (b)

Tool compensation memory	Compensation amount
A	Tool compensation amount (Geometry compensation value + Wear compensation value)
C	Geometry compensation value for H code
	Geometry compensation value for D code
	Wear compensation value for H code
	Wear compensation value for D code

Parameter

	#7	#6	#5	#4	#3	#2	#1	#0
3109							DWT	

[Input type] Parameter input
[Data type] Bit path

#1 DWT Characters G and W in the display of tool wear/geometry compensation amount
0: The characters are displayed at the left of each number.
1: The characters are not displayed.

	#7	#6	#5	#4	#3	#2	#1	#0
3205				OSC				

[Input type] Parameter input
[Data type] Bit

#4 OSC On the offset screen, offset value erasure by a soft key is:
0: Enabled.
1: Disabled.

	#7	#6	#5	#4	#3	#2	#1	#0
3290							GOF	WOF

[Input type] Parameter input
[Data type] Bit path

#0 WOF Setting the tool offset value (tool wear offset) by MDI key input is:
0: Not disabled.

1: Disabled. (With parameters Nos. 3294 and 3295, set the offset number range in which updating the setting is to be disabled.)

> **NOTE**
> When tool offset memory A is selected with the M series, the tool offset value set in this parameter is followed even if geometric compensation and wear compensation are not specified with the T series.

#1 GOF Setting the tool geometry offset value by MDI key input is:

0: Not disabled.

1: Disabled. (With parameters Nos. 3294 and 3295, set the offset number range in which updating the setting is to be disabled.)

3294	Start number of tool offset values whose input by MDI is disabled

3295	Number of tool offset values (from the start number) whose input by MDI is disabled

[Input type] Parameter input
[Data type] Word path
[Valid data range] 0 to 999

When the modification of tool offset values by MDI key input is to be disabled using bits 0 (WOF) and 1 (GOF) of parameter No. 3290, parameters Nos. 3294 and 3295 are used to set the range where such modification is disabled. In parameter No. 3294, set the offset number of the start of tool offset values whose modification is disabled. In parameter No. 3295, set the number of such values. In the following cases, however, none of the tool offset values may be modified:

- When 0 or a negative value is set in parameter No. 3294
- When 0 or a negative value is set in parameter No. 3295
- When a value greater than the maximum tool offset number is set in parameter No. 3294

In the following case, a modification to the values ranging from the value set in parameter No. 3294 to the maximum tool offset number is disabled:

- When the value of parameter No. 3294 added to the value of parameter No. 3295 exceeds the maximum tool offset number

When the offset value of a prohibited number is input through the MDI panel, the warning "WRITE PROTECT" is issued.

[Example] When the following parameter settings are made, modifications to both of the tool geometry offset values and tool wear offset values corresponding to offset numbers 51 to 60 are disabled:

- Bit 1 (GOF) of parameter No. 3290 = 1 (to disable tool geometry offset value modification)
- Bit 0 (WOF) of parameter No. 3290 = 1 (to disable tool wear offset value modification)
- Parameter No. 3294 = 51
- Parameter No. 3295 = 10

If the setting of bit 0 (WOF) of parameter No. 3290 is set to 0 without modifying the other parameter settings above, tool geometry offset value modification only is disabled, and tool wear offset value modification is enabled.

5013	Maximum value of tool wear compensation

[Input type] Parameter input

[Data type] Real path
[Unit of data] mm, inch (offset unit)
[Min. unit of data] The increment system of a tool offset value is followed.
[Valid data range] The settings of bits 3 to 0 (OFE, OFD, OFC, and OFA) of parameter No. 5042 are followed.

For metric input

OFE	OFD	OFC	OFA	Valid data range
0	0	0	1	0 to 9999.99mm
0	0	0	0	0 to 9999.999mm
0	0	1	0	0 to 9999.9999mm
0	1	0	0	0 to 9999.99999mm
1	0	0	0	0 to 999.999999mm

For inch input

OFE	OFD	OFC	OFA	Valid data range
0	0	0	1	0 to 999.999inch
0	0	0	0	0 to 999.9999inch
0	0	1	0	0 to 999.99999inch
0	1	0	0	0 to 999.999999inch
1	0	0	0	0 to 99.9999999inch

This parameter sets the maximum allowable tool wear compensation value. If an attempt is made to set a tool wear compensation value, the absolute value of which exceeds the value set in this parameter, the following alarm or warning is output:

Input from MDI	Warning: DATA IS OUT OF RANGE
Input by G10	Alarm PS0032: ILLEGAL OFFSET VALUE IN G10.

When 0 or a negative value is set, no maximum allowable value is applied.

[Example] When 30.000 is set
As a tool offset value, a value from -30.000 to +30.000 can be input.

5014	Maximum value of incremental input for tool wear compensation

[Input type] Parameter input
[Data type] Real path
[Unit of data] mm, inch (offset unit)
[Min. unit of data] The increment system of a tool offset value is followed.
[Valid data range] The settings of bits 3 to 0 (OFE, OFD, OFC, and OFA) of parameter No. 5042 are followed.

For metric input

OFE	OFD	OFC	OFA	Valid data range
0	0	0	1	0to9999.99mm
0	0	0	0	0to9999.999mm
0	0	1	0	0to9999.9999mm
0	1	0	0	0to9999.99999mm
1	0	0	0	0to999.999999mm

For inch input

OFE	OFD	OFC	OFA	Valid data range
0	0	0	1	0to999.999inch
0	0	0	0	0to999.9999inch
0	0	1	0	0to999.99999inch
0	1	0	0	0to999.999999inch
1	0	0	0	0to99.9999999inch

Set the maximum allowable value for the tool wear compensation value, input as an incremental value. If the incremental input value (absolute value) exceeds the set value, the following alarm or warning message is output:

Input from MDI	Warning: DATA IS OUT OF RANGE
Input by G10	Alarm PS0032: ILLEGAL OFFSET VALUE IN G10.

When 0 or a negative value is set, no maximum allowable value is applied.

Alarm and message

Number	Message	Description
PS0032	ILLEGAL OFFSET VALUE IN G10	In setting an offset amount by G10 or in writing an offset amount by system variables, the offset amount was excessive.

Warning message	Description
DATA IS OUT OF RANGE	The value searched exceeds the permitted range.

11.3 TOOL MANAGEMENT FUNCTION

11.3.1 Tool Management Function

Overview

The tool management function totally manages tool information including information about tool offset and tool life.

Explanation

A tool type number is specified with a T code. The tool type number is any number the user can define freely. With tool type numbers, tools can be grouped by various conditions such as life, compensation value, and cutting conditions. When each type is assumed to have a single tool, tool type numbers are equivalent to unique tool numbers.

For each tool, an information storage area is prepared in the CNC (SRAM). This area contains information such as a tool type number, tool life, tool status (such as a breakage condition), tool compensation number (H, D, G, or W), spindle speed (S), cutting feedrate (F), and freely-definable customize data. Such data is called tool management data.

A cartridge management table that links cartridge information and tool management data is provided so that the CNC can manage the cartridges of the machine and tool change operations. In addition, areas for managing the tools in the spindle and tool standby positions are prepared.

When a tool type number is specified using a T code command, a tool that has the tool type number and the shortest life is searched for, and the cartridge number and pot number of the location where the tool is stored are output to the PMC. Then, a tool change operation using the cartridge number and pot number is enabled by the PMC ladder sequence.

Tool information in the CNC is managed by the tool management data and cartridge management table (including the spindle management table and standby position table).

- Tool management data

As tool management data, information about a tool is registered for each data number.

Tool management function 64 sets	64 sets in total
Tool management function 240 sets	240 sets in total
Tool management function 1000 sets	1000 sets in total

Details of data

The following details the data registered for each data number:

- Tool type number (T code)

Item	Description
Data length	4byte
Valid data range	0,1 to 99,999,999

- Tool life counter

Item	Description
Data length	4byte
Unit of data	When the number of use times is specified: Times When time is specified: Seconds
Valid data range	When the number of use times is specified: 0 to 99,999,999 times When time is specified: 0 to 3,599,999 s (999 hours 59 minutes 59 seconds)

The value of an increment counter, that is, the number of use times (time) is indicated. The remaining life value is [the maximum tool life value minus tool life counter value].

- Maximum tool life value

Item	Description
Data length	4byte
Unit of data	When the number of use times is specified: Times When time is specified: Seconds
Valid data range	When the number of use times is specified: 0 to 99,999,999 times When time is specified: 0 to 3,599,999 s (999 hours 59 minutes 59 seconds)

- Notice life value

Item	Description
Data length	4byte
Unit of data	When the number of use times is specified: Times When time is specified: Seconds
Valid data range	When the number of use times is specified: 0 to 99,999,999 times When time is specified: 0 to 3,599,999 s (999 hours 59 minutes 59 seconds)

If a value other than 0 is set, the tool life expiration notice signal TLCHB <Fn064.3> or TLCHBx <Fn329.4 to 7> is output when the remaining life value of the tool (= maximum tool life value minus tool life counter value) has reached the set value.

- Tool life status

Item	Description
Data length	1byte
Detail data	0: Life management is not performed 1: Tool not yet used 2: Life remains 3: Life expired 4: Tool breakage (skip)

The machine (PMC) determines tool breakage and stores corresponding information through the window. In tool management of the CNC, a broken tool is regarded as being equivalent to tools whose lives have expired.

- Tool information

Item	Description
Data length	1 byte (flag data)
#0 RGS	0: Tool management data is invalid (-) 1: Tool management data is valid (R)

Item	Description
#1 TIM	0: Type for counting the number of use times (C) 1: Type for counting time (T)
#2 BDT	0: Normal tool (N) 1: Oversize tool (B)
#3 LOC	0: Data accessible (U) 1: Data not accessible (L)
#4 SEN	When the tool life status indicates that tool management is not performed: 0: This tool is not searched (-) 1: This tool is searched (S)
#5 to #7	Reserved

When RGS is set to 0 in tool management data, the tool management data is regarded as not being registered even when values are set for other items.

NOTE
Make sure you specify the same life count type for all tools of the same type. You can check tools of the same type for any difference in life count type, using the "check function."

M

- Tool length compensation number (H)

Item	Description
Data length	2byte
Valid data range	0 to 999

- Cutter compensation number (D)

Item	Description
Data length	2byte
Valid data range	0 to 999

T

- Tool geometry compensation number (G)

Item	Description
Data length	2byte
Valid data range	0 to 999

- Tool wear compensation number (W)

Item	Description
Data length	2byte
Valid data range	0 to 999

NOTE
When the machine control type is the combined system type, tool length compensation and cutter compensation numbers are used for paths for the machining center system, and for paths for the lathe system, tool geometry compensation and tool wear compensation numbers are used.

- Spindle speed (S)

Item	Description
Data length	4byte
Unit of data	min^{-1}

Valid data range	1 to 99,999

- Feedrate (F)

Item	Description
Data length	4byte
Unit of data	mm/min, inch/min, deg/min, mm/rev, inch/rev
Valid data range	0 to 99,999,999

As additional tool management data, areas for setting customize data (5 data items including customize data 0 and customize data 1 to 4) are provided without defining specific usage. The user can use these customize data areas freely to set a warning life value, cutting resistance, override value, spindle current value, maximum and minimum S/F, and other items according to the targeted application.

- Customize data 0

Item	Description
Data length	1 byte (bit type)
Valid data range	0 or 1 on a bit-by-bit basis

- Customize data 1 to 4 (to 20) (to 40)

Item	Description
Data length	4byte
Valid data range	-99,999,999 to 99,999,999

- Cartridge management table

The storage status of tools in cartridges is managed with the cartridge management table.

- Multiple cartridge numbers can be defined. (Numbers from 1 to 8, up to eight cartridges)
- The maximum number of pots for all cartridges is 64, 240, or 1000, which depends on whether a tool management data option is selected.
- Cartridge numbers and pot numbers can be assigned freely within cartridge management data by parameter setting (described later).
- The tool management data number adjacent to a pot number is linked with tool data defined in the tool management table. Therefore, the tool attached to the pot is indicated.
- Zero set as a data number indicates that no tool is attached.
- The cartridge management table can be read from and written to through the PMC window and FOCAS2.

The spindle management table and standby position table are provided to indicate special cartridge positions.

- Spindle positions and standby positions, regarded as special cartridge positions, have fixed cartridge numbers 11 to 14 (the positions of the first to fourth spindles) and 21 to 24 (the first to fourth standby positions).
- With the PMC window, the spindle position table and standby position table can be read from and written to.
- Tool life counting is performed only for the tools at the spindle positions.

- Multi-path system

The tool management data and cartridge management table are common data among the paths. The spindle management table and standby position table, however, are treated as independent data for each path.

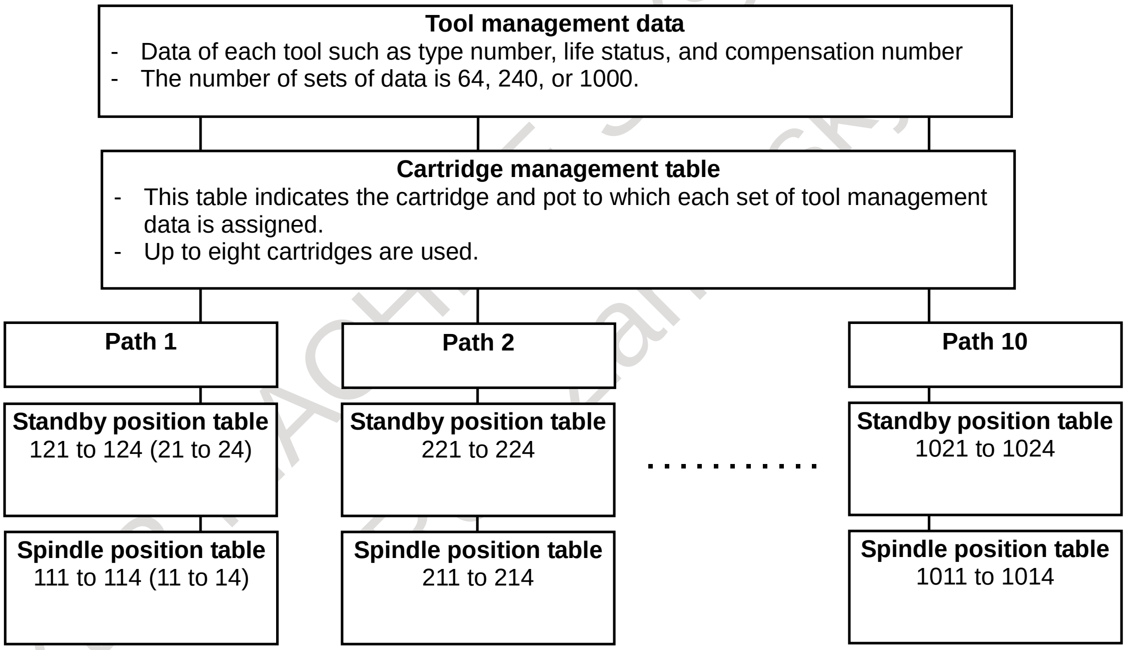
When the spindle table or standby position table is specified as a cartridge from the PMC window, specify the Table 11.3.1 (a), in which the path number is set in the hundred's place:

Table 11.3.1 (a)

	Spindle position			
	First	**Second**	**Third**	**Fourth**
First path	111(11)	112(12)	113(13)	114(14)
Second path	211	212	213	214
Third path	311	312	313	314
Fourth path	411	412	413	414

	Standby position			
	First	**Second**	**Third**	**Fourth**
First path	121(21)	122(22)	123(23)	124(24)
Second path	221	222	223	224
Third path	321	322	323	324
Fourth path	421	422	423	424

NOTE
When specifying 111, 121, and so on to specify the first path, you may specify just 11, 21, and so on.



NOTE
The tool management data and cartridge management table are data common to the M and T series.

- Tool life management and tool change

The CNC performs tool life management, regarding tools having the same tool type number as a group. When a tool type number (T code) is specified by an NC program, the tool management data registered in the CNC is searched to find a tool having the shortest life among the tools with the same tool type number.
The cartridge number and pot number corresponding to the searched tool are output as a T code signal to the PMC. Based on the output cartridge number and pot number, the PMC performs preparation for a tool change (to the next tool). A different tool can also be selected on the PMC side.
The CNC performs tool life counting for each tool that is at a spindle position in the spindle management table.

When the lives of all tools having the tool type number specified by the T code have expired, alarm PS5317, “ALL TOOL LIFE IS OVER” is issued. If there is a tool in the spindle position or standby position, that tool is selected to continue machining.
As the T code signal, a specified tool type number instead of the cartridge number and pot number can also be output directly by parameter setting.
There are two types of tool life management counting methods: counting the number of use times and counting cutting time. One of the counting methods is set in tool information of tool management data.

Other major specifications related to tool life management are as follows:
Tool type number (T code) : Up to 8 digits (1 to 99,999,999)
Maximum tool life value : 99,999,999 times when the number of use times is specified
: 999 hours 59 minutes 59 seconds when time is specified
Life count interval when time is specified : 1 second
Tool life management count restart M code : Enabled
Tool life count override : Enabled

- Examples of performing tool life management

Operation examples of tool life management are given below, in which the tool management data and cartridge management table are set as Table 11.3.1 (b):

Table 11.3.1 (b)
Tool management data

Data No.	Tool type No. (T)	Tool life counter	Maximum tool life value	Tool life status	Tool information	Tool length compensation No. (H)	Cutter compensation No. (D)
1	11111111	985	1000	Not expired	UNCR	1	1
2	11111111	0	1000	Not expired	UNCR	2	2
3	11111111	0	1000	Not expired	UNCR	3	3
4	22222222	0	2000	Not expired	UBCR	31	41

Cartridge management table

No.	Cartridge No.	Pot No.	Tool management data No.
1	1	1	3
2	1	2	12
:	:	:	:
29	1	29	2
30	1	30	1
31	2	1	11
:		:	:
63	2	29	21
64	2	30	0

Spindle management table

Spindle name	Cartridge No. (Spindle No.)	Data No.
Spindle position	11	0

Standby position table

Standby position name	Cartridge No. (Standby position No.)	Data No.
Standby position	21	0

Tool life management is explained below by using the following sample program:

```
Program example
  :
N10 T11111111 ;
  :
```

```
N80 M06 ;
  :
N200 G01 X100.0 F100.0 ;
  :
N999 M30 ;
```

- Selecting a tool having a tool type number and shortest life

The following example explains how a tool having a tool type number specified by a T code is selected:

N10 T11111111 ;

(1) Among tools whose tool type number is 11111111, a tool having the shortest life is searched for(*1). Since the tool with the shortest life is assigned tool management data number 1, the numbers of the cartridge and pot holding this tool are obtained.
    The following tools are not searched:
    - Tools not assigned to any cartridge
    - Tools whose tool life status is 0 (Life management is not performed.)(*2)
    - Tools whose tool life status is 3 (Life has expired.)
    - Tools whose tool life status is 4 (tool breakage)
    - Tools whose tool information bit 0 invalidates the tool management data
    - Tool being edited on the tool management screen
    - Tools whose tool life counter indicates the maximum tool life value.

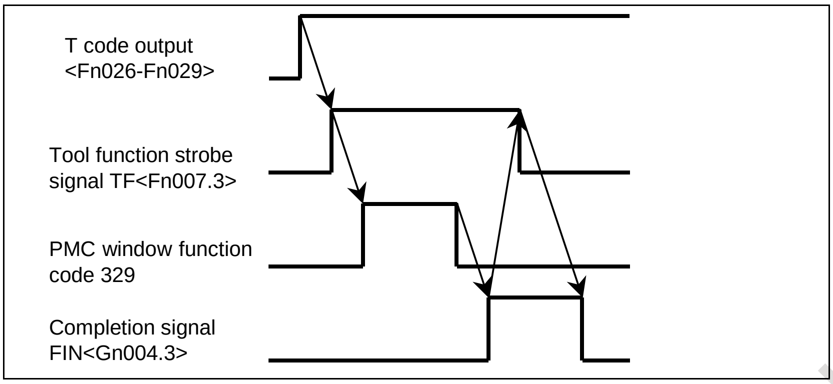
    If multiple tools have the same life value, a search is made according to the following priority:

High	Spindle position
	Standby position
Low	Cartridge

    If a cartridge contains tools having the same life value, the tool with the smaller tool management number takes priority.

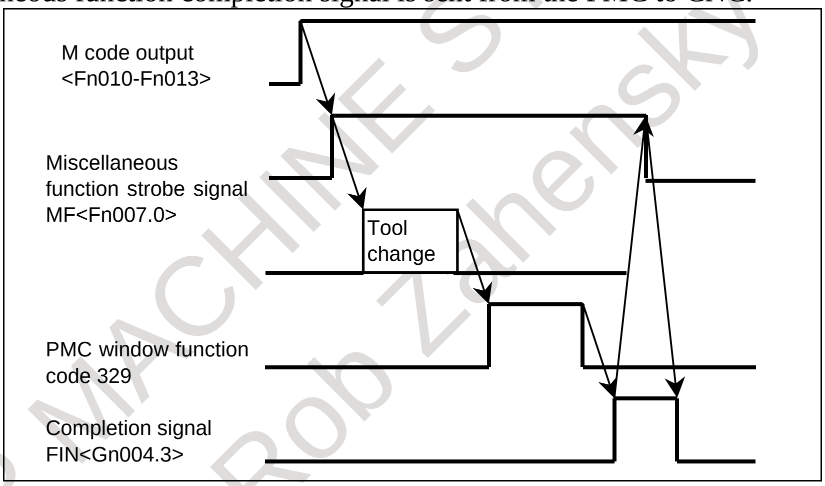
> **NOTE**
> 1 If bit 6 (SWC) of parameter No. 13203 is 1, a tool whose customize data with a customize data number specified in parameter No. 13260 is smallest is searched for instead of a tool with the shortest life.
> 2 Even when the tool life status of a tool shows that life management is not performed (= 0), the tool is targeted for a search operation if bit 4 (SEN) of its tool information is set to 1. In this case, the remaining life is not checked. The cartridge number and pot number of the tool found first are output as the search result.

(2) Since the tool with tool management data number 1 is stored at cartridge number 1 and pot number 30, binary value 0001 is output at PMC addresses <Fn026 to Fn027>, and binary value 0030 is output at <Fn028 to Fn029>.
(3) On the machine side, the tool searched for is moved to the standby position.
(4) By using the PMC window (function code 329), the tool whose cartridge number 1 and pot number 30 in the cartridge management table is moved to the standby position (cartridge number 21).



N80 M06;

(1) In response to the M06 command, M code binary value 0006 is output to PMC F addresses <Fn010 to Fn013> and the MF signal is output to <Fn007.0>.
(2) The machine performs a tool change operation, and moves the tool from the standby position to spindle position.
(3) With the PMC window (function code 329), the tools at the standby position and spindle position in the cartridge management table are changed.
(4) The CNC regards the tool moved to the spindle position (cartridge number 11) by the PMC window (function code 329) as a new tool targeted for tool life management.
(5) The miscellaneous function completion signal is sent from the PMC to CNC.



- When a tool with shortest life is attached at spindle position

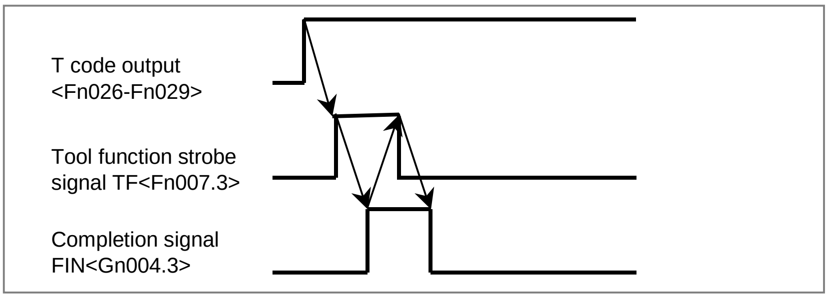
An operation example in which a T code command is issued when a tool with the shortest life is already attached at the spindle position is explained below.

Spindle name	Cartridge No. (Spindle No.)	Data No.
Spindle position	11	1

Standby position name	Cartridge No. (Standby position No.)	Data No.
Standby position	21	0

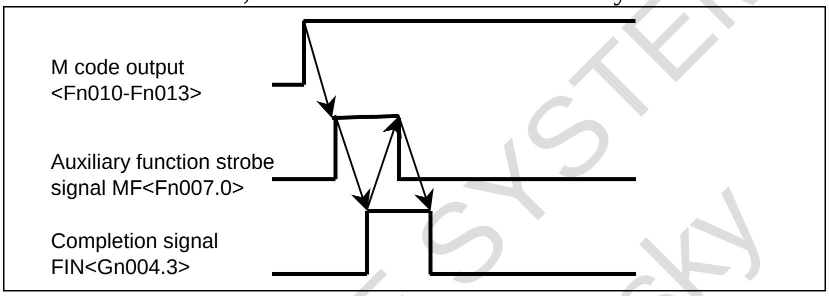
N10 T11111111 ;

(1) From the tools with tool type number 11111111, a tool with the shortest life is searched for.
(2) Since the tool with the shortest life is the tool at the spindle position (tool management data number 1), binary value 0011 is output to PMC addresses <Fn026 to Fn027>. At the addresses indicating the pot number <Fn028 to Fn029>, binary value 0000 is output.
(3) Tool function strobe signal TF is output to the PMC.
(4) Since a tool change operation is not needed, the PMC sends completion signal FIN to the CNC.



N80 M06;

(1) M code binary value 6 is output to the PMC addresses <Fn010 to Fn013>.
(2) Miscellaneous function strobe signal MF <Fn007.0> is output to the PMC.
(3) Since a tool change operation is not needed, the PMC sends completion signal FIN to the CNC.
(4) The CNC starts counting the tool life of the tool held at the spindle position. For the type for counting the number of use times, the life count is incremented by one.



- When the life of the tool being used has expired

An operation example when the tool life of the tool being used (the tool at the spindle position) has expired is explained below.

Tool management data

Data No.	Tool type No. (T)	Tool life counter	Maximum tool life value	Tool life status	Tool information	Tool length compensation No. (H)	Cutter compensation No. (D)
1	11111111	999	1000	Not expired	UNCR	1	1
2	11111111	0	1000	Not expired	UNCR	2	2
3	11111111	0	1000	Not expired	UNCR	3	3

Cartridge management table

No.	Cartridge No.	Pot No.	Tool management data No.
1	1	1	3
2	1	2	12
:	:	:	:
29	1	29	2
30	1	30	0

Spindle management table

Spindle name	Cartridge No. (Spindle No.)	Data No.
Spindle position	11	1

Standby position table

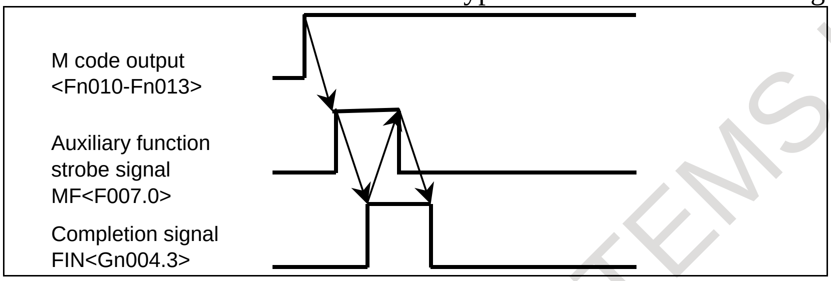
Standby position name	Cartridge No. (Standby position No.)	Data No.
Standby position	21	0

- Type for counting the number of use times

When a life is counted by counting the number of use times, the life count is incremented by one each time M06 (or an M code for restarting tool life counting or T code) is specified.

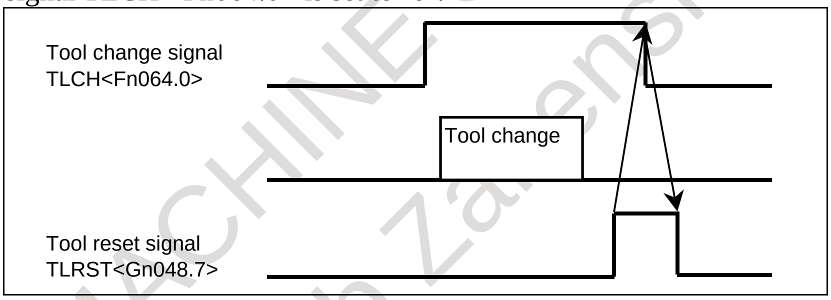
N80 M06;

(1) M code binary value 6 is output to PMC addresses <Fn010 to Fn013>.
(2) Miscellaneous function strobe signal MF <Fn007.0> is output to the PMC.
(3) Since a tool change operation has already completed, no tool change operation is performed.
(4) The PMC sends miscellaneous function completion signal FIN to the CNC.
(5) The CNC increments the life count for the tool held at the spindle position (tool management data No. 1) by one.
(6) The life count reaches 1000 (the maximum tool life), so the tool life expires.
(7) The CNC changes the tool life status for tool management data number 1 to 3 (life has expired).
(8) The CNC searches for a tool that has the same tool type number and has remaining life.



N999 M30;

(1) When the lives of all tools having the same tool type number have expired, tool change signal TLCH <Fn064.0> is set to "1" immediately even during operation.
(2) After a change to a new tool, tool reset signal TLRST <Gn048.7> is set to "1".
(3) Tool change signal TLCH <Fn064.0> is set to "0".



- Type for counting time

Operations performed when a life is counted by counting time are explained below.
Suppose that the tool management data is set as listed below.
Also suppose that the cartridge management table is the same as for the type for counting the number of use times.

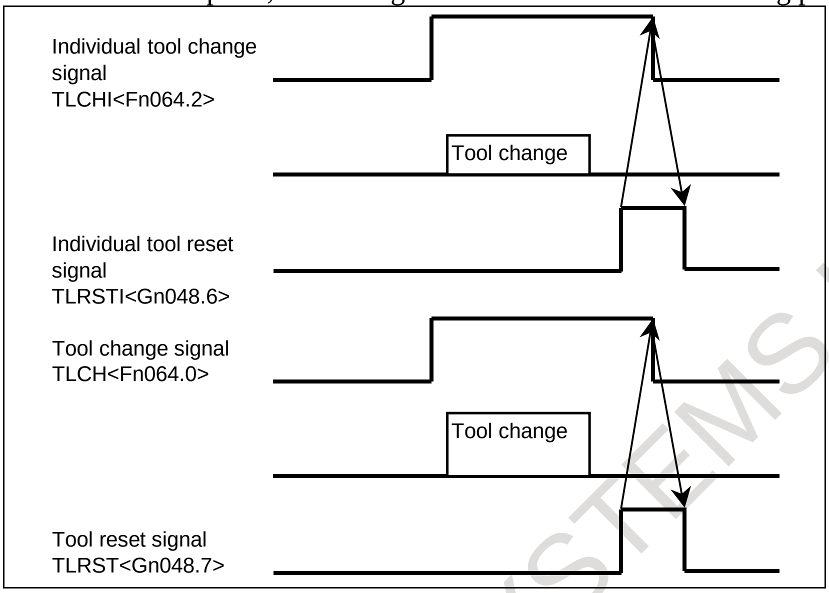
Data No.	Tool type No. (T)	Tool life counter	Maximum tool life value	Tool life status	Tool information	Tool length compensation No. (H)	Cutter compensation No. (D)
1	11111111	3300	3600	Not expired	UNTR	1	1

- N200 G01 X100.0 F100.0 ;

For the type for counting time, the time (in seconds) taken to execute such a cutting block is added to the counter value.

(1) The life count reaches 3600 seconds (the maximum tool life), and the tool life expires.
(2) The CNC changes the tool life status for tool management data number 1 to 3 (life has expired).
(3) The CNC searches for a tool that has the same tool type number and has a remaining life.
(4) Individual tool change signal TLCHI <Fn064.2> is set to "1".

(5) When the lives of all tools having the same tool type number have expired, tool change signal TLCH <Fn064.0> is set to “1“.
(6) Even when the tool life has expired, machining is continued until the machining program ends.



NOTE

Time is counted up while a cutting feed operation after the execution of M06 or a restart M code or T code is in progress. When the spindle is stopped or is rotating, the count-up operation is not performed. The target tools are the tools attached at the first to fourth spindle positions. When one of the following conditions is met, the count-up operation is not performed:

1 The tool life status indicates the invalid state (0) or breakage (4).
2 Even when a cutting feed is performed, the cutting feed is not regarded as being in progress.
   - When the system is in the FIN wait state
   - During in-position check
   - When the cutting feed override is 0%
   - When an interlock is provided
   - When the system is in the spindle speed arrival wait state

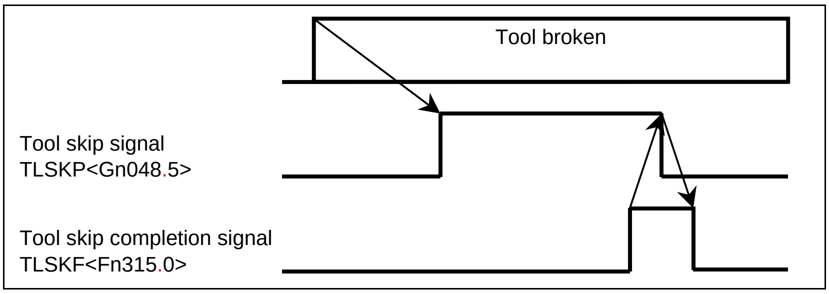
   (The above states can be confirmed from diagnosis data Nos. 000 to 013.)
   - When a machine lock is provided

- When the tool being used is broken

A tool breakage is detected by the machine and is posted to the CNC via the PMC. The PMC posts the tool breakage to the CNC in one of the following three methods:

- The tool life status is changed to 4 (tool breakage) by using the PMC window (function code 332)
- The tool life status is changed to 4 (tool breakage) by using the PMC window (function code 335).
- Tool skip signal TLSKP <Gn048.5> is set to “1“.

The tool placed in the tool breakage state is excluded from the target tools for tool life management when the next and subsequent T codes are specified.



- T code command for specifying a particular tool
