FANUC Series 0*i*-MODEL F Plus

CONNECTION MANUAL (FUNCTION)

B-64693EN-1/01

The products in this manual are controlled based on Japan's "Foreign Exchange and Foreign Trade Law". The export from Japan may be subject to an export license by the government of Japan. Further, re-export to another country may be subject to the license of the government of the country from where the product is re-exported. Furthermore, the product may also be controlled by re-export regulations of the United States government.
Should you wish to export or re-export these products, please contact FANUC for advice.

The products in this manual are manufactured under strict quality control. However, when using any of the products in a facility in which a serious accident or loss is predicted due to a failure of the product, install a safety device.

In this manual we have tried as much as possible to describe all the various matters.
However, we cannot describe all the matters which must not be done, or which cannot be done, because there are so many possibilities.
Therefore, matters which are not especially described as possible in this manual should be regarded as "impossible".

SAFETY PRECAUTIONS

This section describes the safety precautions related to the use of CNC units.
It is essential that these precautions be observed by users to ensure the safe operation of machines equipped with a CNC unit (all descriptions in this section assume this configuration). Note that some precautions are related only to specific functions, and thus may not be applicable to certain CNC units.
Users must also observe the safety precautions related to the machine, as described in the relevant manual supplied by the machine tool builder. Before attempting to operate the machine or create a program to control the operation of the machine, the operator must become fully familiar with the contents of this manual and relevant manual supplied by the machine tool builder.

DEFINITION OF WARNING, CAUTION, AND NOTE

This manual includes safety precautions for protecting the user and preventing damage to the machine. Precautions are classified into **Warning** and **Caution** according to their bearing on safety. Also, supplementary information is described as a **Note**. Read the **Warning**, **Caution**, and **Note** thoroughly before attempting to use the machine.

> ⚠ **WARNING**
> Used if a danger resulting in the death or serious injury of the user is expected to occur if he or she fails to observe the approved procedure.

> ⚠ **CAUTION**
> Used if a danger resulting in the minor or moderate injury of the user or equipment damage is expected to occur if he or she fails to observe the approved procedure.

> **NOTE**
> Used if a supplementary explanation not related to any of WARNING, and CAUTION is to be indicated.

- Read this manual carefully, and store it in a safe place.

GENERAL WARNINGS AND CAUTIONS

⚠ **WARNING**

1 Never attempt to machine a workpiece without first checking the operation of the machine. Before starting a production run, ensure that the machine is operating correctly by performing a trial run using, for example, the single block, feedrate override, or machine lock function or by operating the machine with neither a tool nor workpiece mounted. Failure to confirm the correct operation of the machine may result in the machine behaving unexpectedly, possibly causing damage to the workpiece and/or machine itself, or injury to the user.

2 Before operating the machine, thoroughly check the entered data.
Operating the machine with incorrectly specified data may result in the machine behaving unexpectedly, possibly causing damage to the workpiece and/or machine itself, or injury to the user.

3 Ensure that the specified feedrate is appropriate for the intended operation. Generally, for each machine, there is a maximum allowable feedrate.
The appropriate feedrate varies with the intended operation. Refer to the manual provided with the machine to determine the maximum allowable feedrate.
If a machine is run at other than the correct speed, it may behave unexpectedly, possibly causing damage to the workpiece and/or machine itself, or injury to the user.

4 When using a tool compensation function, thoroughly check the direction and amount of compensation.
Operating the machine with incorrectly specified data may result in the machine behaving unexpectedly, possibly causing damage to the workpiece and/or machine itself, or injury to the user.

5 The parameters for the CNC and PMC are factory-set. Usually, there is not need to change them. When, however, there is not alternative other than to change a parameter, ensure that you fully understand the function of the parameter before making any change.
Failure to set a parameter correctly may result in the machine behaving unexpectedly, possibly causing damage to the workpiece and/or machine itself, or injury to the user.

⚠ CAUTION

1 Immediately after switching on the power, do not touch any of the keys on the MDI unit until the position display or alarm screen appears on the CNC unit. Some of the keys on the MDI unit are dedicated to maintenance or other special operations. Pressing any of these keys may place the CNC unit in other than its normal state. Starting the machine in this state may cause it to behave unexpectedly.
2 The OPERATOR'S MANUAL and programming manual supplied with a CNC unit provide an overall description of the machine's functions. Note that the functions will vary from one machine model to another. Therefore, some functions described in the manuals may not actually be available for a particular model. Check the specification of the machine if in doubt.
3 Some functions may have been implemented at the request of the machine-tool builder. When using such functions, refer to the manual supplied by the machine-tool builder for details of their use and any related cautions.
4 The liquid-crystal display is manufactured with very precise fabrication technology. Some pixels may not be turned on or may remain on. This phenomenon is a common attribute of LCDs and is not a defect.

NOTE

Programs, parameters, and macro variables are stored in non-volatile memory in the CNC unit. Usually, they are retained even if the power is turned off.
Such data may be deleted inadvertently, however, or it may prove necessary to delete all data from non-volatile memory as part of error recovery.
To guard against the occurrence of the above, and assure quick restoration of deleted data, backup all vital data, and keep the backup copy in a safe place.
The number of times to write machining programs to the non-volatile memory is limited.
You must use "High-speed program management" when registration and the deletion of the machining programs are frequently repeated in such case that the machining programs are automatically downloaded from a personal computer at each machining.
In "High-speed program management", the program is not saved to the non-volatile memory at registration, modification, or deletion of programs.

WARNINGS AND CAUTIONS RELATED TO PROGRAMMING

This section covers the major safety precautions related to programming. Before attempting to perform programming, read the supplied OPERATOR'S MANUAL carefully such that you are fully familiar with their contents.

⚠ **WARNING**

1 **Coordinate system setting**
If a coordinate system is established incorrectly, the machine may behave unexpectedly as a result of the program issuing an otherwise valid move command. Such an unexpected operation may damage the tool, the machine itself, the workpiece, or cause injury to the user.

2 **Positioning by nonlinear interpolation**
When performing positioning by nonlinear interpolation (positioning by nonlinear movement between the start and end points), the tool path must be carefully confirmed before performing programming. Positioning involves rapid traverse. If the tool collides with the workpiece, it may damage the tool, the machine itself, the workpiece, or cause injury to the user.

3 **Function involving a rotation axis**
When programming normal-direction (perpendicular) control, pay careful attention to the speed of the rotation axis. Incorrect programming may result in the rotation axis speed becoming excessively high, such that centrifugal force causes the chuck to lose its grip on the workpiece if the latter is not mounted securely. Such mishap is likely to damage the tool, the machine itself, the workpiece, or cause injury to the user.

4 **Inch/metric conversion**
Switching between inch and metric inputs does not convert the measurement units of data such as the workpiece origin offset, parameter, and current position. Before starting the machine, therefore, determine which measurement units are being used. Attempting to perform an operation with invalid data specified may damage the tool, the machine itself, the workpiece, or cause injury to the user.

5 **Constant surface speed control**
When an axis subject to constant surface speed control approaches the origin of the workpiece coordinate system, the spindle speed may become excessively high. Therefore, it is necessary to specify a maximum allowable speed. Specifying the maximum allowable speed incorrectly may damage the tool, the machine itself, the workpiece, or cause injury to the user.

6 **Stroke check**
After switching on the power, perform a manual reference position return as required. Stroke check is not possible before manual reference position return is performed. Note that when stroke check is disabled, an alarm is not issued even if a stroke limit is exceeded, possibly damaging the tool, the machine itself, the workpiece, or causing injury to the user.

⚠ **WARNING**

7 **Tool post interference check**
A tool post interference check is performed based on the tool data specified during automatic operation. If the tool specification does not match the tool actually being used, the interference check cannot be made correctly, possibly damaging the tool or the machine itself, or causing injury to the user. After switching on the power, or after selecting a tool post manually, always start automatic operation and specify the tool number of the tool to be used.

8 **Same address command in same block**
The G code or M code including the same address cannot be commanded on the same block. If you use the same address, it may result in the machine behaving unexpectedly, possibly causing damage to the workpiece and/or machine itself, or injury to the user. Command on separate block.（About address P, refer to the appendix “List of functions include address P in the program command”）

⚠ **CAUTION**

1 **Absolute/incremental mode**
If a program created with absolute values is run in incremental mode, or vice versa, the machine may behave unexpectedly.

2 **Plane selection**
If an incorrect plane is specified for circular interpolation, helical interpolation, or a canned cycle, the machine may behave unexpectedly. Refer to the descriptions of the respective functions for details.

3 **Torque limit skip**
Before attempting a torque limit skip, apply the torque limit. If a torque limit skip is specified without the torque limit actually being applied, a move command will be executed without performing a skip.

4 **Programmable mirror image**
Note that programmed operations vary considerably when a programmable mirror image is enabled.

5 **Compensation function**
If a command based on the machine coordinate system or a reference position return command is issued in compensation function mode, compensation is temporarily canceled, resulting in the unexpected behavior of the machine. Before issuing any of the above commands, therefore, always cancel compensation function mode.

WARNINGS AND CAUTIONS RELATED TO HANDLING

This section presents safety precautions related to the handling of machine tools. Before attempting to operate your machine, read the supplied OPERATOR'S MANUAL carefully, such that you are fully familiar with their contents.

⚠ **WARNING**

1 **Manual operation**
When operating the machine manually, determine the current position of the tool and workpiece, and ensure that the movement axis, direction, and feedrate have been specified correctly. Incorrect operation of the machine may damage the tool, the machine itself, the workpiece, or cause injury to the operator.

2 **Manual reference position return**
After switching on the power, perform manual reference position return as required.
If the machine is operated without first performing manual reference position return, it may behave unexpectedly. Stroke check is not possible before manual reference position return is performed.
An unexpected operation of the machine may damage the tool, the machine itself, the workpiece, or cause injury to the user.

3 **Manual handle feed**
In manual handle feed, rotating the handle with a large scale factor, such as 100, applied causes the tool and table to move rapidly. Careless handling may damage the tool and/or machine, or cause injury to the user.

4 **Disabled override**
If override is disabled (according to the specification in a macro variable) during threading, rigid tapping, or other tapping, the speed cannot be predicted, possibly damaging the tool, the machine itself, the workpiece, or causing injury to the operator.

5 **Origin/preset operation**
Basically, never attempt an origin/preset operation when the machine is operating under the control of a program. Otherwise, the machine may behave unexpectedly, possibly damaging the tool, the machine itself, the tool, or causing injury to the user.

6 **Workpiece coordinate system shift**
Manual intervention, machine lock, or mirror imaging may shift the workpiece coordinate system. Before attempting to operate the machine under the control of a program, confirm the coordinate system carefully.
If the machine is operated under the control of a program without making allowances for any shift in the workpiece coordinate system, the machine may behave unexpectedly, possibly damaging the tool, the machine itself, the workpiece, or causing injury to the operator.

⚠ **WARNING**

7 **Software operator's panel and menu switches**
Using the software operator's panel and menu switches, in combination with the MDI unit, it is possible to specify operations not supported by the machine operator's panel, such as mode change, override value change, and jog feed commands.
Note, however, that if the MDI unit keys are operated inadvertently, the machine may behave unexpectedly, possibly damaging the tool, the machine itself, the workpiece, or causing injury to the user.

8 **RESET key**
Pressing the RESET key stops the currently running program. As a result, the servo axes are stopped. However, the RESET key may fail to function for reasons such as an MDI unit problem. So, when the motors must be stopped, use the emergency stop button instead of the RESET key to ensure security.

⚠ **CAUTION**

1 **Manual intervention**
If manual intervention is performed during programmed operation of the machine, the tool path may vary when the machine is restarted. Before restarting the machine after manual intervention, therefore, confirm the settings of the manual absolute switches, parameters, and absolute/incremental command mode.

2 **Feed hold, override, and single block**
The feed hold, feedrate override, and single block functions can be disabled using custom macro system variable #3004. Be careful when operating the machine in this case.

3 **Dry run**
Usually, a dry run is used to confirm the operation of the machine. During a dry run, the machine operates at dry run speed, which differs from the corresponding programmed feedrate. Note that the dry run speed may sometimes be higher than the programmed feed rate.

4 **Program editing**
If the machine is stopped, after which the machining program is edited (modification, insertion, or deletion), the machine may behave unexpectedly if machining is resumed under the control of that program. Basically, do not modify, insert, or delete commands from a machining program while it is in use.

WARNINGS RELATED TO PARAMETERS

⚠ **WARNING**

1 When machining a workpiece for the first time after modifying a parameter, close the machine cover. Never use the automatic operation function immediately after such a modification. Instead, confirm normal machine operation by using functions such as the single block function, feedrate override function, and machine lock function, or by operating the machine without mounting a tool and workpiece. If the machine is used before confirming that it operates normally, the machine may move unpredictably, possibly damaging the machine or workpiece, and presenting a risk of injury.

2 The CNC and PMC parameters are set to their optimal values, so that those parameters usually need not be modified. When a parameter must be modified for some reason, ensure that you fully understand the function of that parameter before attempting to modify it. If a parameter is set incorrectly, the machine may move unpredictably, possibly damaging the machine or workpiece, and presenting a risk of injury.

WARNINGS RELATED TO EDIT SCREENS FOR TOUCH PANEL

⚠ **WARNING**

FANUC’s touch panel is an analog resistive film type. When two or more points are pressed at the same time, there is a possibility that it behaves as if the center of these points was pressed, and this wrong output or malfunction may cause an accident. Do not create a virtual machine operator’s panel screens on which two or more points are pressed at the same time for touch panel operation.

On the virtual machine operator panel screen, never support safety-related operations that may lose human life or may cause serious damage, or real-time operations such as emergency stop, program start, program stop, axis movements, etc. If there is a failure in the CNC, peripheral units, or cable, wrong outputs or malfunctions may cause an accident. In addition, real-time operation is not guaranteed on the touch panel screen.

GENERAL WARNINGS FOR CNC APPLICATION DEVELOPMENT

⚠ WARNING

Be careful enough for the following warnings when you develop two or more applications or use networks.
If you neglect them, machine may behave in an unexpected working and tool, work piece, and machine may be damaged. In the worst case, there is an operator's extreme risk of death or serious injury.

1 Be careful enough if you write an identical NC data, an identical PMC data or a series of related data set by two or more above applications including network functions. Because they are executed based on each individual cycles (in other words, asynchronous cycles), there is a possibility that the data will be written in an unexpected order.

   Therefore, do NOT write above data in the following cases.
   - Applications and network functions
   - Two or more applications
   - Two or more network functions

   Data, applications and network functions of interest are listed in below. However, all may not be listed completely because new features will be added in the future.

2 Be careful enough that you must prevent PMC signals in the same byte from being written by the following two or more applications including network functions. While an application reads and writes one byte of PMC signals, other applications may write the same byte.

3 Be careful enough if you process a PMC signal set that is related to a NC function by using the following two or more applications including network functions. Because they are executed based on each individual cycles (in other words, asynchronous cycles), there is a possibility that the NC may receive the PMC signal set in an unexpected order.

4 Generally, when multi-byte data are read or written at once among the following two or more applications including network functions, the coherency of the read multi-byte data (in other words, reading all latest data at once) is not guaranteed. To ensure the coherency of the multi-byte data, prepare flags to notify the completion of reading or writing process that is separated from the entity of the data and make the handshaking process to access the data by using the flags.

⚠ **WARNING**

Data List Table

Category	Data
General data for NC	Parameter, Tool compensation value and related data, Work zero offset value and related data, Workpiece coordinate system shift value and related data, Macro variable, P-CODE variable, Program and related data, Tool management function data, Tool life management data, Error compensation related data , Overtravel check (Interference check) related data , Software operator's panel related data
PMC data	PMC signal, PMC parameter
Data for Laser, Punch press or Wire cut	Tool data for punch press and related data, Safety zone data and related data, Laser cutting condition data and related data, Laser oscillator setting data and related data, Wire consumption compensation data, Guide position compensation data, Workpiece leveling data
Other data	Parameters for Data Server, Parameters for network setting

List Table of Applications and Network Functions

Category	Functions
Applications	PMC Ladder, Macro Executor, C Language Executor, FANUC PICTURE, FOCAS2
Network functions	FL-net, EtherNet/IP, PROFINET, Modbus/TCP, PROFIBUS-DP, DeviceNet, CC-Link

5 CNC has functions that read or write PMC signals in other than the G/F address. Be careful enough if the above mentioned applications and network read or write PMC signals used by these functions. When reading or writing the same PMC signal, applications or CNC functions may work in an unexpected manner.
As for the CNC functions of interest, refer to the connection manual (Function) (B-64693EN-1) "Appendix B. List of Functions Using PMC Signals Other Than G/F Address".

WARNINGS RELATED TO DAILY MAINTENANCE

⚠ **WARNING**

1 **Memory backup battery replacement**
When replacing the memory backup batteries, keep the power to the machine (CNC) turned on, and apply an emergency stop to the machine. Because this work is performed with the power on and the cabinet open, only those personnel who have received approved safety and maintenance training may perform this work.
When opening the cabinet and replacing the batteries, be careful not to touch the high-voltage circuits (marked ⚠ and fitted with an insulating cover). Touching the uncovered high-voltage circuits presents an extremely dangerous electric shock hazard.

NOTE

The CNC uses batteries to preserve the contents of its memory, because it must retain data such as programs, offsets, and parameters even while external power is not applied.
If the battery voltage drops, a low battery voltage alarm is displayed on the machine operator's panel or screen.
When a low battery voltage alarm is displayed, replace the batteries within a week. Otherwise, the contents of the CNC's memory will be lost.
Refer to the Section “Method of replacing battery” in the OPERATOR’S MANUAL (Common to T/M series) for details of the battery replacement procedure.

⚠ **WARNING**

2 **Absolute pulse coder battery replacement**

When replacing the memory backup batteries, keep the power to the machine (CNC) turned on, and apply an emergency stop to the machine. Because this work is performed with the power on and the cabinet open, only those personnel who have received approved safety and maintenance training may perform this work.
When opening the cabinet and replacing the batteries, be careful not to touch the high-voltage circuits (marked ⚠ and fitted with an insulating cover).
Touching the uncovered high-voltage circuits presents an extremely dangerous electric shock hazard.

NOTE

The absolute pulse coder uses batteries to preserve its absolute position.
If the battery voltage drops, a low battery voltage alarm is displayed on the machine operator's panel or screen.
When a low battery voltage alarm is displayed, replace the batteries within a week. Otherwise, the absolute position data held by the pulse coder will be lost.
Refer to the FANUC SERVO MOTOR αi series Maintenance Manual for details of the battery replacement procedure.

⚠ **WARNING**

3 **Fuse replacement**

Before replacing a blown fuse, however, it is necessary to locate and remove the cause of the blown fuse.
For this reason, only those personnel who have received approved safety and maintenance training may perform this work.
When replacing a fuse with the cabinet open, be careful not to touch the high-voltage circuits (marked ⚠ and fitted with an insulating cover).
Touching an uncovered high-voltage circuit presents an extremely dangerous electric shock hazard.

⚠ **WARNING**

4 When using the controller unit, display unit, MDI unit, or machine operator's panel, prevent these units from directly exposing to chips or coolants. Even if direct exposure to coolants is prevented, coolants containing sulfur or chlorine at a high activation level, oil-free synthetic-type coolants, or water-soluble coolants at a high alkali level particularly have large effects on the control unit and peripheral units, possibly causing the following failures.

- Coolants containing sulfur or chlorine at a high activation level
  Some coolants containing sulfur or chlorine are at an extremely high activity level. If such a coolant adheres to the CNC or peripheral units, it reacts chemically with a material, such as resin, of equipment, possibly leading to corrosion or deterioration. If it gets in the CNC or peripheral units, it corrodes metals, such as copper and silver, used as component materials, possibly leading to a defective component.
- Synthetic-type coolants having a high permeability
  Some synthetic-type coolants whose lubricating component is, for example, PAG (polyalkylene glycol) have an extremely high permeability. If such a coolant is used even in equipment having a high closeness, it can readily flow into the CNC or peripheral units through, for example, gaskets. It is likely that, if the coolant gets in the CNC or a peripheral unit, it may deteriorate the insulation and damage the components.
- Water-soluble coolants at a high alkali level
  Some coolants whose pH is increased using alkanolamine are so strong alkali that its standard dilution will lead to pH10 or higher. If such a coolant spatters over the surface of the CNC or peripheral unit, it reacts chemically with a material, such as resin, possibly leading to corrosion or deterioration.

PREFACE

Organization of this manual

This manual describes all the NC functions required to enable machine tool builders to design their CNC machine tools. The following items are explained for each function.

1. Overview

Describes feature of the function. Refer to Operator’s Manual as required.

2. Signal

Describes names, functions, output conditions and addresses of the signals required to realize a function.

3. Parameter

Describes parameters related with a function.

4. Alarms and message

Lists the alarms and messages related with a function in a table.

5. Reference item

List the related items of the related manuals in a table.

A list of addresses of all signals and a list of signals are described in the appendix of this manual. Refer to it as required.

Applicable models

The models covered by this manual, and their abbreviations are :

Model name	Abbreviation		
FANUC Series 0*i*-TF Plus	0*i*-TF Plus	Series 0*i*-F Plus	Series 0*i*
FANUC Series 0*i*-MF Plus	0*i*-MF Plus		

> **NOTE**
> 1 For an explanatory purpose, the following descriptions may be used according to the CNC model :
> - 0*i*-TF Plus : Lathe system (T series)
> - 0*i*-MF Plus : Machining center system (M series)
>
> 2 Some functions described in this manual may not be applied to some products. For details, refer to the DESCRIPTIONS (B-64692EN). ".

Description of symbols

The following symbols are used in this manual. These symbols are described below.

- M

Indicates a description that is valid only for the machine center system (M series).
In a general description of the method of machining, a machining center system operation is identified by a phase such as "for milling machining".

- T

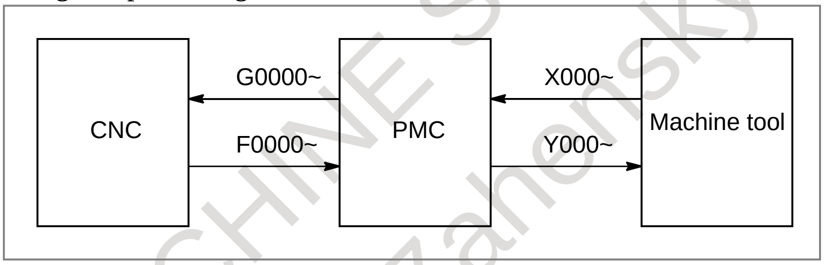
Indicates a description that is valid only for the lathe system (T series).
In a general description of the method of machining, a lathe system operation is identified by a phrase such as "for lathe cutting".

-

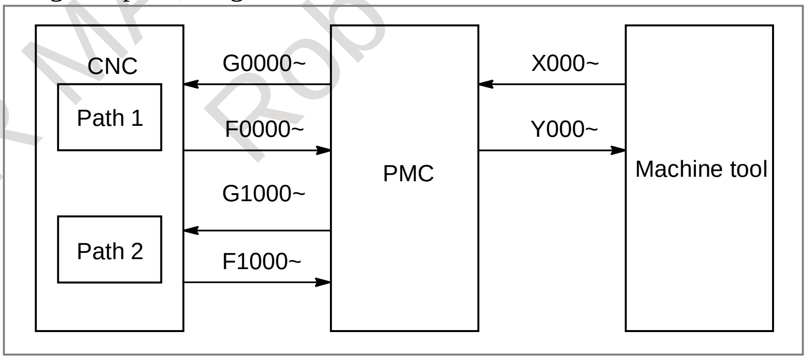
Indicates the end of a description of a system control type.
When a system control type mark mentioned above is not followed by this mark, the description of the system control type is assumed to continue until the next item or paragraph begins. In this case, the next item or paragraph provides a description common to the control types.

Description of signals

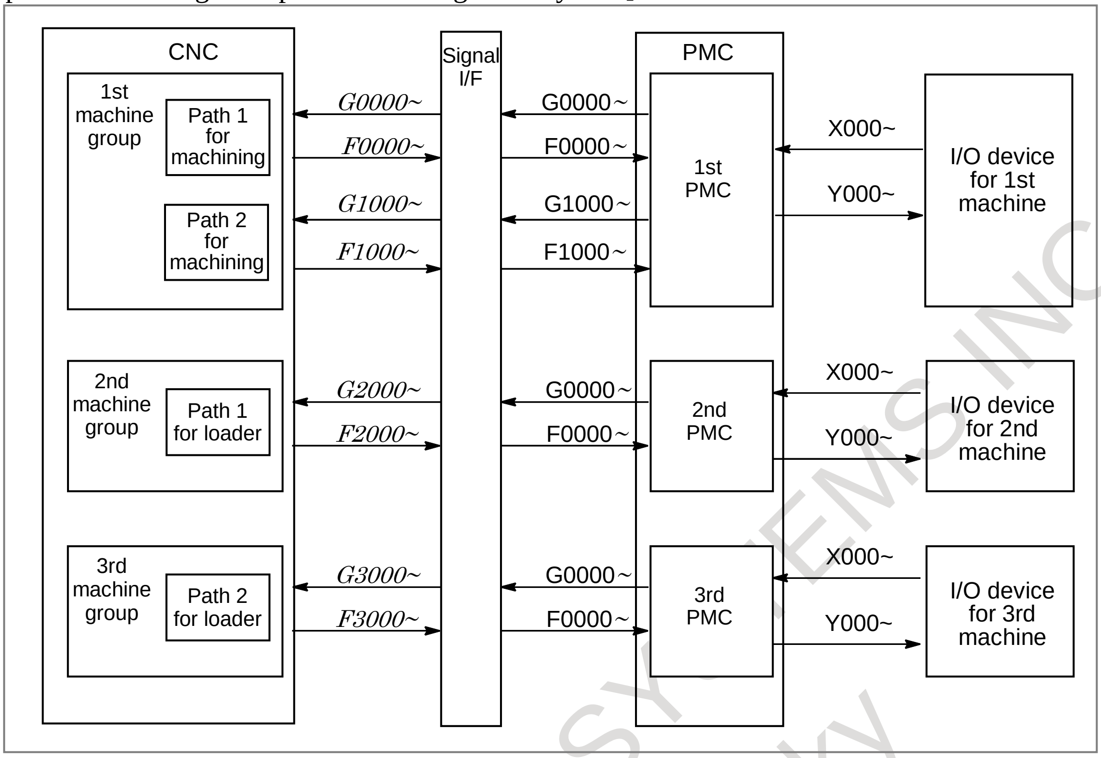
[Example of controlling one path using one PMC]



[Example of controlling two path using one PMC]



[Example of controlling multipath CNC using PMC system]



> **NOTE**
> Each PMC of a multipath PMC system has an independent signal area. The F, G, X, and Y signal addresses of each PMC begin with 0. On the other hand, the F and G signal addresses from the viewpoint of the CNC are fixed for each path number. Note that the F and G signal addresses used in programming of each ladder are different from those from the viewpoint of the CNC.

- Expression of signals

Address / Symbol (#0 to #7 indicates bit position)

Address	#7	#6	#5	#4	#3	#2	#1	#0
Fn000	OP	SA	STL	SPL				RWD

In an item where both lathe system (T series) and machining center system (M series) are described, some signals are covered with shade ( ) in the signal address figure as shown below. This means either lathe system or machining center system does not have this signal. Upper part is for lathe system and lower part is for machining center system.

	#7	#6	#5	#4	#3	#2	#1	#0	
Gn053	*CDZ		ROVLP		UINT			TMRON	T series M series

[Example 1]

The figure above indicates *CDZ is provided only for the lathe system while the other signals for both the lathe system (T series) and machining system (M series).

	#7	#6	#5	#4	#3	#2	#1	#0	
Gn040					OFN9	OFN8	OFN7	OFN6	T series M series

[Example 2]

Signals OFN6 to OFN9 are for machining center system (M series) only.

NOTE

1 The following notational conventions are used in the signal description of each function.

Example) Axis moving signals MV1 to MV8 <Fn102>

↑ ↑ ↑

Signal name Symbol name Signal address

2 For multipath control, one of the following superscripts is attached to the top right of a symbol depending on the signal type.
- Path type (for path 1 on PMC side) : #1
- Path type (for path 2 on PMC side) : #2
- Path type (for path 3 on PMC side) : #3
- Path type : #P
- Controlled axis type : #SV
- Spindle type : #SP
- PMC axis control group type : #PX

Refer to Appendix “List of Addresses“ for details

3 For the signals, a single data number is assigned to 8 bits. Each bit has a different meaning.

4 The letter "n" in each address representation indicates the address position used in each path on the CNC side, as shown below.

1st path : n=0 (No. 0 to 999)
2nd path : n=1 (No. 1000 to 1999)
3rd path : n=2 (No. 2000 to 2999)

5 For a signal of controlled axis type, when the number of axes exceeds eight for each path, set parameter No.3021 to address this situation.

Description of parameters

Parameters are classified by data type as follows:

Data type	Valid data range	Remarks
Bit Bit machine group Bit path Bit axis Bit spindle	0 or 1	
Byte Byte machine group Byte path Byte axis Byte spindle	-128 to 127 0 to 255	Some parameters handle these types of data as unsigned data.
Word Word machine group Word path Word axis Word spindle	-32768 to 32767 0 to 65535	Some parameters handle these types of data as unsigned data.
2-word 2-word machine group 2-word path 2-word axis 2-word spindle	0 to ±999999999	Some parameters handle these types of data as unsigned data.
Real Real machine group Real path Real axis Real spindle	See the Standard Parameter Setting Tables.	

NOTE

1. Each of the parameters of the bit, bit machine group, bit path, bit axis, and bit spindle types consists of 8 bits for one data number (parameters with eight different meanings).
2. For machine group types, parameters corresponding to the maximum number of machine groups are present, so that independent data can be set for each machine group.
3. For path types, parameters corresponding to the maximum number of paths are present, so that independent data can be set for each path.
4. For axis types, parameters corresponding to the maximum number of control axes are present, so that independent data can be set for each control axis.
5. For spindle types, parameters corresponding to the maximum number of spindles are present, so that independent data can be set for each spindle axis.
6. The valid data range for each data type indicates a general range. The range varies according to the parameters. For the valid data range of a specific parameter, see the explanation of the parameter.

- Standard parameter setting tables

This section defines the standard minimum data units and valid data ranges of the CNC parameters of the real type, real machine group type, real path type, real axis type, and real spindle type. The data type and unit of data of each parameter conform to the specifications of each function.

(A) Length and angle parameters (type 1)

Unit of data	Increment system	Minimum data unit	Valid data range
mm deg.	IS-A	0.01	-999999.99 to +999999.99
	IS-B	0.001	-999999.999 to +999999.999
	IS-C	0.0001	-99999.9999 to +99999.9999
inch	IS-A	0.001	-99999.999 to +99999.999
	IS-B	0.0001	-99999.9999 to +99999.9999
	IS-C	0.00001	-9999.99999 to +9999.99999

(B) Length and angle parameters (type 2)

Unit of data	Increment system	Minimum data unit	Valid data range
mm deg.	IS-A	0.01	0.00 to +999999.99
	IS-B	0.001	0.000 to +999999.999
	IS-C	0.0001	0.0000 to +99999.9999
inch	IS-A	0.001	0.000 to +99999.999
	IS-B	0.0001	0.0000 to +99999.9999
	IS-C	0.00001	0.00000 to +9999.99999

(C) Velocity and angular velocity parameters

Unit of data	Increment system	Minimum data unit	Valid data range
mm/min deg/min	IS-A	0.01	0.0 to +999000.00
	IS-B	0.001	0.0 to +999000.000
	IS-C	0.0001	0.0 to +99999.9999
inch/min	IS-A	0.001	0.0 to +96000.000
	IS-B	0.0001	0.0 to +9600.0000
	IS-C	0.00001	0.0 to +4000.00000

If bit 7 (IESP) of parameter No. 1013 is set to 1, the valid data ranges for IS-C are extended as follows:

Unit of data	Increment system	Minimum data unit	Valid data range
mm/min deg/min	IS-C	0.001	0.000 to +999000.000
inch/min	IS-C	0.0001	0.0000 to +9600.0000

(D) Acceleration and angular acceleration parameters

Unit of data	Increment system	Minimum data unit	Valid data range
mm/sec^2 deg./sec^2	IS-A	0.01	0.00 to +999999.99
	IS-B	0.001	0.000 to +999999.999
	IS-C	0.0001	0.0000 to +99999.9999
inch/sec^2	IS-A	0.001	0.000 to +99999.999
	IS-B	0.0001	0.0000 to +99999.9999
	IS-C	0.00001	0.00000 to +9999.99999

If bit 7 (IESP) of parameter No. 1013 is set to 1, the valid data ranges for IS-C are extended as follows:

Unit of data	Increment system	Minimum data unit	Valid data range
mm/min deg/min	IS-C	0.001	0.000 to +999999.999
inch/min	IS-C	0.0001	0.0000 to +99999.9999

⚠ CAUTION

1. Values are rounded up or down to the nearest multiples of the minimum data unit.
2. A valid data range means data input limits, and may differ from values representing actual performance.
3. For information on the ranges of commands to the CNC, refer to Appendix D, "Range of Command Value" of the Operator’s Manual (B-64694EN).

- Parameters of the bit type, bit machine group type, bit path type, bit axis type, and bit spindle type

Data No.	#7	#6	#5	#4	#3	#2	#1	#0
0000			SEQ			INI	ISO	TVC

Data (Data #0 to #7 are bit positions.)

- Parameters other than the bit-type parameters above

Data No.	Data
1023	Number of the servo axis for each axis

NOTE

1 The bits left blank in “description of parameters” and parameter numbers that appear on the display but are not found in the parameter list are reserved for future expansion. They must always be 0.

2 A parameter usable with only one path control type, namely, the lathe system (T series) or the machining center system (M series), is indicated using two rows as shown below. When a row is blank, the parameter is not usable with the corresponding series.

[Example 1]

Parameter HTG is a parameter common to the lathe system (T series) or the machining center system (M series), but Parameters RTV and ROC are parameters valid only for the lathe system (T series).

	#7	#6	#5	#4	#3	#2	#1	#0	
1403	RTV		HTG	ROC					T series
			HTG						M series

[Example 2]

The following parameter is provided only for the machining center system (M series).

1411		T series
	Cutting feedrate	M series

3 When "to" is inserted between two parameter numbers, there are parameters with successive numbers between the two starting and ending parameter numbers, but those intermediate parameter numbers are omitted for convenience.

4 The lower-case letter "x" or "s" following the name of a bit-type parameter indicates the following:

- ”□□□x” : Bit axis type parameters
- ”○○○s” : Bit spindle type parameters

The above servo motors and the corresponding spindles can be connected to the CNC covered in this manual.
This manual mainly assumes that the FANUC SERVO MOTOR α*i* series of servo motor is used. For servo motor and spindle information, refer to the manuals for the servo motor and spindle that are actually connected.

Notes on various kinds of data

NOTE

Machining programs, parameters, macro variables, etc. are stored in the CNC unit internal non-volatile memory. In general, these contents are not lost by the switching ON/OFF of the power. However, it is possible that a state can occur where precious data stored in the non-volatile memory has to be deleted, because of inadvertent erasing, or by a failure restoration. In order to restore rapidly when this kind of mishap occurs, it is recommended that you create a copy of the various kinds of data beforehand.
The number of times to write machining programs to the non-volatile memory is limited.
You must use "High-speed program management" when registration and the deletion of the machining programs are frequently repeated in such case that the machining programs are automatically downloaded from a host computer at each machining.
In "High-speed program management", the program is not saved to the non-volatile memory at registration, modification, or deletion of programs.
Please make the application software by using FOCAS2/ C Language Library to save the changed programs to the non-volatile memory when "High-speed program management" is used.

TABLE OF CONTENTS

APPENDIX

1 AXIS CONTROL

1.1 CONTROLLED AXIS

Overview

The axis composition of Series 0*i*-F Plus is as shown in Table1.1 (a). "Total number of control axes" is sum of "Number of feed axes" and "Number of spindle axes".

Table1.1 (a) Axis composition of Series 0*i*-F Plus

Item		Series 0*i*-MF Plus			Series 0*i*-TF Plus		
		Type 0 Type 1 1-path system	Type 0 Type 1 2-path system	Type 3 Type 5	Type 0 Type 1 1-path system	Type 0 Type 1 2-path system	Type 3 Type 5
Maximum total number of control axes (total/each path)		9 axes	11 axes/ 9 axes	6 axes	9 axes	11 axes/ 9 axes	6 axes
Maximum number of feed axes *1 (total/each path)	Basic	5 axes	8 axes/ 5 axes	5 axes	4 axes	8 axes/5 axes	4 axes
	Controllable axes expansion	7 axes	9 axes/ 7 axes	-	7 axes	9 axes/7 axes	5 axes
Maximum number of spindle axes (total/each path)	Basic	2 axes	2 axes/ 2 axes	1 axis	2 axes	2 axes/2 axes	1 axis
	Spindle axes expansion	-	4 axes/ 3 axes	-	3 axes	4 axes/3 axes	2 axes
Simultaneously controlled axes (each path)		4 axes in the time	4 axes in the time	4 axes in the time	4 axes in the time	4 axes in the time	4 axes in the time
PMC axis control *2 (total)		4 axes int the time	8 axes in the time	4 axes int the time	4 axes int the time	8 axes in the time	4 axes int the time
Number of connected servo motors*3 (HRV3 control/HRV2 control)		10/12	10/12	5	10/12	10/12	5

*1: With PMC Axis. Without "Cs Contour control Axis" and "Spindle control axis with servo motor".
*2: Without "Cs Contour control Axis"
*3: Different according to the main-board.
Total of all path including loader path.
The following are included.
- Servo axis(Including PMC Axis)
- Spindle Control axis with Servo Motor
- EGB dummy axis
- Serial feedback dummy axis

> **NOTE**
> 1. "Controllable axes expansion" and "Spindle axes expansion" are optional function.
> 2. The number of connected servo motors is different according to the main-board.

Whether it is counted by feed-axes/spindle-axes is decided depending on the kind of each axis/spindle. How to count axis/spindle is as shown in Table1.1 (b).

Table1.1 (b) How to count axis/spindle

Item		Number of Feed Axes	Number of Spindle Axes	Total Number of Control Axes (Number of Feed Axes + Number of Spindle Axes)	Number of Connected Servo Motors
Servo Axis(including PMC Axis)		1	0	1	1
Analog Spindle*1		0	1	1	0
Serial Spindle		0	1	1	0
Cs Contour Control	Cs Axis	0	1	1	0
	Virtual Cs Axis*2*3	0	0	0	0
Axis that is controlled by "Spindle Control with Servo Motor"		0	1	1	1
EGB Dummy Axis*3		0	0	0	1*4
Serial Feedback Dummy Axis*3		0	0	0	1*4

*1: Up to 1 axis in the total.
*2: Up to 2 axes in the total. Up to 1 axes in each path.
*3: The total of the following numbers of axes is up to 3 axes in the total.
- Virtual Cs axis
- EGB dummy axis
- Serial feedback dummy axis
*4: It is counted by the number of connected servo motors though the motor is not connected.

Loader Path

When the loader control function is used, the loader path can be used.
In the loader path, the servo axis can be used up to 3 axes. Other axis/spindle cannot be used.
The axis in the loader path is contained in the number of connected servo motors. Refer to Table1.1 (a) for the maximum number of connected servo motors.
The axis in the loader path is not contained in the "Total number of control axes" and "Number of feed axes".

> **NOTE**
> "Function for loader control" is optional function. The number of the usable loader path is different depending on the option composition.

Alarm and message

Number	Message	Description
PS0015	TOO MANY SIMULTANEOUS AXES	A move command was specified for more axes than can be controlled by simultaneous axis control. Either add on the simultaneous axis control extension option, or divide the number of programmed move axes into two blocks.
DS0050	TOO MANY SIMULTANEOUS AXES	A movement was performed along more axes than can be controlled by simultaneous axis control. Check whether a command in the program is specified for more axes than can be controlled by simultaneous axis control.

CONNECTION MANUAL (FUNCTION) (This manual)	Multipath control

1.2 SETTING EACH AXIS

1.2.1 Name of Axes

Overview

Each axis that is controlled by the CNC (including those controlled by the PMC) must be named.
To name an axis, select a desired character from among A, B, C, U, V, W, X, Y, and Z and set the character as the first axis name character (parameter No. 1020).

> **NOTE**
> 1 The same axis name cannot be assigned to more than one axis. (The same axis name can be used on different paths.)
> 2 With the lathe system, when G code system A is used, neither U, V, nor W can be used as an axis name. Only when G code system B or C is used, U, V, and W can be used as axis names.
> 3 When a multiple repetitive canned cycle is used, only X, Y, or Z can be used as the address of a target axis.

- Extended axis name

The extended axis name function can be used to use an axis name consisting of up to three characters.
To use an extended axis name:
<1> Enables the extended axis name function (bit 0 (EEA) of parameter No. 1000 is set to 1).
<2> Set the first character (A, B, C, U, V, W, X, Y, or Z) in parameter No. 1020 (first axis name character).
<3> Set the second character ('0' to '9' and 'A' to 'Z') in parameter No. 1025 (second axis name character).
<4> Set the third character ('0' to '9' and 'A' to 'Z') in parameter No. 1026 (third axis name character).

> **NOTE**
> 1 If the second axis name character is not set for an axis, the third axis name character is invalid.
> 2 When setting 0 to 9 for the second axis name character, do not set A to Z for the third axis name character.
> 3 When an axis name ends with a numeric character, an equal sign (=) is required to be specified between the axis name and the command value.
> 4 In a macro call, no extended axis name can be used as an argument.
> 5 If at least one axis in a path uses an extended axis name when bit 2 (EAS) of parameter No.11308 is set to 0, subscripts (parameter No. 3131) cannot be used for axis names in the path.
> 6 When G code system A is used for a lathe system, X, Y, Z, or C may be used for the first axis name character of an axis. In this case, when a command containing U, V, W, or H as the first axis name character is specified, it is used as the incremental command for the corresponding axis.
> 7 In a multipath system, if an extended axis name is not used on a path or if bit 2 (EAS) of parameter No. No.11308 is set to 1 and subscripts (parameter No. 3131) are not set for axis names, the path number will automatically be the subscript for axis names. To disable the display of axis name subscripts, set a blank (32) of ASCII code in the parameter for specifying an axis name subscript.

> **NOTE**
> 8 If the custom macro function is enabled, the same extended axis name as a reserved word cannot be used. Such an extended axis name is regarded as a reserved word.
> Because of reserved words of custom macros, extended axis names that start with the following combinations of two characters cannot be used:
> AB, AC, AD, AN, AS, AT, AX, BC, BI, BP, CA, CL, CO, US, WH, WR, XO, ZD, ZE, ZO, ZW

	First axis name character (No. 1020)	Second axis name character (No. 1025)	Third axis name character (No. 1026)
Setting	A, B, C, U, V, W, X, Y, Z	0 to 9	0 to 9
		A to Z	0 to 9 A to Z
Correct example <1>	X	1	1
Correct example <2>	X	A	1
Correct example <3>	X	A	B
Incorrect example	X	1	A

Parameter

	#7	#6	#5	#4	#3	#2	#1	#0
1000								**EEA**

[Input type] Parameter input
[Data type] Bit

#0 EEA An extended axis name and extended spindle name are:
0: Invalid
1: Valid

1020	**Program axis name for each axis**

[Input type] Parameter input
[Data type] Byte axis
[Valid data range] 65 to 67 ,85 to 90

An axis name (axis name 1: parameter No. 1020) can be arbitrarily selected from 'A', 'B', 'C', 'U', 'V', 'W', 'X', 'Y', and 'Z'. (When G code system A is used with the lathe system, however, 'U', 'V', and 'W' are not selectable.) When bit 0 (EEA) of parameter No. 1000 is set to 1, the length of an axis name can be extended to three characters by setting axis name 2 (parameter No. 1025) and axis name 3 (parameter No. 1026) (extended axis name).
For axis names 2 and 3, a character from '0' to '9' and 'A' to 'Z' of ASCII code can be arbitrarily selected. However, the setting of axis name 3 for each axis is invalid if axis name 2 is not set. Moreover, if a character from '0' to '9' is set as axis name 2, do not use a character from 'A' to 'Z' as axis name 3.

(Tip) ASCII code

Axis name	X	Y	Z	A	B	C	U	V	W
Setting	88	89	90	65	66	67	85	86	87

When G code system A is used with the lathe system, and the character 'X','Y','Z', or 'C' is used as axis name 1 of an axis, a command with 'U','V','W', or 'H' specified for axis name 1 represents an incremental command for the axis.

NOTE
1. When the setting value is out of range, it can not be recognized as an axis name.
2. When a multiple repetitive canned cycle is used, no character other than 'X','Y', and 'Z' can be used as the address of the target axis.
3. When the custom macro function is enabled, the same extended axis name as a reserved word cannot be used. Such an extended axis name is regarded as a reserved word.
   Because of reserved words of custom macros, extended axis names that start with the following two characters cannot be used:
   AB, AC, AD, AN, AS, AT, AX, BC, BI, BP, CA, CL, CO, US, WH, WR, XO, ZD, ZE, ZO, ZW
4. In a macro call, no extended axis name can be used as an argument.

1025	Program axis name 2 for each axis

1026	Program axis name 3 for each axis

[Input type] Parameter input
[Data type] Byte axis
[Valid data range] 48 to 57, 65 to 90

When axis name extension is enabled (when bit 0 (EEA) of parameter No. 1000 is set to 1), the length of an axis name can be extended to a maximum of three characters by setting axis name 2 and axis name 3. For axis names 2 and 3, a character from '0' to '9' and 'A' to 'Z' of ASCII code can be arbitrarily selected. However, the setting of axis name 3 for each axis is invalid if axis name 2 is not set. Moreover, if a character from '0' to '9' is set as axis name 2, do not use a character from 'A' to 'Z' as axis name 3.

3131	Subscript of axis name

[Input type] Parameter input
[Data type] Byte axis
[Valid data range] 0 to 9, 65 to 90

In order to distinguish axes under synchronization control and tandem control, specify a subscript for each axis name.

Setting value	Meaning
0	Each axis is set as an axis other than a synchronization control axis and tandem control axis.
1 to 9	A set value is used as a subscript.
65 to 90	A set letter (ASCII code) is used as a subscript.

[Example] When the axis name is X, a subscript is added as indicated below.

Setting value	Axis name displayed on a screen such as the position display screen
0	X
1	X1
77	XM
83	XS

If a multi-path system is used, no extended axis name is used within a path, or bit 2 (EAS) of parameter No. 11308 is set to 1 and no subscript is set for the axis names, then the path number is automatically used as the subscript for the axis names. To disable the display of axis name subscripts, set a blank (32) of ASCII code in the parameter for specifying an axis name subscript.

> **NOTE**
> If even one axis in a path uses an extended axis name when bit 2 (EAS) of parameter No. 11308 is set to 0, subscripts cannot be used for axis names in the path.

[Example]

- Example of setting an axis name
  When No. 1020 = 88, No. 1025 = 0, and No. 1026 = 0, the axis name is set to X.
  When No. 1020 = 88, No. 1025 = 65, and No. 1026 = 0, the axis name is set to XA.
  When No. 1020 = 88, No. 1025 = 66, and No. 1026 = 65, the axis name is set to XBA.
  When No. 1020 = 89, No. 1025 = 49, and No. 1026 = 0, the axis name is set to Y1.
  When No. 1020 = 90, No. 1025 = 49, and No. 1026 = 48, the axis name is set to Z10.
  When No. 1020 = 90, No. 1025 = 0, and No. 1026 = 65, the axis name is set to Z.

- Commands having a number at the end of the axis name
  Y1=100.
  Z10=200.

- Commands having an alphabet at the end of the axis name
  X100. or X=100.
  XA200. or XA=200.
  XBA300. or XBA=300.

- Incremental commands of lathe system G-code system A

Absolute command	Incremental command
XA100.	UA100.
Y1=200.	V1=200.
ZC300.	WC300.
C10=400.	H10=400.

- Relationship between the axis names and their settings

Axis name	Setting	Axis name	Setting	Axis name	Setting	Axis name	Setting
0	48	9	57	I	73	R	82
1	49	A	65	J	74	S	83

1.2.2 Increment System

Overview

The increment system consists of the least input increment (for input unit) and least command increment (for output unit, machine unit). The least input increment is the least increment for programming the travel distance. The least command increment is the least increment for moving the tool on the machine. Both increments are represented in mm, inches, or degrees.
There are three types of increment systems as listed in Table 1.2.2 (a). A desired type can be set for each axis using the corresponding bit 0 (ISA), or 1 (ISC) of parameter No. 1013.
The least input increment can be set to metric input or inch input using the G code (G20 or G21) or setting parameter (bit 2 (INI) of parameter No. 0000).
The least command increment is set to either metric or inch system depending on the machine tool in advance. Select the metric or inch system using bit 0 (INM) of parameter No. 1001 in advance.
Any combined use of the inch and metric systems is not allowed. There are functions that cannot be used across axes with different increment systems (such as circular interpolation and cutter compensation).

NOTE
1 The unit (mm or inch) in the table is used for indicating a diameter value for diameter programming (when bit 3 (DIA) of parameter No. 1006 is set to 1) or a radius value for radius programming.
2 Even if the parameters bit 0 (ISA), or 1 (ISC) of parameter No.1013 is changed, the tool offset unit is not changed. Set the tool offset unit by parameters bit 0 (OFA), or 1 (OFC) of parameter No.5042.
3 Some increment systems are unavailable depending on the model. For details, refer to "DESCRIPTIONS" (B-64692EN).

Table 1.2.2 (a) Increment system

Name of an increment system	Least input increment		Least command increment		Maximum stroke	
IS-A	0.01	mm	0.01	mm	±999999.99	mm
	0.001	inch	0.001	inch	±99999.999	inch
	0.01	deg	0.01	deg	±999999.99	deg
IS-B	0.001	mm	0.001	mm	±999999.999	mm
	0.0001	inch	0.0001	inch	±99999.9999	inch
	0.001	deg	0.001	deg	±999999.999	deg
IS-C	0.0001	mm	0.0001	mm	±99999.9999	mm
	0.00001	inch	0.00001	inch	±9999.99999	inch
	0.0001	deg	0.0001	deg	±99999.9999	deg

When bit 7 (IPR) of parameter No. 1004, which multiplies the input increment by 10, is set to 1 and a value is specified with no decimal point, the specifications of each increment system are changed as listed in Table1.2.2 (b).

Table1.2.2 (b)

Name of an increment system	Least input increment		Least command increment		Maximum stroke	
IS-B	0.01	mm	0.001	mm	±999999.999	mm
	0.001	inch	0.0001	inch	±99999.9999	inch
	0.01	deg	0.001	deg	±999999.999	deg

Name of an increment system	Least input increment	Least command increment	Maximum stroke
IS-C	0.001 mm	0.0001 mm	±99999.9999 mm
	0.0001 inch	0.00001 inch	±9999.99999 inch
	0.001 deg	0.0001 deg	±99999.9999 deg

Parameter

	#7	#6	#5	#4	#3	#2	#1	#0
0000						INI		

[Input type] Setting input

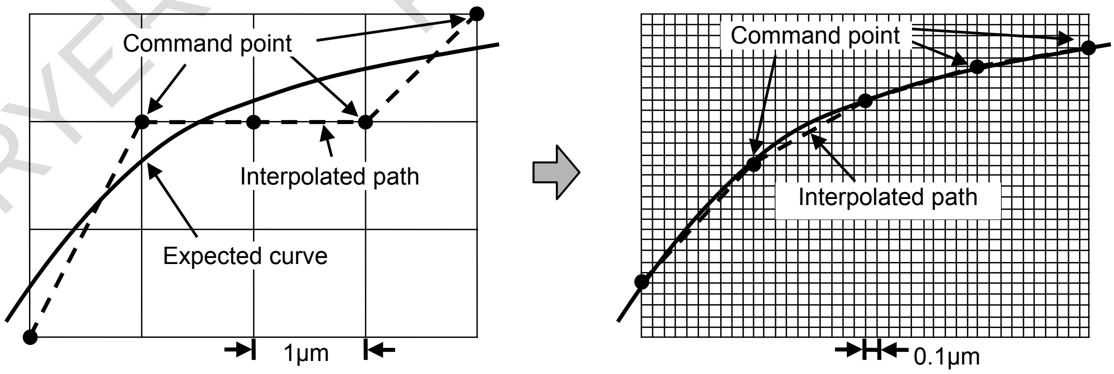
OPERATOR'S MANUAL (B-64694EN)	Increment system

1.2.2.1 High precision program command

Overview

In the program command to the axis address, the value that is one digit smaller than incremental system is enabled to command and analysis.

Features) Workpiece composed of free-form surface can be reproduced in high precision
- Incremental system is not changed, but program command unit is distributed to high precision
- The high precision machining can be achieved with keeping the usage of the machine
- In the machine of incremental system 1µm, the machining program 0.1µm is executable



Incremental system B (1µm)

Resolution of program command 0.1µm
(Incremental system C equally)
-> It becomes near expected curve.

Fig. 1.2.2.1 (a) Example in incremental system B

This function is enabled in all increment system (IS-A to C).
This function is activated when bit 0 (HPC) of parameter No.10478 is set to 1.

> **NOTE**
> 1 This function is a basic function.
> 2 This function is enabled to the axis address command (X,Y,Z, etc). It is invalid to the I, J, K, R command of circular interpolation etc.
> 3 This function doesn't relate to the detection unit.

Explanation

- Normal (When bit 0 (HPC) of parameter No.10478 is set to 0)

Conventionally, the axis address command of program has been rounded off a digit that was one digit smaller than the least incremental system.
When the command below least incremental system is described, it is became command of least incremental system.

Example) In case that input unit is metric, and increment system is 1μm (IS-B)
Program command

```
X10.0004    ->  X10.000
X10.0005    ->  X10.001
X10.00043   ->  X10.000
X10.00056   ->  X10.001
```

- High precision program command(When bit 0 (HPC) of parameter No.10478 is set to 1)

In the program command to the axis address with decimal point, the value that is one digit smaller than incremental system is enabled to command and analysis.
A digit that is 2 digits smaller than the least increment is system rounded off.
It is inputted the command in the unit to a digit that is 1 digit smaller than the least increment system.
This function is enabled for each program command of MEM / MDI / RMT mode.

Example) In case that input unit is metric, and increment system is 1μm (IS-B)
Program command

```
X10.0004    ->  X10.0004
X10.0005    ->  X10.0005
X10.00043   ->  X10.0004
X10.00056   ->  X10.0006
```

> **NOTE**
> When the bit 7 (IPR) of parameter No.1004 set to 1 (the least input increment is 10 times greater than the least command increment) and a number with no decimal point is specified, this function is disabled. The axis command value below incremental system is effective.

- Program example

Program command)

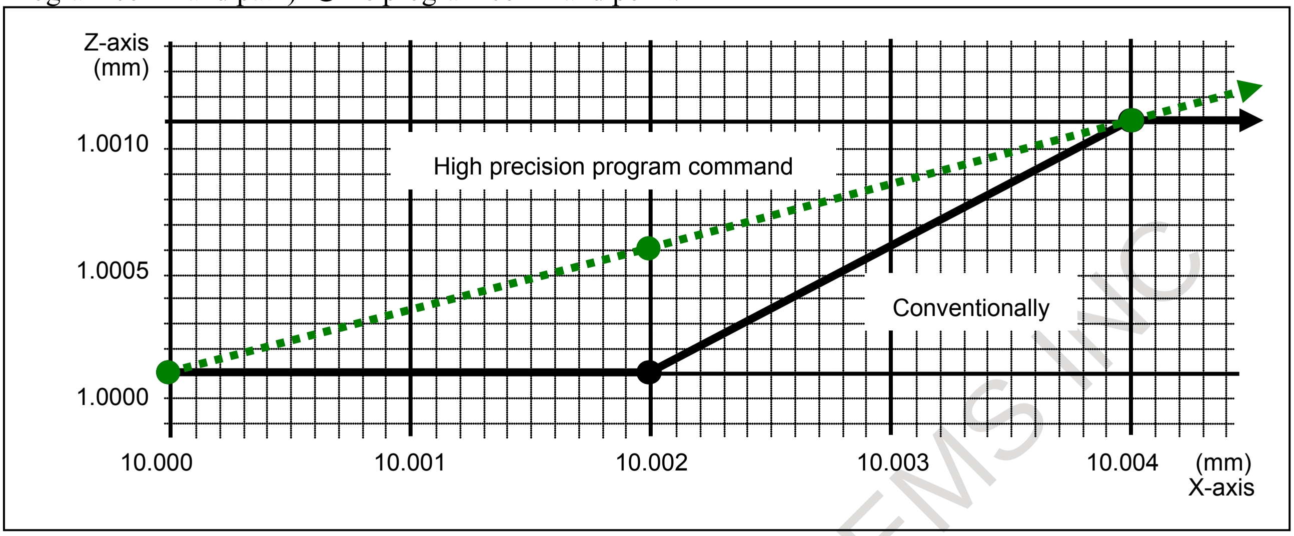
Conventionally command
(Z-axis : 3 digits after the decimal point)

```
G90 G01 ;
  :
N10 X10.000 Z1.000 ;
N20 X10.002 Z1.000 ;
N20 X10.004 Z1.001 ;
  :
```

High precision program command
(Z-axis : 4 digits after the decimal point)

```
G90 G01 ;
  :
N10 X10.000 Z1.0000 ;
N20 X10.002 Z1.0005 ;
N30 X10.004 Z1.0010 ;
  :
```

Program command path) ● is program command point.



- Valid range of various kind data

The valid data range of the maximum stroke and the federate has been not changed by this function.
It is the same as incremental system.

- Command by macro variable

When the macro variable is used for the command value at the axis address where this function is valid, it is analyzed as the command with a decimal point.
The number of decimals is enhanced by 1 digit.

Example) Input unit is metric, and increment system is B (1μm)
In case #500=12.34543
The program command is interpreted as follows.
X[#500] -> X12.3454

- Coordinate screen, program check screen, FOCAS2 and system variables that obtained coordinate value,

When this function is enabled, it is the value of incremental system as same conventional.

- Function that high precision program command is not applied

Functions	Note
Excluding the axis address command	Ex) I, J, K, Q, P, R of circular interpolation, etc…
Sync coefficient of Electronic gear box 2 pair (G81.5)	Gear ration is same as so far
G10 command (Setting command of various data)	same as so far
Dwell command (G04)	same as so far
Waiting function by specifying start point	The judgment position is coordinates of incremental system.
Auxiliary function output in moving axis (G50.9)	It judge by coordinates of incremental system, and the auxiliary function is output.
Stored Stroke Check 2 (G22 X_ Y_ Z_ I_ J_ K_)	As for Coordinate of plus direction (X,Y,Z) the high precision is applied. As for Coordinate of minus direction (I,J,K) the high precision is not applied. (Data of incremental system)
Second auxiliary functions (B)	same as so far
Canned Grinding Cycle (for Grinding machine) (G71 to G75, G77 to G79)	Address A, B command and Grinding range α is same so far

1.2.3 Specifying the Rotation Axis

Overview

Bit 0 (ROTx) of parameter No.1006 can be used to set each axis to a linear axis or rotary axis. Bit 1 (ROSx) of parameter No. 1006 can be used to select the rotary axis type, A or B, for each axis. See the explanation of the parameters for details of types A and B.
When the roll-over function is used, the values displayed for absolute coordinates are rounded by the shift amount per rotation, as set in parameter No. 1260. This can prevent coordinates for the rotary axis from overflowing. Displayed values for relative coordinates are also rounded by the angle corresponding to one rotation when bit 2 (RRLx) of parameter No. 1008 is set to 1. The roll-over function is enabled by setting bit 0 (ROAx) of parameter No. 1008 to 1 (for the rotation axis).
For an absolute command, the coordinates after the tool has moved are values rounded by the angle corresponding to one rotation set in parameter No. 1260.
The tool moves in the direction in which the final coordinates are closest when bit 1 (RABx) of parameter No. 1008 is set to 0. For an incremental command, the tool moves the angle specified in the command.

> **NOTE**
> Rotary axis roll–over function cannot be used together with the indexing function (M series) of the index table. To disable the indexing function (M series), set 1 in bit 0 (ITI) of parameter No. 5501 or 0 in bit 3 (IXC) of parameter No. 8132.

Parameter

	#7	#6	#5	#4	#3	#2	#1	#0
1006							ROSx	ROTx

[Input type] Parameter input
[Data type] Bit axis

> **NOTE**
> When at least one of these parameters is set, the power must be turned off before operation is continued.

#0 ROTx
#1 ROSx Setting linear or rotary axis.

ROSx	ROTx	Meaning
0	0	Linear axis (1) Inch/metric conversion is done. (2) All coordinate values are linear axis type. (Is not rounded in 0 to 360°) (3) Stored pitch error compensation is linear axis type (Refer to parameter No.3624)

ROSx	ROTx	Meaning
0	1	Rotary axis (A type) (1) Inch/metric conversion is not done. (2) Machine coordinate values and relative coordinate values are rounded in 0 to 360°. Absolute coordinate values are rounded or not rounded by bits 0 (ROAx) and 2 (RRLx) of parameter No.1008. (3) Stored pitch error compensation is the rotation type. (Refer to parameter No.3624) (4) Automatic reference position return (G28, G30) is done in the reference position return direction and the move amount does not exceed one rotation.
1	1	Rotary axis (B type) (1) Inch/metric conversion is not done. (2) Machine coordinate values, absolute coordinate values and relative coordinate values are linear axis type. (Is not rounded in 0 to 360°). (3) Stored pitch error compensation is linear axis type (Refer to parameter No.3624) (4) Cannot be used with the rotary axis roll-over function and the index table indexing function (M series)
Except for the above.		Setting is invalid (unused)

	#7	#6	#5	#4	#3	#2	#1	#0
1008						RRLx	RABx	ROAx

[Input type] Parameter input
[Data type] Bit axis

> **NOTE**
> When at least one of these parameters is set, the power must be turned off before operation is continued.

#0 ROAx The rotary axis roll-over is
0: Invalid
1: Valid

> **NOTE**
> ROAx specifies the function only for a rotary axis (for which bit 0 (ROTx) of parameter No.1006, is set to 1)

#1 RABx In the absolute commands, the axis rotates in the direction
0: In which the distance to the target is shorter.
1: Specified by the sign of command value.

> **NOTE**
> RABx is valid only when ROAx is 1.

#2 RRLx Relative coordinates are
0: Not rounded by the amount of the shift per one rotation
1: Rounded by the amount of the shift per one rotation

> **NOTE**
> 1 RRLx is valid only when ROAx is 1.
> 2 Assign the amount of the shift per one rotation in parameter No.1260.

1260	The shift amount per one rotation of a rotary axis

> **NOTE**
> When this parameter is set, the power must be turned off before operation is continued.

[Input type] Parameter input
[Data type] Real axis
[Unit of data] Deg
[Min. unit of data] Depend on the increment system of the applied axis
[Valid data range] 0 or positive 9 digit of minimum unit of data (refer to the standard parameter setting table (B))
(When the increment system is IS-B, 0.0 to +999999.999)

Set the shift amount per one rotation of a rotary axis.
For the rotary axis used for cylindrical interpolation, set the standard value.

	#7	#6	#5	#4	#3	#2	#1	#0
5501								
								ITI

[Input type] Parameter input
[Data type] Bit path

#0 ITI The index table indexing function (M series) is:
0: Enabled.
1: Disabled.

> **NOTE**
> To enable the index table indexing function, set bit 3 (IXC) of parameter No. 8132 to 1 in addition to this parameter. The index table indexing function is enabled only when both ITI and IXC are enabled.

For the rotary axis used for cylindrical interpolation, set the standard value.

	#7	#6	#5	#4	#3	#2	#1	#0
8132								
					IXC			

> **NOTE**
> When this parameter is set, the power must be turned off before operation is continued.

[Input type] Parameter input
[Data type] Bit

#3 IXC Index table indexing function (M series) is:
0: Not Used.
1: Used.

> **NOTE**
> When enabling the index table indexing function, set bit 0 (ITI) of parameter No. 5501 to 0 in addition to this parameter. The index table indexing function is enabled only when both ITI and IXC are enabled.

Note

> **NOTE**
> Rotary axis roll-over function cannot be used together with the indexing function of (M series) the index table.

OPERATOR'S MANUAL (B-64694EN)	Rotary axis roll-over function

1.2.4 Controlled Axes Detach

Overview

These signals release the specified control axes from control by the CNC. When attachments are used (such as a detachable rotary table), controlled axis detach signals or bit 7 (RMVx) of parameter No. 0012 are selected according to whether the attachments are mounted. When multiple rotary tables are used in turn, the tables must use motors of the same model.

> ⚠ **WARNING**
> For a vertical axis, in particular, it is necessary to prepare a sequence that starts operating the mechanical brake before the control axis detach operation.
> When this method is applied to a vertical axis, special care should be taken.

Signal

Controlled axis detach signals DTCH1 to DTCH8<Gn124>

[Classification] Input signal

[Function] These signals detach the control axes from control.
These signals are provided for each control axis; the affixed number of the signal name shows the control axis number.

DTCHx

x : 1 ..... The 1st axis is detached.
2 ..... The 2nd axis is detached.
3 ..... The 3rd axis is detached.
: :

[Operation] When the signals are "1", the control unit operates as follows:

<1> Position control is not executed at all. Servo motor excitation is cut.
<2> Servo alarm on the axis is ignored.
<3> Axis interlock signal is assumed to be zero on the detached axis.
<4> A command for automatic or manual operation for the axis does not cause an alarm, but the operation is restrained because the axis interlock signal is "0". In an automatic operation, the execution may stop and hold at the block. Do not execute any command for automatic or manual operation for the axis.
<5> Position display also displays the position of the detached axis.

Controlled axis detach status signals MDTCH1 to MDTCH8<Fn110>

[Classification] Output signal

[Function] These signals notify the PMC that the corresponding axes have been released from control.
These signals are provided for each control axis; the affixed number of the signal name shows the control axis number.
MDTCHx
x : 1 ..... The 1st axis is detached.
2 ..... The 2nd axis is detached.
3 ..... The 3rd axis is detached.
: :

[Output cond.] These signals are "1" in the following case:
- When the corresponding axes are released from control
These signals are "0" in the following case:
- When the corresponding axes are under control

Signal address

	#7	#6	#5	#4	#3	#2	#1	#0
Gn124	DTCH8	DTCH7	DTCH6	DTCH5	DTCH4	DTCH3	DTCH2	DTCH1

Fn110	MDTCH8	MDTCH7	MDTCH6	MDTCH5	MDTCH4	MDTCH3	MDTCH2	MDTCH1

Parameter

	#7	#6	#5	#4	#3	#2	#1	#0
0012	RMVx							

[Input type] Setting input
[Data type] Bit axis

#7 RMVx Releasing the assignment of the control axis for each axis
0: Not released
1: Released
(Equivalent to the control axis detachment signals DTCH1, DTCH2, and so forth <G0124>)

> **NOTE**
> 1. RMVx is valid when bit 7 (RMBx) of parameter No. 1005 is set to 1.
> 2. Switch RMVx while the axis is stopping. When switching while the axis is moving, the control axis is detached after the movement of the axis is completed.

	#7	#6	#5	#4	#3	#2	#1	#0
1005	RMBx	MCCx						

[Input type] Parameter input
[Data type] Bit axis

#6 MCCx If a multi-axis amplifier is used, and another axis of the same amplifier is placed in the control axis detach state, the MCC signal of the servo amplifier is:
0: Turned off.
1: Not turned off.

> **NOTE**
> This parameter can be set for a control axis.

#7 RMBx The control axis detachment signal for each axis and the setting input parameter (bit 7 (RMV) of parameter No. 0012) are:

0: Invalid
1: Valid

	#7	#6	#5	#4	#3	#2	#1	#0
1818			APDx					

[Input type] Parameter input
[Data type] Bit axis

#5 APDx In the axis with absolute position detector (absolute pulse coder), when the axis is released from state of control axis detach:

0: The parameter APZ (bit 4 of parameter No. 1815) is changed to 0 automatically and the alarm DS0300 is generated.
1: The parameter APZ (bit 4 of parameter No. 1815) remains at 1. After the release of control axis detach, the machine and workpiece coordinate systems are automatically set by using an absolute position detector (absolute pulse coder).

> ⚠ **WARNING**
> 1 It is necessary to detach and attach control axis on the same axis (and the same detector). Do not exchange the axis, etc.
> 2 Do not move an axis of rotary axis (A type) (machine coordinate values are rounded in 0 to 360°.) by more than 180°during control axis detach.
> 3 In case of using the control axis detach function during automatic operation, change controlled axis detach signal DTCH1 to DTCH8 while FIN wait state by using an M code without buffering (parameter No.3411 to No.3432).
> 4 If magnetic pole detection is used, magnetic pole detection is needed when the control axis is reconnected after control axis detach.

Note

> **NOTE**
> 1 Controlled axis detach signals DTCH1 <G124.0>, DTCH2 <G124.1>, DTCH3 <G124.2>, 0 can be changed from “1” to “0” or from “0” to “1” when the power is first turned on or when no movement is being executed along the corresponding axis. If these signals are changed from “0” to “1” when the tool is moving along the corresponding axis, the axis is released from control upon completion of the movement.
> 2 For these signals to be enabled, bit 7 (RMBx) of parameter No. 1005 must be set, indicating the axes are detachable. The signal is invalid for axis without setting.
> 3 Setting bit 7 (RMVx) of parameter No. 0012 from the MDI unit detaches the axes in the same way as these signals.

NOTE

4 Those axes that are released from control lose their reference positions. Reference position return must, therefore, be performed for the axes prior to executing move commands for the axes. Specifying a move command before reference position return has been performed causes alarm PS0224 "ZERO RETURN NOT FINISHED" to be output.
If an axis for which an absolute position detector is used (bit 5 (APCx) of parameter No. 1815 is set to 1) is released from control, the correspondence between the machine position and reference position is lost. Consequently, bit 4 (APZx) of parameter No. 1815 indicating that the correspondence is established is set to 0, resulting in alarm DS0300 "APC ALARM: NEED REF RETURN". After an axis is released from control, perform reference position return to bring the machine position into correspondence with the reference position. But these operations can be omitted by setting bit 5 (APDx) of parameter No.1818 is set to 1.

5 When the control axis detach function is used, however, servo software cannot identify the type of detector in a case where the power to the CNC is turned on with the detector detached from the controlled axis. And an alarm such as a communication alarm may be issued. Such an alarm can be avoided by setting bit 3 (COMSRC) of parameter No. 2017 to 1 "the detector on the semi-closed side is αi/βi pulse coder at all times". Refer to "FANUC AC SERVO MOTOR αi/βi series PARAMETER MANUAL (B-65270EN)" for details.

1.2.5 Outputting the Movement State of an Axis

Overview

The movement state of each axis can be output to the PMC.

Signal

Axis moving signals MV1 to MV8<Fn102>

[Classification] Output signal

[Function] These signals indicate that a control axis is moving.
The signals are provided for each control axis, and the number in the signal name corresponds to the control axis number.

MVx
x : 1 ..... The 1st axis is moving.
2 ..... The 2nd axis is moving.
3 ..... The 3rd axis is moving.
: :
: :

[Output cond.] The signals turn to "1" in the following cases:
- The corresponding axis has started moving.
- In manual handle feed mode, the handle feed axis of the corresponding axis has been elected.

The signals turn to "0" in the following case:
- The corresponding axis has stopped moving and enters the in-position status.

Axis moving direction signals MVD1 to MVD8<Fn106>

[Classification] Output signal

[Function] These signals indicate the movement direction of control axis.
They are provided for each control axis, and the number in the signal name corresponds to the control axis number.

MVDx

x : 1 ..... The moving direction of the 1st axis is minus.
2 ..... The moving direction of the 2nd axis is minus.
3 ..... The moving direction of the 3rd axis is minus.
: :
: :

[Output cond.] "1" indicates the corresponding axes are moving in the minus direction, and "0" indicates they are moving in the plus direction.

> ⚠ **CAUTION**
> These signals maintain their condition during a stop. This signal keeps "1" even if it stops after moving in the minus direction.

Signal address

	#7	#6	#5	#4	#3	#2	#1	#0
Fn102	MV8	MV7	MV6	MV5	MV4	MV3	MV2	MV1
Fn106	MVD8	MVD7	MVD6	MVD5	MVD4	MVD3	MVD2	MVD1

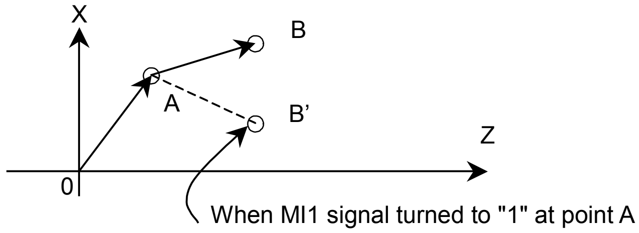
Caution

> ⚠ **CAUTION**
> Axis moving signals and axis moving direction signals are output in both automatic and manual operations.

1.2.6 Mirror Image

Overview

Mirror image can be applied to each axis, either by signals or by parameters (setting input is acceptable). All movement directions are reversed during automatic operation along axes to which a mirror image is applied. Moreover, the absolute coordinate is updated to the same direction as a programmed path, and the machine coordinate and the relative coordinate are updated to the opposite direction from a programmed path.



Mirror image (Example for lathe system)

Fig. 1.2.6 (a)

Mirror image check signals MMI1 to MMI8 <Fn108> indicate whether mirror image is applied to each axis. System variable #3007 contains the same information.
Wrong operation prevention function displays the axis status to the left of the axis name in the display of the machine coordinates, absolute coordinates, relative coordinates, and remaining travel amounts.
Please refer to OPERATOR'S MANUAL (B-64694EN) for details.

Explanation

- Shifting workpiece coordinate system

When operation using mirror image is executed after the workpiece coordinate system is specified, absolute coordinates are updated in the opposite direction with machine coordinates, the workpiece coordinate system is shifted from the machine coordinate system.
This shifted amount can be cancelled by the following operation.

- Manual reference position return
- Workpiece coordinate system preset (G92.1, G50.3)
- Each axis workpiece coordinate system preset signals WPRST1-WPRST8<Gn358>

- Programmable mirror image (G50.1, G51.1)

When programmable mirror image (machining center system) and ordinary mirror image are specified at the same time, programmable mirror image is applied first.

- Retrace

Mirror image is enabled during reverse execution and forward reexecution of the retrace function. Therefore, it is necessary during the reverse execution and the forward reexecution to make mirror image in the same state as the forward execution.

Limitation

- Manual operation and automatic reference position return

Even if mirror image is applied, the following directions are not reversed.

- Direction of manual operation
- Direction of movement, from the intermediate position to the reference position during automatic reference position return (G28)

In these cases, the machine coordinate and the relative coordinate are updated to the same direction as a movement, and the absolute coordinate is updated to the opposite direction from a movement.

M

- Boring cycle (G76 and G87)

Even if mirror image is applied, shift direction for boring cycles (G76 and G87) is not reversed.

- High precision oscillation function

Never attempt to apply mirror image about the oscillation axis.

- Manual linear/circular interpolation

Manual operation of Manual linear/circular interpolation, never use mirror image.

- Program restart, Quick program restart

The tool cannot be returned to a correct position when mirror image is used. However, P type return is possible for a block that switched between ON and OFF most recently or a subsequent block. In this case, mirror image signal status present when the program was interrupted must be maintained.

- Manual intervention and return

When performing manual intervention and return, never use mirror image.

- Tool retract and recover

When retracting the tool manually in the tool withdrawal mode, do not use mirror image.

M

- Single direction positioning

Mirror image is not applied in parameter No.5440 set direction. Even in the mirror image mode, the direction of single direction positioning remains unchanged.

If positioning of linear interpolation type is used, and the state of mirror image when a single direction positioning block is looked ahead differs from the state of mirror image when the execution of the block is started, an alarm is issued. When switching mirror image in the middle of a program, disable looking ahead by specifying a non-buffering M code. Then, switch mirror image when there is no look-ahead block.

- Arbitrary speed threading

Thread cannot be re-machined with mirror image applied.

- General purpose retract

The retract direction is the movement direction of the machine regardless of whether mirror image is valid or not. (A mirror image is not applied to the updating of absolute coordinates.)

- AI contour control II

In the speed control with the cutting feed, the travel direction on the Z-axis is determined with the appropriate NC command. Therefore, if mirror image is applied on the Z-axis, the direction on the Z-axis cannot be determined. When using the speed control with the cutting load, do not use mirror image.

Signal

Mirror image signals MI1 to MI8<Gn106>

[Classification] Input signal

[Function] Select whether to apply a mirror image to each axis.

[Operation] Apply mirror image to those axes for which the signals are "1".

These signals are provided for the controlled axes on a one-to-one basis. A number appended to a signal name represents the controlled axis number.

MIx

x : 1 ..... Applies mirror image to the 1st axis.
2 ..... Applies mirror image to the 2nd axis.
3 ..... Applies mirror image to the 3rd axis.
: :
: :

The mirror image signal can be turned to "1" in the following cases:

(1) During offset cancel;
(2) When the CNC is in the automatic operation stop state and not in the feed hold state.

Mirror image check signals MMI1 to MMI8<Fn108>

[Classification] Output signal

[Function] These signals indicate the mirror image condition of each axis.

The mirror image can be set with the CNC setting data in addition to the input signal from the machine side (PMC).A mirror image is applied by the logical sum of both, and the state is notified to the PMC.

These signals are provided for every control axis; the numeral in the signal name indicates the relevant control axis number.

MMIx

x : 1 ..... Mirror image is applied to the 1st axis
2 ..... Mirror image is applied to the 2nd axis
3 ..... Mirror image is applied to the 3rd axis
: :
: :

[Output cond.] These signals turn to "1" when:

- Mirror image signal MIx of the corresponding axis is 1; or
- Mirror image of the corresponding axis is turned on by setting data.

These signals turn to "0" when:

- Mirror image signal (MIx) of the corresponding axis is 0 and the setting of the mirror image is turned off.

Signal address

	#7	#6	#5	#4	#3	#2	#1	#0
Gn106	MI8	MI7	MI6	MI5	MI4	MI3	MI2	MI1

	#7	#6	#5	#4	#3	#2	#1	#0
Fn108	MMI8	MMI7	MMI6	MMI5	MMI4	MMI3	MMI2	MMI1

Parameter

	#7	#6	#5	#4	#3	#2	#1	#0
0012								MIRx

[Input type] Setting input
[Data type] Bit axis

#0 MIRx Mirror image for each axis
0: Mirror image is off. (Normal)
1: Mirror image is on. (Mirror)

	#7	#6	#5	#4	#3	#2	#1	#0
3129						MRE		

[Input type] Parameter input
[Data type] Bit path

#2 MRE When mirror image is used, relative coordinates are:
0: Updated with respect to the machine coordinates.
1: Updated with respect to the absolute coordinates.

Set this parameter to 1 when handling relative coordinates in the same way as for the lathe system of the FS16*i*/18*i*/21*i*.

Caution

⚠ **CAUTION**

1 No programmable mirror image (machining center system) affects mirror image check signals MMI1 to MMI8 <Fn108>.
2 Even when the mirror image is applied, commands which do not actuate mirror image (such as automatic reference position return and manual operation) do not affect mirror image check signals MMI1 to MMI8 <Fn108>.

1.2.7 Follow-up

Overview

If the machine moves in the state in which position control on controlled axes is disabled (during servo-off, emergency stop, or servo alarm), feedback pulses are accumulated in the error counter. The

CNC reflects the machine movement corresponding to the error count in the current position managed by the CNC. This operation is referred to as follow-up. When follow-up is performed, the current position managed by the CNC does not shift from the actual machine position.
You can select whether to perform follow-up for axes when the servo is turned off.
Follow-up is always performed during emergency stop or a servo alarm.

Explanation

- When follow-up is not performed for the axes for which the servo is turned off

When a follow-up signal *FLWU <Gn007.5> is “1” or a bit 0 (FUPx) of parameter No.1819 is 1, follow-up is not performed. The error is added to the error counter as a servo error.
In this case, the machine moves to compensate for the error when the servo off signal SVF1 to SVF8 <Gn126> changes to “0”.
In general, follow-up is not used if the machine is mechanically clamped when position control is disabled for the controlled axes.

- When follow-up is performed for the axes for which the servo is turned off

When a bit 0 (FUPx) of parameter No.1819 is 0 and a follow-up signal *FLWU is “0”, the follow-up function is performed.
That is, it is considered that there is a command corresponding to the movement of the machine, and update the present position of the CNC so that the error counter to zero. In this case, even if the servo-off signal is restored to "0", the position of the machine remains dislocated. However, since the present position of the CNC is moving corresponding to the actual position of the machine, so, if it executes the program with cycle start at the state, it moves to the correct position with the first absolute command. In general, follow-up is used with a mechanical handle (a method of moving a motor by a mechanical handle mechanism and moving a machine).

⚠ CAUTION

1 If, during automatic operation, a servo off signal is issued with the setting that causes follow-up to be performed (a bit 0 (FUPx) of parameter No.1819 = 0 and a follow-up signal *FLWU<Gn007.5> = “0”), even if the machine is moved with external force or other means, the travel distance will not immediately reflected in the program coordinate system. Until it is reflected, the machine path will be shifted by the amount of movement due to the external force as in the Fig. 1.2.7 (a) .

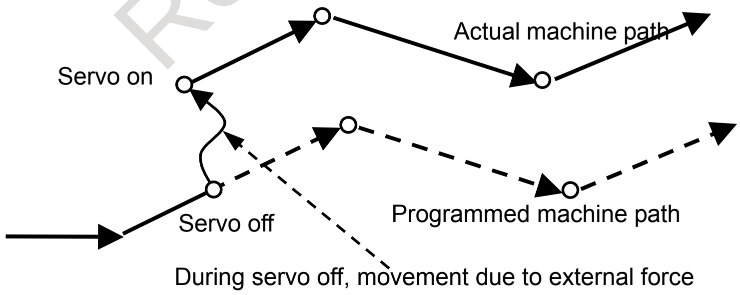

Fig. 1.2.7 (a)

The following method is available to reflect the amount of movement during servo off in the program coordinate system. If not wishing to shift the path, be sure to follow the procedure below to adjust the coordinates and execute an absolute command.

- Exit from automatic operation with a reset, single block stop, or feed hold, and then make a restart.

> ⚠ **CAUTION**
> 2 If a servo off signal is issued with the setting that does not cause follow-up to be performed (a bit 0 (FUPx) of parameter No.1819 = 1 or a follow-up signal *FLWU<Gn007.5> = "1"), even if the machine is moved with external force or other means, the machine will be retracted by the travel distance in the servo on state and, therefore, the path will never shift in subsequent automatic operation. The amount of movement due to the external force in the servo off state is regarded as a servo positional deviation and is stored inside the CNC. Thus, when a servo on signal is issued, axis moving occurs to cancel this servo positional deviation. The machine moves at a speed in accordance with the servo loop gain and if the amount is large, this may give the machine a shock.

Signal

Follow-up signal *FLWU<Gn007.5>

[Classification] Input signal
[Function] Select whether to perform follow-up when the servo is turned off for those axes for which bit 0 (FUPx) of parameter No.1819 is 0.
[Operation] 0: Performs follow-up.
1: Does not perform follow-up.

Signal address

	#7	#6	#5	#4	#3	#2	#1	#0
Gn007			*FLWU					

Parameter

	#7	#6	#5	#4	#3	#2	#1	#0

CONNECTION MANUAL (FUNCTION) (this manual)	Servo off/mechanical handle feed

1.2.8 Servo off/Mechanical Handle Feed

Overview

Place the controlled axes in the servo off state, stop the current to the servo motor, which disables position control. However, the position detection feature functions continuously, so the current position is not lost.

These signals are used to prevent the servo motors from overloading when the tools on the axes are mechanically clamped under certain machining conditions on the machine, or to move the machine by driving the motors by mechanical handles.

Please refer to “Follow-up” for details of follow-up in the servo off state.

Signal

Servo off signals SVF1 to SVF8<Gn126>

[Classification] Input signal

[Function] Select whether to place each axis in the servo off state.
These signals are provided for the controlled axes on a single axis basis. A number appended to a signal represents a controlled axis number.

SVFx

x : 1 ..... Servo off for the first axis
2 ..... Servo off for the second axis
3 ..... Servo off for the third axis
: :

[Operation] These signals put the axes for which the signals are “1” in the servo off state (the current to the servo motor is stopped). This disables position control. However, the position detection feature continues to function, so the current position is not lost.

Signal address

	#7	#6	#5	#4	#3	#2	#1	#0
Gn126	SVF8	SVF7	SVF6	SVF5	SVF4	SVF3	SVF2	SVF1

Caution

⚠ **CAUTION**

1 In general, interlock is applied to an axis while the servo off signal for that axis is "1".

2 The mechanical clamp is done by using the auxiliary function. Set the timing for the auxiliary function, mechanical clamp and servo off signals as shown in the Fig. 1.2.8 (a). The clamp command auxiliary function should be executed only after the distribution end signal DEN <Fn001.3> turned to "1".

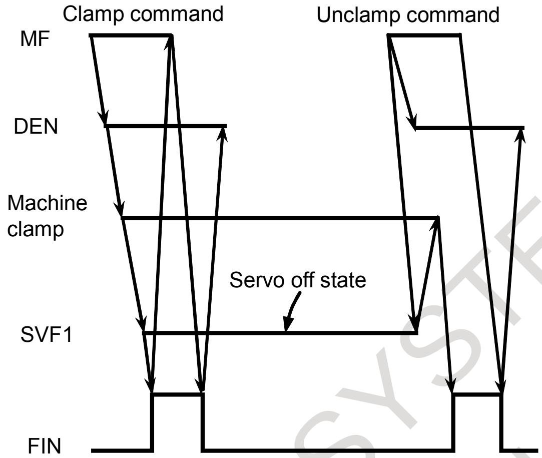

Fig. 1.2.8 (a)

3 If, during automatic operation, a servo off signal is issued with the setting that causes follow-up to be performed (a bit 0 (FUPx) of parameter No.1819 = 0 and a follow-up signal *FLWU<Gn007.5> = "0"), even if the machine is moved with external force or other means, the travel distance will not immediately reflected in the program coordinate system. Until it is reflected, the machine path will be shifted by the amount of movement due to the external force as in the Fig. 1.2.8 (b).

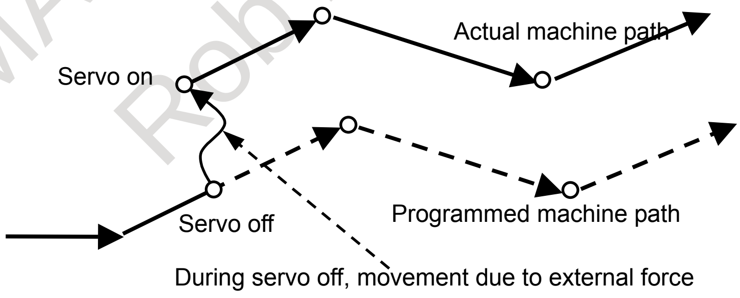

Fig. 1.2.8 (b)

The following method is available to reflect the amount of movement during servo off in the program coordinate system. If not wishing to shift the path, be sure to follow the procedure below to adjust the coordinates and execute an absolute command.

- Exit from automatic operation with a reset, single block stop, or feed hold, and then make a restart.

> ⚠ **CAUTION**
> 4 If a servo off signal is issued with the setting that does not cause follow-up to be performed (a bit 0 (FUPx) of parameter No.1819 = 1 or a follow-up signal *FLWU<Gn007.5> = "1"), even if the machine is moved with external force or other means, the machine will be retracted by the travel distance in the servo on state and, therefore, the path will never shift in subsequent automatic operation. The amount of movement due to the external force in the servo off state is regarded as a servo positional deviation and is stored inside the CNC. Thus, when a servo on signal is issued, axis moving occurs to cancel this servo positional deviation. The machine moves at a speed in accordance with the servo loop gain and if the amount is large, this may give the machine a shock.
> 5 If the positioning deviation exceeds the value set in the parameter No.1830 in servo-off state, alarm SV0410, "EXCESS ERROR (STOP)" is occurred. If the parameter No.1830 is set to 0, the positioning deviation is not checked in servo-off state.

Parameter

1830	Axis-by-axis positional deviation limit at servo-off time

[Input type] Parameter input
[Data type] 2-word axis
[Unit of data] Detection unit
[Valid data range] 0 to 99999999

This parameter is used to set a positional deviation limit at servo-off time, on an axis-by-axis basis.
If the value specified with this parameter is exceeded at servo-off time, a servo alarm is issued to cause an immediate stop (same as an emergency stop). Usually, set the same value as a positional deviation limit at stop time.

> **NOTE**
> If this parameter is set to 0, the positioning deviation is not checked in servo-off state.

1.2.9 Position Switch

Overview

Position switch signals can be output to the PMC while the machine coordinates along a controlled axes are within a specified ranges.
Using parameters, specify arbitrary controlled axes and machine coordinate operating ranges for which position switch signals PSW01 to PSW16 <Fn070,Fn071> are output.
Up to 10 position switch signals can be output.
Up to 16 points can be expanded by setting bit 1 (EPW) of parameter No. 6901 to 1.

> ⚠ **CAUTION**
> The position switch function is enabled after reference position return is completed.

Signal

Position switch signals PSW01 to PSW16<Fn070, Fn071>

[Classification] Output signal

[Function] Indicates that the machine coordinates along the controlled axes specified by parameters Nos. 6910 to 6925 are within the ranges specified by parameters Nos. 6930 to 6945 and 6950 to 6965.
The position switch signal corresponding to the n-th position switch function is PSWn.
(n : 1 to 16)

[Output cond.] These signals are “1” in the following case:

- When the machine coordinates along the controlled axes are within the specified ranges.

These signals are “0” in the following case:

- When the machine coordinates along the controlled axes are not within the specified ranges.

Signal address

	#7	#6	#5	#4	#3	#2	#1	#0
Fn070	PSW08	PSW07	PSW06	PSW05	PSW04	PSW03	PSW02	PSW01
Fn071	PSW16	PSW15	PSW14	PSW13	PSW12	PSW11	PSW10	PSW09

Parameter

	#7	#6	#5	#4	#3	#2	#1	#0
6901						PSA	EPW	

[Input type] Parameter input
[Data type] Bit path

#1 EPW The number of position switches is:
0: Not extended.
1: Extended.

#2 PSA In determination of a position switch function operation range, a servo delay amount (positional deviation) and a delay amount in acceleration/deceleration control are:
0: Not considered.
1: Considered.

6910	Controlled axis for which the 1-st position switch function is performed (PSWA01)
to	to
6925	Controlled axis for which the 16-th position switch function is performed (PSWA16)

[Input type] Parameter input
[Data type] Byte path
[Valid data range] 0 to Number of controlled axes

Set the controlled axis number (intra-path relative axis number) corresponding to one of the first to sixteenth position switch functions. When the machine coordinate of the corresponding axis is within a parameter-set range, the corresponding position switch signal is output to the PMC.

> **NOTE**
> The setting of 0 means that the position switch function of the number is not used.

6930	**Maximum value of the operating range of the 1-st position switch (PSW101)**
to	**to**
6945	**Maximum value of the operating range of the 16-th position switch (PSW116)**

[Input type] Parameter input
[Data type] Real path
[Unit of data] mm, inch, deg (machine unit)
[Min. unit of data] Depend on the increment system of the reference axis
[Valid data range] 9 digit of minimum unit of data (refer to standard parameter setting table (A))
(When the increment system is IS-B, -999999.999 to +999999.999)

Set the maximum value of the operating range of the first to sixteenth position switches.

> **NOTE**
> 1 For a diameter-specified axis, use diameter values to specify the parameters used to set the maximum and minimum values of an operating range.
> 2 The position switch function is enabled upon completion of reference position return.
> 3 Please do not specify the range that steps over 360° for the rotation axis.

6950	**Minimum value of the operating range of the 1-st position switch (PSW201)**
to	**to**
6965	**Minimum value of the operating range of the 16-th position switch (PSW216)**

[Input type] Parameter input
[Data type] Real path

[Min. unit of data] Depend on the increment system of the reference axis
[Valid data range] 9 digit of minimum unit of data (refer to standard parameter setting table (A))
(When the increment system is IS-B, -999999.999 to +999999.999)

Set the minimum value of the operating range of the first to sixteenth position switches.

> **NOTE**
> 1 For a diameter-specified axis, use diameter values to specify the parameters used to set the maximum and minimum values of an operating range.
> 2 The position switch function is enabled upon completion of reference position return.
> 3 Please do not specify the range that steps over 360° for the rotation axis.

1.2.10 High-Speed Position Switch

Overview

The high-speed position switch function monitors the current position at shorter intervals than the normal position switch function to output a high-speed precise position switch signal.

In the same way as for the normal position switch function, using parameters, specify arbitrary controlled axes and machine coordinate operating ranges for which position switch signals are output.
Up to six high-speed position signals can be output. Up to 16 points can be expanded by setting bit 7 (HPE) of parameter No. 8500 to 1.

> ⚠ **CAUTION**
> The high-speed position switch function is enabled after reference position return is completed.

Explanation

- Output addresses of high-speed position switch signals

High-speed position switch signals are output to the PMC Y signal addresses set using parameter No. 8565. If a nonexistent address is set for the parameter, the high-speed position switch function is disabled. If you do not want to use the PMC Y signal addresses, you can set bit 0 (HPF) of parameter No. 8501 to 1 to use high-speed position switch signals as normal output signals (using F signal addresses).

> ⚠ **WARNING**
> Never use the Y signal used on the PMC ladder. In case of using it with mistakes, the machine may perform unexpected operation.

Signal

High-speed position switch signals HPS01 to HPS16<Yxxx,Yxxx+1><Fn293,Fn294>

[Classification] Output signal

[Function] Indicates that the machine coordinates along the controlled axes specified by parameters Nos. 8570 to 8579 and 12201 to 12206 are within the ranges specified by parameters Nos. 8580 to 8589, 12221 to 12226, 8590 to 8599, and 12241 to 12246.
The position switch signal corresponding to the n-th position switch function is HPSn.
(n : 1 to 16)

[Output cond.] These signals are "1" in the following case:
- When the machine coordinate value along the controlled axis is within a specified range.

These signals are "0" in the following case:
- When the machine coordinate value the along the controlled axis is not within a specified range.

Signal address

	#7	#6	#5	#4	#3	#2	#1	#0
Yxxx	HPS08	HPS07	HPS06	HPS05	HPS04	HPS03	HPS02	HPS01
Yxxx+1	HPS16	HPS15	HPS14	HPS13	HPS12	HPS11	HPS10	HPS09

xxx indicates the address set using parameter No. 8565.
When bit 0 (HPF) of parameter No. 8501 is set to 1, the signal addresses are F293 and F294. (Y signal addresses are not used.)

Parameter

	#7	#6	#5	#4	#3	#2	#1	#0
8500	HPE							

[Input type] Parameter input
[Data type] Bit path

#7 HPE The maximum number of high-speed position switches is:
0: 6.

1: 16.

	#7	#6	#5	#4	#3	#2	#1	#0
8501							HPS	HPF

[Input type] Parameter input
[Data type] Bit path

> **NOTE**
> When at least one of these parameters is set, the power must be turned off before operation is continued.

#0 HPF The output signal of a high-speed position switch is output to:
0: Address Y.
1: Address F.

#1 HPS The current position used with the high-speed position switch:
0: Considers a servo error.
1: Does not consider a servo error.

	#7	#6	#5	#4	#3	#2	#1	#0
8504	E08	E07	E06	E05	E04	E03	E02	E01
8505	E16	E15	E14	E13	E12	E11	E10	E09

[Input type] Parameter input
[Data type] Bit path

E01 to E16 These parameters specify whether to enable or disable each corresponding high-speed position switch.
The Table 1.2.10 (a) shows the correspondence between the bits and switches.
The settings of each bit have the following meaning:
0: The switch corresponding to the bit is enabled.
1: The switch corresponding to the bit is disabled (always outputs 0).

Table 1.2.10 (a)

Parameter	Switch
E01	1st high-speed position switch
E02	2nd high-speed position switch
E03	3rd high-speed position switch
:	:
E16	16th high-speed position switch

8565	Output address of the high-speed position switch signal

> **NOTE**
> When this parameter is set, the power must be turned off before operation is continued.

[Input type] Parameter input
[Data type] Word path
[Valid data range] 0 to 126

This parameter sets a Y signal address to which the high-speed position switch signal is output. The Y signal addresses consisting of the value set in this parameter and the set value plus 1 are used.
If a nonexistent address is set, the high-speed position switch function is disabled. When bit 0 (HPF) of parameter No. 8501 is set to 1, however, this parameter has no effect.

Table 1.2.10 (b) Relationship between the high-speed position switches and the addresses to be output

	Signal address to be output	Controlled axes number	Maximum operation range	Minimum operation range
1st to 8th	“Value set in the parameter No.8565”	8570 to 8577	8580 to 8587	8590 to 8597
9th to 16th	“Value set in the parameter No.8565” + 1	8578 to 8579, 12201 to 12206	8588 to 8589, 12221 to 12226	8598 to 8599, 12241 to 12246

> ⚠ **WARNING**
> 1 Be sure not to use any Y signal already used in the PMC ladder with this function. If used, the machine may behave in an unexpected manner.
> 2 If you want to use high-speed position switches for multiple paths, use a different Y signal output address for each path.

> ⚠ **CAUTION**
> 1 Specifying a nonexistent signal address causes the high-speed position switch function to be disabled.
> 2 Y signal address Y127 cannot be specified for this function.
> 3 Address output signals (Y1001 and above) on the M-NET board cannot be specified for this function.
> 4 When "0" is set to the parameter, it is output to Y0 and Y1. Please set the available address when the high-speed position switch is used.

8570	**Controlled axis for which the first high-speed position switch function is performed**
to	**to**
8579	**Controlled axis for which the tenth high-speed position switch function is performed**

12201	**Controlled axis for which the eleventh high-speed position switch function is performed**
to	**to**
12206	**Controlled axis for which the sixteenth high-speed position switch function is performed**

[Input type] Parameter input
[Data type] Byte path
[Valid data range] 1 to number of controlled axes

Each of these parameters sets a controlled axis number for which each of the first to sixteenth high-speed position switch functions is performed.
Set 0 for the number corresponding to a high-speed position switch which is not to be used.

NOTE
Parameters Nos. 8576 to 8579 and 12201 to 12206 are valid only when bit 7 (HPE) of parameter No. 8500 is 1.

8580	Maximum value of the operation range of the first high-speed position switch
to	to
8589	Maximum value of the operation range of the tenth high-speed position switch

12221	Maximum value of the operation range of the eleventh high-speed position switch
to	to
12226	Maximum value of the operation range of the sixteenth high-speed position switch

[Input type] Parameter input
[Data type] Real path
[Unit of data] mm, inch, deg (machine unit)
[Min. unit of data] Depend on the increment system of the reference axis
[Valid data range] 9 digit of minimum unit of data (refer to standard parameter setting table (A))
(When the increment system is IS-B, -999999.999 to +999999.999)

Each of these parameters sets the maximum value of the operation range of each of the first to sixteenth high-speed position switches. If such a setting that maximum value < minimum value is made, no operation range exists, so that the high-speed position switch does not operate.

NOTE
Parameters Nos. 8586 to 8589 and 12221 to 12226 are valid only when bit 7 (HPE) of parameter No. 8500 is 1.

8590	Minimum value of the operation range of the first high-speed position switch
to	to
8599	Minimum value of the operation range of the tenth high-speed position switch

12241	Minimum value of the operation range of the eleventh high-speed position switch
to	to
12246	Minimum value of the operation range of the sixteenth high-speed position switch

[Input type] Parameter input
[Data type] Real path
[Unit of data] mm, inch, deg (machine unit)
[Min. unit of data] Depend on the increment system of the reference axis
[Valid data range] 9 digit of minimum unit of data (refer to standard parameter setting table (A))
(When the increment system is IS-B, -999999.999 to +999999.999)

Each of these parameters sets the minimum value of the operation range of each of the first to sixteenth high-speed position switches. If such a setting that maximum value < minimum value is made, no operation range exists, so that the high-speed position switch does not operate.

NOTE
Parameters Nos. 8596 to 8599 and 12241 to 12246 are valid only when bit 7 (HPE) of parameter No. 8500 is 1.

1.2.11 Axis Total Travel Distance Display

Overview

Total travel distance of axis is calculated, the distance of each axis is displayed on the diagnosis screen. If target distance is set, signal indicates that the travel distance exceeds the target.

Explanation

- Display of total travel distance

Total travel distance of axis is displayed on diagnosis data Nos. 365 and 366. When bit 3 (ETD) of parameter No. 8906 is 1, this function is valid.
Diagnosis data No. 365 becomes 0 when total travel distance clear signal TDCx<Gn726> is set to "1" from "0".
Diagnosis data No. 366 becomes 0 when it exceeds the upper limit.
When bit 3 (ETD) of parameter No. 8906 is 0, this function is executed as follows:

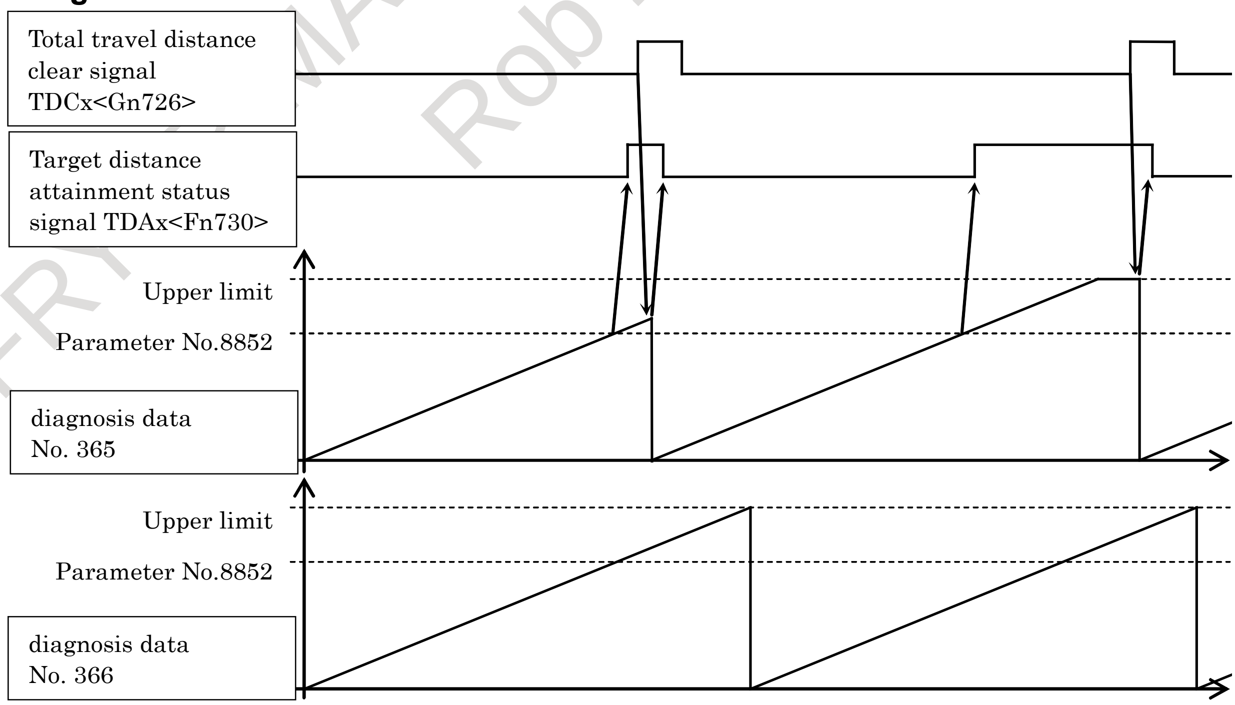
- Total travel distance is not calculated. However, the value calculated in the past is displayed.
- Diagnosis data No. 365 is not cleared by total travel distance clear signal TDCx<Gn726>.

	Total travel distance clear signal TDCx<Gn726> is set to "1" from "0"	Travel distance exceeds the upper limit.
Diagnosis data No. 365	Becomes 0	Keeps the upper limit
Diagnosis data No. 366	Doesn't become 0	Becomes 0

- Indication of target distance attainment

When total travel distance (diagnosis data No. 365) exceeds the target distance set in parameter No. 8852, target distance attainment status signal TDAx<Fn730> becomes "1". Even if travel distance exceeds target, the accumulation of diagnostic data(No.365) continues.
When bit 3 (ETD) of parameter No. 8906 is 1, this function is valid. If bit 3 (ETD) of parameter No. 8906 is 0 or the value set in parameter No.8852 is outside the data range, target distance attainment status signal TDAx<Fn730> always becomes 0.

Timing chart



NOTE
1 Total travel distance is not calculated at the following command:
- Feedrate control of PMC axis control of when bit 2 (VCP) of parameter No. 8007 is 1 and bit 4 (EVP) of parameter No. 8005 is 0.
- Torque control of PMC axis control of when follow-up is not performed (bit 4 (TQF) of parameter No. 1803 is 0).

2 Total travel distance of axis to which servo is invalid (bit 4 (KSVx) of parameter No. 11802) is not calculated.
3 In the axis during servo-off with follow-up (bit 0 (FUPx) of parameter No.1819 is 0 and follow-up signal *FLWU<Gn007.5> is “0”), the travel distance by the external force is added to total travel distance.

Parameter

	#7	#6	#5	#4	#3	#2	#1	#0
8906					ETD			

[Input type] Parameter input
[Data type] Bit

NOTE
When at least one of these parameters is set, the power must be turned off before operation is continued.

#3 ETD Axis total travel distance display is:
0: Invalid.
1: Valid.

8852	Target distance of each axis

[Input type] Parameter input
[Data type] 2-word axis
[Unit of data] m, 100 inch, 360 deg
[Valid data range] 1 to 999999999

When diagnosis data No. 365 exceeds the value set in this parameter, target distance attainment status signal TDAx<Fn730> become "1".

NOTE
1 In case of rotation axis, unit of data is 360 degree. In case of linear axis, unit of data is m or 100 inch according to the least command increment.
2 If the value set in this parameter is outside the data range or bit 3 (ETD) of parameter No. 8906 is 0, target distance attainment status signal TDAx<Fn730> always becomes 0.
3 This parameter is specified as radius specification. Diameter/radius specification does not affect this parameter.

Signal

Total travel distance clear signal TDC1 to TDC8<Gn726>

[Classification] Input signal

[Function] Total travel distance (diagnosis data No. 365) of the corresponding axis becomes 0.

[Operation] When these signals are set to "1" from "0", total travel distance (diagnosis data No. 365) of the corresponding axis becomes 0.

> **NOTE**
> 1 When bit 3 (ETD) of parameter No. 8906 is 1, these signals are valid. If bit 3 (ETD) of parameter No. 8906 is 0, diagnosis data No. 365 doesn't become 0.
> 2 Set these signals to "0" after confirming either of the following conditions:
> - Target distance attainment status signal TDAx<Fn730> becomes “0” from “1”
> - Diagnosis data No. 365 becomes 0
> - 128 msec or more have passed since these signals became “1”

Target distance attainment status signal TDA1 to TDA8<Fn730>

[Classification] Output signal

[Function] These signals indicate that the travel distance exceeds the target.

[Output cond.] These signals become “1” when:

- Total travel distance (diagnosis data No. 365) exceeds the target distance set in parameter No. 8852.

These signals become “0” when:

- Total travel distance (diagnosis data No. 365) doesn’t exceed the target distance set in parameter No. 8852.

> **NOTE**
> When bit 3 (ETD) of parameter No. 8906 is 1, these signals are valid. If bit 3 (ETD) of parameter No. 8906 is 0 or the value set in parameter No.8852 is outside the data range, these signals always become 0.

Signal address

	#7	#6	#5	#4	#3	#2	#1	#0
Gn726	TDC8	TDC7	TDC6	TDC5	TDC4	TDC3	TDC2	TDC1

	#7	#6	#5	#4	#3	#2	#1	#0
Fn730	TDA8	TDA7	TDA6	TDA5	TDA4	TDA3	TDA2	TDA1

Diagnosis data

365	Total travel distance (clearable)
366	Total travel distance

[Data type] 2-word axis
[Unit of data] m, 100 inch, 360 deg
[Valid data range] 0 to 42949672 (When unit of data is m)
0 to 16909320 (When unit of data is 100 inch)
0 to 4294967295 (When unit of data is 360 deg)

Total travel distance of axis is displayed.
When total travel distance clear signal TDCx<Gn726> is set to "1" from "0", diagnosis data No. 365 becomes 0. Diagnosis data No. 366 becomes 0 when it exceeds the upper limit.

	Total travel distance clear signal TDCx<Gn726> is set to "1" from "0"	Travel distance exceeds the upper limit.
Diagnosis data No. 365	Becomes 0	Keeps the upper limit
Diagnosis data No. 366	Doesn't become 0	Becomes 0

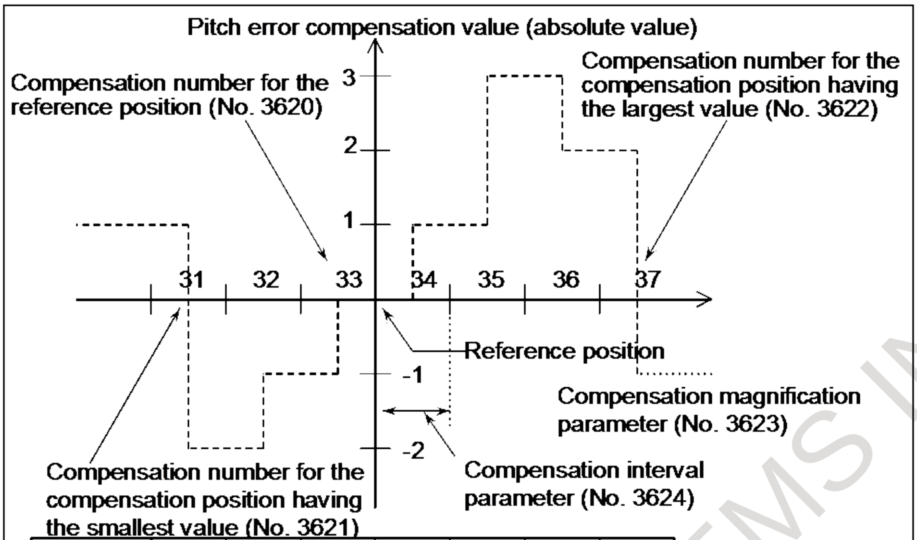
NOTE
1 In case of rotation axis, unit of data is 360 degree. In case of linear axis, unit of data is m or 100 inch according to the least command increment.
2 If bit 3 (ETD) of parameter No. 8906 is 1, total travel distance is calculated.
3 If bit 3 (ETD) of parameter No. 8906 is 0, total travel distance is not calculated. However, the value calculated in the past is displayed.
4 These diagnosis data are displayed as radius specification. Diameter/radius specification does not affect these diagnosis data.

1.3 ERROR COMPENSATION

1.3.1 Stored Pitch Error Compensation

Overview

If pitch error compensation data is specified, pitch errors of each axis can be compensated in detection units per axis.
Pitch error compensation data is set for each compensation position at the intervals specified for each axis. The origin of compensation is the reference position to which the tool is returned.
Pitch error compensation data can be set with external devices such as the Handy File (see OPERATOR'S MANUAL). Compensation data can also be set directly with the MDI unit.
The following parameters must be set for pitch error compensation. Set the pitch error compensation value for each pitch error compensation position number set by these parameters.
In the following example of Fig. 1.3.1 (a), 33 is set for the pitch error compensation number at the reference position.



Compensation position number	31	32	33	34	35	36	37
Compensation value to be set	-3	+1	+1	+1	+2	-1	-3

Fig. 1.3.1 (a)

- Pitch error compensation position at the reference position (for each axis): Parameter No.3620
- Pitch error compensation position having the smallest value (for each axis): Parameter No.3621
- Pitch error compensation position having the largest value (for each axis): Parameter No.3622
- Pitch error compensation magnification (for each axis): Parameter No.3623
- Interval of the pitch error compensation positions (for each axis): Parameter No.3624

Explanation

- Specifying the compensation position

To assign the compensation positions for each axis, specify the positive direction or the negative direction relative to the compensation position No. of the reference position. If the machine stroke exceeds the specified range on either the positive direction or the negative direction, the pitch error compensation does not apply beyond the range.

- Compensation position number

1536 compensation positions from No. 0 to 1535 are available on the pitch error setting screen. Assign arbitrary positions for each axis using parameters.
The number of the compensation position at the reference position (parameter No.3620), number of the compensation position having the smallest value (parameter No.3621), and number of the compensation position having the largest value (parameter No.3622) must be set for each axis.
The name of each axis is displayed before the smallest compensation position number on the pitch error setting screen.

- Interval of compensation positions

The pitch error compensation positions are equally spaced to parameter No. 3624. Set the space between two adjacent positions for each axis.
The minimum interval between pitch error compensation positions is limited and obtained from the following equation:
Minimum interval of pitch error compensation positions = maximum feedrate (rapid traverse rate)/7500
Unit :

Minimum interval of pitch error compensation positions: mm, inches, deg.
Maximum feed rate: mm/min, inch/min, deg/min

[Example]

When the maximum rapid traverse rate is 15000 mm/min, the minimum interval between pitch error compensation positions is 2 mm.

Example

- For linear axis

- Machine stroke: -400 mm to +800 mm
- Interval between the pitch error compensation positions: 50 mm
- No. of the compensation position of the reference position: 40

If the above is specified, the No. of the farthest compensation position in the negative direction is as follows:

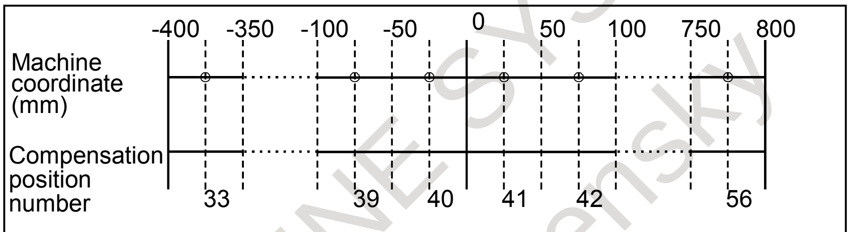
No. of the compensation position of the reference position - (Machine stroke on the negative side/Interval between the compensation positions) + 1= 40 - 400/50 + 1= 33

No. of the farthest compensation position in the positive direction is as follows:

No. of the compensation position of the reference position + (Machine stroke on the positive side/Interval between the compensation positions)= 40 + 800/50= 56

A fraction of the division of machine stroke on the negative/positive side by interval between the compensation positions is raised up to an integer.

The correspondence between the machine coordinate and the compensation position No. is as Fig. 1.3.1(b):



Compensation values are output at the positions indicated by ○.

Fig. 1.3.1 (b)

Therefore, set the parameters as Table 1.3.1 (a):

Table 1.3.1 (a)

Parameter	Setting value
3620 : Compensation number for the reference position	40
3621 : Smallest compensation position number	33
3622 : Largest compensation position number	56
3623 : Compensation magnification	1
3624 : Interval between pitch error compensation positions	50.0

The compensation amount is output at the compensation position No. corresponding to each section between the coordinates.

The Fig. 1.3.1 (c) is an example of the compensation amounts.

Number	33	34	35	36	37	38	39	40	41	42	43	44	45	46	47	48	49	...	56
Compensation value	-2	-1	-1	+2	0	+1	0	+1	+2	+1	0	-1	-1	-2	0	+1	+2	...	1

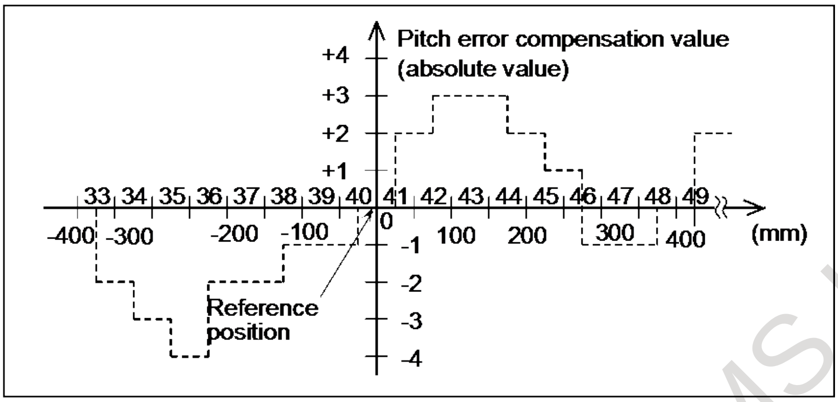


Fig. 1.3.1 (c)

- For rotary axis

- Amount of movement per rotation: 360°
- Interval between pitch error compensation positions: 45°
- No. of the compensation position of the reference position: 60

In the above case, the number of the most distance compensation position on the - side is equal to the number of the compensation position of the reference position + 1 = 60 + 1 = 61 for a rotary axis.
The No. of the farthest compensation position in the positive direction is as follows:
No. of the compensation position of the reference position + (Move amount per rotation/Interval between the compensation positions)= 60 + 360/45= 68
The correspondence between the machine coordinate and the compensation position No. is as Fig. 1.3.1 (d):

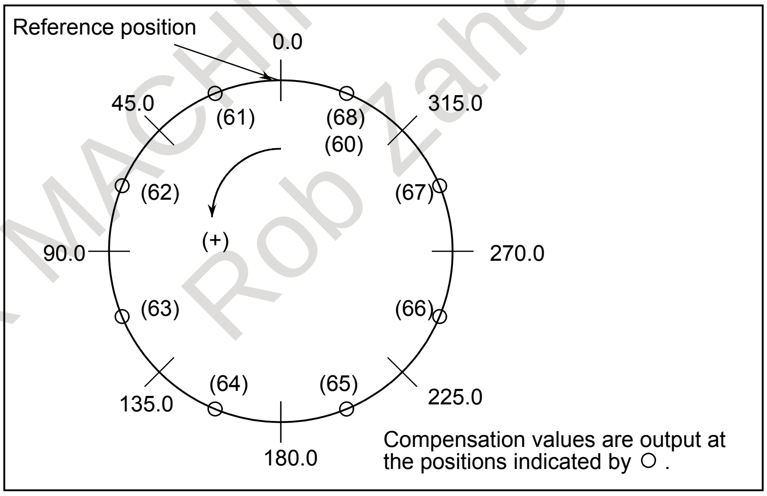

Fig. 1.3.1 (d)

Therefore, set the parameters as Table 1.3.1 (b):

Table 1.3.1 (b)

Parameter	Setting value
3620 : Compensation number for the reference position	60
3621 : Smallest compensation position number	61
3622 : Largest compensation position number	68
3623 : Compensation magnification	1
3624 : Interval between pitch error compensation positions	45.0
3625 : Movement value per rotation	360.0

If the sum of the compensation values for positions 61 to 68 is not 0, pitch error compensation values are accumulated for each rotation, causing positional deviation.
The same value must be set for compensation positions 60 and 68.

The Fig. 1.3.1 (e) is an example of compensation amounts.

Number	60	61	62	63	64	65	66	67	68
Compensation value	+1	-2	+1	+3	-1	-1	-3	+2	+1

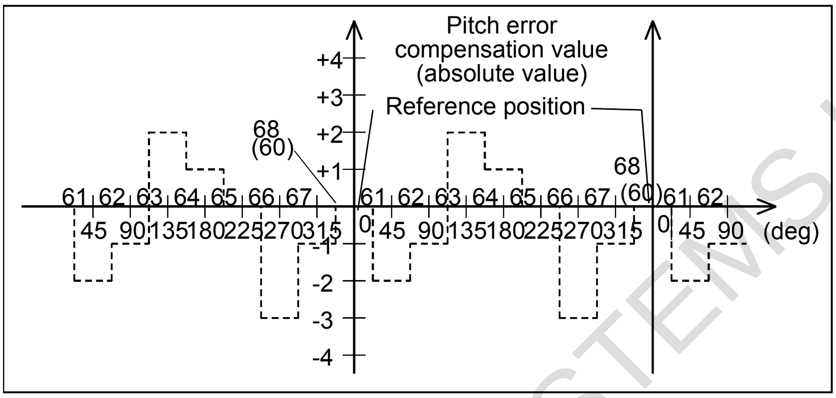

Fig. 1.3.1 (e)

Procedure for displaying and setting the pitch error compensation data

Procedure

1 Set the following parameters:

- Number of the pitch error compensation point at the reference position (for each axis) : Parameter No. 3620
- Number of the pitch error compensation point having the smallest value (for each axis) : Parameter No. 3621
- Number of the pitch error compensation point having the largest value (for each axis) : Parameter No. 3622
- Pitch error compensation magnification (for each axis) : Parameter No. 3623
- Interval of the pitch error compensation points (for each axis) : Parameter No. 3624
- Travel distance per revolution of pitch error compensation of the rotary axis type (for each axis) : Parameter No. 3625

When using bi-directional pitch error compensation (setting bit 0 (BDPx) of parameter No. 3605 to 1), specify the following parameters in addition to the pitch error compensation parameter.

- Number of the pitch error compensation point at the negative end (for travel in the positive direction, for each axis) : Parameter No. 3621
- Number of the pitch error compensation point at the positive end (for travel in the positive direction, for each axis) : Parameter No. 3622
- Number of the pitch error compensation point at the negative end (for travel in the negative direction, for each axis) : Parameter No. 3626
- Pitch error compensation in the reference position when moving to the reference position from opposite to the reference position return direction (for each axis) : Parameter No. 3627

2 Press function key SYSTEM.

3 When the display unit is 10.4-inch, press the continuous menu key ▷, then press chapter selection soft key [PITCH ERROR]. The following screen is displayed:

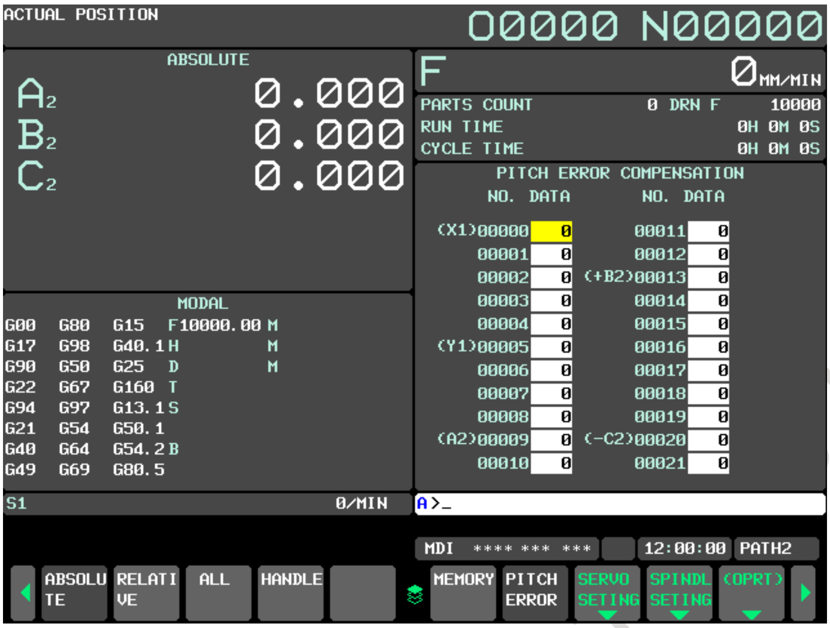

Fig. 1.3.1 (f) PITCH ERROR COMPENSATION screen (10.4-inch display unit)

3 When the display unit is 15/19-inch, press vertical soft key [PITCH ERROR]. The following screen is displayed:

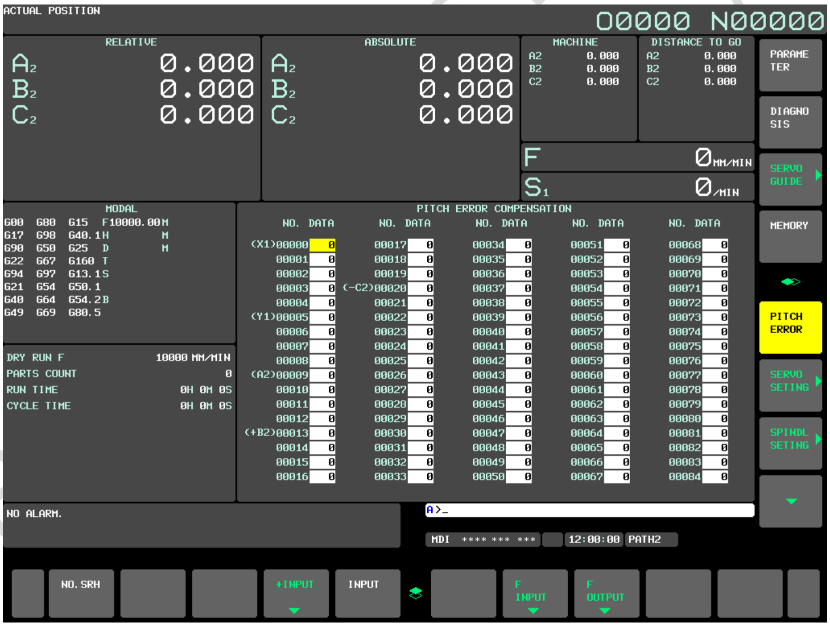

Fig. 1.3.1 (g) PITCH ERROR COMPENSATION screen (15-inch display unit)

4 Move the cursor to the compensation point number to be set in either of the following ways:
- Enter the compensation point number and press the soft key [NO.SRH].
- Move the cursor to the compensation point number using the page keys,  and , and cursor keys, , , , and .

5 Enter a value with numeric keys and press soft key [INPUT].

If bit 5 (PAD) of parameter No. 11350 is 1, an axis name is displayed next to the compensation point number set in parameter No. 3621 for determining the most negative pitch error compensation point number. Also, if the bi-directional pitch error compensation function is enabled, "+ axis name" is displayed next to the compensation point number set in parameter No. 3621 for setting the compensation point during movement in the positive direction, and "- axis name" is displayed next to the compensation point number set in parameter No. 3626 for setting the compensation point during movement in the negative direction.

NOTE
1 If the setting of the pitch error compensation parameter is not correct, the axis name of that axis is not displayed.
2 For a rotation axis, an axis name is displayed next to the pitch error compensation point number of the reference position set in parameter No. 3620.

Parameter

3620	Number of the pitch error compensation position for the reference position for each axis

NOTE
When this parameter is set, the power must be turned off before operation is continued.

[Input type] Parameter input
[Data type] Word axis
[Valid data range] 0 to 1535

Set the number of the pitch error compensation position for the reference position for each axis.

3621	Number of the pitch error compensation position at extremely negative position for each axis

NOTE
When this parameter is set, the power must be turned off before operation is continued.

[Input type] Parameter input
[Data type] Word axis
[Valid data range] 0 to 1535

Set the number of the pitch error compensation position at the extremely negative position for each axis.

3622	Number of the pitch error compensation position at extremely positive position for each axis

NOTE
When this parameter is set, the power must be turned off before operation is continued.

[Input type] Parameter input
[Data type] Word axis
[Valid data range] 0 to 1535

Set the number of the pitch error compensation position at the extremely positive position for each axis.
This value must be larger than set value of parameter No.3620.

3623	Magnification for pitch error compensation for each axis

NOTE
When this parameter is set, the power must be turned off before operation is continued.

[Input type] Parameter input
[Data type] Byte axis
[Valid data range] 0 to 100

Set the magnification for pitch error compensation for each axis.
If the magnification is set to 1, the same unit as the detection unit is used for the compensation data.
If 0 is set, compensation is not performed.

3624	Interval between pitch error compensation positions for each axis

NOTE
When this parameter is set, the power must be turned off before operation is continued.

[Input type] Parameter input
[Data type] Real axis
[Unit of data] mm, inch, deg (machine unit)
[Min. unit of data] Depend on the increment system of the applied axis
[Valid data range] See the description below.

The pitch error compensation positions are arranged with equal spacing. The space between two adjacent positions is set for each axis. The minimum interval between pitch error compensation positions is limited and obtained from the following equation:
Minimum interval between pitch error compensation positions = maximum feedrate/7500
Unit : mm, inch, deg or mm/min, inch/min, deg/min

[Example] When the maximum feedrate is 15000 mm/min, the minimum interval between pitch error compensation positions is 2 mm.

3625	Travel distance per revolution in pitch error compensation of rotary axis type

NOTE
When this parameter is set, the power must be turned off before operation is continued.

[Input type] Parameter input
[Data type] Real axis
[Unit of data] mm, inch, deg (machine unit)
[Min. unit of data] Depend on the increment system of the applied axis
[Valid data range] See the description below.

If the pitch error compensation of rotary axis type is performed (bit 1 (ROSx) of parameter No. 1006 is set to 0 and bit 0 (ROTx) of parameter No. 1006 is set to 1), set the travel distance per revolution. The travel distance per revolution does not have to be 360 degrees, and a cycle of pitch error compensation of rotary axis type can be set.
However, the travel distance per revolution, compensation interval, and number of compensation points must satisfy the following condition:

(Travel distance per revolution)
= (Compensation interval) × (Number of compensation points)

The compensation at each compensation point must be set so that the total compensation per revolution equals 0.

> **NOTE**
> If 0 is set, the travel distance per revolution becomes 360 degrees.

Warning

> ⚠ **WARNING**
> - **Compensation value range**
>   Compensation values can be set within the range from -127 × compensation magnification (detection unit) to +127 × compensation magnification (detection unit). The compensation magnification can be set for each axis within the range from 0 to 100 in parameter 3623.
> - **Pitch error compensation of the rotary axis**
>   For the rotating axis, the interval between the pitch error compensation positions shall be set to one per integer of the amount of movement (normally 360°) per rotation. The sum of all pitch error compensation amounts per rotation must be made to 0. Also, set the same compensation value to a position and the same position with one rotation.
> - **Conditions where pitch error compensation is not performed**
>   Note that the pitch error is not compensated in the following cases:
>   - When the machine is not returned to the reference position after turning on the power. This excludes the case where an absolute position detector is employed.
>   - If the interval between the pitch error compensation positions is 0.
>   - If the compensation position Nos. on the positive or negative direction do not fall within the range of 0 to 1535.
>   - For linear axis, if the compensation position Nos. do not conform to the following relationship:
>   Negative side ≤ Reference position < Positive side

Note

> **NOTE**
> For multipath control, axes that have the same axis name but that have different paths must use different compensation position Nos.

	Outputting Pitch Error Compensation Data

1.3.2 Backlash Compensation

Overview

- Backlash compensation

Function for compensating for lost motion on the machine. Set a compensation value in parameter No. 1851, in detection units from 0 to ±9999 pulses for each axis.

- Backlash compensation for each rapid traverse and cutting feed

When the bit 4 (RBK) of parameter No.1800 is set to 1, more precise machining can be performed by changing the backlash compensating value depending on the feedrate, the rapid traverse or the cutting feed.

Let the measured backlash at cutting feed be A and the measured backlash at rapid traverse be B. The backlash compensating value is shown Table 1.3.2 (a) depending on the change of feedrate (cutting feed or rapid traverse) and the change of the direction of movement.

Table 1.3.2 (a)

Change of feedrate / Change of direction of movement	Cutting feed to cutting feed	Rapid traverse to rapid traverse	Rapid traverse to cutting feed	Cutting feed to rapid traverse
Same direction	0	0	±α	±(-α)
Opposite direction	±A	±B	±(B+α)	±(B+α)

- $\alpha = (A-B) / 2$ (However, if α is not an integer, it is $\alpha = (A-(B-1)) / 2$.)
- The positive or negative direction for compensating values is the direction of movement.

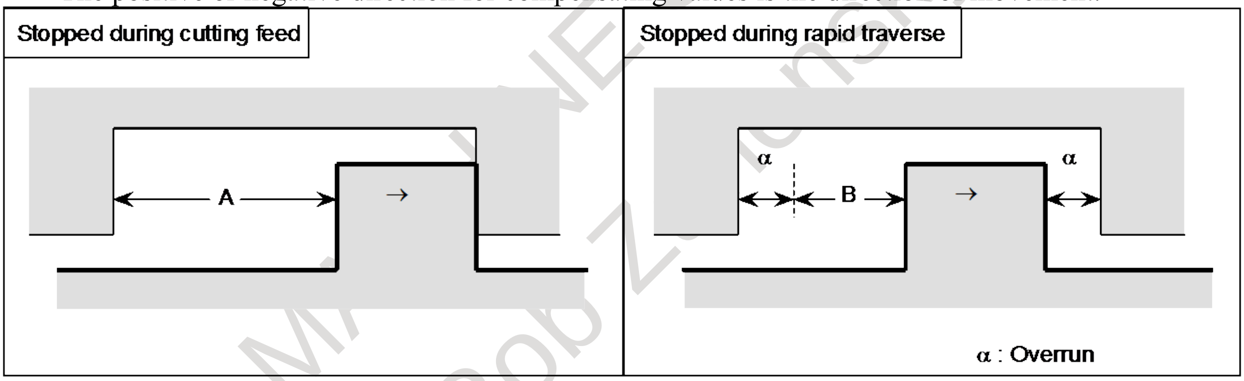

Fig. 1.3.2 (a)

- Assign the measured backlash at cutting feed (A) in parameter No. 1851 and that at rapid traverse (B) in parameter No. 1852.

- Tolerance for reverse pulse of the axis moving direction

The output of the backlash compensation pulse is controlled, from reversing of the movement direction of the axis to multiplying the movement value (unit of detection) that set by the parameter (No.1853).

As a result, the output of the backlash compensation pulse to the movement minutely repeated can be controlled.

And, the tolerance parameter (No.1853) for reverse pulse of the axis moving direction is also effective in the following functions.

- Backlash compensation for each rapid traverse and cutting feed
  (Backlash of the same direction is excluded)
- Smooth backlash compensation

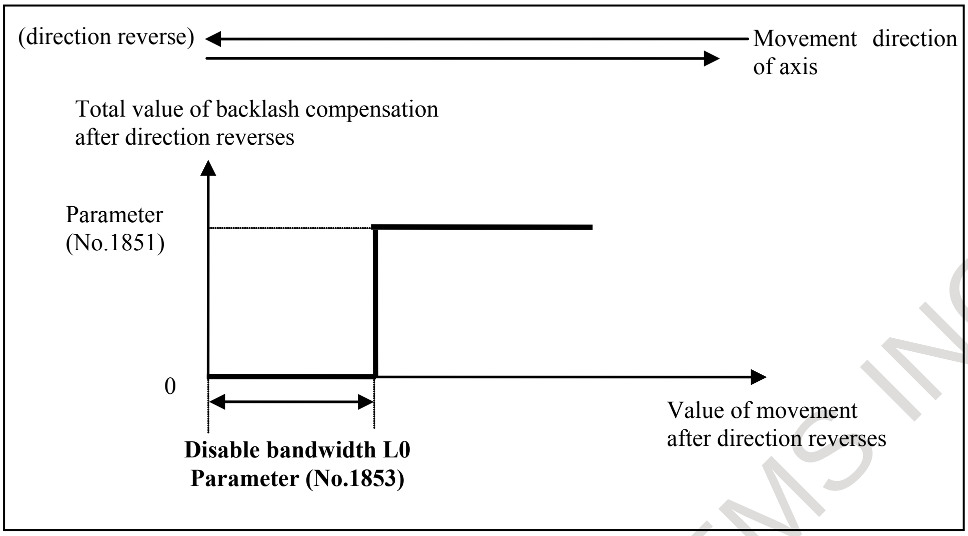

Fig. 1.3.2 (b) Tolerance for reverse pulse of the axis moving direction

> **NOTE**
> When an excessive value is input to the parameter (No.1853) of this function, the backlash compensation for each rapid traverse and cutting feed output of the same direction is done.
> When the backlash must be invalided, please adjust compensation value parameter (No.1848,1851,1852) to 0.

Parameter

	#7	#6	#5	#4	#3	#2	#1	#0
1800				RBK				

[Input type] Parameter input
[Data type] Bit path

#4 RBK Backlash compensation applied separately for rapid traverse and cutting feed
0: Not performed
1: Performed

	#7	#6	#5	#4	#3	#2	#1	#0
1802				BKL15x				

[Input type] Parameter input
[Data type] Bit axis

#4 BKL15x When the direction of a movement is determined in backlash compensation:
0: The compensation amount is not considered.
1: The compensation amount (pitch error, straightness, external machine coordinate system shift, etc.) is considered.

1851	Backlash compensating value for each axis

[Input type] Parameter input
[Data type] Word axis
[Unit of data] Detection unit
[Valid data range] -9999 to 9999
Set the backlash compensating value for each axis.

When the machine moves in a direction opposite to the reference position return direction after the power is turned on, the first backlash compensation is performed.

1852	Backlash compensating value used for rapid traverse for each axis

[Input type] Parameter input
[Data type] Word axis
[Unit of data] Detection unit
[Valid data range] -9999 to 9999

Set the backlash compensating value used in rapid traverse for each axis. (This parameter is valid when bit 4 (RBK) of parameter No. 1800 is set to 1.) More precise machining can be performed by changing the backlash compensating value depending on the feedrate, the cutting feed or the rapid traverse positioning. Let the measured backlash at cutting feed be A and the measured backlash at rapid traverse be B. The backlash compensating value is shown Table 1.3.2 (b) depending on the change of feedrate (cutting feed or rapid traverse) and the change of the direction of movement.

Table 1.3.2 (b)

Change of feedrate / Change of direction of movement	Cutting feed to cutting feed	Rapid traverse to rapid traverse	Rapid traverse to cutting feed	Cutting feed to rapid traverse
Same direction	0	0	$\pm\alpha$	$\pm(-\alpha)$
Opposite direction	$\pm$A	$\pm$B	$\pm(B+\alpha)$	$\pm(B+\alpha)$

NOTE
1 α=(A-B)/2 (However, if α is not an integer, it is α= (A-(B-1)) / 2.)
2 The positive or negative direction for compensating values is the direction of movement.

1853	Tolerance for reverse pulse of axis moving direction of backlash compensation

[Input type] Parameter input
[Data type] 2-word axis
[Unit of data] Detection unit
[Valid data range] 0 to 999999999

The tolerance value for reverse pulse of the axis moving direction of the backlash compensation is set.
After the value set by the parameter at time when the direction of the movement changed is moved, the backlash compensation pulse is output.
When this parameter set to 0, the function of invalid bandwidth is disabled, and the backlash compensation is done when the direction of the movement is changed.

Caution

⚠ **CAUTION**
The backlash compensation for each rapid traverse and cutting feed is not performed until the first reference position return is completed after the power is turned on. Under this state, the normal backlash compensation is performed according to the value specified in parameter No. 1851 irrespective of a rapid traverse or a cutting feed.

Note

NOTE

1. When backlash compensation is applied separately for cutting feed and rapid traverse, jog feed is regarded as cutting feed.
2. If parameter No.1851 is changed when the backlash compensation or the backlash compensation for each rapid traverse and cutting feed is performed; the new compensation value becomes valid when the machine moves in a direction opposite to the reference return direction.
3. If parameter No.1852 is changed when the backlash compensation for each rapid traverse and cutting feed is performed; the new compensation value becomes valid when the machine moves at rapid traverse regardless of direction.

1.3.3 Smooth Backlash

Explanation

With normal backlash compensation, all backlash compensating value are output at the location where the direction of axis moving reverses. (Fig. 1.3.3 (a))

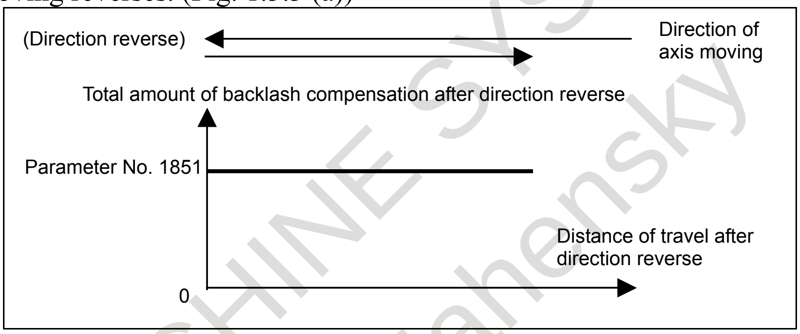

Fig. 1.3.3 (a) Normal backlash compensation

With smooth backlash compensation, backlash compensating value are output in accordance with the distance from the location where the direction of axis moving reverses, so that fine backlash compensation corresponding to the characteristics of the machine is possible. (Fig. 1.3.3 (b))

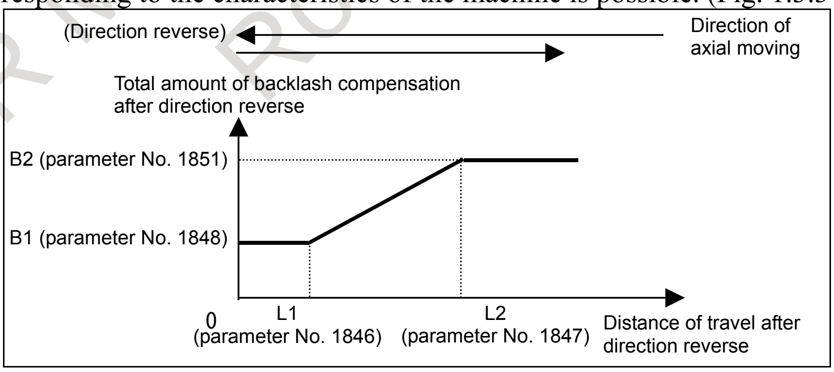

Fig. 1.3.3 (b) Smooth backlash compensation

To enable this function set SBL, bit 2 of parameter No. 1817, to 1.

- First stage backlash compensation output

At the location where the direction of axis moving reverses, the first stage backlash compensation output is performed. Set the first stage backlash compensation B_1, using parameter No.1848.

- Second stage backlash compensation output

At the point the tool moves by the distance L1 from the location where the direction of axis moving reverses, the second stage backlash compensation output is started. And, at the point the tool moves by the distance L2 from the location where the direction of axis moving reverses, the second stage backlash compensation output is terminated. The total amount of backlash at the stage where the second stage backlash compensation output is terminated, or B2, is the same as the backlash compensation set using parameter No.1851. Set the distances L1 and L2, using parameters Nos. 1846 and 1847, respectively. The rate of increase of the second stage backlash compensation output is calculated from the following equation.

$$\textit{Rate of increase of second backlash compensation output} = \frac{\textit{Parameter}\,\text{No.}1851 - B_1}{L_2 - L_1} \qquad (1)$$

If backlash compensation for each rapid traverse and cutting feed is enabled (RBK, bit 4 of parameter No. 1800 = 1), the total amount of backlash compensation at the stage where the second stage backlash compensation output is terminated, or B2, is the backlash compensation as determined by parameters Nos. 1852 and 1851, the reversed direction, and the rapid traverse/cutting feed mode. The rate of increase of the second stage backlash compensation output remains the same as that during cutting. (Expression 1)
The following shows an example in which the tool is changed from cutting feed to rapid traverse feed and the direction reverses. (Fig. 1.3.3 (c))

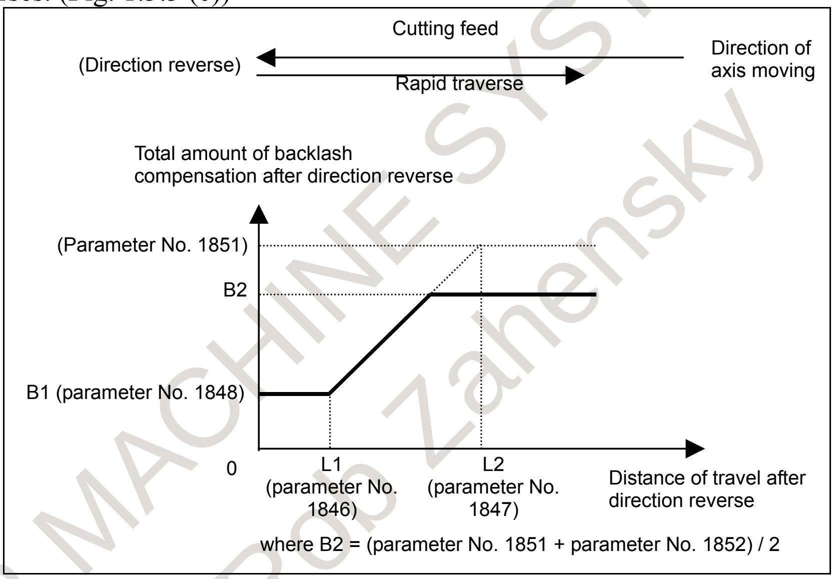

Fig. 1.3.3 (c) In the case of a change from cutting feed to rapid traverse

Parameter

	#7	#6	#5	#4	#3	#2	#1	#0
1800				RBK				

[Input type] Parameter input
[Data type] Bit path

#4 RBK Backlash compensation applied separately for cutting feed and rapid traverse
0: Not performed
1: Performed

	#7	#6	#5	#4	#3	#2	#1	#0
1817						SBL		

[Input type] Parameter input
[Data type] Bit axis

> **NOTE**
> When this parameter is set, the power must be turned off before operation is continued.

#2 SBL Smooth backlash compensation is :
0: Disabled.
1: Enabled.

1846	Distance for starting the second stage of smooth backlash compensation

[Input type] Parameter input
[Data type] 2-word axis
[Unit of data] Detection unit
[Valid data range] 0 to 999999999

For each axis, set the distance from the point where the axis movement direction is reversed to the point where the second stage of smooth backlash compensation is started.

If the following condition is not satisfied, smooth backlash compensation is disabled:
Value of parameter No. 1846 ≥ 0
Value of parameter No. 1846 < value of parameter No. 1847

1847	Distance for ending the second stage of smooth backlash compensation

[Input type] Parameter input
[Data type] 2-word axis
[Unit of data] Detection unit
[Valid data range] 0 to 999999999

For each axis, set the distance from the point where the axis movement direction is reversed to the point where the second stage of smooth backlash compensation is ended.

If the following condition is not satisfied, smooth backlash compensation is disabled:
Value of parameter No. 1846 ≥ 0
Value of parameter No. 1846 < value of parameter No. 1847

1848	Value of the first stage of smooth backlash compensation

[Input type] Parameter input
[Data type] Word axis
[Unit of data] Detection unit
[Valid data range] -9999 to 9999

Set the value of the first stage of smooth backlash compensation for each axis.
If the setting of this parameter is larger than the total backlash compensation value, smooth backlash compensation is not performed.
When a negative value is set for the backlash compensating value for each axis (parameter No. 1851), set a negative value in this parameter. If the sign set in this parameter is different from that set for the backlash compensating value for each axis (parameter No. 1851), compensation is performed, assuming that the value of the first stage of smooth backlash compensation is 0.

1851	Backlash compensating value for each axis

[Input type] Parameter input
[Data type] Word axis
[Unit of data] Detection unit
[Valid data range] -9999 to 9999

Set the backlash compensating value for each axis.
When the machine moves in a direction opposite to the reference position return direction after the power is turned on, the first backlash compensation is performed.

1852	Backlash compensating value used for rapid traverse for each axis

[Input type] Parameter input
[Data type] Word axis
[Unit of data] Detection unit
[Valid data range] -9999 to 9999

Set the backlash compensating value used in rapid traverse for each axis. (This parameter is valid when bit 4 (RBK) of parameter No. 1800 is set to 1.) More precise machining can be performed by changing the backlash compensating value depending on the feedrate, the cutting feed or the rapid traverse positioning. Let the measured backlash at cutting feed be A and the measured backlash at rapid traverse be B. The backlash compensating value is shown below depending on the change of feedrate (cutting feed or rapid traverse) and the change of the direction of movement.

Change of feedrate / Change of direction of movement	Cutting feed to cutting feed	Rapid traverse to rapid traverse	Rapid traverse to cutting feed	Cutting feed to rapid traverse
Same direction	0	0	$\pm\alpha$	$\pm(-\alpha)$
Opposite direction	$\pm$A	$\pm$B	$\pm(B+\alpha)$	$\pm(B+\alpha)$

NOTE
1 $\alpha=(A-B)/2$
2 The positive or negative direction for compensating values is the direction of movement.

	#7	#6	#5	#4	#3	#2	#1	#0
11601		SBN						

[Input type] Parameter input
[Data type] Bit

#6 SBN When the dual position feedback or the monitoring semi-full error is used in servo function, the smooth backlash compensation is executed :
0: According to the setting of bit 4 of parameter No.2206 and bit 5 of parameter No.2010.
1: In the semi-closed loop side.

1.3.4 Straightness Compensation

Overview

For a machine tool with a long stroke, deviations in straightness between axes may affect the machining accuracy. For this reason, when an axis moves, other axes are compensated in detection units to improve straightness. This improvement results in better machining accuracy.
When an axis (parameters Nos. 5711 to 5716) moves, the corresponding compensation axis (parameters Nos. 5721 to 5726) is compensated.
That is, the compensation axis is compensated at the pitch error compensation position (See Subsection “Stored Pitch Error Compensation”) of the moving axis.

- Relation between pitch error compensation points and straightness compensation

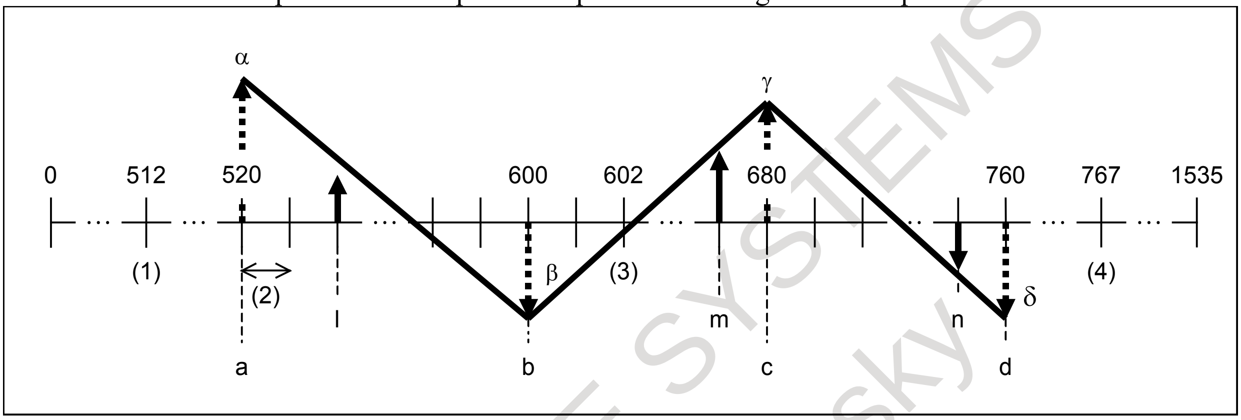

Fig. 1.3.4 (a)

To perform straightness compensation, stored pitch error compensation must be set for the moving axis.
(1) Number of the most distant pitch error compensation point on the - side (parameter No.3621)
(2) Pitch error compensation point interval (parameter No. 3624)
(3) Number of the pitch error compensation point of the reference position (parameter No. 3620)
(4) Number of the most distant pitch error compensation point on the + side (parameter No. 3622)
In Fig. 1.3.4 (a), (1), (3) and (4) are 512, 602 and 767, respectively.
Straightness compensation parameters must be set.
a,b,c,d : Compensation point numbers. (parameters Nos. 5731 to 5754, Nos. 13301 to 13324)
α,β,γ,δ : Compensation amounts at compensation points a, b, c and d (parameters Nos. 5761 to 5784, Nos. 13351 to 13374)
In Fig. 1.3.4 (a), a, b, c and d are 520, 600, 680 and 760, respectively.
Unlike stored pitch error compensation, whose amount is set up for an individual compensation point, an amount of straightness compensation is calculated for individual compensation points by setting up four typical points and compensation amounts for them.
Example:
In above figure, the compensation amount at the individual compensation point is as follows
At compensation point l between compensation point a and point b:

$\alpha + (\beta-\alpha) / (b-a) \times (l-a)$

At compensation point m between compensation point b and point c:

$\beta + (\gamma-\beta) / (c-b) \times (m-b)$

At compensation point n between compensation point c and point d:

$\gamma + (\delta-\gamma) / (d-c) \times (n-c)$

Example

Imagine a table whose Y-axis ball screw is placed on its X-axis ball screw. If the X-axis ball screw is inclined at a certain angle because of, for example, bending, the machining precision related to the Y-axis becomes low because its ball screw is affected by the gradient of the X-axis ball screw. (Left figure shown Fig. 1.3.4 (b))

Specifying the X-axis and Y-axis, respectively, as a moving axis and a compensation axis by means of straightness compensation causes the Y-axis (compensation axis) position to be compensated according to the X-axis (moving axis) position, thus increasing the machining precision. (Right figure shown Fig. 1.3.4 (b))

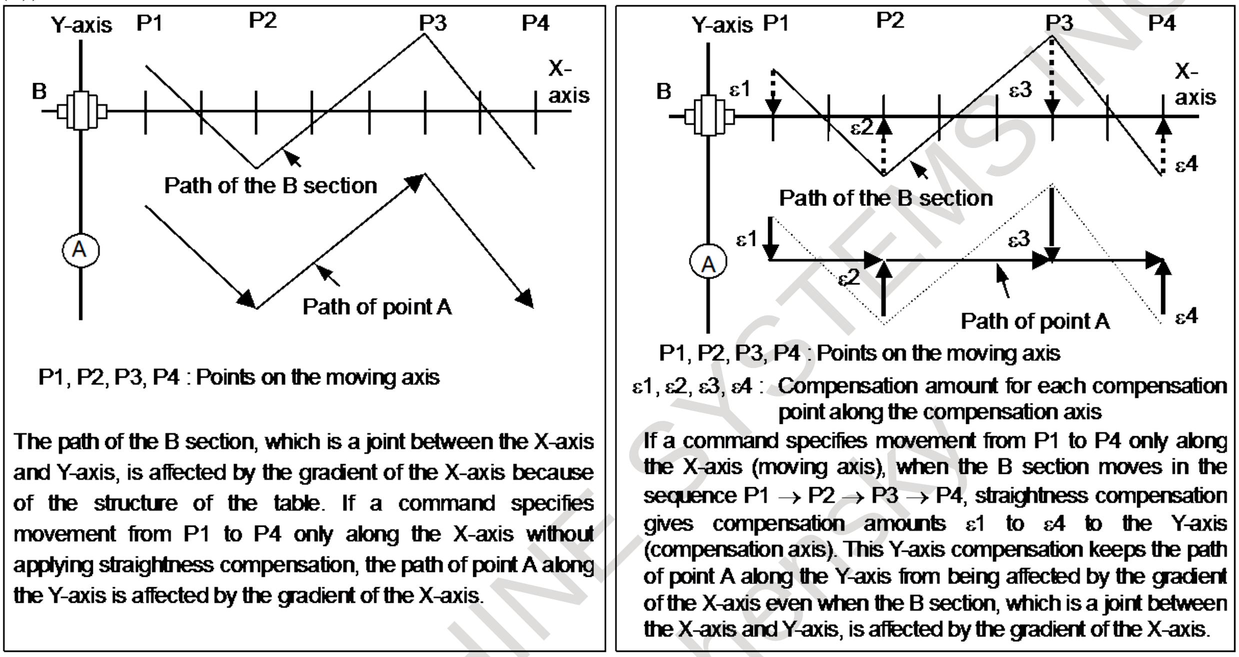

Fig. 1.3.4 (b)

- Function without turning off the power changing parameter of straightness compensation value

The compensation value of straightness compensation on each compensation point (parameter No. 5761 to 5784, No.13351 to 13374) can be changed without turning off the power by G10, pmc-window or MDI input.

The rewritten data is reflected from the following compensation point.

This function is activated when bit 0 (RSR) of parameter No.5700 is set to 1.

NOTE

1. When all axes have stopped, the parameters of the compensation value can be changed.
2. Please change the data of the interpolated straightness compensation (No.6000 to 9071 of pitch error setting screen) on the reference point (compensation value = 0).
3. When an illegal value is set to the compensation value parameter in each compensation point, the alarm DS5046"ILLEGAL PARAMETER (S-COMP.)" is generated.
   At this time, when the movement axis is moved by the manual operation method etc, the straightness compensation becomes invalid only the axis that sets an illegal value.

(1) Operation when the compensation value parameter is changed
When the compensation value parameter in each compensation point (a to d point) of the straightness compensation is changed, the changed value is reflected from the next pitch error compensation point.

Example)
The compensation point number (parameter No.5731 to 5733) of movement axis 1 is set to "a", "b" and "c". And, the value (parameter No.5761 to 5763) of the compensation in each compensation point is set to "α", "β" and " γ".
When the value "β" of the compensation of movement axis 1 is changed to "β' " and "γ" is changed to "γ' ", the value of the compensation becomes like the solid line of Fig. 1.3.4 (c).

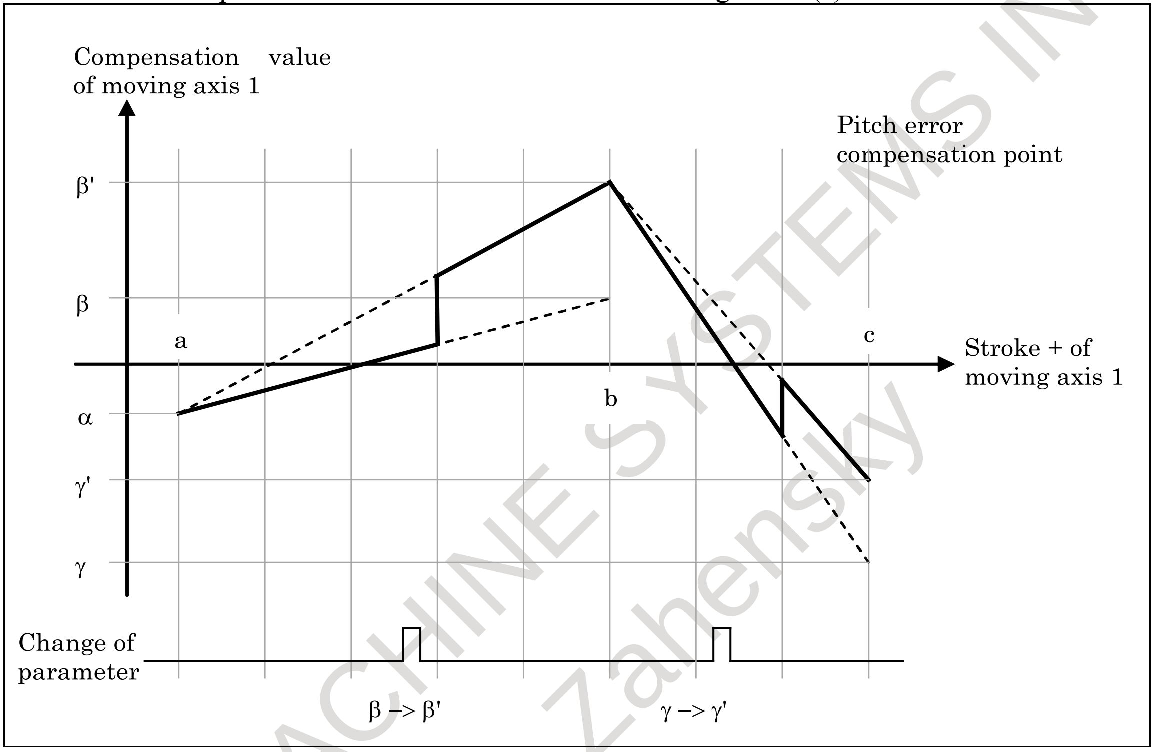

Fig. 1.3.4 (c) Example

(2) The value of compensation in reference point
The compensation value of reference point is outputed based on the setting of the parameter.

Example)
The compensation point number (parameter No.5731 to 5733) of movement axis 1 is set to "a", "b" and "c". And, the value (paremter No.5761 to 5763) of the compensation in each compensation point is set to "α", "β" and " γ".
However, the compensation point number "a" is set to be a compensation point number of the reference point. At this time, it becomes like the solid line of Fig. 1.3.4 (d).

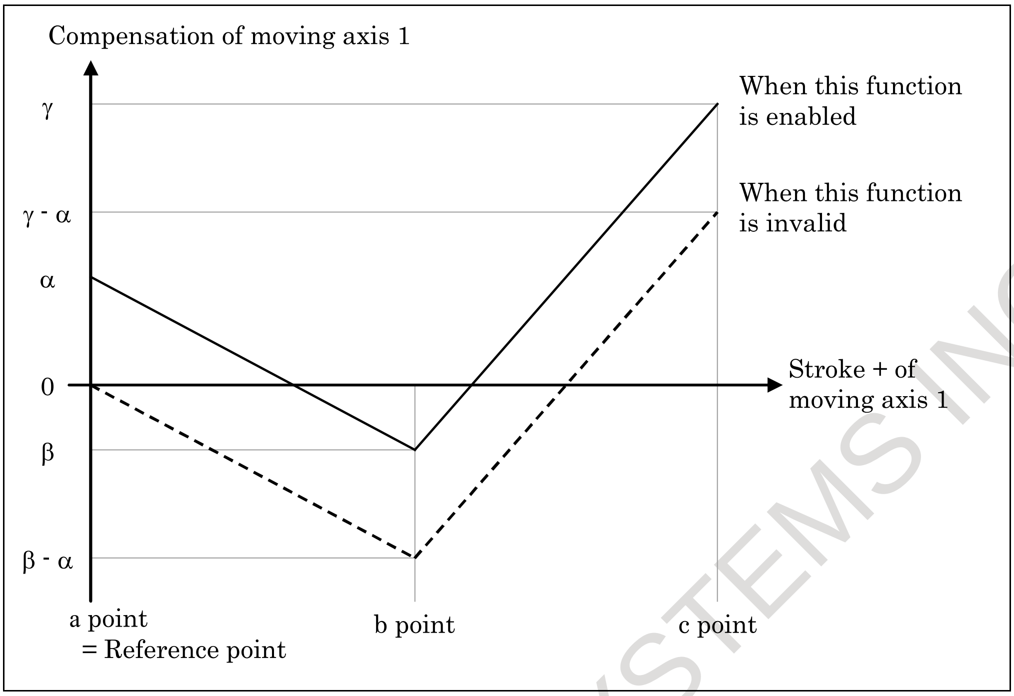

Fig. 1.3.4 (d) Example

> **NOTE**
> When this function is invalid, the value of the compensation becomes 0 in the reference point. (Dotted line of Fig. 1.3.4 (d))

Parameter

	#7	#6	#5	#4	#3	#2	#1	#0
5700								RSR

[Input type] Parameter input
[Data type] Bit path

#0 RSR When the compensation value data (parameter No.5761 to 5784, No.13351 to 13374) of the straightness compensation is set, the power off/on is :
0: Required.
1: Not required.

> **NOTE**
> 1 When this parameter is set, the power must be turned off before operation is continued.
> 2 When this function is enabled and the compensation value of straightness compensation on each compensation point (parameter No. 5761 to 5784, No.13351 to 13374) is changed, the alarm of turning off the power is not generated.

5711	Straightness compensation : Axis number of moving axis 1

5712	Straightness compensation : Axis number of moving axis 2

13364	Compensation corresponding compensation point number d of moving axis 5
13371	Compensation corresponding compensation point number a of moving axis 6
to	to
13374	Compensation corresponding compensation point number d of moving axis 6

NOTE
When these parameters are set, the power must be turned off before operation is continued.

[Input type] Parameter input
[Data type] Word path
[Unit of data] Detection unit
[Valid data range] -32767 to 32767
Each of these parameters sets a compensation value for each moving axis compensation point.

Alarm and message

Number	Message	Description
PW1103	ILLEGAL PARAMETER (S-COMP.128)	The parameter for setting 128 straightness compensation points or the parameter compensation data is incorrect,
PW5046	ILLEGAL PARAMETER (S-COMP.)	The parameter for setting straightness compensation is incorrect.
DS5046	ILLEGAL PARAMETER (S-COMP.)	The parameter for setting straightness compensation is incorrect.

Note

NOTE

1. To use this function, the stored pitch error compensation is required.
2. The straightness compensation function can be used after a moving axis and its compensation axis have returned to the reference position.
3. After setting parameters for straightness compensation, be sure to turn off the NC power. (When bit 0 (RSR) of parameter No.5700 is set to 1, the part of parameter is excluded.)
4. Set parameters for straightness compensation according to the following conditions:
   - The difference of compensation at a compensation point must be within the range -127 to 127. The difference of compensation at a compensation point between compensation point a and point b is (β-α) / (b-a).
   - Compensation positions must be set so that "a≤b≤c≤d" is satisfied.
   - Compensation positions must exist between the compensation position with the largest positive value and that with the largest negative value in the stored pitch error compensation data for each axis. Four compensation positions can be set to 0 at a time. In this case, compensation is not performed.
5. To add the straightness compensation function, the stored pitch error compensation is needed.
   In this case, the number of compensation positions of each axis between the compensation position with the largest positive value and that with the largest negative value in the stored pitch error compensation data must be equal to or less than 1536.
6. Straightness compensation data is superposed on stored pitch error compensation data and output. Straightness compensation is performed at pitch error compensation intervals.
7. Straightness compensation does not allow the moving axis to be used as a compensation axis. To implement such compensation, use inclinaiton compensation (see Subsection "Inclination Compensation").

1.3.5 Interpolated Straightness Compensation

Overview

The interpolated straightness compensation function has the progress of the following two features as compared to the straightness compensation function. Therefore, more precise compensation can be realized.

- Straightness compensation at 128 points (The amount of compensation points increases.)
- Interpolated straightness compensation (Compensation data is output by dividing in between the pitch error compensation position.)

Table 1.3.5 (a) Functional comparison

	Straightness compensation	Interpolated straightness compensation
Amount of compensation points	4 points	Maximum 128 points
Interval of compensation	Interval of pitch error compensation position	Least command increment (*1)
Setting of compensation data	Parameter	PITCH ERROR COMPENSATION screen
Range of compensation data	- 32767 to 32767	-127 to 127 (*2)

(*1) Compensation data is output by dividing in between the pitch error compensation position on the moving axis.
(*2) Actual compensation data is the value that is multiplied by the magnification parameters (Nos. 13391 to 13396) to a set value.

> **NOTE**
> 1 To use this function, the stored pitch error compensation is required.
> 2 For the amount of compensation points of the moving axis, the interpolated straightness compensation function becomes the same as the stored pitch error compensation function. Therefore, the amount of pitch error compensation points of the moving axis must be within 128 points.

Explanation

- Specifying the compensation point number of the moving axis

1. Set the smallest compensation point number of the moving axis to parameter Nos. 13381 to 13386.
2. The following data are calculated automatically according to the stored pitch error compensation point number.
   - The largest compensation point number of the moving axis
   - The compensation point number for the reference position of the moving axis

Relationship of the stored pitch error compensation point number and the interpolated straightness compensation point number of the moving axis is in Fig. 1.3.5 (a)

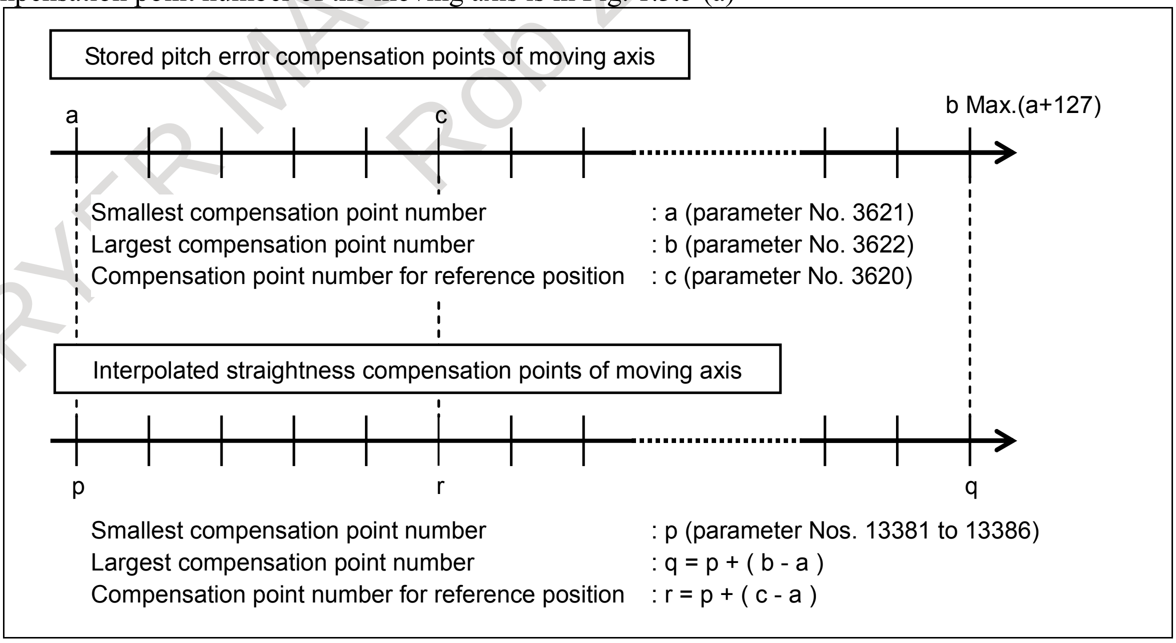

Fig. 1.3.5 (a) Relationship of the compensation point number

NOTE

In the interpolated straightness compensation function and the stored pitch error compensation function, the following data are the same value.

- Amount of compensation points
- Interval of compensation positions of the moving axis

- Setting of compensation data

Compensation data is set on the "PITCH ERROR COMPENSATION" screen.
Set it corresponding to the compensation point number of the moving axis. It is set in the range of -127 to 127 in the increase or decrease value from the previous compensation point number. And it is multiplied by the magnification parameters (Nos. 13391 to 13396).

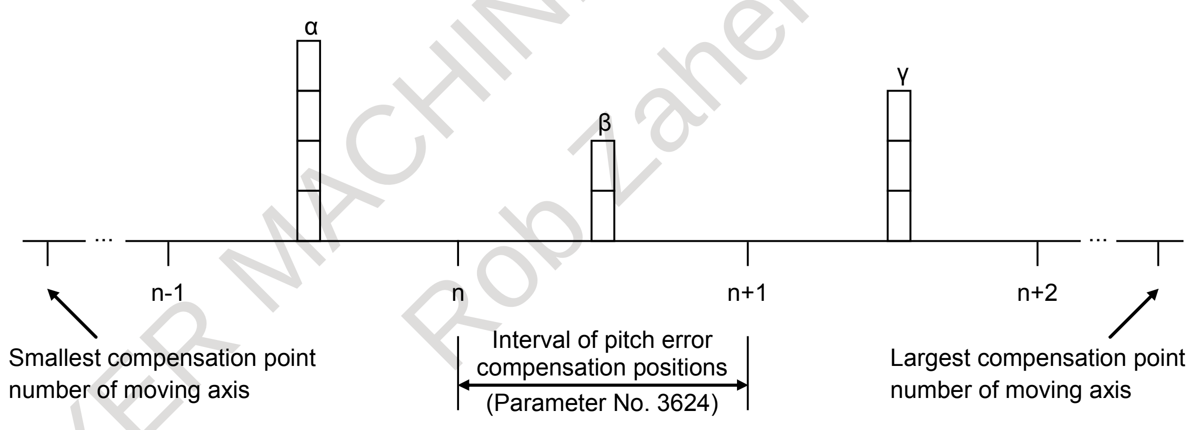
In addition to input with MDI unit on the screen, it is possible with the following ways.

- Input with G10 L50
- Input/output with the I/O unit interface
- Input from the PMC window (function code: 18)

In these methods, the compensation data can be input/output in parameter format in the same way as with the stored pitch error compensation data. In the interpolated straightness compensation function, parameter number is a value by adding 20000 to the compensation point number.
For more information, please refer to the description of each function.

- Compensation system

When the compensation data is set as shown in Fig. 1.3.5 (b), it is output by dividing in between the compensation position as shown in Fig. 1.3.5 (c). Therefore, the compensation axis becomes more smooth motion.



Compensation point number	...	n-1	n	n+1	n+2	...
Compensation data	...	...	α(4)	β(2)	γ(3)	...

Fig. 1.3.5 (b) Setting of compensation data

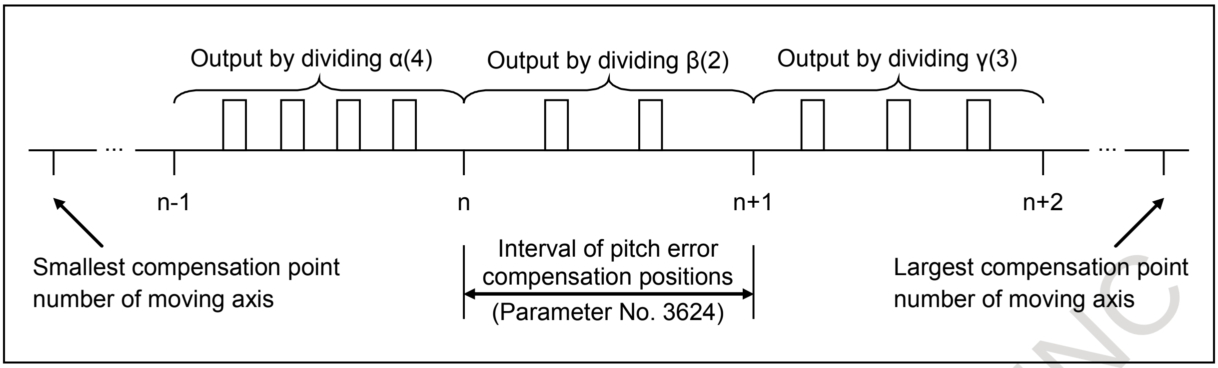


Fig. 1.3.5 (c) Interpolation system for interpolated straightness compensation

- Position display in interpolated straightness compensation

The interpolated straightness compensation amount is not reflected in position display.
The value in which interpolated straightness compensation amounts and other compensation amounts are integrated from power-on is displayed in diagnosis data No. 361.

- Setting of parameter

1. Set the parameter for stored pitch error compensation of the moving axis.
   - Compensation point number for reference position : Parameter No. 3620
   - Smallest compensation point number : Parameter No. 3621
   - Largest compensation point number : Parameter No. 3622
2. Set the parameter for interpolated straightness compensation.
   - Smallest compensation point number of moving axis : Parameter Nos. 13381 to 13386
   - Axis number of moving axis : Parameter Nos. 5711 to 5716
   - Axis number of compensation axis : Parameter Nos. 5721 to 5726
   - Magnification for compensation data : Parameter Nos. 13391 to 13396

Parameter setting examples

For the combination of the moving axis and the compensation axis, it can be set as shown in Table 1.3.5 (b) to Table 1.3.5 (e).

Table 1.3.5 (b) A single compensation axis can be set for a single moving axis.

Setting of moving axis		Setting of compensation axis		Effective magnification
Parameter No.	Setting	Parameter No.	Setting	
5711	1	5721	2	Value set in parameter No. 13391
5712	3	5722	4	Value set in parameter No. 13392
5713	5	5723	6	Value set in parameter No. 13393
5714	7	5724	8	Value set in parameter No. 13394
5715	9	5725	10	Value set in parameter No. 13395
5716	11	5726	12	Value set in parameter No. 13396

The 1st set : The 2nd axis is compensated according to the movement of the 1st axis.
The 2nd set : The 4th axis is compensated according to the movement of the 3rd axis.
The 3rd set : The 6th axis is compensated according to the movement of the 5th axis.
The 4th set : The 8th axis is compensated according to the movement of the 7th axis.
The 5th set : The 10th axis is compensated according to the movement of the 9th axis.
The 6th set : The 12th axis is compensated according to the movement of the 11th axis.

Table 1.3.5 (c) Two or more compensation axes can be set for a single moving axis.

Setting of moving axis		Setting of compensation axis		Effective magnification
Parameter No.	Setting	Parameter No.	Setting	
5711	1	5721	2	Value set in parameter No. 13391
5712	1	5722	3	Value set in parameter No. 13392
5713	1	5723	4	Value set in parameter No. 13393
5714	1	5724	5	Value set in parameter No. 13394

Setting of moving axis		Setting of compensation axis		Effective magnification
Parameter No.	Setting	Parameter No.	Setting	
5715	1	5725	6	Value set in parameter No. 13395
5716	1	5726	7	Value set in parameter No. 13396

The 1st set : The 2nd axis is compensated according to the movement of the 1st axis.
The 2nd set : The 3rd axis is compensated according to the movement of the 1st axis.
The 3rd set : The 4th axis is compensated according to the movement of the 1st axis.
The 4th set : The 5th axis is compensated according to the movement of the 1st axis.
The 5th set : The 6th axis is compensated according to the movement of the 1st axis.
The 6th set : The 7th axis is compensated according to the movement of the 1st axis.

Table 1.3.5 (d) A compensation axis can be set as a moving axis.

Setting of moving axis		Setting of compensation axis		Effective magnification
Parameter No.	Setting	Parameter No.	Setting	
5711	1	5721	2	Value set in parameter No. 13391
5712	2	5722	3	Value set in parameter No. 13392
5713	3	5723	4	Value set in parameter No. 13393
5714	4	5724	5	Value set in parameter No. 13394
5715	5	5725	6	Value set in parameter No. 13395
5716	6	5726	7	Value set in parameter No. 13396

The 1st set : The 2nd axis is compensated according to the movement of the 1st axis.
The 2nd set : The 3rd axis is compensated according to the movement of the 2nd axis.
The 3rd set : The 4th axis is compensated according to the movement of the 3rd axis.
The 4th set : The 5th axis is compensated according to the movement of the 4th axis.
The 5th set : The 6th axis is compensated according to the movement of the 5th axis.
The 6th set : The 7th axis is compensated according to the movement of the 6th axis.

NOTE
The movement by the compensation in one set, does not become the subject to compensation on the other set.

Table 1.3.5 (e) Two or more moving axes can be set for a single compensation axis.

Setting of moving axis		Setting of compensation axis		Effective magnification
Parameter No.	Setting	Parameter No.	Setting	
5711	1	5721	7	Value set in parameter No. 13391
5712	2	5722	7	Value set in parameter No. 13392
5713	3	5723	7	Value set in parameter No. 13393
5714	4	5724	7	Value set in parameter No. 13394
5715	5	5725	7	Value set in parameter No. 13395
5716	6	5726	7	Value set in parameter No. 13396

The 1st set : The 7th axis is compensated according to the movement of the 1st axis.
The 2nd set : The 7th axis is compensated according to the movement of the 2nd axis.
The 3rd set : The 7th axis is compensated according to the movement of the 3rd axis.
The 4th set : The 7th axis is compensated according to the movement of the 4th axis.
The 5th set : The 7th axis is compensated according to the movement of the 5th axis.
The 6th set : The 7th axis is compensated according to the movement of the 6th axis.

NOTE
When a compensation axis has two or more moving axes, it is compensated by the sum of the compensation data for each moving axis.

Parameter

	#7	#6	#5	#4	#3	#2	#1	#0
3605						IPCx		

[Input type] Parameter input
[Data type] Bit axis

NOTE
When this parameter is set, the power must be turned off before operation is continued.

#2 IPCx Interpolated straightness compensation function is:
0: Not used.
1: Used.
Specify the value of this parameter for the moving axis.

5700						SM2		

[Input type] Parameter input
[Data type] Bit path

#2 SM2 In the straightness compensation function, magnification parameters (parameters Nos. 13391 to 13396) are treated as follows:
0: When more than one moving axis is set with the same number, the setting of the magnification parameter for the moving axis set first is used.
1: When more than one moving axis is set with the same number, the setting of the magnification parameter for each axis is used.

5711	Straightness compensation : Axis number of moving axis 1
5712	Straightness compensation : Axis number of moving axis 2
5713	Straightness compensation : Axis number of moving axis 3
5714	Straightness compensation : Axis number of moving axis 4
5715	Straightness compensation : Axis number of moving axis 5
5716	Straightness compensation : Axis number of moving axis 6

NOTE
When these parameters are set, the power must be turned off before operation is continued.

[Input type] Parameter input
[Data type] Byte path
[Valid data range] 1 to Number of controlled axes
Set the axis numbers of moving axes for straightness compensation.
When 0 is set, compensation is not performed.

5721	Straightness compensation : Axis number of compensation axis 1 for moving axis 1
5722	Straightness compensation : Axis number of compensation axis 2 for moving axis 2
5723	Straightness compensation : Axis number of compensation axis 3 for moving axis 3

5724	Straightness compensation : Axis number of compensation axis 4 for moving axis 4
5725	Straightness compensation : Axis number of compensation axis 5 for moving axis 5
5726	Straightness compensation : Axis number of compensation axis 6 for moving axis 6

> **NOTE**
> When these parameters are set, the power must be turned off before operation is continued.

[Input type] Parameter input
[Data type] Byte path
[Valid data range] 1 to Number of controlled axes

13381	Number of the straightness compensation point at the extremely negative position of moving axis 1
13382	Number of the straightness compensation point at the extremely negative position of moving axis 2
13383	Number of the straightness compensation point at the extremely negative position of moving axis 3
13384	Number of the straightness compensation point at the extremely negative position of moving axis 4
13385	Number of the straightness compensation point at the extremely negative position of moving axis 5
13386	Number of the straightness compensation point at the extremely negative position of moving axis 6

> **NOTE**
> When these parameters are set, the power must be turned off before operation is continued.

[Input type] Parameter input
[Data type] Word path
[Valid data range] 6000 to 6767

Set the number of the straightness compensation point at the extremely negative position for each moving axis.
When the value set in this parameter is out of the valid data range, an alarm is issued and compensation cannot be performed.

13391	Magnification for straightness compensation for moving axis 1
13392	Magnification for straightness compensation for moving axis 2
13393	Magnification for straightness compensation for moving axis 3
13394	Magnification for straightness compensation for moving axis 4
13395	Magnification for straightness compensation for moving axis 5
13396	Magnification for straightness compensation for moving axis 6

> **NOTE**
> When these parameters are set, the power must be turned off before operation is continued.

[Input type] Parameter input
[Data type] Byte path
[Valid data range] 0 to 100

Set the magnification for straightness compensation for each moving axis.

When the magnification is set to 1, the unit of compensation data is the same as the detection unit. When the magnification is set to 0, straightness compensation is not performed.

Alarm and message

Number	Message	Description
SV1100	S-COMP.VALUE OVERFLOW	The straightness compensation has exceeded the maximum of 32767.
PW1103	ILLEGAL PARAMETER (S-COMP.128)	The setting of a parameter for straightness compensation at 128 points or the setting of compensation data is not correct.
PW5046	ILLEGAL PARAMETER (S-COMP)	The setting of a parameter related to straightness compensation contains an error. Possible causes include: - A non-existent axis number is set in a moving or compensation axis parameter. - The straightness compensation point numbers do not have correct magnitude relationships. - No straightness compensation point is found between the furthest pitch error compensation point in the negative region and that in the positive region. - The compensation per compensation point is either too large or too small.

Caution

⚠ **CAUTION**

1. To use this function, stored pitch error compensation is required.
2. The number of compensation points located between the furthest compensation point in the negative region and that in the positive region on each axis of stored pitch error compensation must not exceed 128.
3. The compensation point interval is the same as that of stored pitch error compensation (parameter No. 3624).
4. The compensation magnification can be set separately from that for stored pitch error compensation.
5. Straightness compensation is superposed with the data for stored pitch error compensation before being output.
6. If the motion value is high, multiple compensation pulses may be output at a time depending on the straightness compensation.
7. After setting parameters for straightness compensation, turn off the power to the NC and then back ON for the settings to take effect.
8. Interpolated straightness compensation cannot be used at the same time as conventional straightness compensation for a single moving axis. Interpolated straightness compensation can, however, be used together with conventional straightness compensation for different moving axes.

1.3.6 Interpolated Straightness Compensation 3072 Points

Overview

By adding this function to the interpolated straightness compensation, the number of compensation points which can be used is expanded to 3072. The number of points which can be used for one pair of interpolated straightness compensation is also expanded to 1536. As a result, higher accurate machining can be realized for a machine tool with a long stroke that requires straightness compensation, by more exact interpolated straightness compensation.

Explanation

Table 1.3.6 lists the number of compensation points which can be used for interpolated straightness compensation.

Table 1.3.6

	Interpolated straightness compensation	When interpolated straightness compensation 3072 points are added to interpolated straightness compensation
Points which can be set	768 points (used for all 6 pairs)	3072 points (used for all 6 pairs)
Points which can be set for one pair	128 points	1536 points
Setting screen	Set the points in Nos. 6000 to 6767 in the pitch error setting screen.	Set the points in Nos. 6000 to 9071 in the pitch error setting screen.

Caution

⚠ **CAUTION**

1 To use this function, the stored pitch error compensation and interpolated straightness compensation is required.
2 The compensation point interval is the same as that of stored pitch error compensation (parameter No. 3624).
3 The method for using this function is the same as for using interpolated straightness compensation. The related parameters are also the same as for interpolated straightness compensation. The valid data range of parameter Nos. 13381 to 13386 (number of the straightness compensation point at the extremely negative position) is changed to 6000 to 9071, however.
4 When this function is used, the number of compensation points located between the furthest compensation point in the negative region and that in the positive region on each axis of stored pitch error compensation must not exceed 1536.
5 Set parameters so that the total number of compensation points for moving axes used for six pairs of interpolated straightness compensation does not exceed 3072.

1.3.7 Inclination Compensation

Overview

By compensating for those errors in tools such as feed screws that depend on the position of the machine system in detection units, machining precision can be improved and mechanical life can be prolonged. Compensation is performed along an approximate straight line formed with a parameter-specified compensation point and a compensation amount related to it.

Explanation

Three approximate straight lines are formed with four parameter-specified compensation points and compensation amounts related to the respective compensation points. Inclinaiton compensation is carried out along these approximate straight lines at pitch error compensation intervals. The inclinaiton compensation amount is added to the pitch error compensation amount.

- Relation between pitch error compensation points and inclination compensation

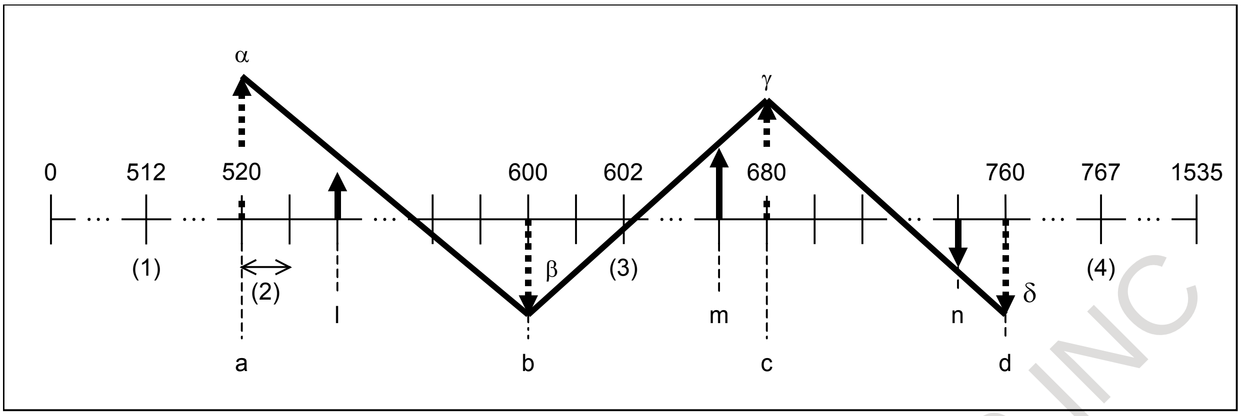

Fig. 1.3.7

To perform inclinaiton compensation, stored pitch error compensation must be set for the axis subject to compensation.

(1) Number of the most distant pitch error compensation point on the - side (parameter No.3621)
(2) Pitch error compensation point interval (parameter No. 3624)
(3) Number of the pitch error compensation point of the reference position (parameter No. 3620)
(4) Number of the most distant pitch error compensation point on the + side (parameter No. 3622)

InFig. 1.3.7, (1), (3) and (4) are 512, 602 and 767, respectively.

Inclinaiton compensation parameters must be set.

a,b,c,d : Compensation point numbers. (parameters Nos. 5861 to 5864)

α,β,γ,δ : Compensation amounts at compensation points a, b, c, and d (parameters Nos. 5871 to 5874)

In Fig. 1.3.4 (d)Fig. 1.3.7, a, b, c and d are 520, 600, 680, and 760, respectively.

Unlike stored pitch error compensation, whose amount is set up for an individual compensation point, an amount of inclinaiton compensation is calculated for individual compensation points by setting up four typical points and compensation amounts for them.

Example:

In above figure, the compensation amount at the individual compensation point is as follows

At compensation point l between compensation point a and point b:

$\alpha + (\beta-\alpha) / (b-a) \times (l-a)$

At compensation point m between compensation point b and point c:

$\beta + (\gamma-\beta) / (c-b) \times (m-b)$

At compensation point n between compensation point c and point d:

$\gamma + (\delta-\gamma) / (d-c) \times (n-c)$

Parameter

5861	**Inclination compensation : Compensation point number a for each axis**
5862	**Inclination compensation : Compensation point number b for each axis**
5863	**Inclination compensation : Compensation point number c for each axis**
5864	**Inclination compensation : Compensation point number d for each axis**

NOTE

When these parameters are set, the power must be turned off before operation is continued.

[Input type] Parameter input
[Data type] Word axis
[Valid data range] 0 to 1535
These parameters set the compensation points for inclination compensation. The points are set for the compensation point numbers for stored pitch error compensation.

5871	Inclination compensation : Compensation α at compensation point number a for each axis
5872	Inclination compensation : Compensation β at compensation point number b for each axis
5873	Inclination compensation : Compensation γ at compensation point number c for each axis
5874	Inclination compensation : Compensation δ at compensation point number d for each axis

[Input type] Parameter input
[Data type] Word axis
[Unit of data] Detection unit
[Valid data range] -32767 to 32767
Each of these parameters sets a compensation value for each axis compensation point.

Alarm and message

Number	Message	Description
PW1102	ILLEGAL PARAMETER (I-COMP.)	The parameter for setting slope compensation is incorrect. This alarm occurs in the following cases: • When the number of pitch error compensation points on the axis on which slope compensation is executed exceeds 1536 between the most negative side and most positive side • When the size relationship between the slope compensation point Nos. is incorrect • When the slope compensation point is not located between the most negative side and most positive side of pitch error compensation • When the compensation per compensation point is too small or too great.

Note

NOTE

1 To use this function, Stored pitch error compensation is required. The number of compensation points located between the most distant compensation point on the + side of each axis and the most distant compensation point on the + side in stored pitch error compensation must not exceed 1536.
2 Inclinaiton compensation is enabled after the reference position is established on the compensation axis.
3 When setting parameters Nos. 5861 to 5864 (compensation point numbers a to d for individual axes), turn off the power to the NC and then back ON for the settings to take effect.
4 During automatic operation, it is possible to overwrite parameters Nos. 5871 to 5874, but make sure that all axes are stopped beforehand. If any of parameters Nos. 5871 to 5874 (compensation amounts at compensation points a to d for individual axes) is changed, the compensation amount determined from the compensation amount after the change is output after the point at which to output the compensation amount for the next inclinaiton compensation is passed.

NOTE

5 Parameters must satisfy the following conditions:
   - The difference of compensation at a compensation point must be within the range -127 to 127. The difference of compensation at a compensation point between compensation point a and point b is $(\beta-\alpha)$ / (b-a).
   - Compensation points must satisfy the following relationships: $a \le b \le c \le d$.
   - Compensation points must be located between the most distant compensation point in stored pitch error compensation on the - side of each axis and the most distant compensation point on the + side. If all four points are equal to 0, compensation is not performed.

6 Inclinaiton compensation is superimposed on the stored pitch error compensation data.

7 This function is applied to both linear and rotation axes.

8 The compensation amount at the reference position is output based on parameter settings. The first compensation pulse is output when the compensation point is reached.

Warning

⚠ **WARNING**

If any of parameters Nos. 5871 to 5874 (compensation amounts at compensation points a to d for individual axes) is changed, very large compensation may be output depending on the setting. Great care should be taken.

1.3.8 Bi-directional Pitch Error Compensation

Overview

In bi-directional pitch error compensation, different pitch error compensation amounts can be set for travel in the positive direction and that in the negative direction, so that pitch error compensation can be performed differently in the two directions, in contrast to stored pitch error compensation, which does not distinguish between the directions of travel. In addition, when the direction of travel is reversed, the compensation amount is automatically calculated from the pitch error compensation data to perform compensation in the same way as in backlash compensation. This reduces the difference between the paths in the positive and negative directions.

Explanation

- Setting data

1. Setting parameters

   Set the following parameters for each axis. For detail of parameter setting, refer to the subsection of "Stored Pitch Error Compensation".

Table 1.3.8 (a)

Parameter number	Description
3605#0	Bidirectional pitch error compensation, 1: Enabled / 0: Disabled
3620	Number of the pitch error compensation point of the reference position
3621	Number of the most distant pitch error compensation point on the - side for travel in the positive direction
3622	Number of the most distant pitch error compensation point on the + side for travel in the positive direction
3623	Pitch error compensation magnification
3624	Pitch error compensation point interval
3625	For a rotary axis, amount of travel per rotation in pitch error compensation

Parameter number	Description
3626	Number of the most distant pitch error compensation point on the - side for travel in the negative direction
3627	Pitch error compensation amount (absolute value) at the reference position when the machine moves to the reference position in the direction opposite to that of a reference position return

2. Pitch error compensation data
   The compensation point numbers for bi-directional pitch error compensation can be from 0 to 1535 and from 3000 to 4535. This data may be used for both the positive and negative directions. Note, however, that the set of compensation data for a given axis cannot extend over 1535 and 3000.

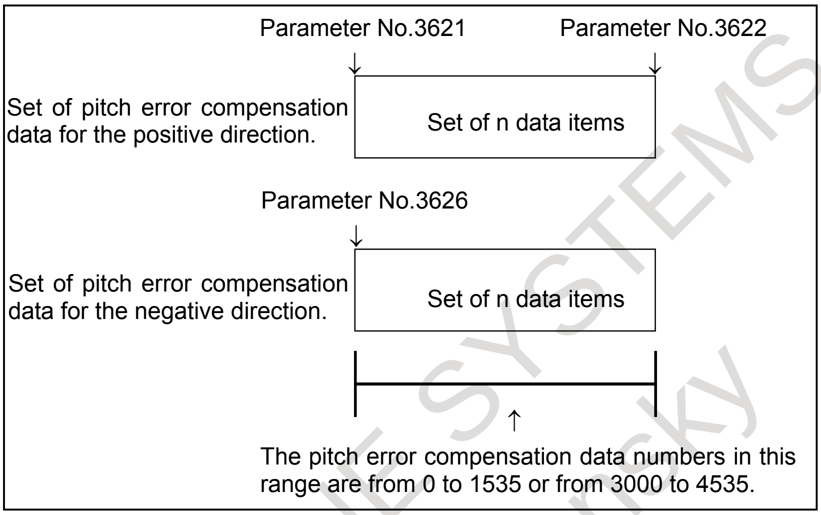

Fig. 1.3.8 (a)

- Data setting example

If the direction of a manual reference position return is positive on an axis (linear axis) having the pitch error amounts shown in the figure below (Fig. 1.3.8 (b)), set the data given in the table below (Table 1.3.8 (b)).

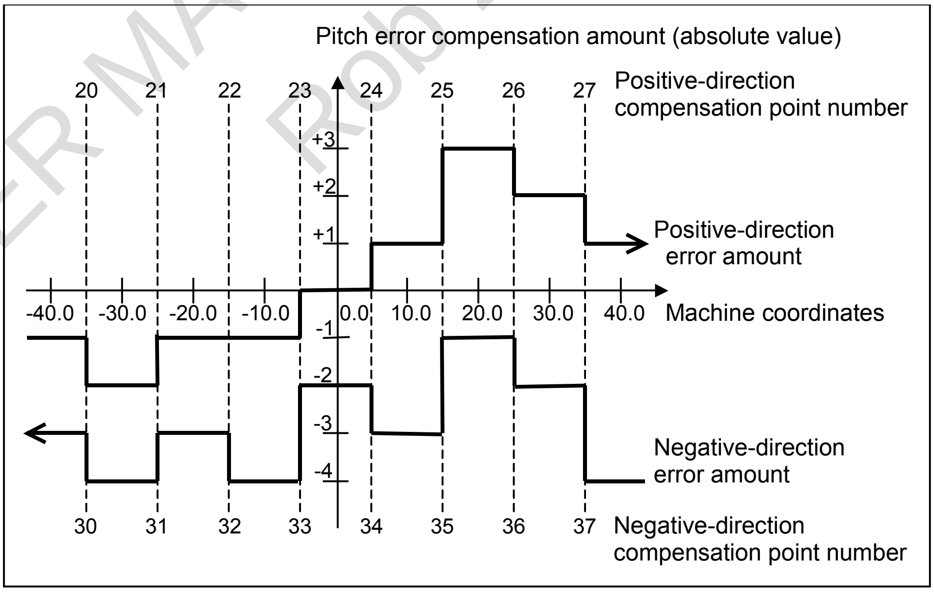

Fig. 1.3.8 (b)

Table 1.3.8 (b) Positive-direction pitch error data

Compensation point number	20	21	22	23	24	25	26	27
Compensation amount to be set	-1	+1	0	+1	+1	+2	-1	-1

As pitch error data, always set incremental values as viewed in the negative direction (direction toward the left in Fig. 1.3.8 (b)).

Table 1.3.8 (c) Negative-direction pitch error data

Compensation point number	30	31	32	33	34	35	36	37
Compensation amount to be set	-1	+1	-1	+2	-1	+2	-1	-2

Set negative-direction pitch error data for all the points for which positive-direction pitch error data has been set.
As negative-direction pitch error data, always set incremental values as viewed in the positive-direction.

Table 1.3.8 (d)

Parameter number	Setting	Description
3605#0	1	Bi-directional pitch error compensation, 1: Enabled / 0: Disabled
3620	23	Number of the pitch error compensation point for the reference position
3621	20	Number of the most distant pitch error compensation point on the - side for travel in the positive direction
3622	27	Number of the most distant pitch error compensation point on the + side for travel in the positive direction
3623	1	Pitch error compensation magnification
3624	10.0	Pitch error compensation point interval
3625	-	For a rotary axis, amount of travel per rotation in pitch error compensation
3626	30	Number of the most distant pitch error compensation point on the - side for travel in the negative direction
3627	-2	Pitch error compensation amount (absolute value) at the reference position when the machine moves to the reference position in the direction opposite to that of the reference position return

This example assumes that the direction of a manual reference position return is positive. For parameter No. 3627, therefore, set -2, which is the pitch error compensation amount (absolute value) at the reference position when the machine moves to the reference position in the negative direction.

- Compensation example

If, in the setting example given in the previous section, the machine moves

0.0 to 40.0,
40.0 to -40.0, and
-40.0 to 0.0

for a manual reference position return, pitch error compensation pulses are output as follows:

Machine coordinate	0.0	5.0	15.0	25.0	35.0	40.0
Compensation pulse	-	+1	+2	-1	-1	-5

Machine coordinate	35.0	25.0	15.0	5.0	-5.0	-15.0	-25.0	-35.0	-40.0
Compensation pulse	+2	+1	-2	+1	-2	+1	-1	+1	+2

Machine coordinate	-35.0	-25.0	-15.0	-5.0	0.0
Compensation pulse	-1	+1	0	+1	-

When the travel direction changes from positive to negative at the position of 40.0, the compensation for the reverse of the travel direction is output.

A pulse of -5 is the result of the following calculation:

-5 = (-4) - (+1)

(+1): Pitch error associated with the positive-direction absolute value at the position of 40.0

(-4): Pitch error associated with the negative-direction absolute value at the position of 40.0

Fig. 1.3.8 (c)

When the travel direction changes from negative to positive at the position of -40.0, the compensation for the reverse of the travel direction is output.

A pulse of +2 is the result of the following calculation:

+2 = (-1) - (-3)

(-3): Pitch error associated with the negative-direction absolute value at the position of -40.0

(-1): Pitch error associated with the positive-direction absolute value at the position of -40.0

Fig. 1.3.8 (d)

- Setting and displaying data

All pitch error the compensation data can be displayed and set on the conventional screen for the pitch error compensation data.

And those data can be input and output by the following methods.

- Input by MDI
- Input by G10
- Input and output by input/output device interface
- Input by PMC window (function code 18)

(It is not possible to input and output by the method other than the above methods.)

Compensation data for bi-directional pitch error compensation can be input/output in parameter format in the same way as stored pitch error compensation data. A pitch error compensation point number plus 20000 is the corresponding parameter number. (The format is the same as that for pitch error compensation data.)

Parameter

	#7	#6	#5	#4	#3	#2	#1	#0
3605								**BDPx**

[Input type] Parameter input
[Data type] Bit axis

> **NOTE**
> When this parameter is set, the power must be turned off before operation is continued.

#0 BDPx Both-direction pitch error compensation is:

0: Not used.
1: Used.

3620 **Number of the pitch error compensation position for the reference position for each axis**

> **NOTE**
> When this parameter is set, the power must be turned off before operation is continued.

[Input type] Parameter input
[Data type] Word axis
[Valid data range] 0 to 1535
Set the number of the pitch error compensation position for the reference position for each axis.

3621 **Number of the pitch error compensation position at extremely negative position for each axis**

> **NOTE**
> When this parameter is set, the power must be turned off before operation is continued.

[Input type] Parameter input
[Data type] Word axis
[Valid data range] 0 to 1535
Set the number of the pitch error compensation position at the extremely negative position for each axis.

3622 **Number of the pitch error compensation position at extremely positive position for each axis**

> **NOTE**
> When this parameter is set, the power must be turned off before operation is continued.

[Input type] Parameter input
[Data type] Word axis
[Valid data range] 0 to 1535
Set the number of the pitch error compensation position at the extremely positive position for each axis.
This value must be larger than set value of parameter No.3620.

3623 **Magnification for pitch error compensation for each axis**

> **NOTE**
> When this parameter is set, the power must be turned off before operation is continued.

[Input type] Parameter input
[Data type] Byte axis
[Valid data range] 0 to 100
Set the magnification for pitch error compensation for each axis.
If the magnification is set to 1, the same unit as the detection unit is used for the compensation data.
If 0 is set, compensation is not performed.

3624	Interval between pitch error compensation positions for each axis

NOTE
When this parameter is set, the power must be turned off before operation is continued.

[Input type] Parameter input
[Data type] Real axis
[Unit of data] mm, inch, deg (machine unit)
[Min. unit of data] Depend on the increment system of the applied axis
[Valid data range] See the description below.

The pitch error compensation positions are arranged with equal spacing. The space between two adjacent positions is set for each axis. The minimum interval between pitch error compensation positions is limited and obtained from the following equation:
Minimum interval between pitch error compensation positions = maximum feedrate/7500
Unit : mm, inch, deg or mm/min, inch/min, deg/min
Example:
When the maximum feedrate is 15000 mm/min, the minimum interval between pitch error compensation positions is 2 mm.

3625	Travel distance per revolution in pitch error compensation of rotary axis type

NOTE
When this parameter is set, the power must be turned off before operation is continued.

[Input type] Parameter input
[Data type] Real axis
[Unit of data] mm, inch, deg (machine unit)
[Min. unit of data] Depend on the increment system of the applied axis
[Valid data range] See the description below.

If the pitch error compensation of rotary axis type is performed (bit 1 (ROSx) of parameter No. 1006 is set to 0 and bit 0 (ROTx) of parameter No. 1006 is set to 1), set the travel distance per revolution. The travel distance per revolution does not have to be 360 degrees, and a cycle of pitch error compensation of rotary axis type can be set.
However, the travel distance per revolution, compensation interval, and number of compensation points must satisfy the following condition:
(Travel distance per revolution) = (Compensation interval) × (Number of compensation points)
The compensation at each compensation point must be set so that the total compensation per revolution equals 0.

NOTE
If 0 is set, the travel distance per revolution becomes 360 degrees.

3626	Number of the both-direction pitch error compensation position at extremely negative position (for movement in the negative direction)

NOTE
When this parameter is set, the power must be turned off before operation is continued.

[Input type] Parameter input
[Data type] Word axis
[Valid data range] 0 to 1535, 3000 to 4535

When using both-direction pitch error compensation, set the number of compensation point at the farthest end in the negative direction for a movement in the negative direction.

> **NOTE**
> 1 For a movement in the positive direction, set the compensation point number at the farthest end in the negative direction in parameter No. 3621.
> 2 A set of compensation data items for a single axis should not be set to lie astride 1535 and 3000.

3627	Pitch error compensation at reference position when a movement to the reference position is made from the direction opposite to the direction of reference position return

> **NOTE**
> When this parameter is set, the power must be turned off before operation is continued.

[Input type] Parameter input
[Data type] Word axis
[Unit of data] Detection unit
[Valid data range] -32768 to 32767

Set the absolute value of pitch error compensation at reference position when a movement to the reference position is made from the negative direction if the direction of reference position return (bit 5 (ZMI) of parameter No. 1006) is positive or from the positive direction if the direction of reference position return is negative.

Note

> **NOTE**
> 1 To use this function, Stored pitch error compensation is required.
> 2 This function is enabled after a manual reference position return or an automatic reference position return with the same sequence as that of a manual reference position return is performed. When an absolute position detector is used, however, the function is enabled after the power is turned on.
> 3 When the machine moves to the reference position in the reference position return direction, set the absolute value of the pitch error compensation pulse to 0.
> 4 When this function and backlash compensation are used at the same time, the pulse resulting from backlash compensation is superimposed on the compensation pulse when the travel direction is reversed.
> 5 When this function is used for a rotary axis, the sum of the pitch error compensation amounts per rotation about the rotary axis must be 0 for both the positive and negative directions.
> 6 The function cannot be used with the inclination compensation function.

1.3.9 Interpolation Type Pitch Error Compensation

Overview

In stored pitch error compensation, the pitch error compensation pulse at each pitch error compensation point is output in the interval between that point and the next compensation point, as shown in the figure below (Fig. 1.3.9 (a)).

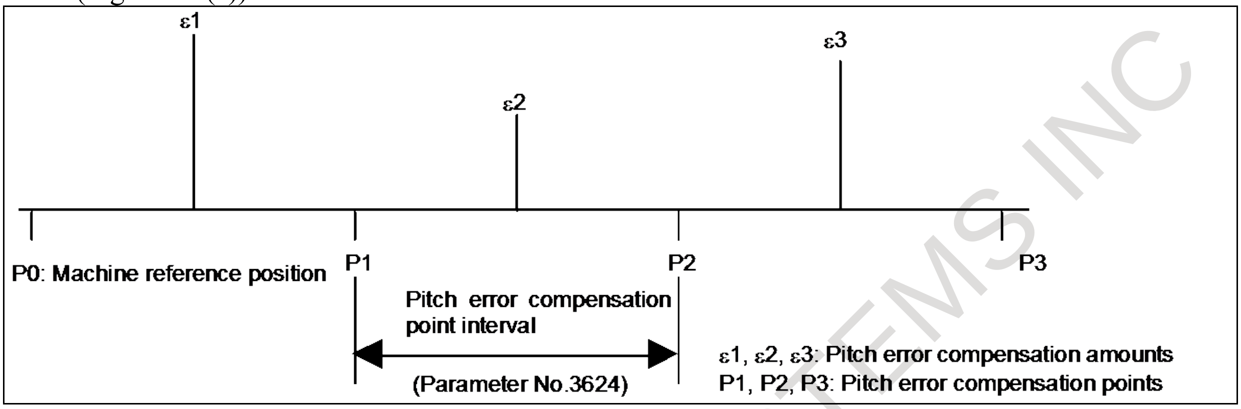

Fig. 1.3.9 (a) Stored pitch error compensation

In interpolation type pitch error compensation, the compensation amount at each error compensation point is divided into pulses in the interval between that point and the next point on the travel axis and output, as shown in the figure below. (Fig. 1.3.9 (b))

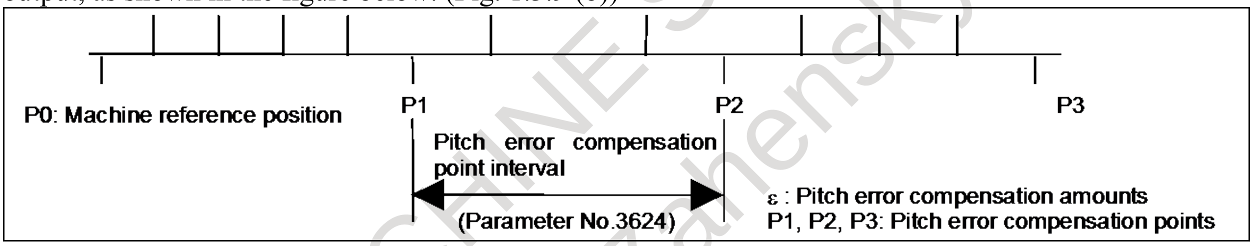

Fig. 1.3.9 (b) Interpolation Type Pitch Error Compensation Method

- Setting the parameters

When interpolation type pitch error compensation is used, the following parameters are assigned the same values as those in stored pitch error compensation.

- Number of the pitch error compensation point of the reference position on each axis:
  Parameter No.3620
- Number of the most distant pitch error compensation point on the - side of each axis:
  Parameter No.3621
- Number of the most distant pitch error compensation point on the + side of each axis:
  Parameter No.3622
- Pitch error compensation magnification for each axis: Parameter No.3623
- Pitch error compensation point interval on each axis: Parameter No.3624

- Minimum pitch error compensation point interval

Compensation pulses are divided at intervals of pitch error compensation point interval and output by interpolation type pitch error compensation,
Interpolation type pitch error compensation outputs compensation pulses smoother than stored pitch error compensation. But if the feedrate is high, multiple compensation pulses may be output at the same time.
The setting pitch error compensation point interval greater than minimum value calculated by the following formula had better be used in order to output smoother compensation pulses even if the feedrate is high.
Minimum pitch error compensation point interval (mm)= (Fmax/7500)×(Pmax+1)
Fmax : Maximum feedrate(mm/min)

Pmax : Maximum pitch error compensation amount((Maximum value of set amount of pitch error compensation of each compensation point)×(Pitch error compensation magnification))(Detection unit)
Example)
If the maximum feedrate is 15000 mm/min and the maximum pitch error compensation amount is equal to seven pulses, the minimum compensation interval is 16mm.

Parameter

	#7	#6	#5	#4	#3	#2	#1	#0
3605							IPPx	

[Input type] Parameter input
[Data type] Bit axis

> **NOTE**
> When this parameter is set, the power must be turned off before operation is continued.

#1 IPPx Interpolation type pitch error compensation is:
0: Not used.
1: Used.

In interpolation type pitch error compensation, a compensation value at each point in each error completion point interval is divided for output of one pulse at equally spaced intervals.
If a high feedrate is used, multiple compensation pulse may be output at a time.
A minimum interval where multiple compensation pulses are not output at a time is determined by the following expression:
Minimum pitch error compensation point interval (mm)= (Fmax/7500) × (Pmax+1)
Fmax: Maximum feedrate(mm/min)
Pmax: Maximum pitch error compensation value((Maximum value of set amount of pitch error compensation of each compensation point)×(Pitch error compensation magnification))(Detection unit)
Example:
When the maximum feedrate is 15000 mm/min, and the maximum pitch error compensation value is 7 pulses, the minimum compensation point interval is 16mm.

> **NOTE**
> Interpolation type pitch error compensation cannot be used with spindle positioning.

Note

> **NOTE**
> 1 To use this function, Stored pitch error compensation is required.
> 2 This function is available in bi-directional pitch error compensation.

1.3.10 About Differences among Pitch Error Compensation, Straightness Compensation, and Inclinaiton Compensation (for Reference Purposes)

Overview

Any of pitch error compensation, straightness compensation, and inclinaiton compensation is applied to each compensation point based on the machine position at parameter-specified compensation intervals into which the machine stroke is divided.
Both inclinaiton compensation and straightness compensation use the same compensation intervals and compensation points as for pitch error compensation. However, they use their own compensation amounts defined for respective compensation functions.

Explanation

- Pitch error compensation

For pitch error compensation, a compensation amount is set up for each compensation point. The compensation amount is output at each compensation point.

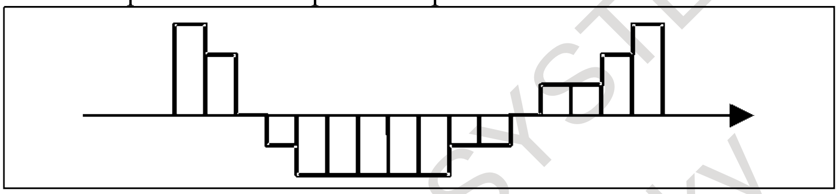

Fig. 1.3.10 (a)

- Bi-directional pitch error compensation

For bi-directional pitch error compensation, a compensation amount can be varied according to the axis movement direction.

- Interpolation type pitch error compensation

Interpolation type pitch error compensation outputs divided compensation pulses between compensation points, so smoother pitch error compensation can be realized.

- Inclinaiton compensation

In inclinaiton compensation, four typical pitch error compensation points (a, b, c, and d) are selected from pitch error compensation points and specified as inclinaiton compensation points, and compensation amounts are set up only for these four points; a compensation amount is not set up for every individual point.
For pitch error compensation points between inclinaiton compensation points, the NC calculates and outputs amounts that match inclinaiton compensation. Inclinaiton compensation can be applied if a pitch error has a constant gradient.

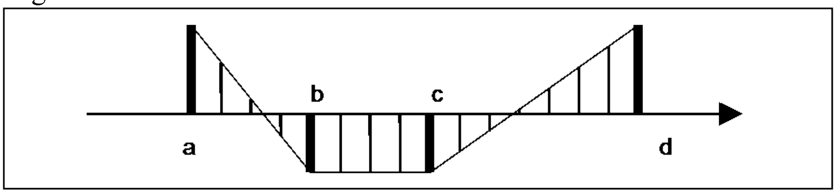

Fig. 1.3.10 (b)

- Straightness compensation

In straightness compensation, similarly to inclinaiton compensation, four typical pitch error compensation points (a, b, c, and d) are selected from pitch error compensation points and specified as straightness compensation points, and compensation amounts are set up only for these four points. For pitch error compensation points between straightness compensation points, the NC calculates and outputs amounts that match straightness compensation.

Straightness compensation largely differs from inclinaiton compensation in that the moving axis is not a compensation axis; inclinaiton compensation is applied directly to the moving axis. This relationship is specified by a parameter (for example, to apply compensation to the Y-axis as movement occurs along the X-axis).

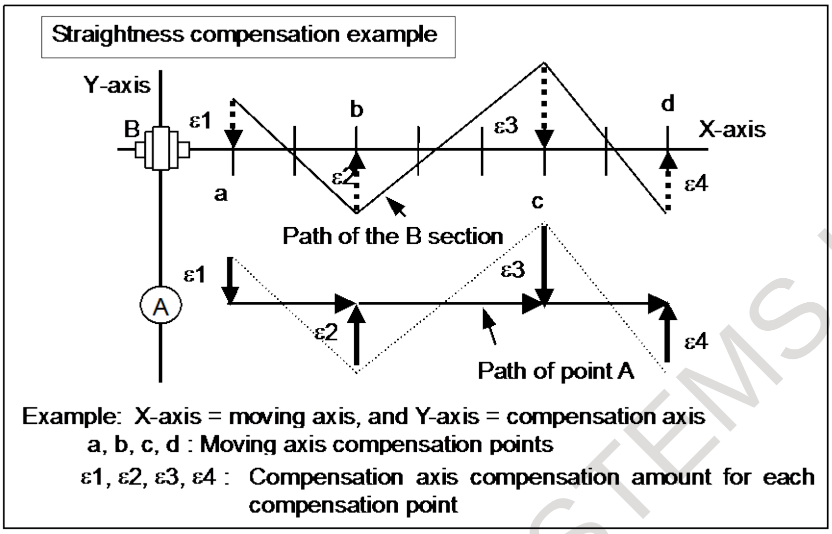

Fig. 1.3.10 (c)

1.3.11 Axis Name Display of Pitch Error Compensation

On the pitch error compensation screen, the axis name can be displayed to the left of the number of each compensation point used for pitch error compensation of each axis.
Whether to display the axis name can be selected using bit 5 (PAD) of parameter No. 11350.
When this function is enabled, the pitch error compensation screen is displayed as shown in Fig. 1.3.11 (a) or Fig. 1.3.11 (b).

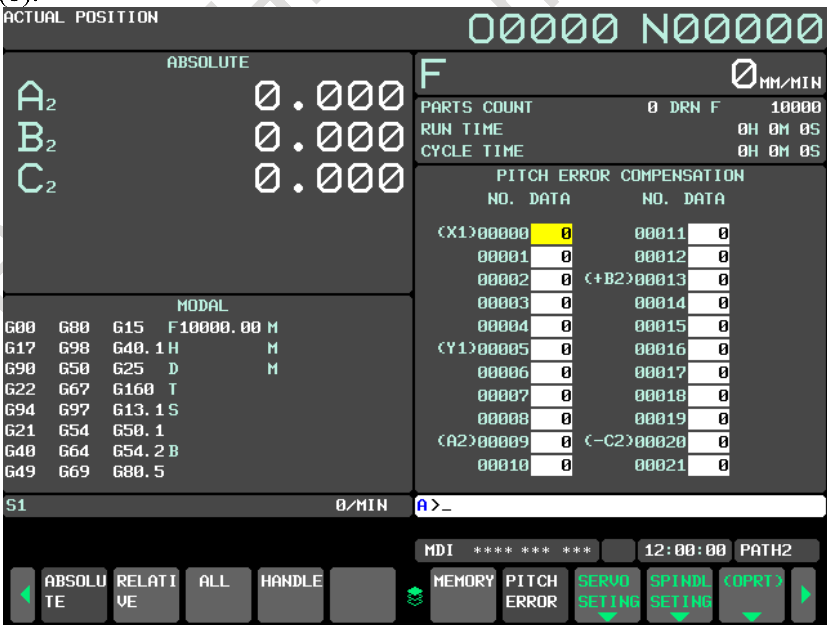

Fig. 1.3.11 (a) Pitch error compensation screen
(when the bi-directional pitch error compensation function is enabled and axis name extension is disabled)

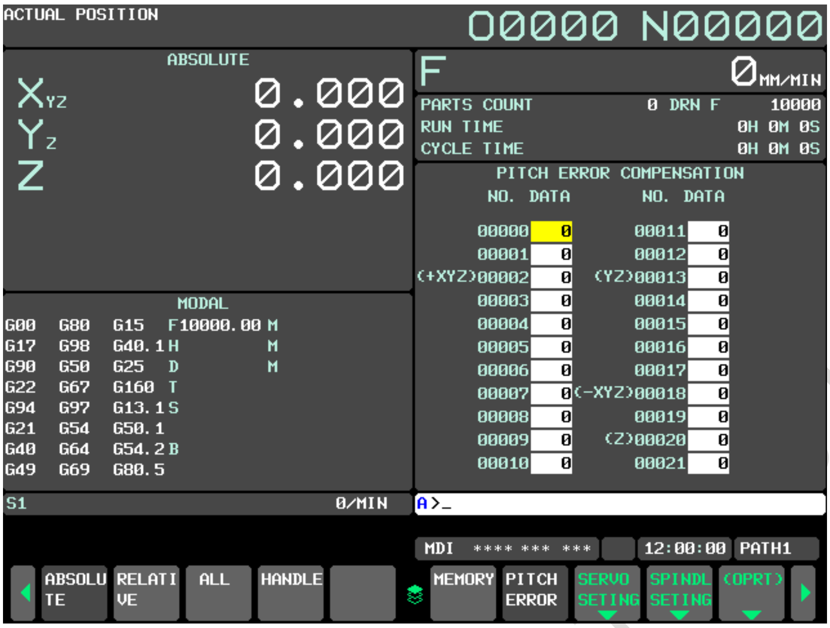

Fig. 1.3.11 (b) Pitch error compensation screen
(when the bi-directional pitch error compensation function
and axis name extension are enabled)

1.3.11.1 Setting of axis name display

The axis name is displayed to the left of the compensation point number set in parameter No. 3621, which sets the number of the pitch error compensation point at the extremely negative position. When the bi-directional pitch error compensation function is enabled, "(+ axis name)" is displayed to the left of the compensation point number set in parameter No. 3621, which sets the compensation point number for a movement in the positive direction, and "(- axis name)" is displayed to the left of the compensation point number set in parameter No. 3626, which sets the compensation point number for a movement in the negative direction.

> **NOTE**
> 1 When an invalid parameter is set for pitch error compensation, the relevant axis name is not displayed.
> 2 For a rotary axis, the axis name is displayed to the left of the number of the pitch error compensation point for the reference position set in parameter No. 3620.

1.3.11.2 Parameter

	#7	#6	#5	#4	#3	#2	#1	#0
11350			PAD					

[Input type] Parameter input
[Data type] Bit

> **NOTE**
> When this parameter is set, the power must be turned off before operation is continued.

#5 PAD On the pitch error compensation screen, axis names are:
0: Not displayed.
1: Displayed.

1020	Program axis name for each axis

[Input type] Parameter input
[Data type] Byte axis
Set a program axis name for each axis.

> **NOTE**
> When this parameter is not set, the axis name displayed on the pitch error compensation screen is “(X)”.

3621	Number of the pitch error compensation position at extremely negative position for each axis

> **NOTE**
> When this parameter is set, the power must be turned off before operation is continued.

[Input type] Parameter input
[Data type] Word axis
Set the number of the pitch error compensation position at the extremely negative position for each axis.

3626	Number of the both-direction pitch error compensation position at extremely negative position (for movement in the negative direction)

> **NOTE**
> When this parameter is set, the power must be turned off before operation is continued.

[Input type] Parameter input
[Data type] Word axis
When using both-direction pitch error compensation, set the number of compensation point at the farthest end in the negative direction for a movement in the negative direction.

3620	Number of the pitch error compensation position for the reference position for each axis

> **NOTE**
> When this parameter is set, the power must be turned off before operation is continued.

[Input type] Parameter input
[Data type] Word axis
Set the number of the pitch error compensation position for the reference position for each axis.

1.3.12 Stored Pitch Error Compensation Total Value Input function

General

The stored pitch error compensation data can be input as a total value whose origin is the reference position.
In the conventional specification, it is necessary to calculate the difference between two consecutive compensation data. But the measured value that is a total value from the base point can be input directly when bit 0 (APE) of parameter No. 3602 is set to 1.

This function is effective to the following functions.
- Stored Pitch Error Compensation
- Bi-directional Pitch Error Compensation
- Interpolation Type Pitch Error Compensation
- Interpolation Type Straightness Compensation
- Spindle Command Synchronous Control Independent Pitch Error Compensation

NOTE
1 Stored Pitch Error Compensation is necessary to use this function.
2 If bit 0 (APE) of parameter No. 3602 is changed, the data of stored pitch error compensation is cleared automatically at next power on.

Explanation

If bit 0 (APE) of parameter No. 3602 is set to 1, pitch error compensation screen is enhanced as shown in the following Fig.1.3.12 (b), and inputting data becomes a total value from the base point.

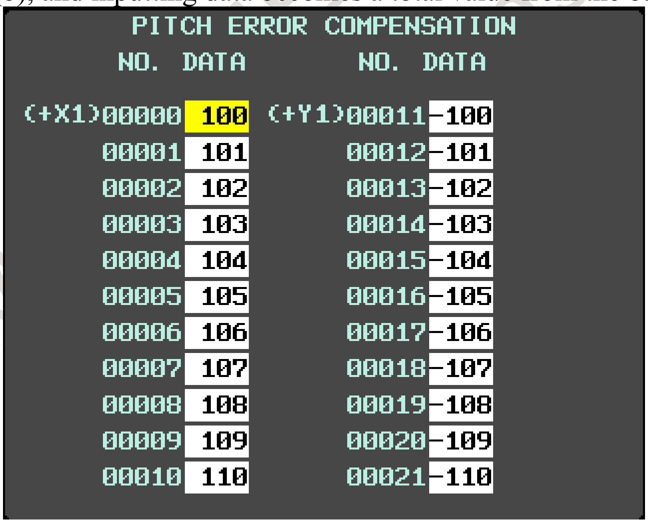

Fig.1.3.12 (a) Input screen by incremental value

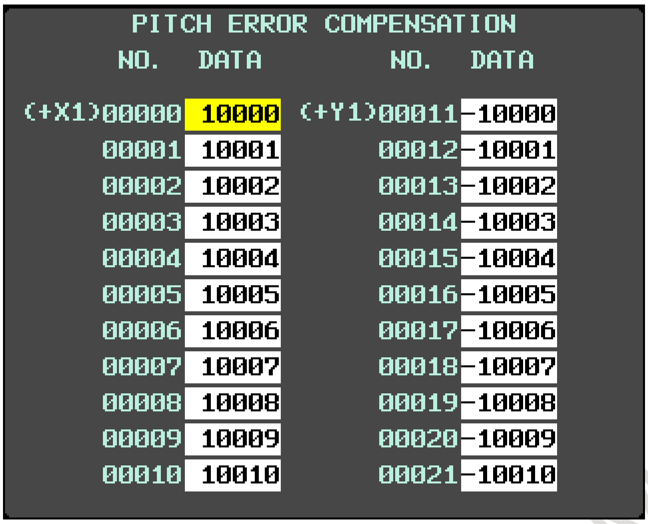

Fig.1.3.12 (b) Input screen by total value

The compensation data is input by a total value whose origin is the reference position. Please set 0 to the compensation data at the reference position.
The range of the value is –32768 to +32767. If the input value exceeds this range, the warning massage “DATA IS OUT OF RANGE” is displayed.
The difference between two consecutive data must be within –128 to +127. If the difference exceeds this range, the warning message “DIFFERENCE WITH NEAR IS RANGE OVER” is displayed and the compensation value is displayed in red color. When this warning is generated, if a program is executed in any path, alarm PS0527 “ILLEGAL DATA IN PITCH ERROR” occurs.

The compensation number that is checked the difference of compensation data is decided by considering the setting of the parameters shown in Table 1.3.12 (a).

Table 1.3.12 (a) Parameters that decides effective compensation number.

Parameter No.	Description
No.3601#1	Spindle command synchronous control independent pitch error compensation is not used (0) / used (1)
No.3602#0	The input type of stored pitch error compensation data is an incremental value (0) / a total value (1)
No.3605#0	Bi-directional pitch error compensation is not used (0) / used (1)
No.3605#2	Interpolation type straightness compensation is not used (0) / used (1)
No.3621	Number of the pitch error compensation point at extremely negative position.
No.3622	Number of the pitch error compensation point at extremely positive position.
No.3623	Pitch error compensation magnification.
No.3624	Pitch error compensation point interval.
No.3626	Number of the bi-directional pitch error compensation point at extremely negative position. (for travel in the negative direction)
No.3666	Number of the spindle command synchronous control independent pitch error compensation point at extremely negative position.
No.3671	Number of the spindle command synchronous control independent pitch error compensation point at extremely positive position.
No.3676	Number of the spindle command synchronous control independent bi-directional pitch error compensation point at extremely negative position. (for travel in the negative direction)
No.5711 to No.5716	Axis number of moving axis for straightness compensation.
No.5721 to No.5726	Axis number of compensation axis for straightness compensation.
No.13381 to No.13386	Number of the interpolation type straightness compensation point at extremely negative position.

Example1)

When bi-directional pitch error compensation and interpolation type straightness compensation are enabled, if parameters in Table 1.3.12 (b) are set, the compensation number that is checked the difference of compensation data is

No.100 to No.200 : The compensation number of stored pitch error compensation.
No.3100 to No.3200: The compensation number of bi-directional pitch error compensation.
No.6000 to No.6100: The compensation number of interpolation type straightness compensation.

Table 1.3.12 (b) Sample setting 1

Parameter No.	Setting value
No.3602#0	1
No.3605#0 (1st-axis)	1
No.3605#2 (1st-axis)	1
No.3621 (1st-axis)	100
No.3622 (1st-axis)	200
No.3623 (1st-axis)	1
No.3624 (1st-axis)	10.0
No.3626 (1st-axis)	3100
No.5711	1
No.5721	2
No.13381	6000

Example2)

When only stored pitch error compensation and bi-directional pitch error compensation are specified, pitch error compensation number 0 to 1535 and 3000 to 4535 are available. If parameters in Table 1.3.12 (c) are set, the compensation number that is checked the difference of compensation data is

No.100 to No.200 : The compensation number of stored pitch error compensation.
No.4500 to No.4600: The compensation number of bi-directional pitch error compensation.

Table 1.3.12 (c) Sample setting 2

Parameter No.	Setting value
No.3602#0	1
No.3605#0 (1st-axis)	1
No.3621 (1st-axis)	100
No.3622 (1st-axis)	200
No.3623 (1st-axis)	1
No.3624 (1st-axis)	10.0
No.3626 (1st-axis)	4500

As the No.4536 to No.4600 are not available, the data of these numbers are assumed to be 0. If the data set in No.4535 is larger than 128, the difference of compensation data between No.4535 and No.4536 is also over -128. This will be cause of warning “DIFFERENCE WITH NEAR IS RANGE OVER”.

The specification other than total value input is same as the conventional function. Please refer to the specification of the following functions.

- Stored Pitch Error Compensation
- Bi-directional Pitch Error Compensation
- Interpolation Type Pitch Error Compensation
- Interpolation Type Straightness Compensation
- Spindle Command Synchronous Control Independent Pitch Error Compensation

- Method of inputting and outputting compensation data on pitch error compensation screen

If the input type of stored pitch error compensation data is a total value (bit 0 (APE) of parameter No. 3602 is set to 1), the formats to output by the operation on pitch error compensation screen are the following.

The L1 data is added to the conventional format.

Example of stored pitch error compensation)

N10000 Q0 L1 P1000
N10001 Q0 L1 P995
N10002 Q0 L1 P990
N10003 Q0 L1 P995

Example of bi-directional pitch error compensation)

N20000 Q0 L1 P1000
N20001 Q0 L1 P995
N20002 Q0 L1 P990
N20003 Q0 L1 P995

This data can be input on the pitch error compensation screen when bit 0 (APE) of parameter No. 3602 is set to 1. If the data with L1 is input when bit 0 (APE) of parameter No. 3602 is set to 0, or the data without L1 is input when bit 0 (APE) of parameter No. 3602 is set to 1, alarm SR1300 “ILLEGAL ADDRESS” is caused.

- Input of pitch error compensation data by program

When bit 0 (APE) of parameter No. 3602 is set to 1, please execute the program by adding the L1 data to the conventional format.

Example of G10 command:

```
G10L50;
N10000 L1 R1000;
N10001 L1 R995;
N10002 L1 R990;
N10003 L1 R995;
G11;
```

If the program with L1 is executed when bit 0 (APE) of parameter No. 3602 is set to 0 or the program without L1 is executed when bit 0 (APE) of parameter No. 3602 is set to 0, alarm PS1300 “ILLEGAL ADDRESS” is caused.

NOTE

If the compensation data is changed when the input format is total value type(bit 0 (APE) of parameter No. 3602 is set to 1), power must be turned off before operation is continued.

- Example of total value input in case of bi-directional pitch error compensation

When the axis is linear axis and the direction of a manual reference position return is positive, set the data given in the Table 1.3.12 (d), if the pitch error amounts should be set in the Fig. 1.3.12 (c).

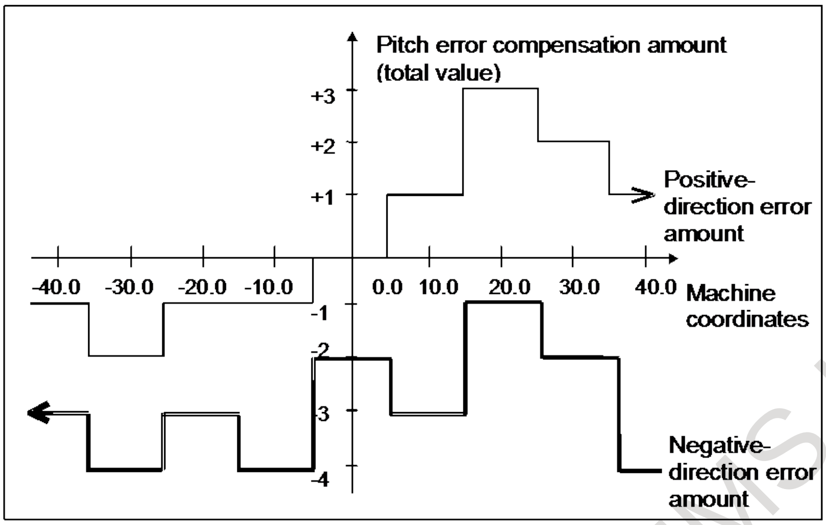

Fig. 1.3.12 (c) Example of bi-directional pitch error compensation

Table 1.3.12 (d) Parameter setting of bi-directional pitch error compensation

Parameter number	Setting of Input by Incremental value	Setting of Input by Total value	Description
3602#0	0	1	The input type of stored pitch error compensation data is, 0: An incremental value / 1: A total value
3605#0	1	1	Bi-directional Pitch Error Compensation, 0: Disabled / 1: Enabled
3620	23	24	Number of the pitch error compensation point for the reference position
3621	20	20	Number of the most distant pitch error compensation point on the - side for travel in the positive direction
3622	27	28	Number of the most distant pitch error compensation point on the + side for travel in the positive direction
3623	1	1	Pitch error compensation magnification
3624	10.000	10.000	Pitch error compensation point interval
3625	-	-	For a rotation axis, amount of travel per rotation in pitch error compensation
3626	30	30	Number of the most distant pitch error compensation point on the - side for travel in the negative direction
3627	-2	0	Pitch error compensation amount (total value) at the reference position when the machine moves to the reference position in the direction opposite to that of the reference position return

This example assumes that the direction of a manual reference position return is positive.
In case of Input by Incremental value:
The variation at the division of compensation areas is set.
As for parameter No. 3627, set -2, which is the pitch error compensation amount (total value) at the reference position when the machine moves in the negative direction.
In case of Input by Total value:
The value at the center of the compensation area is set. Therefore, one compensation point increases.
The parameter No. 3627 is not used.

Positive-direction pitch error data is as Table 1.3.12 (e).

Table 1.3.12 (e) Compensation value in positive direction

Compensation point number	Input by Incremental value	Input by Total value
20	-1	-1
21	+1	-2
22	0	-1
23	+1	-1
24	+1	0
25	+2	+1
26	-1	+3
27	-1	+2
28	-	+1

Negative-direction pitch error data is as Table 1.3.12 (f).

Table 1.3.12 (f) Compensation value in negative direction

Compensation point number	Input by Incremental value	Input by Total value
30	-1	-3
31	+1	-4
32	-1	-3
33	+2	-4
34	-1	-2
35	+2	-3
36	-1	-1
37	-2	-2
38	-	-4

Example of total value input in case of rotary axis

- Amount of movement per rotation: 360°
- Interval between pitch error compensation positions: 45°
- Number of the compensation position of the reference position: 60

In the above case, the number of the most distance compensation position on the - side is equal to the number of the compensation position of the reference position + 1 = 60 + 1 = 61 for a rotary axis.
The number of the farthest compensation position in the positive direction is as follows:
Number of the compensation position of the reference position + (Move amount per rotation/Interval between the compensation positions)= 60 + 360/45= 68
The correspondence between the machine coordinate and the compensation position number is as Fig. 1.3.12 (d)

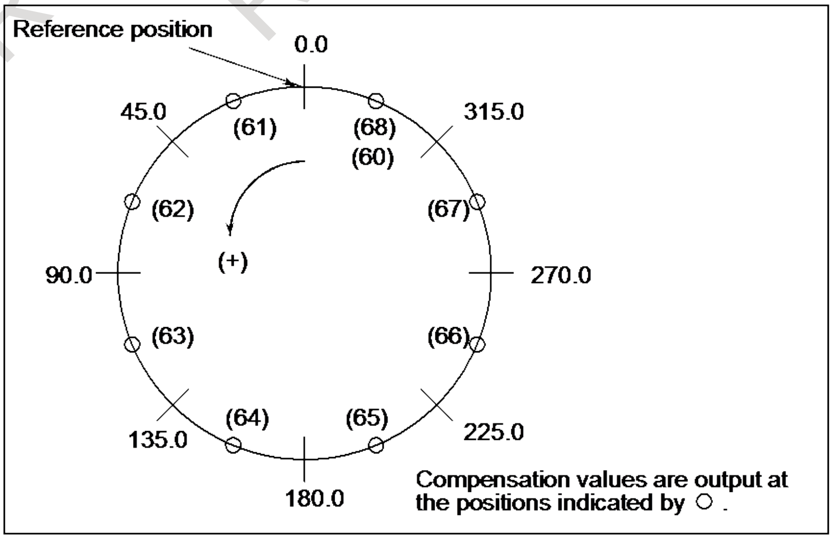

Fig. 1.3.12 (d) Example of rotary axis pitch error compensation

Therefore, set the parameters as Table 1.3.12 (g).

The parameter setting for the rotary axis in case of total value input is same as that of incremental value input.

Table 1.3.12 (g) Parameter setting of rotary axis pitch error compensation

Parameter number	Setting of Input by Incremental value	Setting of Input by Total value	Description
3602#0	0	1	The input type of stored pitch error compensation data is, 0: An incremental value / 1: A total value
3620	60	60	Number of the pitch error compensation point for the reference position
3621	61	61	Number of the most distant pitch error compensation point on the - side for travel in the positive direction
3622	68	68	Number of the most distant pitch error compensation point on the + side for travel in the positive direction
3623	1	1	Pitch error compensation magnification
3624	45.000	45.000	Pitch error compensation point interval
3625	360.000	360.000	For a rotation axis, amount of travel per rotation in pitch error compensation

When incremental value input is enabled, if the sum of the compensation values for positions 61 to 68 is not 0, pitch error compensation values are accumulated for each rotation, causing positional deviation. When total value input is enabled, set the value 0 in compensation positions 60 and 68.

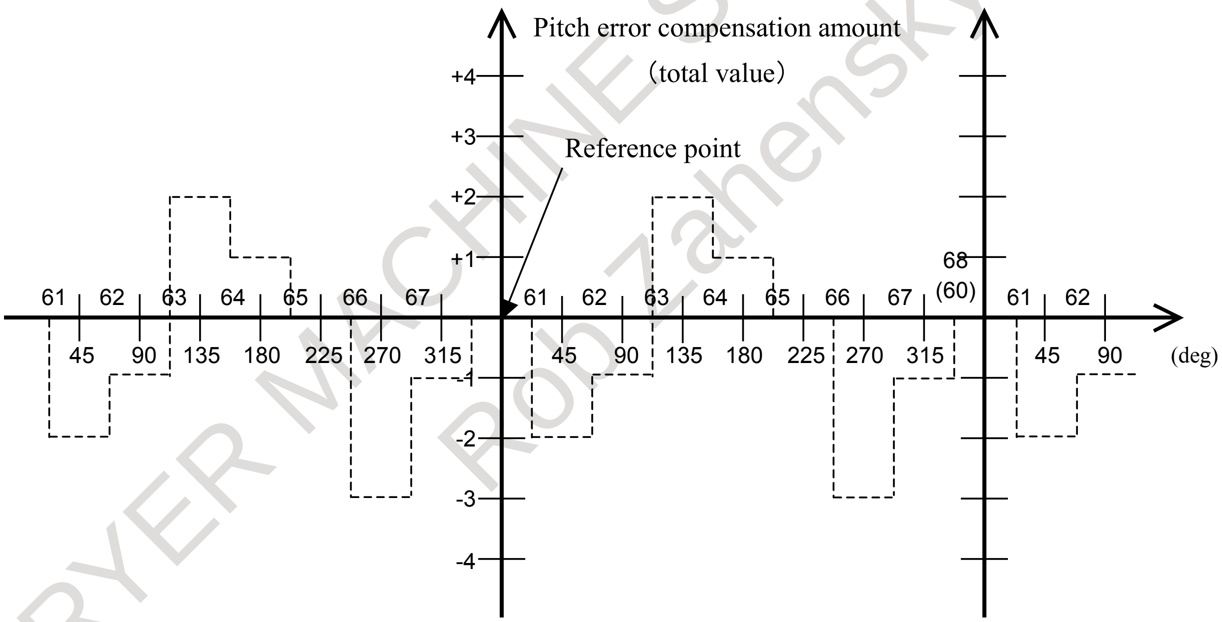

Fig. 1.3.12 (e) Compensation value of rotary axis expressed with linear axis

Table 1.3.12 (h) Compensation value of rotary axis

Compensation point number	(deg)	Input by Incremental value	Input by Total value
60	0	+1	0
61	45	-2	-2
62	90	+1	-1
63	135	+3	+2
64	180	-1	+1
65	225	-1	0
66	270	-3	-3
67	315	+2	-1
68	360	+1	0

Parameter

	#7	#6	#5	#4	#3	#2	#1	#0
3602								APE

[Input type] Parameter input
[Data type] Bit

> **NOTE**
> When this parameter is set, the power must be turned off before operation is continued.

#0 APE The input type of stored pitch error compensation data is:
0: An incremental value.
1: A total value.

This function is effective to the following functions.
- Stored Pitch Error Compensation
- Bi-directional Pitch Error Compensation
- Interpolation Type Pitch Error Compensation
- Interpolation Type Straightness Compensation
- Spindle Command Synchronous Control Independent Pitch Error Compensation

> **NOTE**
> If this parameter is changed, the data of stored pitch error compensation is cleared automatically at next power on.

Warning

Massage	Description
DATA IS OUT OF RANGE	The pitch error compensation total value exceeds the range of –32768 to +32767. Input was denied.
DIFFERENCE WITH NEAR IS RANGE OVER	The difference between two consecutive data is exceeds the range of –128 to +127. Please modify the compensation data.

Alarm and message

Number	Massage	Description
PS0527	ILLEGAL DATA IN PITCH ERROR	In the effective pitch error compensation points that is decided by considering the setting of the parameters, the difference between two consecutive data exceeds the range of -128 to +127. Please correct the pitch error compensation data or change the parameter.
PS1300	ILLEGAL ADDRESS	The axis No. address was specified even though the parameter is not an axis–type while loading parameters or pitch error compensation data from a tape or by entry of the G10 parameter. Axis No. cannot be specified in pitch error compensation data.

1.4 SETTINGS RELATED TO SERVO-CONTROLLED AXES

The servo interface features the following:

- Digitally controlled AC servo motor
- Motor feedback with serial Pulsecoders
  - (1) Absolute Pulsecoder with a resolution of 1,000,000 pulses/rev
  - (2) Absolute Pulsecoder with a resolution of 65,536 pulses/rev
  - (3) Incremental Pulsecoder with a resolution of 10,000 pulses/rev
- Scale feedback with A/B/Z signal interface

1.4.1 Parameters Related to Servo

Overview

Terms frequently used in explanation of parameters related to servo systems are listed below:

Least command increment.........The minimum unit of a command to be given from CNC to the machine tool

Detection unit............................The minimum unit which can detect the machine tool position

Command multiplier (CMR).....A constant to enable the weight of CNC command pulses to meet the weight of pulses from the detector

Detection multiplier (DMR)......A constant to enable the weight of CNC command pulses to meet the weight of pulses from the detector

> ⚠ **CAUTION**
> The relations among the least command increment, detection unit, CMR, and DMR are as specified below.
> Least command increment = CMR × detection unit
> Detection unit =
> Move amount per revolution of motor /
> (DMR × number of pulses of detector per revolution)
> The flexible feed gear function in the digital servo defines constant DMR using two parameters (Nos. 2084 and 2085) n and m (DMR = n/m).

Parameter

	#7	#6	#5	#4	#3	#2	#1	#0
1800							CVR	

[Input type] Parameter input
[Data type] Bit path

#1 CVR When velocity control ready signal VRDY is set ON before position control ready signal PRDY comes ON
0: A servo alarm is generated.
1: A servo alarm is not generated.

	#7	#6	#5	#4	#3	#2	#1	#0
1815			APCx	APZx			OPTx	

[Input type] Parameter input
[Data type] Bit axis

> **NOTE**
> When at least one of these parameters is set, the power must be turned off before operation is continued.

#1 OPTx The separate position detector is:
0: Not to be used (semi-closed system)
1: To be used (full-closed system)

> **NOTE**
> 1 In case of using the absolute position detector (bit 5 (APCx) of parameter No.1815 is set to 1), please set the following parameters that correspond to the absolute position detector which is actually used.
> - Parameter No.1815#6, No.1815#0, No.1817#3, No.1868, No.2275#1, No.2394
>
> If these parameters are not set correctly, the machine coordinates are not correctly established at power-on.
> 2 Set this parameter to 1 when using a linear scale with reference marks or a linear scale with distance-coded reference marks (serial) (full-closed system).

#4 APZx Machine position and position on absolute position detector when the absolute position detector is used
0: Not corresponding
1: Corresponding

When an absolute position detector is used, after primary adjustment is performed or after the absolute position detector is replaced, this parameter must be set to 0, power must be turned off and on, then manual reference position return must be performed. This completes the positional correspondence between the machine position and the position on the absolute position detector, and sets this parameter to 1 automatically.

#5 APCx Position detector
0: Other than absolute position detector
1: Absolute position detector (absolute Pulsecoder)

> **NOTE**
> 1 In case of using FANUC absolute pulsecoder as absolute position detector for the rotary axis A type that machine coordinate values are rounded in 0 to 360°, set bit 6 (RON) of parameter No. 1815 to 0. If the parameter is not set correctly, the machine coordinates are not correctly established at power-on.
> 2 In case of using a rotary scale without rotary data made by another company as absolute position detector, please refer to "CORRESPONDENCE OF ROTARY SCALE WITHOUT ROTARY DATA" in this manual and set an appropriate value corresponding to the detector. If the parameter is not set correctly, the machine coordinates are not correctly established at power-on.
> 3 When the servo axis is disabled (bit 4 (KSVx) of parameter No. 11802 is set to 1), an absolute position detector cannot be used (bit 5 (APCx) of parameter No. 1815 cannot be set to 1). If an absolute position detector is used, alarm SV0301, "APC ALARM; COMMUNICATION ERROR" is issued.

	#7	#6	#5	#4	#3	#2	#1	#0
1816		DM3x	DM2x	DM1x				

[Input type] Parameter input
[Data type] Bit axis

> **NOTE**
> When at least one of these parameters is set, the power must be turned off before operation is continued.

#4 DM1
#5 DM2
#6 DM3

By using DM1, DM2, and DM3, a detection multiplication factor (DMR) is set.
This parameter is valid when a separate position detector (AB phase) is used and parameters Nos. 2084 and 2085 are not set.

DM3	DM2	DM1	DMR
0	0	0	1/2
0	0	1	1
0	1	0	3/2
0	1	1	2
1	0	0	5/2
1	0	1	3
1	1	0	7/2
1	1	1	4

1820	Command multiplier for each axis (CMR)

> **NOTE**
> When this parameter is set, the power must be turned off before operation is continued.

[Input type] Parameter input
[Data type] Byte axis
[Valid data range] See below :

Set a command multiplier indicating the ratio of the least command increment to the detection unit for each axis.
Least command increment = detection unit × command multiplier

About relationship between the increment system and the least command increment, see Section "Increment System" in "SETTING EACH AXIS".

Setting command multiply (CMR), detection multiply (DMR), and the capacity of the reference counter

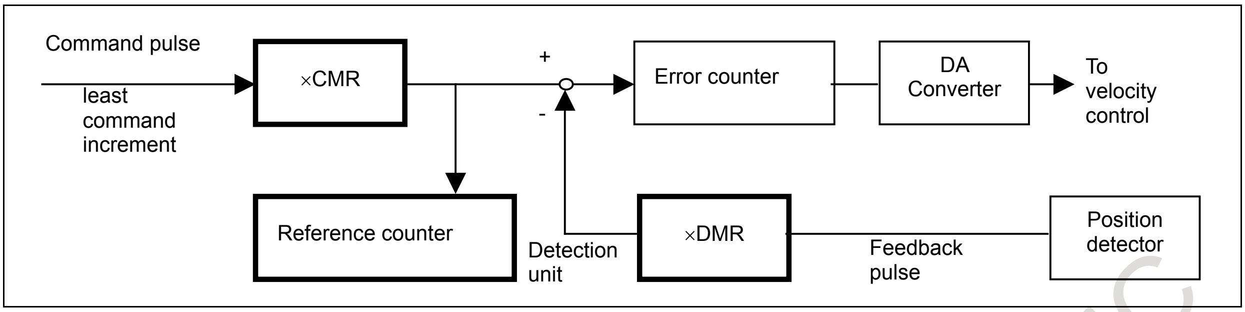

Fig. 1.4.1 (a)

Set CMR and DMR so that the pulse weight of + input (command from the CNC) into the error counter matches the pulse weight of -input (feedback from the position detector).

[Least command increment]/CMR=[Detection unit]=
[Feedback pulse unit]/DMR

[Least command increment]
Minimum unit of commands issued from the CNC to the machine

[Detection unit]
Minimum unit for machine position detection

The unit of feedback pulses varies, depending on the type of detector.

[Feedback pulse unit]=
[Amount of travel per rotation of the Pulsecoder]/
[Number of pulses per rotation of the Pulsecoder]

As the size of the reference counter, specify the grid interval for the reference position return in the grid method.

[Size of the reference counter]=[Grid interval]/[Detection unit]
[Grid interval]=[Amount of travel per rotation of the Pulsecoder]

The setting of a command multiplier is as follows:

(1) When command multiplier is 1 to 1/27
Set value = 1 / command multiplier + 100
Valid data range : 101 to 127

(2) When command multiply is 0.5 to 48
Set value = 2 × command multiplier
Valid data range : 1 to 96

> **NOTE**
> If a feedrate exceeding the feedrate found by the expression below is used, an incorrect travel amount may result or a servo alarm may be issued. Be sure to use a feedrate not exceeding the feedrate found by the following expression:
> Fmax[mm/min] = 196602 $\times 10^4 \times$ least command increment / CMR

1821	Reference counter size for each axis

> **NOTE**
> When this parameter is set, the power must be turned off before operation is continued.

[Input type] Parameter input
[Data type] 2-word axis
[Unit of data] Detection unit

[Valid data range] 0 to 999999999

Set a reference counter size.

As a reference counter size, specify a grid interval for reference position return based on the grid method.

When a value less than 0 is set, the specification of 10000 is assumed.

1825	Servo loop gain for each axis

[Input type] Parameter input

[Data type] Word axis

[Unit of data] 0.01/sec

[Valid data range] 1 to 32767

Set the loop gain for position control for each axis.

When the machine performs linear and circular interpolation (cutting), the same value must be set for all axes. When the machine requires positioning only, the values set for the axes may differ from one another. As the loop gain increases, the response by position control is improved. A too large loop gain, however, makes the servo system unstable.

The relationship between the positioning deviation (the number of pulses counted by the error counter) and the feedrate is expressed as follows:

Positioning deviation = Feedrate / (60 × Loop gain)

Unit : Positioning deviation mm, inch or deg

Feedrate mm/min, inch/min, or deg/min

Loop gain 1/sec

1828	Positioning deviation limit for each axis in movement

[Input type] Parameter input

[Data type] 2-word axis

[Unit of data] Detection unit

[Valid data range] 0 to 99999999

Set the positioning deviation limit in movement for each axis.

If the positioning deviation exceeds the positioning deviation limit during movement, a servo alarm SV0411, “EXCESS ERROR (MOVING)” is generated, and operation is stopped immediately (as in emergency stop).

Generally, set the positioning deviation for rapid traverse plus some margin in this parameter. Refer to the following set value.

$$\textbf{Setting value} = \frac{\textbf{Rapid traverse rate}^{(\textbf{Note 1})}}{\textbf{60} \times \textbf{Servo loop gain}^{(\textbf{Note 2})}} \times \frac{1}{\textbf{Detection unit}} \times 1.2 \textbf{ to } 1.5$$

> ⚠ **CAUTION**
> If this parameter is not set correctly, machine or workpiece can be damaged.

> **NOTE**
> 1 Usually, this value is parameter No.1420. When the maximal feedrate of each axis exceeds parameter No.1420 according to the command and override, the value is the maximal feedrate of the each axis.
> 2 Usually, this value is parameter No.1825. When the servo loop gains other than parameter No.1825 is effective, the value is actual servo loop gains.

1829	Positioning deviation limit for each axis in the stopped state

[Input type] Parameter input
[Data type] 2-word axis
[Unit of data] Detection unit
[Valid data range] 0 to 99999999

Set the positioning deviation limit in the stopped state for each axis.
If, in the stopped state, the positioning deviation exceeds the positioning deviation limit set for stopped state, a servo alarm SV0410 is generated, and operation is stopped immediately (as in emergency stop).

1850	Grid shift and reference position shift for each axis

> **NOTE**
> When this parameter is set, the power must be turned off before operation is continued.

[Input type] Parameter input
[Data type] 2-word axis
[Unit of data] Detection unit
[Valid data range] -99999999 to 99999999

To shift the reference position, the grid can be shifted by the amount set in this parameter.
Up to the maximum value counted by the reference counter can be specified as the grid shift.
In case of bit 4 (SFDx) of parameter No. 1008 is 0: Grid shift
In case of bit 4 (SFDx) of parameter No. 1008 is 1: Reference point shift

> **NOTE**
> For setting the reference position without dogs, only the grid shift function can be used.
> (The reference position shift function cannot be used.)

1.4.2 Absolute Position Detection

Overview

An absolute position detector (absolute Pulsecoder) is an incremental Pulsecoder with an absolute counter. It detects the absolute position based on the value of the absolute counter. For an axis on which an absolute position detector is mounted, no reference position return is required at power-on because the machine position is always stored with batteries if the power to the CNC is turned off.
When the machine position has been brought into correspondence with the absolute position detector, the current position is read from the absolute counter at CNC power on and the machine and workpiece coordinate systems are automatically set using the value. In this case, you can immediately start automatic operation.
Restrictions described in the OPERATOR’S MANUAL and others that include those listed below are removed:

- "Reference position return is required after power-on."
- "The CNC can be used after reference position return is performed after power-on."

Explanation

- Parameter setting for the absolute position detector

Please set the following parameters that correspond to the absolute position detector.
Parameter No.1815#1, No.1815#6, No.1815#0, No.1817#3, No.1868, No.2275#1, No.2394

Please refer to "CORRESPONDENCE OF ROTARY SCALE WITHOUT ROTARY DATA" in this manual.

> ⚠ **WARNING**
> Set the parameters that correspond to the absolute position detector which is actually used. If the parameter is not set correctly, the machine coordinates are not correctly established at power-on.

1. Linear axis

	Parameter No.						
	1815#1	**1815#6**	**1815#0**	**1817#3**	**1868**	**2275#1**	**2394**
Semi-closed feedback loop	0	0	0	0	0	0	0
Full-closed feedback loop	1	0	0	0	0	0	0

2. Rotary axis (A type)

	Parameter No.						
	1815#1	**1815#6**	**1815#0**	**1817#3**	**1868**	**2275#1**	**2394**
Semi-closed feedback loop (a scale with rotary data)	0	0	0	0	0	0	0
Semi-closed feedback loop (a scale without rotary data)	0	1	0	0	0	*1	*1
Full-closed feedback loop (a scale with rotary data)	1	0	0	0	0	0	0
Full-closed feedback loop (a scale without rotary data)	1	1	0	0	0	*1	*1

3. Rotary axis (B type)

	Parameter No.						
	1815#1	**1815#6**	**1815#0**	**1817#3**	**1868**	**2275#1**	**2394**
Semi-closed feedback loop (a scale with rotary data)	0	0	0	0	0	0	0
Semi-closed feedback loop (a scale without rotary data)	0	0	*2	*2	*2	*1	*1
Full-closed feedback loop (a scale with rotary data)	1	0	0	0	0	0	0
Full-closed feedback loop (a scale without rotary data)	1	0	*2	*2	*2	*1	*1

*1 These parameters are set according to the detector which is actually used. For details, please refer to "CORRESPONDENCE OF ROTARY SCALE WITHOUT ROTARY DATA".

*2 These parameters are set according to movable range of rotary axis. For details, please refer to "CORRESPONDENCE OF ROTARY SCALE WITHOUT ROTARY DATA".

- **About a rotary data in detector.**

The rotary data is number of revolution which is counted up or down per one rotation.
There are both "a scale with rotary data" and "a scale without rotary data" by detector.

- A scale with rotary data

  For detector manufactured by FANUC, all detectors are “a scale with rotary data”.
  Example of detector which manufactured by FANUC

  -Semi-closed system
  - When a detector with αi servo motor (αi Pulsecoder) is used.
  - When αiCZ sensors is used with a synchronous built-in servo motor.

  - Full-closed system
  - When αiCZ sensors is used as a separate detector.

- When αA1000S sensors which is separate pulsecoder is used as a separate detector.

- A scale without rotary data

For the following detectors, these are "a scale without rotary data".
The following detectors are not all of the detector which is "a scale without rotary data".

- HEIDENHAIN
  RCN223F / RCN727F
- Magnescale
  RU77
- MITSUBISHI HEAVY INDUSTRIES
  MPRZ Series
- RENISHAW
  RESOLUTE (rotary encoder)

NOTE
Please make sure to confirm the using detector to the detector manufacturers.

- Coordinate systems at power-on

(1) The machine and workpiece coordinate systems are automatically set. When bit 3 (PPD) of parameter No. 3104 is set to 1, the relative position display is preset. When parameter PPD is set to 0, it is also possible to preset relative coordinates with machine coordinates by setting bit 5 (PWR) of parameter No. 11277 to 1.
(2) The amount of shift by coordinate system setting (G92 for the M series or G50 for the T series) or local coordinate system setting (G52) is cleared.

- Setting the zero point of an absolute position detector

In the following cases, set the zero point of an absolute position detector (bring the counter value of the absolute position detector into correspondence with the reference position):

- Primary adjustment is performed (after the reference position is determined).
- The reference position is changed.
- An absolute position detector is replaced with another.
- A servo motor is replaced with another.
- Alarm DS0300 is issued.
- The file memory is replaced with another.
- Parameter data is cleared.

To set the zero point of an absolute position detector, the following two methods are available: One method using manual reference position return and the other using MDI operation.

- Manual reference position return

Follow the procedure below to perform manual reference position return.
(1) Set bit 4 (APZ) of parameter No. 1815 to 0. Alarms PW0000 and DS0300 are displayed.
(2) Turn the power off, then on again. Alarm DS0300 is displayed.
(3) Perform manual reference position return. When manual reference position return is completed, bit 4 (APZ) of parameter No. 1815 is automatically set to 1.
(4) Press the reset button to release alarm DS0300.
Operation in step (3) can also be performed by reference position setting without DOG, reference point setting with mechanical stopper, or reference point setting with mechanical stopper by grid method.

- Setting the zero point using MDI operation

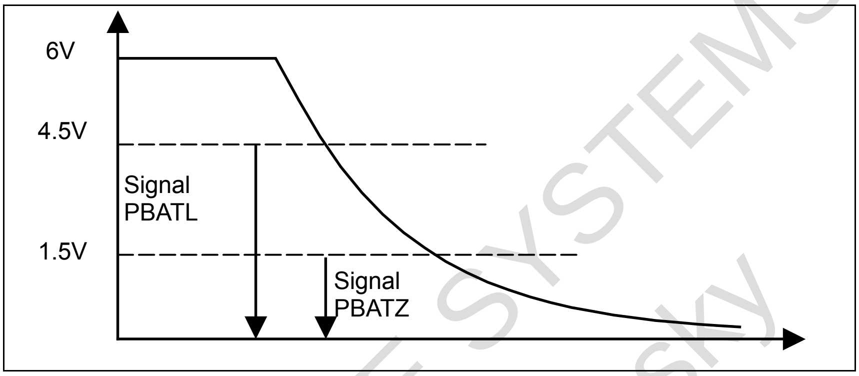
Follow the procedure below to set the zero point using MDI operation.
(1) Set bit 4 (APZ) of parameter No. 1815 to 0. Alarms PW0000 and DS0300 are displayed.
(2) Turn the power off, then on again. Alarm DS0300 is displayed.
(3) Move the tool to the reference position in jog, manual handle, or manual incremental feed.
(4) Set bit 4 (APZ) of parameter No. 1815 to 1. Alarm PW0000 is displayed.

(5) Turn the power off, then on again.

> ⚠ **CAUTION**
> If setting the zero point using MDI operation causes the reference position to be lost for some reason, any FANUC service personnel and end user cannot restore the reference position accurately. In this case, you should ask the machine tool builder to restore the accurate reference position, which requires an immense amount of time for restoration. So, do not use MDI operation to set the zero point. For details, see "Reexecuting zero point setting" described later.

- Voltage of backup batteries

Normally, the voltage of the backup batteries for the absolute position detector is 6 V. The voltage drops as time goes on.



When the voltage of the backup batteries becomes 4.5 V or less

- When the voltage of the backup batteries becomes 4.5 V or less, "APC" is highlighted and blinks in the state display area on the screen, and absolute position detector battery voltage low alarm signal PBATL <Fn172.7> is set to "1".
- When the power to the CNC is turned off, then on again without replacing the backup batteries and the counter value data of the absolute position detector is retained, alarm DS0307, "APC ALARM: BATTERY LOW 1" is displayed. Signal PBATL remains set to "1".
- In this status, when emergency stop is canceled or the reset key is pressed, alarm DS0307 is released, but "APC" is highlighted and blinks in the state display area on the screen. Signal PBATL remains set to "1".
- When the batteries are replaced with ones the voltage of which is higher than or equal to the rating and the reset key is pressed, "APC" in the status display area on the screen goes out and signal PBATL is set to "0".

> ⚠ **CAUTION**
> If a battery voltage low alarm is displayed, replace the batteries with new ones immediately. If the batteries are not replaced, the counter value data of the absolute position detector is lost.

When the voltage of the backup batteries becomes 1.5 V or less

- When the voltage of the backup batteries is 1.5 V or less, if the power to the CNC is turned off, the battery voltage is assumed to be 0, and the counter value data of the absolute position detector is lost. When the power to the CNC is turned on again, alarm DS0300, "APC ALARM: NEED REF RETURN" and alarm DS0306, "APC ALARM: BATTERY VOLTAGE 0" are displayed, and absolute position detector battery voltage zero alarm signal PBATZ <Fn172.6> is set to "1".
  At this time, bit 4 (APZ) of parameter No. 1815, which indicates that the correspondence between the machine position and the position on the absolute position detector is established, is set to 0.

- In this status, when emergency stop is canceled or the reset key is pressed, only alarm DS0306 is released. Signal PBATZ remains set to “1”.
- Follow the procedure below to set the zero point of the absolute position detector.
  1 Replace the batteries with ones the voltage of which is higher than or equal to the rating.
  2 Rotate the motor manually at least one turn.
  3 Turn the power to the CNC and servo amplifier off.
  4 Turn the power to the CNC and servo amplifier on.
  5 Set the zero point of the absolute position detector. After that, press the reset key to release alarm DS0300.
- When the power to the CNC is turned off, then on again after the batteries are replaced with ones the voltage of which is higher than or equal to the rating, signal PBATZ is set to “0”.

- Reexecuting zero point setting

If any of the following states occurs after the zero point of an absolute position detector is set, the reference position is lost, which requires the reexecution of zero point setting:

- An event occurred, which set any bit of diagnosis data Nos. 310 and 311 to 1. (For example, the voltage of the backup batteries became 1.5 V or less, or a parameter was updated, which caused the reference position to be lost.)
- A failure occurred in the pulse coder or motor, and it was replaced.

In this case, if the zero point is set using MDI operation, any FANUC service personnel and end user cannot restore the reference position accurately, and you should ask the machine tool builder to restore the accurate reference position, which requires an immense amount of time for restoration. So, do not use MDI operation to set the zero point. The following table lists other methods for setting the zero point to restore the reference position.

Table 1.4.2 (a) Reference position restoration

Zero point setting method	Overview	Advantages	Disadvantages
Manual reference position return	Uses the grid position created by the detector and a deceleration dog to establish the reference position.	Enables the reference position to be restored most reliably.	Requires a deceleration dog.
Reference position setting without DOG	Uses the grid position created by the detector and starts reference position return operation near the reference position to establish the reference position without dogs.	- Requires no deceleration dog. - Allows the reference position to be restored easily when the position at which to start restoring the reference position is clear.	Cannot restore the reference position if the position at which to start restoring the reference position is not clear.
Reference point setting with mechanical stopper	Butts the tool against the mechanical stopper along an axis and makes the tool withdraw a set distance from the mechanical stopper to establish the reference position.	- Requires no deceleration dog. - Allows the reference position to be restored very easily.	Lacks the positional accuracy of the reference position when the following factors are taken into account: Deformation of the part where the tool is butted, foreign matters attached to the part, etc.

Zero point setting method	Overview	Advantages	Disadvantages
Reference point setting with mechanical stopper by grid method	Butts the tool against the mechanical stopper along an axis and makes the tool withdraw to the grid position created by the detector to establish the reference position.	- Requires no deceleration dog. - Allows the reference position to be restored very easily. - Enables the accurate reference position to be established since the grid position is used.	

> ⚠ **CAUTION**
> 1 Do not use MDI operation to set the zero point. It is impossible to restore the reference position accurately using this method.
> 2 Use manual reference position return using a grid whenever possible.
> 3 To use reference position setting without DOG, be sure to place the eye mark indicating the start position of reference position return at a position where it can be seen without removing the cover and other parts of the machine and make the mark last after long-time machine operation.
> 4 To use reference point setting with mechanical stopper with using no grid, design the machine so that the part where the tool is butted is not deformed and is free from chips and other foreign matters.
> 5 Be sure to attach a manual which details the method for reference position return along each axis to the machine.

- Rotary axis A type

When the increment system (bit 0 to 1 (ISA or ISC) of parameter No. 1013) is changed for an axis in the following status, bit 4 (APZ) of parameter No. 1815 is set to 0 to set the status of the correspondence between the machine position and the position on the absolute position detector to unestablished:

- The zero point is established using the absolute position detector. (Bits 4 (APC) and 5 (APZ) of parameter No. 1815 = 1)
- Rotary axis A type (Bit 0 (ROT) of parameter No. 1006 = 1, Bit 1 (ROS) of parameter No. 1006 = 0)
- Bit 6 (RON) of parameter No. 1815 = 0

By setting the bit to 0, alarm DS0300 is issued and the zero point of the absolute position detector must always be set again, which prevents malfunction caused if zero point setting is not performed again.
At this time, bit 0 (PR1) of diagnosis data No. 310 is set to 1.

- Information of setting the zero point

The method of setting the zero point can be confirmed by diagnosis data No.3520.

- When the servo axis is disabled (bit 4 (KSVx) of parameter No. 11802 is set to 1)

An absolute position detector cannot be used (bit 5 (APCx) of parameter No. 1815 cannot be set to 1).
If an absolute position detector is used, alarm SV0301, "APC ALARM; COMMUNICATION ERROR" is issued.

Signal

Absolute position detector battery voltage low alarm signal PBATL<Fn172.7>

[Classification] Output signal
[Function] Notifies that the life of the absolute position detector battery is about to expire.
[Operation] These signal is “1” in the following case:

- The battery voltage for the absolute position detector becomes lower than or equal to the rating. The battery need be replaced in the immediate future.

These signal is “0” in the following case:

- The battery voltage for the absolute position detector is higher than or equal to the rating.

Absolute position detector battery voltage zero alarm signal PBATZ<Fn172.6>

[Classification] Output signal

[Function] Notifies that the life of the absolute position detector battery has expired.

[Operation] These signals are “1” in the following case:

- The batteries for the absolute position detector have run out. The batteries need be replaced in the status in which the power to the machine is on.

These signals are “0” in the following case:

- The batteries for the absolute position detector feed the voltage required for data backup.

Signal address

	#7	#6	#5	#4	#3	#2	#1	#0
Fn172	PBATL	PBATZ						

Diagnosis data

Why bit 4 (APZ) of parameter No. 1815 is set to 0 can be checked using diagnosis data Nos. 310 and 311. After any bit of diagnosis data Nos. 310 and 311 is set to 1, it remains set to 1 until the zero point of the absolute position detector on the axis is set. Each bit of diagnosis data Nos. 310 and 311 is described below with its corresponding cause.

	#7	#6	#5	#4	#3	#2	#1	#0
310		DTH	ALP		BZ2	BZ1	PR2	PR1

PR1 One of the following parameters were changed:
No.1815#0, No.1815#1, No.1815#6, No.1817#3, No.1820, No.1821, No.1822, No.1823, No.1850, No.1868, No.1869, No.1874, No.1875, No.1876, No.1878, No.1883, No.1884, No.2022, No.2084, No.2085, No.2179, increment system for a rotary axis A type (see “Explanation” for details.), No.11802#6, No.11810

PR2 The value of bit 1 (ATS) of parameter No. 8303 was changed. Alternatively, when bit 7 (SMA) of parameter No. 8302 was set to 1, APZ of the relevant axis for synchronous operation became 1.

BZ1 A battery voltage of 0 V was detected. (Inductosyn)

BZ2 A battery voltage of 0 V was detected. (separate position detector)

ALP Although the α Pulsecoder did not indicate one turn, the zero point was set using MDI operation.
Alternatively, the CNC could not obtain a valid value from the absolute Pulsecoder.

DTH An axis was released from control by using controlled axis detach signal DTCH <Gn124> or bit 7 (RMV) of parameter No. 0012.

	#7	#6	#5	#4	#3	#2	#1	#0
311		DUA	XBZ	GSG	AL4	AL3	AL2	AL1

AL1 SV alarms SV0301 to SV0305 were issued.

AL2 When bit 1 (CRF) of parameter No. 1819 was 1, soft disconnect alarm SV0445 or SV0447 or abnormal analog signal alarm SV0646 was detected.

AL3 A battery voltage of 0 V was detected. (built-in serial Pulsecoder)

AL4 Count miss alarm SV0367 was detected.

GSG Disconnection alarm ignore signal NDCAL <Gn202> was changed from “1” to “0”.

XBZ A battery voltage of 0 V or count miss alarm SV0382 was detected. (separate position detector installed for each serial method)

DUA When bit 1 (CRF) of parameter No. 1819 was 1, excess error (semi-full) alarm SV0421 was detected.

If a battery low alarm is issued, the cause of the issuance can be checked with diagnosis data No. 3019.

	#7	#6	#5	#4	#3	#2	#1	#0
3019			EXP	INP	ABP			

[Data type] Axis

ABP Battery low in the phase A/B

ANP Battery low in the serial Pulsecoder (built-in position detector)

EXP Battery low in the serial separate position detector

3520	Information of setting the zero point for absolute position detection

[Data type] Byte axis

[Unit of data] None

[Valid data range] 0 to 3

To set the zero point of absolute position detection:

0 : is not performed yet.

1 : was performed by the manual reference position return.

2 : was performed by MDI operation.

3 : was performed by the reading of parameter file.

Parameter

	#7	#6	#5	#4	#3	#2	#1	#0
1803	NFP							

[Input type] Parameter input

[Data type] Bit path

#7 NFP If position matching between the machine position and absolute position detector is not performed even once, follow-up operation is:

0: Not performed.

1: Performed.

	#7	#6	#5	#4	#3	#2	#1	#0
1815		RONx	APCx	APZx			OPTx	

[Input type] Parameter input

[Data type] Bit axis

> **NOTE**
> When at least one of these parameters is set, the power must be turned off before operation is continued.

#1 OPTx The separate position detector is:

0: Not to be used (semi-closed system)

1: To be used (full-closed system)

> **NOTE**
> In case of using the absolute position detector (bit 5 (APCx) of parameter No.1815 is set to 1), please set the following parameters that correspond to the absolute position detector which is actually used.
> - parameter No.1815#6, No.1815#0, No.1817#3, No.1868, No.2275#1, No.2394
>
> If these parameters are not set correctly, the machine coordinates are not correctly established at power-on.

#4 APZx Machine position and position on absolute position detector when the absolute position detector is used

0: Not corresponding
1: Corresponding

When an absolute position detector is used, after primary adjustment is performed or after the absolute position detector is replaced, this parameter must be set to 0, power must be turned off and on, then manual reference position return must be performed. This completes the positional correspondence between the machine position and the position on the absolute position detector, and sets this parameter to 1 automatically.

#5 APCx Position detector

0: Other than absolute position detector
1: Absolute position detector (absolute Pulsecoder)

> **NOTE**
> 1 In case of using FANUC absolute pulsecoder as absolute position detector for the rotary axis A type that machine coordinate values are rounded in 0 to 360°, set bit 6 (RON) of parameter No.1815 to 0. If the parameter is not set correctly, the machine coordinates are not correctly established at power-on.
> 2 In case of using a rotary scale without rotary data made by another company as absolute position detector, please refer to "CORRESPONDENCE OF ROTARY SCALE WITHOUT ROTARY DATA" in this manual and set an appropriate value corresponding to the detector. If the parameter is not set correctly, the machine coordinates are not correctly established at power-on.
> 3 When the servo axis is disabled (bit 4 (KSVx) of parameter No. 11802 is set to 1), an absolute position detector cannot be used (bit 5 (APCx) of parameter No. 1815 cannot be set to 1). If an absolute position detector is used, alarm SV0301, "APC ALARM; COMMUNICATION ERROR" is issued.

#6 RONx With a rotary axis A type, a rotary encoder for detecting an absolute position within one revolution is:

0: Not used.
1: Used.

NOTE
1. This parameter is available for only the rotary axis A type with an absolute position detector (absolute Pulsecoder).This function cannot be used for a rotary scale with distance-coded reference marks (serial) or for a distance coded rotary scale interface (phase A/B).
2. Set this parameter to 1 for the rotary axis A type using a rotary scale without rotary data such as HEIDENHAIN rotary scale RCN 223F, 727F, etc.
   Set this parameter to 0 in any other case. If the parameter is not set correctly, the machine coordinates are not correctly established at power-on.
3. When this parameter is set, machine position and position on absolute position detector become uncorresponding. Consequently, the bit 4 (APZ) parameter No. 1815 (indicating that the correspondence is established) is set to 0, and alarm DS0300 is issued. Why the parameter bit 4 (APZ) parameter No. 1815 is set to 0 can be checked using bit 0 of diagnosis data No. 310.

	#7	#6	#5	#4	#3	#2	#1	#0
1817					SCRx			

[Input type] Parameter input
[Data type] Bit axis

NOTE
When at least one of these parameters is set, the power must be turned off before operation is continued.

#3 SCRx Specifies whether to convert scale data by using threshold position (parameter No. 1868) so that rotary axis B type is available, in the case of the axis B type that use a rotary scale without data (the number of rotation), whose movable range is under one rotation:
0 : Not to convert.
1 : To convert.

NOTE
1. This parameter is available for only the rotary axis B type with an absolute position detector (absolute Pulsecoder) or a rotary scale with distance-coded reference marks (serial). This function cannot be used for distance coded rotary scale interface (phase A/B).
2. Don't set this parameter in the case of no uncontinuous point within movable range of rotary axis even if the rotary axis B type.
3. When this parameter is set, machine position and position on absolute position detector become uncorresponding. Consequently, the bit 4 (APZ) of parameter No. 1815 (indicating that the correspondence is established) is set to 0, and alarm DS0300 is issued. Why the bit 4 (APZ) of parameter No. 1815 is set to 0 can be checked using bit 0 of diagnosis data No. 310.

NOTE

4. This function cannot be used together with the bit 0 (RVSx) of parameter No. 1815 = 1 that save rotary data by CNC, in the case of a rotary axis B type whose movable range is over one rotation.
5. In this function, the amount of one rotation of rotary axis assumes 360, and the machine position 0 assumes the reference position. It is not possible to apply to a rotary axis other than the above-mentioned setting.
6. Set the parameter No. 1240 to 0.

	#7	#6	#5	#4	#3	#2	#1	#0
1819							CRFx	

[Input type] Parameter input
[Data type] Bit axis

#1 CRFx When the servo alarm SV0445 (soft disconnection), SV0447 (hard disconnection (separate)), or SV0421 (dual position feedback excessive error) is issued:
0: The reference position established state is not affected.
1: The reference position unestablished state is assumed. (Bit 4 (APZ) of parameter No. 1815 is set to 0.)

1860	Value 1 for the zero point of the absolute position detector
1861	Value 2 for the zero point of the absolute position detector
1862	Value 3 for the zero point of the absolute position detector

NOTE

When this parameter is set, the power must be turned off before operation is continued.

[Input type] Locked parameter
[Data type] 2-word axis

Parameters Nos.1860 to 1862 are values for the zero point of the absolute position detector (association with reference position and the counter value of the absolute position detector).
The CNC automatically sets parameters Nos.1860 to 1862 when correspondence between the reference position and the absolute position detector is performed.
It is not available to set parameters Nos.1860 to 1862 by using inputting of MDI operation, FOCAS2, PMC window or programmable parameter input(G10).

The zero point data of the absolute position detection can be restored and parameters Nos.1860 to 1862 can be set, by the parameter input from connected I/O unit or by restoring the SRAM area of boot system.
When the zero point data of the absolute position detection are restored, be careful about the following.

- When the zero point data of absolute position detection are restored, back up them right before the restoring and use backup data.
- When the motor or the detector is exchanged, the zero point data of absolute position detection cannot be restored. After exchange, set the zero point of the absolute position detector again.

- When the zero point data of the absolute position detection are restored by them of the other machine, the zero point of the absolute position detector is set to wrong position. Don't restore the zero point data of absolute position detection by them of the other machine.
- When the zero point data of absolute position detection are backed up with reference position not established and restored by backup data, setting of the zero point of the absolute position detector is required after restoring.

> ⚠ **WARNING**
> If the zero point of the absolute position detector is not set properly, the machine coordinate system is not established correctly.

1868	Threshold position for converting scale data (each axis)

> **NOTE**
> When this parameter is set, the power must be turned off before operation is continued.

[Input type] Parameter input
[Data type] Real axis
[Unit of data] deg (machine unit)
[Min. unit of data] Depend on the increment system of the applied axis
[Valid data range] 0 or positive 9 digit of minimum unit of data (Refer to the standard parameter setting table (B))
(When the increment system is IS-B, 0.0 to +999999.999)

In the case that scale data of a rotary scale without rotary data is larger than the scale data of the threshold position (this parameter value), it is converted to be continuous data in movable range by subtracting data of one rotation. The position out of movable range (angle from an uncontinuous point) must be set as threshold position. As for the axis for which this parameter is set to 0, conversion of scale data is not performed.

> **NOTE**
> 1 This parameter is available for only the rotary axis B type with an absolute position detector (absolute Pulsecoder) or a rotary scale with distance-coded reference marks (serial), for which the bit 3 (SCRx) of parameter No. 1817 is set to 1.This function cannot be used for distance coded rotary scale interface (phase A/B).
> 2 This function cannot be used for distance coded rotary scale interface (phase A/B).
> 3 Don't set this parameter in the case of no uncontinuous point within movable range of rotary axis even if the rotary axis B type.
> 4 When this parameter is set, machine position and position on absolute position detector become uncorresponding. Consequently, the bit 4 (APZ) of parameter No. 1815 (indicating that the correspondence is established) is set to 0, and alarm DS0300, "APC ALARM: NEED REF RETURN" is issued. Why the bit 4 (APZ) of parameter No. 1815 is set to 0 can be checked using bit 0 of diagnosis data No. 310.

	#7	#6	#5	#4	#3	#2	#1	#0
2275							RCNCLR	

[Input type] Parameter input
[Data type] Bit axis

#1 RCNCLR The number of revolution is:
0: Not to be cleared.
1: To be cleared. (To use the RCN220, RCN223, or RCN723, set the bit to 1.)
This function bit is to be set in combination with the number of data mask digits, described in parameter No.2394.

> **NOTE**
> This parameter is set according to the detector which is actually used. For details, please refer to "CORRESPONDENCE OF ROTARY SCALE WITHOUT ROTARY DATA".

2394	Number of data mask digits

[Input type] Parameter input
[Data type] Word axis
[Setting value] 5 or 8
The value to be set in this parameter depends on the detector. At present, only the following detectors require clearing the speed data. Set 5 to use the RCN220, and set 8 to use the RCN223, or RCN723. This parameter is to be set in combination with bit 1 (RCNCLR) of parameter No.2275.

> **NOTE**
> 1 The rotary data of the RCN220, RCN223, or RCN723 is maintained while the power to the separate detector interface unit is on. The data, however, is cleared when the unit is turned off.
> Since the rotary data becomes undetermined depending on where the power is turned off, it is necessary to make a setting to clear the rotary data. In addition, for this reason, the RCN220,RCN223, and RCN723 cannot be used with a linear axis.
> However, the detectors are available with a linear axis even if the rotary data is cleared by setting bit 6 (RVL) of parameter No.11802 is set to 1 and bit 0 (RVS) of parameter No.1815 is set to 1.
> 2 This parameter is set according to the detector which is actually used. For details, please refer to "CORRESPONDENCE OF ROTARY SCALE WITHOUT ROTARY DATA".

	#7	#6	#5	#4	#3	#2	#1	#0
11277			PWR					

[Input type] Parameter input
[Data type] Bit path

#5 PWR When a coordinate system is set at power-on using an absolute position detector (absolute pulse coder) with bit 3 (PPD) of parameter No. 3104 set to 0:
0: The axis is preset with 0.
1: The axis is preset with machine coordinates.

	#7	#6	#5	#4	#3	#2	#1	#0
11802				KSVx				

[Input type] Parameter input
[Data type] Bit axis

> **NOTE**
> When this parameter is set, the power must be turned off before operation is continued.

#4 KSVx Servo axis is:
0: Enabled.
1: Disabled.

> **NOTE**
> 1 This setting is effective regardless of the value of parameter No. 1023.
> 2 If this setting is made for the axis subject to Cs axis contour/spindle positioning, Cs axis contour/spindle positioning will be disabled.
> 3 When the servo axis is disabled (bit 4 (KSVx) of parameter No. 11802 is set to 1), an absolute position detector cannot be used (bit 5 (APCx) of parameter No. 1815 cannot be set to 1). If an absolute position detector is used, alarm SV0301, "APC ALARM; COMMUNICATION ERROR" is issued.

Alarm and message

Number	Message	Description
PS0090	REFERENCE RETURN INCOMPLETE	1. The reference position return cannot be performed normally because the reference position return start point is too close to the reference position or the speed is too slow. Separate the start point far enough from the reference position, or specify a sufficiently fast speed for reference position return. 2. An attempt was made to set the zero position for the absolute position detector by return to the reference position when it was impossible to set the zero point. Rotate the motor manually at least one turn, and set the zero position of the absolute position detector after turning the CNC and servo amplifier off and then on again.
DS0300	APC ALARM: NEED REF RETURN	A setting to zero position for the absolute position detector (association with reference position and the counter value of the absolute position detector) is required. Perform the return to the reference position. This alarm may occur with other alarms simultaneously. In this case, other alarms must be handled first.
DS0306	APC ALARM: BATTERY VOLTAGE 0	The battery voltage of the absolute position detector has dropped to a level at which data can no longer be held. Or, the power was supplied to the Pulsecoder for the first time. The battery or cable is thought to be defective. Replace the battery with the machine turned on.
DS0307	APC ALARM: BATTERY LOW 1	The battery voltage of the absolute position detector has dropped to a level at which a replacement is required. Replace the battery with the machine turned on.
DS0308	APC ALARM: BATTERY LOW 2	The battery voltage of the absolute position detector dropped to a level at which a replacement was required in the past. (including during power off) Replace the battery with the machine turned on.

Number	Message	Description
DS0309	APC ALARM: REF RETURN IMPOSSIBLE	An attempt was made to set the zero point for the absolute position detector by MDI operation when it was impossible to set the zero point. Rotate the motor manually at least one turn, and set the zero position of the absolute position detector after turning the CNC and servo amplifier off and then on again.
SV0301	APC ALARM: COMMUNICATION ERROR	1. Since the absolute-position detector of the phase A/B caused a communication error, the correct machine position could not be obtained. (data transfer error) The absolute-position detector, cable, or servo interface module is thought to be defective. 2. When the servo axis is disabled, an absolute position detector cannot be used. Check the setting of bit 5 (APCx) of parameter No. 1815 and bit 4 (KSVx) of parameter No. 11802.
SV0302	APC ALARM: OVER TIME ERROR	Since the absolute-position detector of the phase A/B caused an overtime error, the correct machine position could not be obtained. (data transfer error) The absolute-position detector, cable, or servo interface module is thought to be defective.
SV0303	APC ALARM: FRAMING ERROR	Since the absolute-position detector of the phase A/B caused a framing error, the correct machine position could not be obtained. (data transfer error) The absolute-position detector, cable, or servo interface module is thought to be defective.
SV0304	APC ALARM: PARITY ERROR	Since the absolute-position detector of the phase A/B caused a parity error, the correct machine position could not be obtained. (data transfer error) The absolute-position detector, cable, or servo interface module is thought to be defective.
SV0305	APC ALARM: PULSE ERROR	Since the absolute-position detector of the phase A/B caused a pulse error, the correct machine position could not be obtained. The absolute-position detector, or cable is thought to be defective.
SV0306	APC ALARM: OVER FLOW ERROR	Since the amount of positional deviation overflowed, the correct machine position could not be obtained. Check to see the parameters Nos. 2084 or 2085.
SV0307	APC ALARM: MOVEMENT EXCESS ERROR	Since the machine moved excessively, the correct machine position could not be obtained.

Caution

⚠ CAUTION

For an absolute position detector, batteries are used because the absolute position must be retained. When the battery voltage becomes low, a battery low alarm for the absolute position detector is displayed on the machine operator's panel or screen. If a battery voltage low alarm is displayed, replace the batteries with new ones immediately. If the batteries are not replaced, the absolute position data in the absolute position detector is lost.

Note

NOTE

1 For the procedure for replacing batteries, refer to the method for replacing batteries in "MAINTENANCE" in the OPERATOR'S MANUAL.
2 When replacing batteries with new ones after alarm DS0306, "APC ALARM: BATTERY VOLTAGE 0" is issued, manually rotate the motor at least one turn and turn the power to the CNC and servo amplifier off, then on again. Then, set the zero point of the absolute position detector (using manual reference position return or MDI operation).
If the above operation is not performed, alarm PS0090 or DS0309 is issued.
3 Do not set parameters Nos. 1860 to 1862 because the CNC automatically sets them when the zero point of an absolute position detector is set (the counter value of the absolute position detector is brought into correspondence with the reference position).

1.4.3 FSSB Setting

Overview

Connecting the CNC control section to servo amplifiers and spindle amplifiers via a high-speed serial bus (FANUC Serial Servo Bus, or FSSB), which uses only one fiber optics cable, can significantly reduce the amount of cabling in machine tool electrical sections.
In a system using the FSSB, it is necessary to set up the following parameters to specify its axes.

Table 1.4.3 (a) Parameters related to FSSB

Parameter No.	Contents
1023	Number of the servo axis for each axis
1902#1	Whether FSSB automatic setting is not completed (0) or completed (1)
2013#0	Whether HRV3 current loop is not used (0) or used (1)
3717	Spindle amplifier number of each spindle
11802#4	Whether the servo axes are enabled (0) or disabled (1)
24000 to 24095	ATR value corresponding to each slave on each FSSB line
24096 to 24103	Connector number of each separate detector interface unit

These parameters can be specified using the following three methods:

1. Manual setting 1
   Parameters are defaulted according to the setting of parameters Nos. 1023 and 3717. There is no need to specify parameters Nos. 24000 to 24095 and 24096 to 24103. No automatic setting is used. Note that some functions are unusable.

2. Automatic setting
   FSSB-related parameters are automatically specified by entering FSSB-related information on the FSSB setting screen.

3. Manual setting 2
   FSSB-related parameters are directly entered.

Explanation

- Slave

In an FSSB-based system, a fiber optics cable is used to connect the CNC to servo amplifiers or spindle amplifiers and separate detector interface units (hereafter referred to as separate detectors). These amplifiers and separate detectors are called slaves. The two-axis amplifier consists of two slaves, and the three-axis amplifier consists of three slaves. Slave numbers 1, 2 to 32 are sequentially assigned to slaves for each FSSB line. Number 1 is assigned to the slave nearest to the CNC.

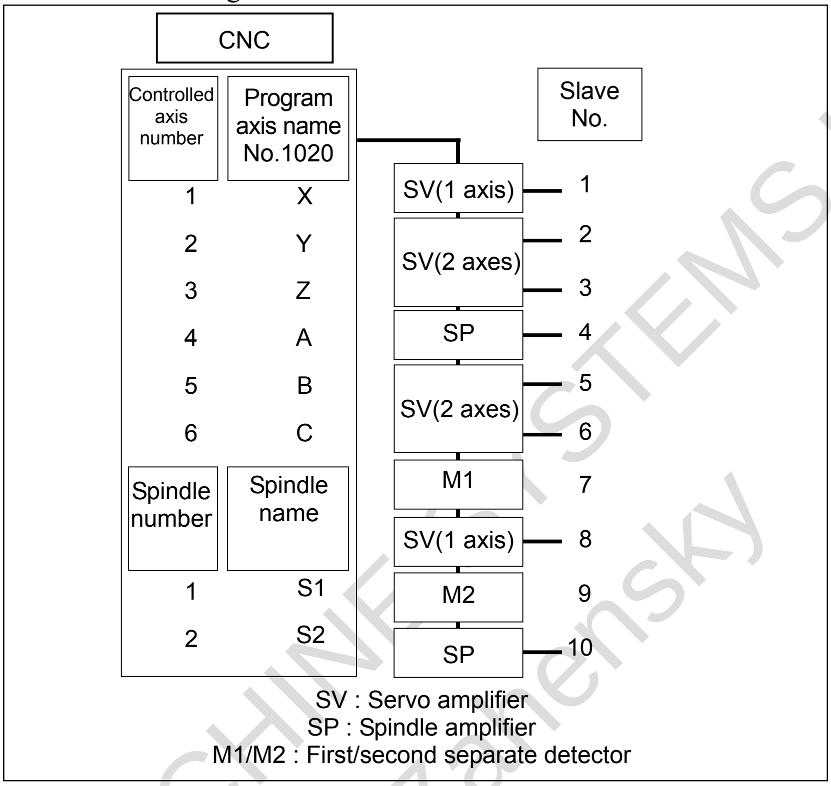


Fig. 1.4.3 (a) Slave

- Manual setting 1

The manual setting 1 is valid when the following parameter have the following values:

Bit 0 (FMD) of parameter No. 1902 = 0
Bit 1 (ASE) of parameter No. 1902 = 0

By manual setting 1, the values set for parameters Nos. 1023 and 3717 are used for setting slave numbers at power-on. Specifically, an axis for which parameter No. 1023 is set to 1 is connected to the amplifier nearest to the CNC, while an axis for which parameter No. 1023 is set to 2 is the second one from the CNC. A spindle for which parameter No. 3717 is set to 1 is connected to the spindle amplifier nearest to the CNC, while a spindle for which parameter No. 3717 is set to 2 is the Second one from the CNC.

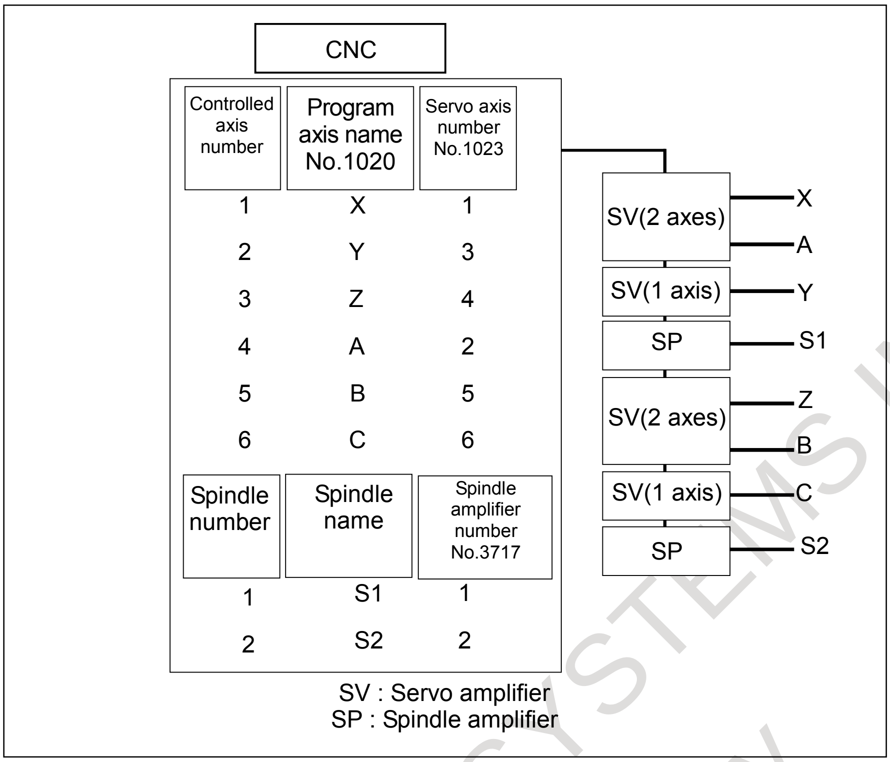

Fig. 1.4.3 (b) Setting example (manual setting 1)

By manual setting 1, some of the following functions and values cannot be used, as described below. To use the following functions and values, use automatic setting or manual setting 2.

- No separate detector can be used.
- No number can be skipped in parameter No. 1023 (other than the unavailable servo axis numbers, multiple of 8 and value obtained by subtracting 1 from a multiple of 8). For example, if servo axis number 3 is set for an axis without setting servo axis number 2 to any axis, manual setting 1 cannot be performed.
- No number can be skipped in parameter No. 3717 (spindle amplifier number of each spindle). For example, if spindle amplifier number 3 is set for a spindle without setting spindle amplifier number 2 to any spindle, manual setting 1 cannot be performed.
- The following servo functions cannot be used:
  - Servo HRV3 control
  - Tandem control
  - Electronic gear box (EGB)

- Automatic setting

Automatic setting can be used on the FSSB setting screen, if the following parameter is set as follows:
Bit 0 (FMD) of parameter No. 1902 = 0

On the FSSB setting screen, automatic setting should be enabled by means of the following procedure:

1 Make settings on the servo amplifier setting screen.
2 Make settings on the spindle amplifier setting screen.
3 Make settings on the axis setting screen.
4 Press the soft key [SETTING] to perform automatic setting. If setting data contains an error, a warning message is displayed. Set correct data again.

In this way, FSSB-related parameters are set. When each parameter has been set up, bit 1 (ASE) of parameter No. 1902 is set to 1. Switching the power off then back on again causes FSSB setting to be performed according to these parameter settings.
For details of the FSSB setting screen, see the FSSB data display and setting procedure, described below.

NOTE

1 Set the following items before executing FSSB automatic setting:
  - Set parameter No. 1020 (program axis name for each axis).
  - If you use the electronic gear box (EGB) function, set bit 0 (SYN) of parameter No. 2011 to 1 for the EGB slave axis and EGB dummy axis.

2 There are the following restrictions on FSSB automatic setting:
  - The current loop (HRV) is common to all axes.
  - Since any servo axis number is not skipped when parameter No. 1023 is set, the numbers cannot be set so that a specific servo axis number is skipped.

3 FSSB automatic setting cannot be performed when at least one of the following settings is made:
  - The FSSB setting mode is the manual setting 2 mode (bit 0 (FMD) of parameter No. 1902 is set to 1).
  - The serial feedback dummy function is enabled (bit 0 (DMY) of parameter No. 2009 is set to 1).
  - A servo axis is disabled for all axes (bit 4 (KSV) of parameter No. 11802 is set to 1).
  - One connector on an separate detector interface unit is used for more than one axes (bit 5 (SSC) of parameter No. 14476 is set to 1).

- Manual setting 2

After bit 0 (FMD) of parameter No. 1902 is set to 1 or automatic setting has been terminated (bit 1 (ASE) of parameter No. 1902 is set to 1), manual setting 2 for each parameter for axis setting can be performed. To perform manual setting 2, set parameters related to FSSB. Refer to the Parameter Manual for the definition of each parameter.

Example of setting parameters

- When separate detector interface units are connected

NOTE

When servo HRV3 control is used, the number of units connected to each FSSB line is limited. For details, refer to "Connection to the amplifier" in "Connection Manual (Hardware)" (B-64693EN).

1.4.3.1 FSSB setting screen

The FSSB setting screen displays FSSB-related information. This information can also be specified by the operator.

1 Press function key [SYSTEM].

2 To display [FSSB], press the [▷] continuous menu page key several times.

3 Pressing the soft key [FSSB] causes the [CONNECTION STATUS] screen (or the previously selected FSSB setting screen) to appear, with the following soft keys displayed.

Fig. 1.4.3.1 (a) Soft keys on the FSSB setting screen

There are seven FSSB setting screens: [CONNECTION STATUS], [SERVO AMPLIFIER SETTING], [SPINDLE AMPLIFIER SETTING], [SEPARATE DETECTOR INTERFACE UNIT], [AXIS SETTING], [SERVO AMPLIFIER MAINTENANCE], and [SPINDLE AMPLIFIER MAINTENANCE].

(1) Pressing the soft key [CONECT STATUS] causes the [CONNECTION STATUS] screen to appear.
(2) Pressing the soft key [SERVO AMP] causes the [SERVO AMPLIFIER SETTING] screen to appear.
(3) Pressing the soft key [SPNDLE AMP] causes the [SPINDLE AMPLIFIER SETTING] screen to appear.
(4) Pressing the soft key [PULSE MODULE] causes the [SEPARATE DETECTOR INTERFACE UNIT] screen to appear.
(5) Pressing the soft key [AXIS] causes the [AXIS SETTING] screen to appear.
(6) Pressing the soft key [SERVO MAINTE] causes the [SERVO AMPLIFIER MAINTENANCE] screen to appear.
(7) Pressing the soft key [SPNDLE MAINTE] causes the [SPINDLE AMPLIFIER MAINTENANCE] screen to appear.

(1) Connection status screen

The connection status screen displays the connection status of slaves connected to the FSSB at power-on.

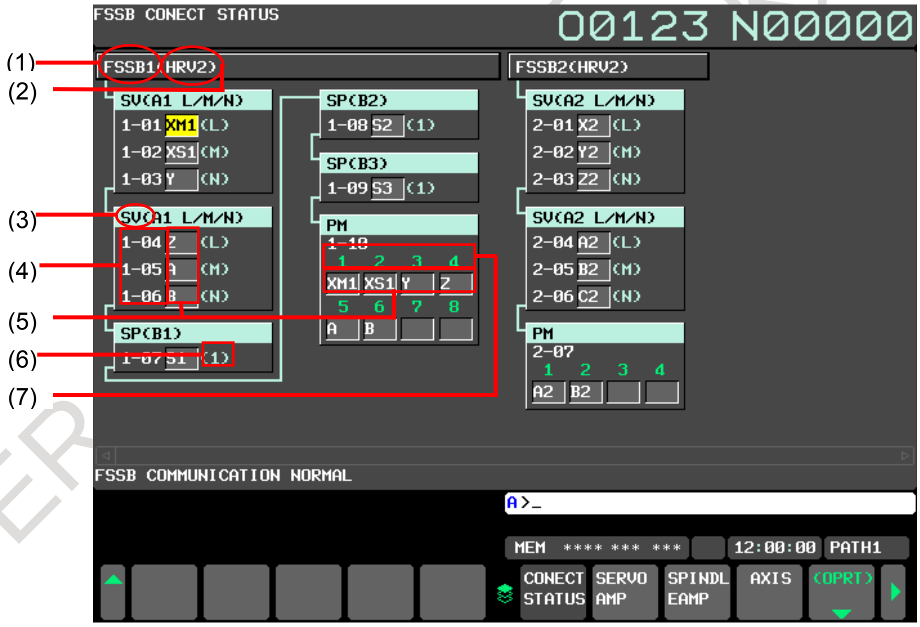

Fig. 1.4.3.1 (b) Connection status screen

The connection status screen displays the following items:

<1> FSSB1,FSSB2 ....FSSB line number
The FSSB line number is displayed. (FSSB1: First FSSB line, FSSB2: Second FSSB line)

<2> HRV2,HRV3, HRV- ....Current loop
The current loop for each FSSB line is displayed. “HRV-” may be displayed when no servo amplifier is connected to the FSSB or an FSSB-related alarm is issued.

<3> SV,SP,PM ....Slave type
The type of slave connected to the FSSB is displayed. (SV: Servo amplifier, SP: Spindle amplifier, PM: Separate detector interface unit)

<4> 1-01 to 1-32, 2-01 to 2-32 ....Slave number

An FSSB line number (1: First FSSB line, 2: Second FSSB line), a hyphen (-), and a slave number (connection number for the line) are displayed. (The maximum number of slaves per line is 32.)

<5> XM1,XS1,Y,Z,A,B .... Program axis name, Spindle name
The program axis name or spindle name set for each amplifier or separate detector interface unit is displayed.

<6> L,M,N,1 .... Amplifier axis order
The axis order for each amplifier is displayed. (L: First axis for a servo amplifier, M: Second axis for a servo amplifier, N: Third axis for a servo amplifier, 1: First spindle for a spindle amplifier)

<7> 1 to 8 .... Connector number
The connector number of a separate detector interface unit is displayed.

NOTE
When using the serial feedback dummy function by first axis of a multi-axis amplifier, the connection status is not correctly displayed.

When the softkey [(OPRT)] is pressed, the following softkey is displayed.

When the softkey [CURRENT] is pressed, current connection status is displayed.
When the alarm related to FSSB occurs and the softkey [ALARM] is pressed, the problem part is displayed in red judging from the data that compares with the FSSB connection state normally established in the past and the present FSSB connection.
When the softkey [SYSA HISTRY1] or [SYSA HISTRY2] is pressed, the problem part is displayed in red juding from the data that compares with the FSSB connection state normally established in the past and System alarm history data.

(2) Servo amplifier setting screen
The servo amplifier setting screen displays servo amplifier information.

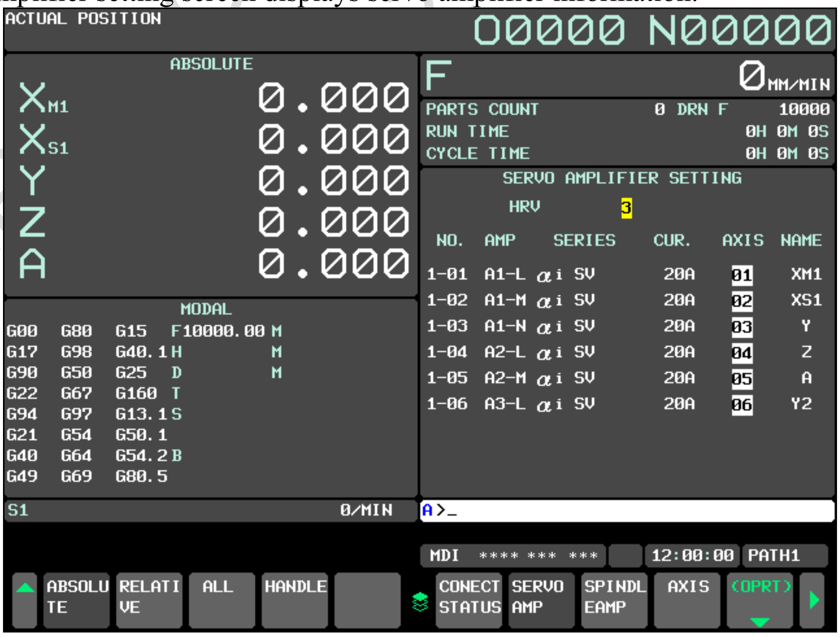

Fig. 1.4.3.1 (c) Servo amplifier setting screen

The servo amplifier setting screen consists of the following items:

- HRV .... Current loop

The current loop to be set at FSSB automatic setting is displayed. This value does not indicate the current effective current loop. (2: Servo HRV2 control, 3: Servo HRV3 control)

- NO..Slave number
  An FSSB line number (1: First FSSB line, 2: Second FSSB line), a hyphen (-), and a slave number (connection number for the line) are displayed. (The maximum number of slaves per line is 32.)
- AMP..Amplifier type
  This consists of the letter A, which stands for “servo amplifier”, a number indicating the placing of the servo amplifier, as counted from that nearest to the CNC, and an alphabetic character indicating the axis order in the servo amplifier (L: First axis, M: Second axis, N: Third axis).
- The following items are displayed as servo amplifier information:
  - SERIES.................Servo amplifier type and series
    (The display of the series name “β*i* SV” is not supported)
  - CUR. ....Maximum rating current
- AXIS ....Controlled axis number
  The controlled axis number assigned to the servo amplifier is displayed. “0” is displayed if an FSSB-related alarm is issued or no controlled axis number is assigned.
- NAME..Program axis name
  The program axis name corresponding to a particular controlled axis number set in parameter No. 1020 is displayed. When the axis number is 0, nothing is displayed.

(3) Spindle amplifier setting screen
The spindle amplifier setting screen displays spindle amplifier information.

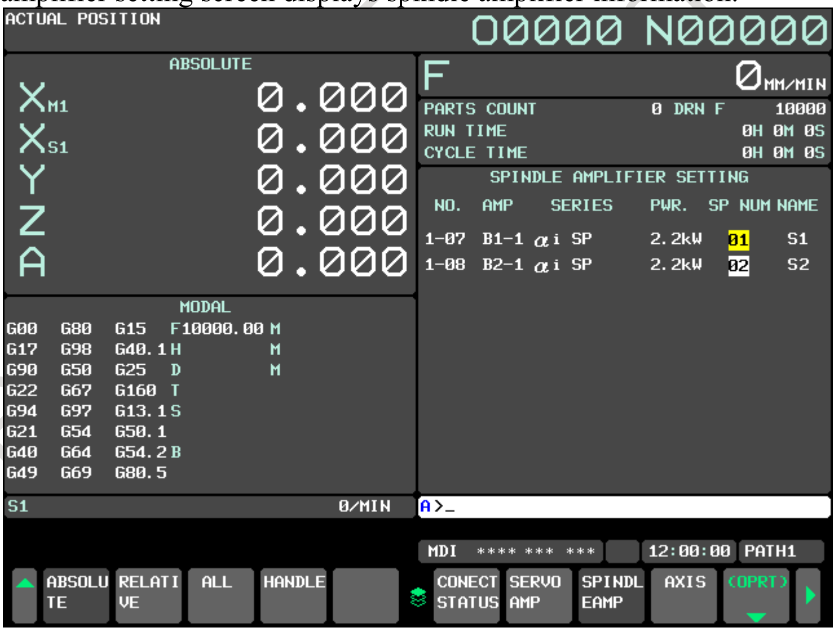

Fig. 1.4.3.1 (d) Spindle amplifier setting screen

The spindle amplifier setting screen consists of the following items:

- NO..Slave number
  An FSSB line number (1: First FSSB line, 2: Second FSSB line), a hyphen (-), and a slave number (connection number for the line) are displayed. (The maximum number of slaves per line is 32.)
- AMP..Amplifier type
  This consists of the letter B, which stands for “spindle amplifier”, a number indicating the placing of the spindle amplifier, as counted from that nearest to the CNC, and an alphabetic character indicating the axis order in the spindle amplifier (1: First spindle for a spindle amplifier).

- The following items are displayed as spindle amplifier information:
  - SERIES..................Spindle amplifier type and series
  - PWR.......................Maximum output
- SP NUM...Spindle number
  The spindle number assigned to the spindle amplifier is displayed. “0” is displayed if an FSSB-related alarm is issued or no spindle number is assigned.
- NAME...Spindle name
  The spindle name corresponding to the spindle number is displayed. When the spindle number is 0, nothing is displayed.

(4) Separate detector interface unit screen
The separate detector interface unit screen displays information on separate detector interface units.

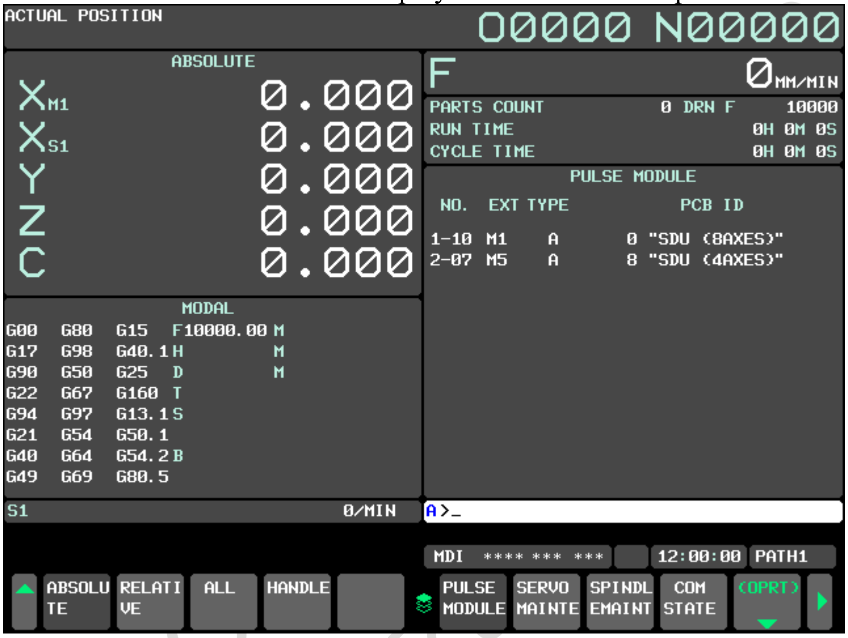

Fig. 1.4.3.1 (e) Separate detector interface unit screen

The separate detector interface unit screen displays the following items:

- NO...Slave number
  An FSSB line number (1: First FSSB line, 2: Second FSSB line), a hyphen (-), and a slave number (connection number for the line) are displayed. (While the maximum number of slaves per line is 32, the maximum number of separate detector interface units per line is 4.)
- The following items are displayed as separate detector interface unit information:
  - EXT
    This consists of the letter M, which stands for "separate detector interface unit", and a number indicating the placing of the separate detector interface unit, as counted from that nearest to the CNC. For the second FSSB line, M5 is displayed for the first separate detector interface unit since the number starts from 5.
  - TYPE
    This is a letter indicating the type of the separate detector interface unit.
  - PCB ID
    The ID of the separate detector interface unit is displayed.
    The separate detector interface unit ID is followed by SDU (8AXES) when 8-axes separate detector interface unit or SDU (4AXES) when 4-axes separate detector interface unit.

(5) Axis setting screen
The axis setting screen displays the information of axis.

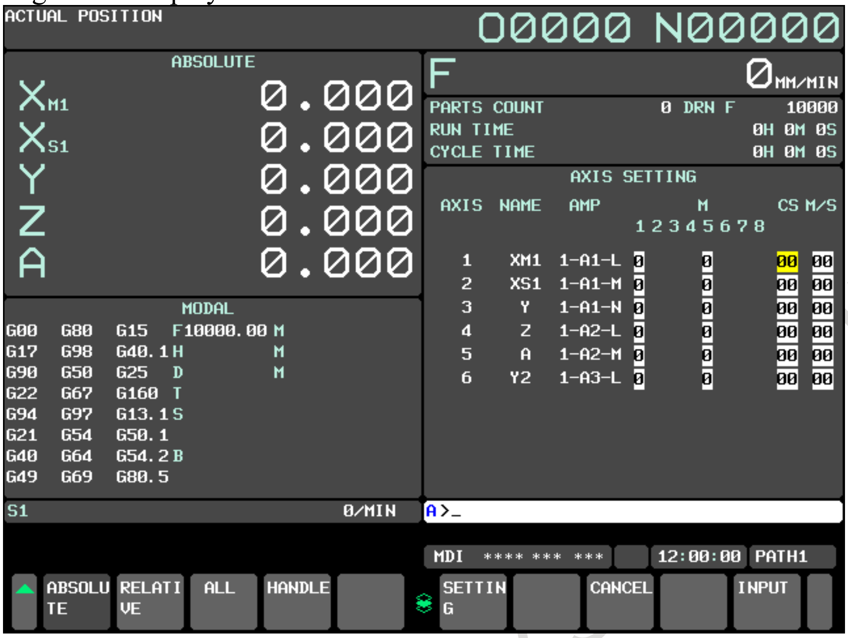

Fig. 1.4.3.1 (f) Axis setting screen

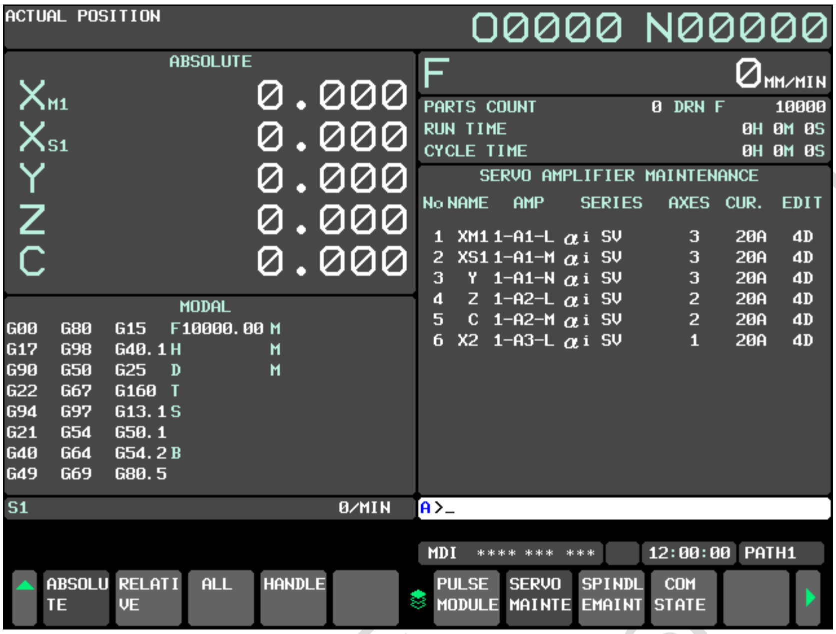
The axis setting screen displays the following items. Any item that cannot be set is not displayed. (When the first and fifth separate detector interface units are connected and Cs contour control and tandem control can be used, the screen shown in Fig. 1.4.3.1 (f) is displayed.)

- AXIS ....Controlled axis number
  This item is the placing of the NC controlled axis.
- NAME..........Program axis name for each axis
- AMP.............FSSB line number and amplifier type of the servo amplifier connected to each axis
- M1 ....Connector number of the first separate detector interface unit
- M2 ....Connector number of the second separate detector interface unit
- M3 ....Connector number of the third separate detector interface unit
- M4 ....Connector number of the fourth separate detector interface unit
- M5 ....Connector number of the fifth (first unit for the second FSSB line) separate detector interface unit
- M6 ....Connector number of the sixth separate detector interface unit
- M7 ....Connector number of the seventh separate detector interface unit
- M8 ....Connector number of the eighth separate detector interface unit
  Connector numbers set by FSSB automatic setting are displayed.
- Cs ....Cs contour controlled axis
  The spindle number for the Cs contour controlled axis set by FSSB automatic setting is displayed.
- M/S...............Master axis / Slave axis (Slave axis / Dummy axis)
  Either of the following settings is displayed: Master axis/slave axis setting for tandem control or slave axis/dummy axis setting for the electronic gear box (EGB) set by FSSB automatic setting.

The M1 to M8, Cs, and M/S values are to be set by FSSB automatic setting and do not indicate current effective settings. The previous values set normally are displayed first after power-on. “0” is displayed when an FSSB-related alarm is issued.

(6) Servo amplifier maintenance screen
The servo amplifier maintenance screen displays maintenance information for servo amplifiers. This screen consists of the following two pages, either of which can be selected by pressing the cursor keys [←] and [→].



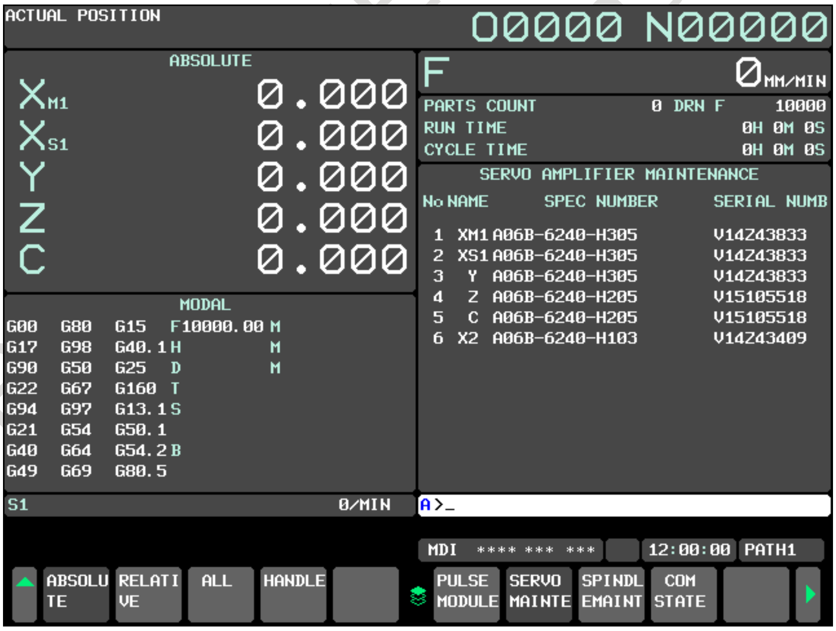


Fig. 1.4.3.1 (g) Servo amplifier maintenance screen

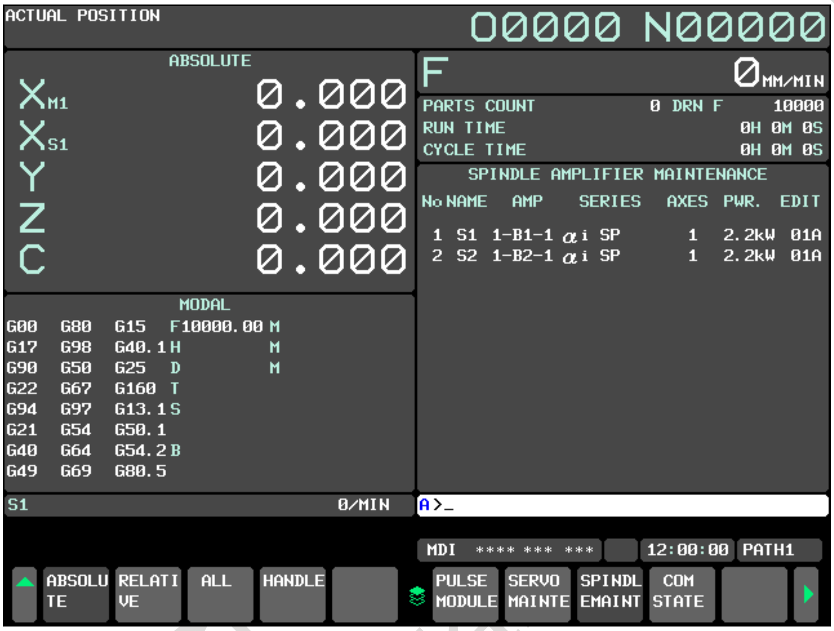
The servo amplifier maintenance screen displays the following items:

- No........................ Controlled axis number
- NAME................. Program axis name for each axis
- AMP.................... FSSB line number and amplifier type of the servo amplifier connected to each axis
- SERIES .... Type and series of the servo amplifier connected to each axis (The display of the series name "β*i*SV" is not supported)
- AXES .... Maximum number of axes controlled by a servo amplifier connected to each axis

- CUR. .... Maximum rating current for servo amplifiers connected to each axis
- EDIT .... Version number of a servo amplifier connected to each axis
- SPEC NUMBER. Amplifier drawing number of the servo amplifier connected to each axis
- SERIAL NUMB . Serial number of the servo amplifier connected to each axis

(7) Spindle amplifier maintenance screen
The spindle amplifier maintenance screen displays maintenance information for spindle amplifiers. This screen consists of the following two pages, either of which can be selected by pressing the cursor keys  and .



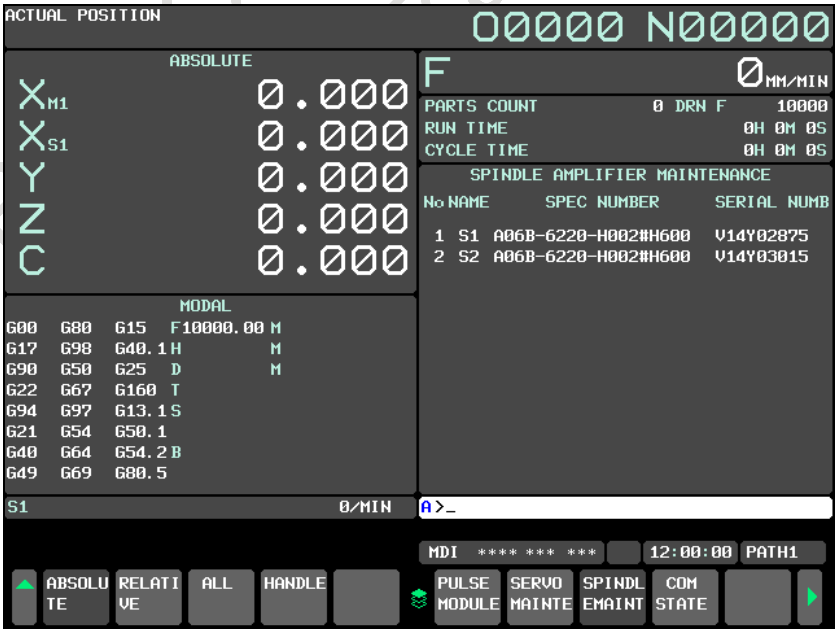


Fig. 1.4.3.1 (h) Spindle amplifier maintenance screen

The spindle amplifier maintenance screen displays the following items:

- No........................ Spindle number
- NAME................. Spindle name

- AMP .... FSSB line number and amplifier type of the spindle amplifier connected to each axis
- SERIES .... Type and series of the spindle amplifier connected to each axis
- AXES .... Maximum number of axes controlled by a spindle amplifier connected to each axis
- PWR.................... Rated output of the spindle amplifier connected to each axis
- EDIT .... Version number of a spindle amplifier connected to each axis
- SPEC NUMBER. Amplifier drawing number of the spindle amplifier connected to each axis
- SERIAL NUMB . Serial number of the spindle amplifier connected to each axis

1.4.3.2 FSSB automatic setting procedure

To perform FSSB automatic setting, set items on the FSSB setting screens in (1) to (3) below.

(1) Servo amplifier setting screen

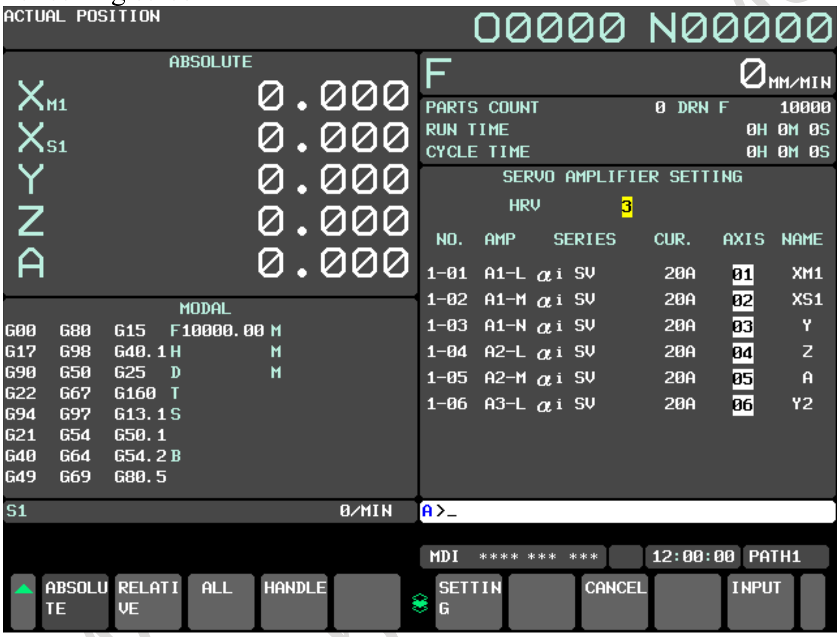

Fig. 1.4.3.2 (a) Servo amplifier setting

The servo amplifier setting screen displays the following items:

- HRV .... Current loop
  For this item, enter a value between 2 to 3.
  If a number that falls outside this range is entered, the warning message, “DATA IS OUT OF RANGE” appears.
- AXIS .... Controlled axis number
  For this item, enter a value of between 0 and the maximum number of controlled axes.
  If a number that falls outside this range is entered, the warning message, “DATA IS OUT OF RANGE” appears. Setting 0 means that the relevant servo amplifier is not used.

(2) Spindle amplifier setting screen

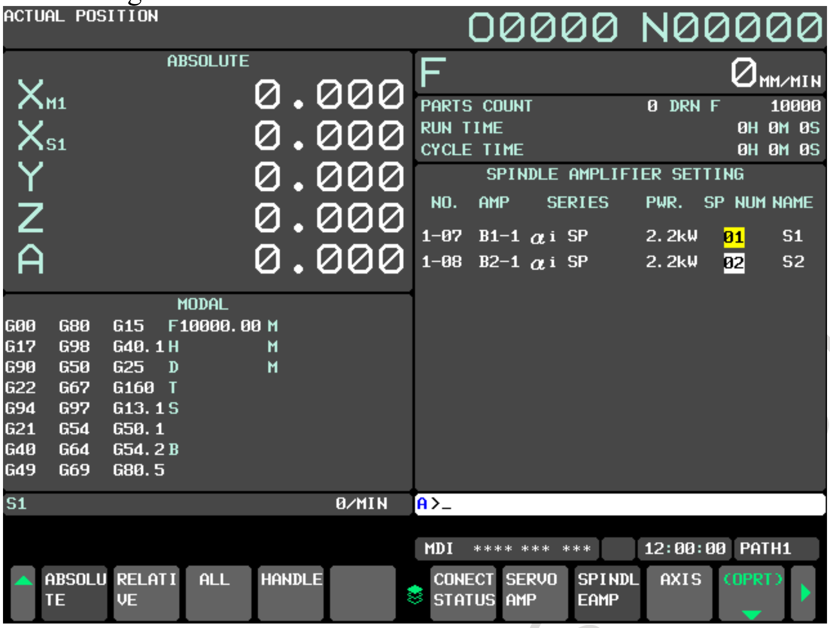

Fig. 1.4.3.2 (b) Spindle amplifier setting

The spindle amplifier setting screen displays the following items:

- SP NUM.............. Spindle number
  For this item, enter a value of between 0 and the maximum number of spindles.
  If a number that falls outside this range is entered, the warning message, "DATA IS OUT OF RANGE" appears. Setting 0 means that the relevant spindle amplifier is not used.

(3) Axis setting screen

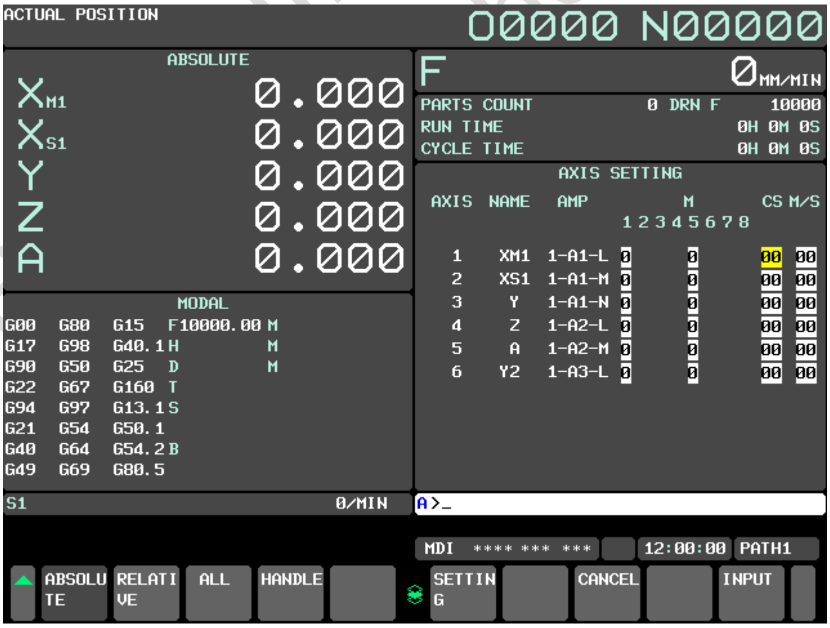

Fig. 1.4.3.2 (c) Axis setting

On the axis setting screen, the following items can be specified:

- M1............. Connector number of the first separate detector interface unit
- M2............. Connector number of the second separate detector interface unit
- M3............. Connector number of the third separate detector interface unit
- M4............. Connector number of the fourth separate detector interface unit

- M5............. Connector number of the fifth (first unit for the second FSSB line) separate detector interface unit
- M6............. Connector number of the sixth separate detector interface unit
- M7............. Connector number of the seventh separate detector interface unit
- M8............. Connector number of the eighth separate detector interface unit
  For an axis that uses each separate detector interface unit, enter a connector number using a number 1 to 8 (maximum number of connectors on a separate detector interface unit).
  When a separate detector interface unit is not used, enter 0. If a number that falls outside this range is entered, the warning message, "DATA IS OUT OF RANGE" appears. For a separate detector interface unit which is not connected, items are not displayed and values cannot be entered.

Table 1.4.3.2 (a) Connectors and corresponding connector numbers

Connector	Connector number
JF101	1
JF102	2
JF103	3
JF104	4
JF105	5
JF106	6
JF107	7
JF108	8

- CS.............. Cs contour controlled axis
  Enter a spindle number between 1 and the maximum number of spindles for the Cs contour controlled axis. When a Cs contour controlled axis is not used, enter 0. If a number that falls outside this range is entered, the warning message, "DATA IS OUT OF RANGE" appears. When Cs contour control cannot be used, this item is not displayed and any value cannot be entered.
- M/S............ Master axis / Slave axis (Slave axis / Dummy axis)
  Enter an odd number for the master axis and an even number for the slave axis for tandem control. These numbers must be consecutive and within a range between 1 and the maximum number of controlled axes. Enter an odd number for the slave axis and an even number for the dummy axis for the electronic gear box (EGB). These numbers must be consecutive and within a range between 1 and the maximum number of controlled axes. If a number that falls outside this range is entered, the warning message, "DATA IS OUT OF RANGE" appears. For the slave and dummy axes for EGB, set bit 0 (SYN) of parameter No. 2011 to 1. When both tandem control and electronic gear box cannot be used, this item is not displayed and any value cannot be entered.

On an FSSB setting screen (other than the connection status screen, servo amplifier maintenance screen, or spindle amplifier maintenance screen), pressing the soft key [(OPRT)] displays the following soft keys:

Fig. 1.4.3.2 (d) FSSB automatic setting soft keys

To enter data, place the machine in the MDI mode or the emergency stop state, position the cursor to a desired input item position, then enter desired data and press the soft key [INPUT].

(Alternatively, press the  key on the MDI unit.)

When the soft key [SETTING] is pressed after data has been entered, a warning message listed below is displayed if the entered data contains an error. When the data is valid, the corresponding FSSB-related parameters are set up. To restore the previous value normally set if, for example, an entered value is incorrect, press the soft key [CANCEL].
When this screen is first displayed after power-on, the previous values set normally are displayed.

FSSB automatic setting warning messages

If an invalid setting is detected at FSSB automatic setting, a warning message listed below is displayed. EGB dummy axis setting means setting an even number for M/S on the axis setting screen for an axis for which bit 0 (SYN) of parameter No. 2011 is set to 1. EGB slave axis setting means setting an odd number for M/S on the axis setting screen for an axis for which bit 0 (SYN) of parameter No. 2011 is set to 1.

Warning message	Cause
Cs and M/S are set with the same axis	On the axis setting screen, a value is specified for Cs and M/S for an axis. Do not specify any value for Cs and M/S simultaneously.
Cs and M1-8 are set with the same axis	On the axis setting screen, a value is specified for Cs and M1-8 for an axis. Do not specify any value for Cs and M1-8 simultaneously.
Same number is set in AXIS	On the servo amplifier setting screen, an axis number is set more than once. Specify each axis number only once.
Same number is set in SP NUM	On the spindle amplifier setting screen, a spindle number is set more than once. Specify each spindle number only once.
Same number is set in CS	On the axis setting screen, a value is set for Cs more than once. Specify each value for Cs only once.
Same number is set in M/S	On the axis setting screen, a value is set for M/S more than once. Specify each value for M/S only once.
AXIS and Cs are set with the same axis	An axis number for which a value is set for Cs on the axis setting screen is set for AXIS on the servo amplifier setting screen. Do not set any axis number for which a value is set for Cs, on the servo amplifier setting screen.
Too many slaves (HRV3)	The maximum number (15) of slaves per FSSB line for servo HRV3 control is exceeded. Reduce the number of slaves connected to an FSSB line to 15 or less.
Too many slaves (HRV2)	The maximum number (32) of slaves per FSSB line for servo HRV2 control is exceeded. Reduce the number of slaves connected to an FSSB line to 32 or less.
AXIS is set with EGB dummy axis	An axis number set for EGB dummy axis setting is set for AXIS on the servo amplifier setting screen. Do not set any axis number for EGB dummy axis setting, on the servo amplifier screen.
M/S setting is illegal(EGB)	For M/S, the EGB slave axis setting corresponding to an EGB dummy axis setting is not made. Make the EGB slave axis setting.
AXIS is not set with EGB slave axis	An axis number for EGB slave axis setting is not set for AXIS on the servo amplifier setting screen. Set the axis number for EGB slave axis setting, on the servo amplifier setting screen.
AXIS is not set with M/S axis	An axis number set for M/S on the axis setting screen is not set for AXIS on the servo amplifier setting screen. Set the axis number for M/S, on the servo amplifier setting screen.
EGB dummy axis setting is illegal	EGB dummy axis setting is made when 32 slaves are connected to the second FSSB line. Decrease the number of slaves connected to the second FSSB line.
M/S setting is illegal	Invalid M/S setting. Correct the M/S setting.
Setting is illegal(servo)	Invalid servo axis setting (servo amplifier setting, axis setting). Correct the servo axis setting.
Setting is illegal(spindle)	Invalid spindle setting. Correct the spindle setting.

> ⚠ **CAUTION**
> For the parameters to be specified on the FSSB setting screen, do not attempt to directly enter values on the parameter screen using the MDI or a G10 command. Use only the FSSB setting screen to enter values for these parameters.

Examples of FSSB automatic setting

Examples of FSSB automatic setting for the listed functions are shown below:

- Example 1 Servo HRV2 control (Servo HRV3 control)
- Example 2 Separate detector interface unit

- Example 3 Cs contour control
- Example 4 Tandem control
- Example 5 Electronic gear box

- Example 1 Servo HRV2 control

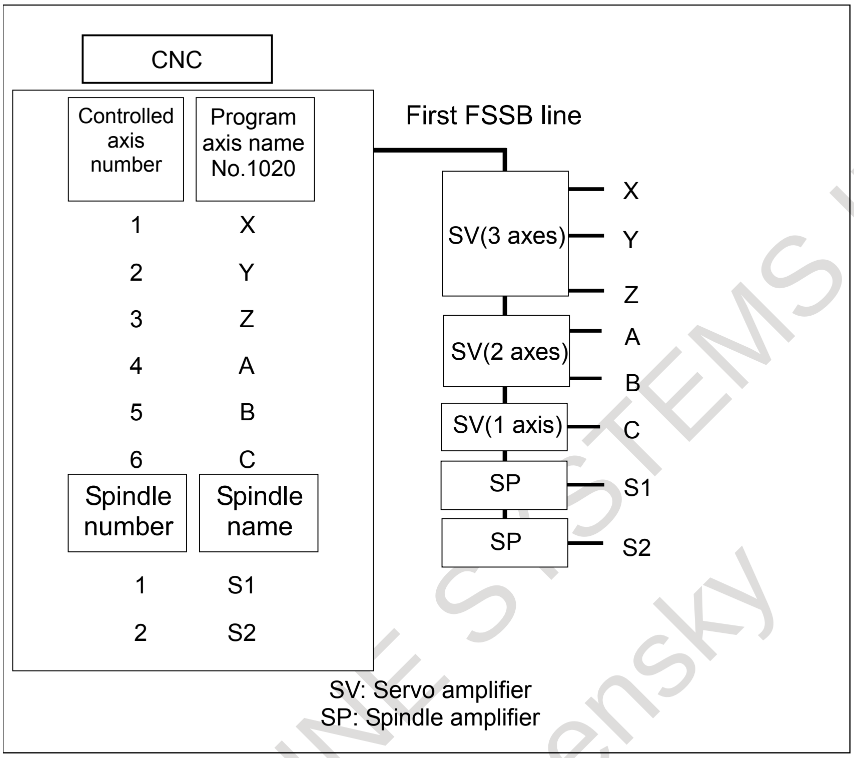

Fig. 1.4.3.2 (e) Setting example (servo HRV2 control)

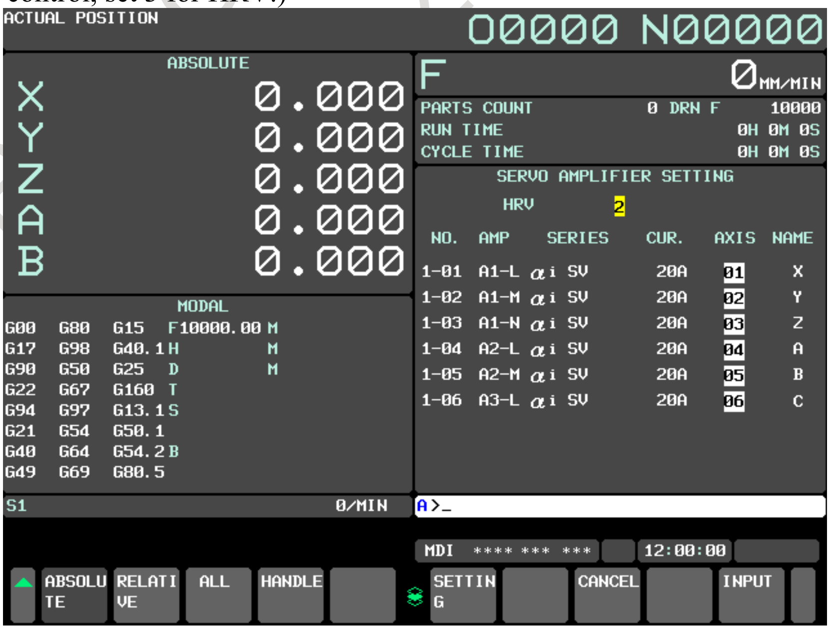
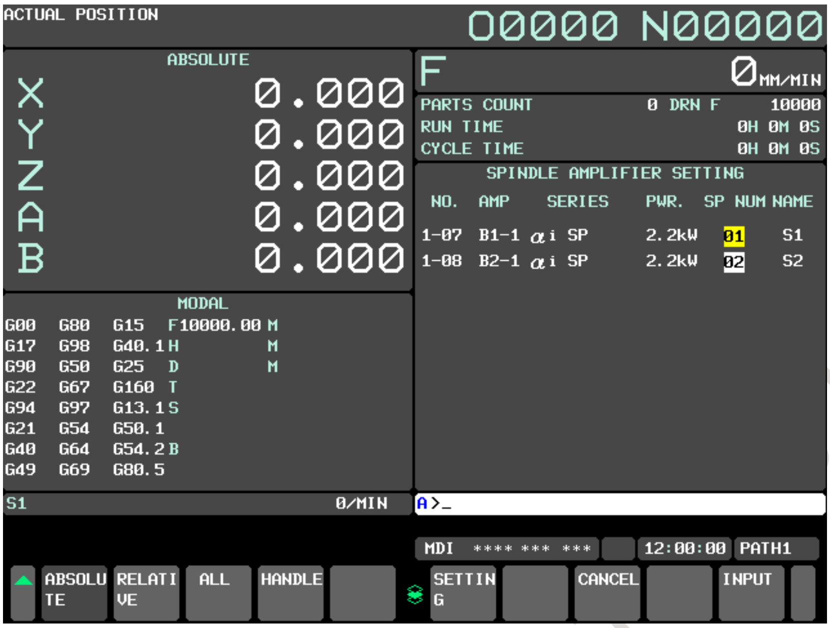
<1> On the servo amplifier setting screen, enter 2 for HRV and 1, 2, 3, 4, 5, and 6 for AXIS. (To set servo HRV3 control, set 3 for HRV.)



<2> On the spindle amplifier setting screen, enter 1 and 2 for SP NUM.



<3> Press the soft key [SETTING] to perform FSSB automatic setting.

- Example 2 Separate detector interface unit

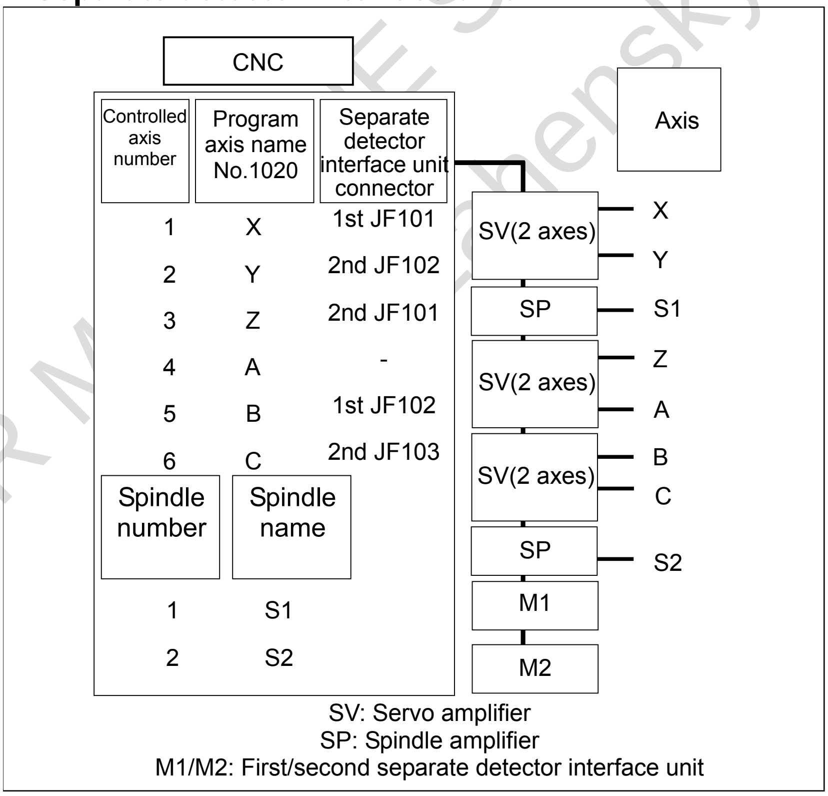


Fig. 1.4.3.2 (f) Setting example (separate detector interface unit)

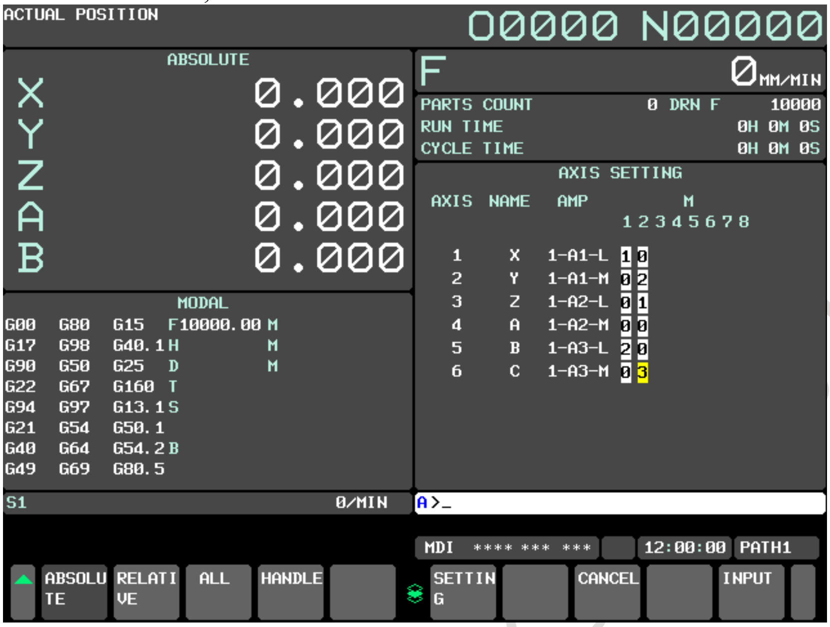
<1> On the axis setting screen, enter 1 in M1 for the X-axis, 2 in M2 for the Y-axis, 1 in M2 for the Z-axis, 2 in M1 for the B-axis, and 3 in M2 for the C-axis.



<2> Press the soft key [SETTING] to perform FSSB automatic setting.

- Example 3 Cs contour control

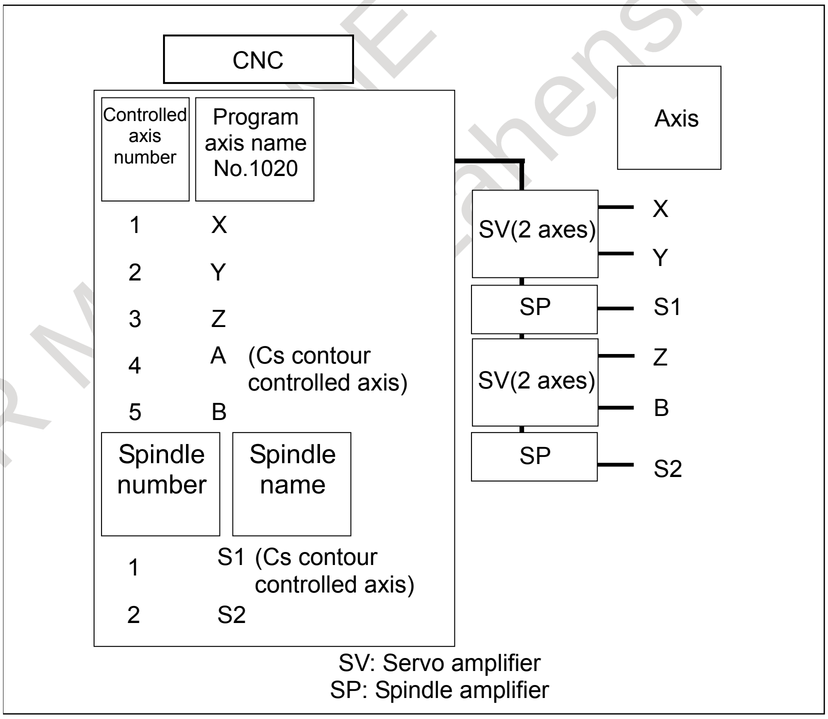


Fig. 1.4.3.2 (g) Setting example (Cs contour control)

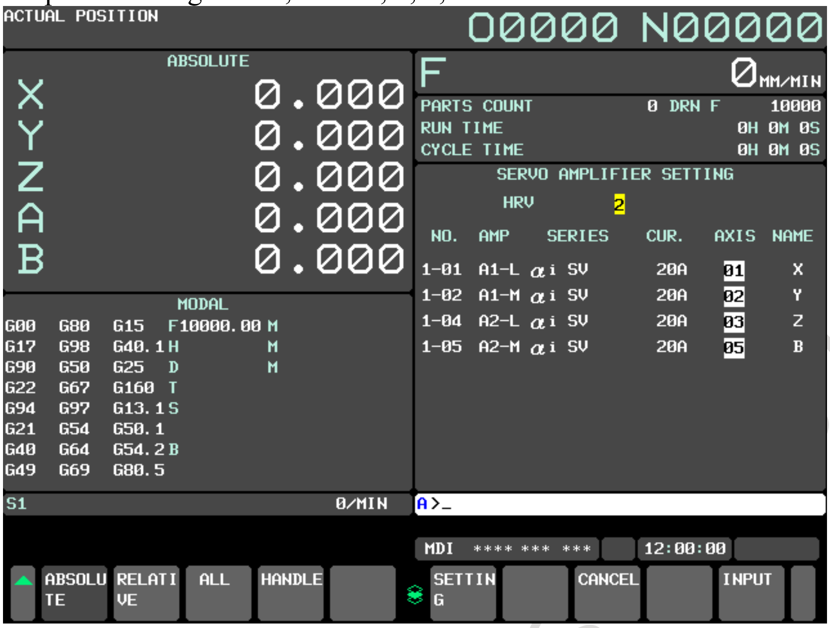
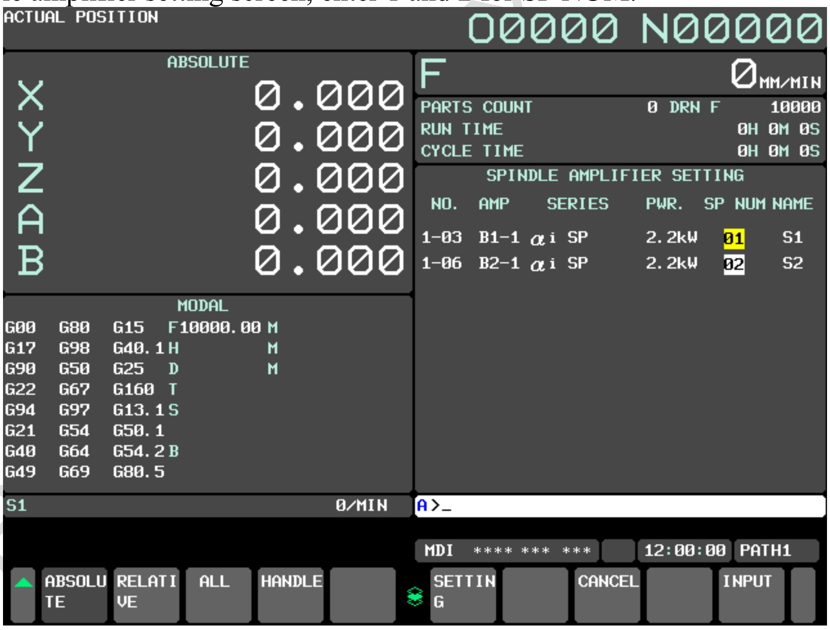
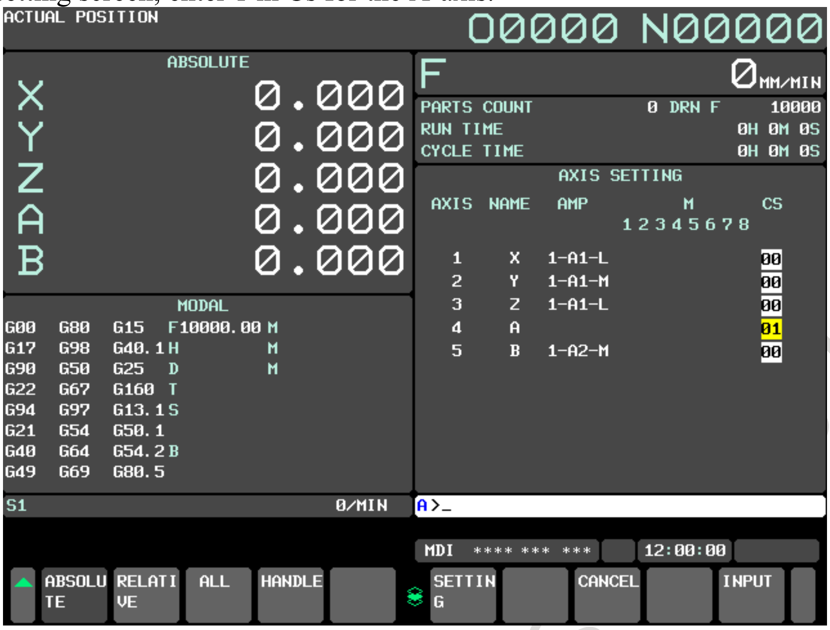
<1> On the servo amplifier setting screen, enter 1, 2, 3, and 5 for AXIS.



<2> On the spindle amplifier setting screen, enter 1 and 2 for SP NUM.



<3> On the axis setting screen, enter 1 in Cs for the A-axis.



<4> Press the soft key [SETTING] to perform FSSB automatic setting.

- Example 4 Tandem control

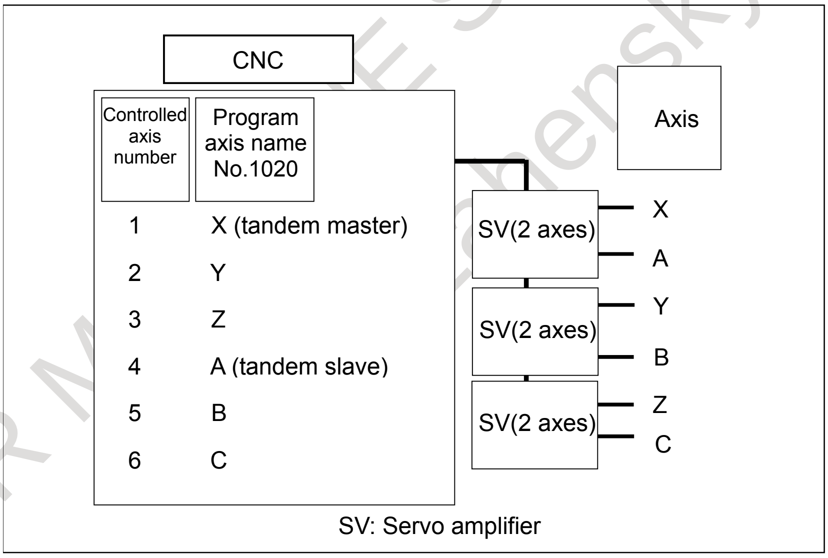


Fig. 1.4.3.2 (h) Setting example (tandem control)

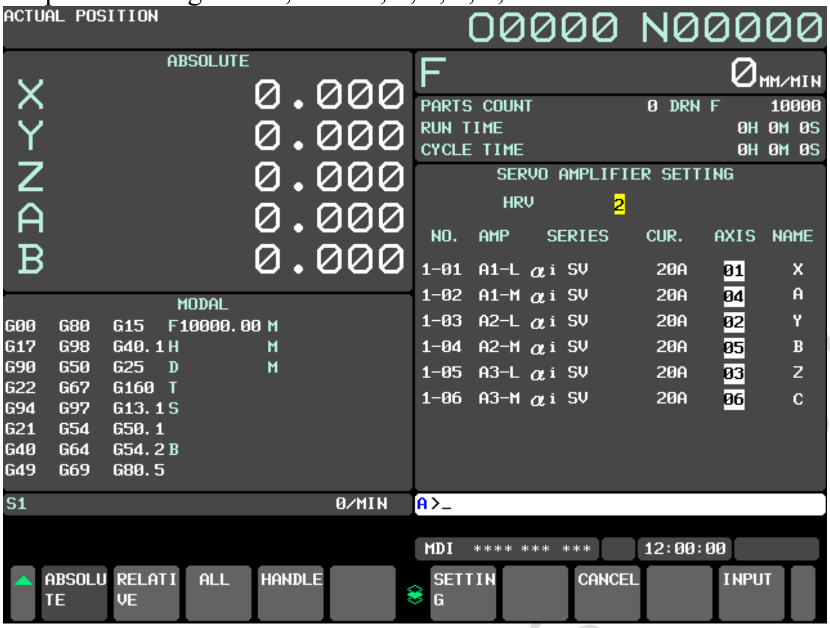
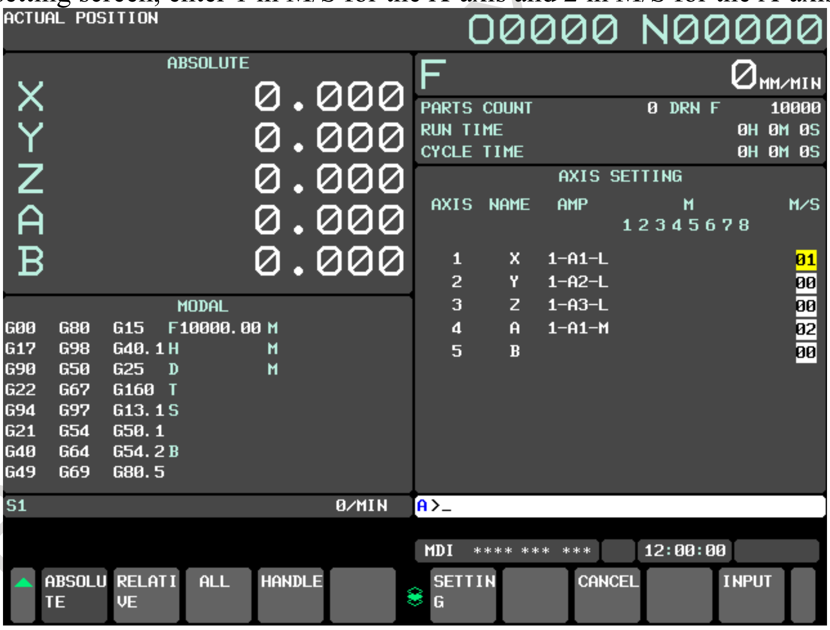
<1> On the servo amplifier setting screen, enter 1, 4, 2, 5, 3, and 6 for AXIS.



<2> On the axis setting screen, enter 1 in M/S for the X-axis and 2 in M/S for the A-axis.



<3> Press the soft key [SETTING] to perform FSSB automatic setting.

- Example 5 Electronic gear box

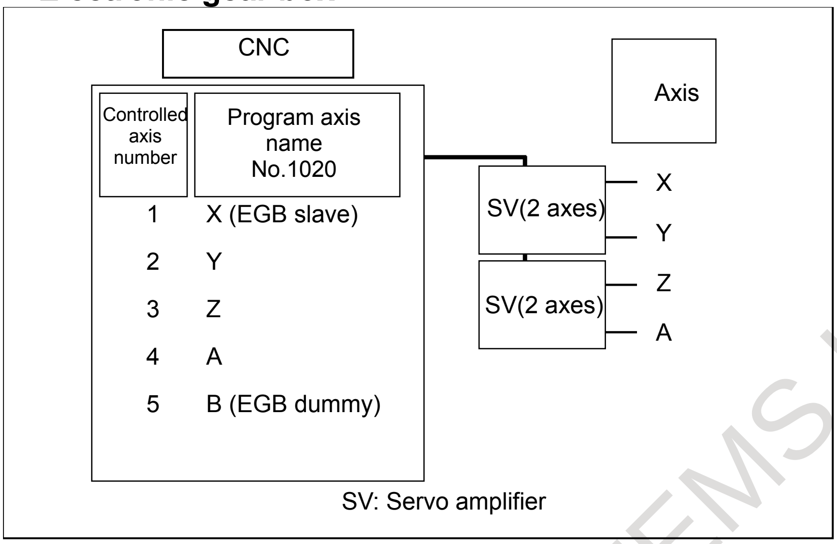


Fig. 1.4.3.2 (i) Setting example (electronic gear box)

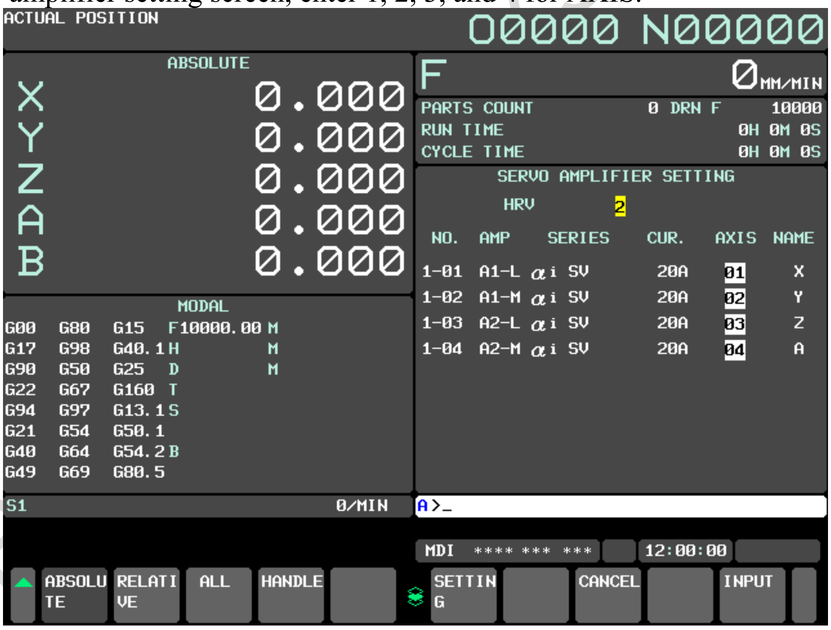
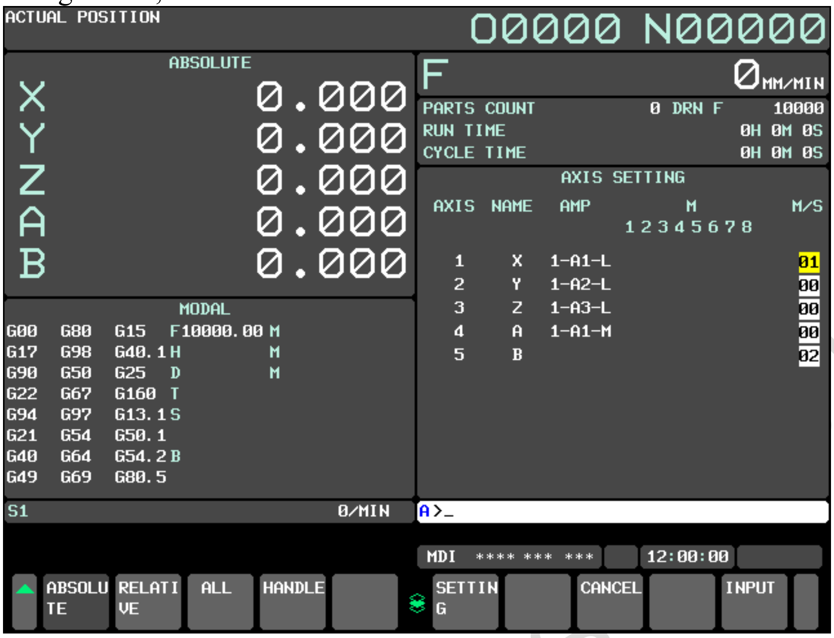
<1> For the X- and B-axes, set bit 0 (SYN) of parameter No. 2011 to 1.
<2> On the servo amplifier setting screen, enter 1, 2, 3, and 4 for AXIS.



<3> On the axis setting screen, enter 1 in M/S for the X-axis and 2 in M/S for the B-axis.



<4> Press the soft key [SETTING] to perform FSSB automatic setting.

Parameter

1023	Number of the servo axis for each axis

> **NOTE**
> When this parameter is set, the power must be turned off before operation is continued.

[Input type] Parameter input
[Data type] Byte axis
[Valid data range] 0 to 78

This parameter associates each control axis with a specific servo axis. Usually, set the same number as a controlled axis number and its corresponding servo axis number.
The control axis number is the order number that is used for setting the axis-type parameters or axis-type machine signals
Any multiple of 8 and the value obtained by subtracting 1 from a multiple of 8 cannot be set, however. When the number of controlled axes is 7 or more, set numbers with skipping any multiple of 8 and the value obtained by subtracting 1 from a multiple of 8.

- Example of setting when the number of controlled axes is 6 or less

Parameter No.1023	Setting value
(1st axis)	1
(2nd axis)	2
(2rd axis)	3
(4th axis)	4
(5th axis)	5
(6th axis)	6

- Example of setting when the number of controlled axes is 7 or more

Parameter No.1023	Setting value
(1st axis)	1
(2nd axis)	2
(2rd axis)	3
(4th axis)	4
(5th axis)	5
(6th axis)	6
(7th axis)	9
(8th axis)	10
(9th axis)	11
(10th axis)	12
(11th axis)	13
(12th axis)	14
(13th axis)	17
(14th axis)	18

- With an axis for which Cs contour control/spindle positioning is to be performed, set -(spindle number) as the servo axis number.
  Example)
  When exercising Cs contour control on the fourth controlled axis by using the first spindle, set -1.
- For tandem controlled axes or electronic gear box (EGB) controlled axes, two axes need to be specified as one pair. So, make a setting as described below.
  Tandem axis: For a master axis, set an odd (1, 3, 5, ...) servo axis number. For a slave axis to be paired, set a value obtained by adding 1 to the value set for the master axis.
  EGB axis: For a slave axis, set an odd (1, 3, 5, ...) servo axis number. For a dummy axis to be paired, set a value obtained by adding 1 to the value set for the slave axis.

	#7	#6	#5	#4	#3	#2	#1	#0
1902							ASE	FMD

[Input type] Parameter input
[Data type] Bit

NOTE
When at least one of these parameters is set, the power must be turned off before operation is continued.

#0 FMD The FSSB setting mode is:
0: Automatic setting mode.
(When the relationship between an axis and amplifier is defined on the FSSB setting screen, parameters Nos. 1023, 2013#0, 2014#0, 3717, 11802#4, 24000 to 24103 are automatically set.
1: Manual setting 2 mode.
(Parameters Nos. 1023, 2013#0, 2014#0, 3717, 11802#4, 24000 to 24103 are to be manually set.)

#1 ASE When automatic setting mode is selected for FSSB setting (when the bit 0 (FMD) parameter No. 1902 is set to 0), automatic setting is:
0: Not completed.
1: Completed.

This bit is automatically set to 1 upon the completion of automatic setting.

	#7	#6	#5	#4	#3	#2	#1	#0
3716								A/Ss

[Input type] Parameter input
[Data type] Bit spindle

> **NOTE**
> When this parameter is set, the power must be turned off before operation is continued.

#0 A/Ss Spindle motor type is :
0: Analog spindle.
1: Serial spindle.

> **NOTE**
> 1 When FSSB setting is used, the setting of serial spindle is required.
> 2 When a serial spindle is used, enable the spindle serial output (bit 5 (SSN) of parameter No.8133 is 0).

3717	Spindle amplifier number of each spindle

> **NOTE**
> When this parameter is set, the power must be turned off before operation is continued.

[Input type] Parameter input
[Data type] Byte spindle
[Valid data range] 0 to Maximum number of controlled axes

Set a spindle amplifier number to be assigned to each spindle.
0: No spindle amplifier is connected.
1: Spindle motor connected to amplifier number 1 is used.
2: Spindle motor connected to amplifier number 2 is used.
to
n: Spindle motor connected to amplifier number n is used.

NOTE

1 In addition, it is necessary to set FSSB. Refer to Parameter Nos.24000 to 24095 for details.
2 If value of this parameter is larger than the maximum value, the alarm SP1996, "ILLEGAL SPINDLE PARAMETER SETTING" occurs.
3 If the spindle motor is treated as hypothetical Cs axis control or spindle control with servo motor, set this parameter to “0”.
4 In the display order of the parameter No.982, the spindle axes since the spindle axis that 0 is set to this parameter become invalid, too. However, the case that the spindle motor is treated as hypothetical Cs axis control or spindle control with servo motor is excepted.
Example) On the following setting, S3 and S4 spindle axes are invalid when the spindle motor of S3 is not treated as hypothetical Cs axis control or spindle control with servo motor.

Display order of No.982	Setting value of No.982	Setting value of No.3717
S1	1	1
S2	2	2
S3	1	0
S4	2	3

	#7	#6	#5	#4	#3	#2	#1	#0
14476			SSC					

[Input type] Parameter input
[Data type] Bit

NOTE

When this parameter is set, the power must be turned off before operation is continued.

#5 SSC The number of ATR values for a separate detector interface unit connector is:
0: Only 1.
1: More than 1.

NOTE

When this parameter is set to 1, FSSB automatic setting cannot be performed.

24000	ATR value corresponding to slave 01 on first FSSB line
24001	ATR value corresponding to slave 02 on first FSSB line
to	to
24031	ATR value corresponding to slave 32 on first FSSB line

> **NOTE**
> When these parameters are set, the power must be turned off before operation is continued.

[Input type] Parameter input
[Data type] Word
[Valid data range] 1001 to 1046, 2001 to 2016, 3001 to 3004, 1000

Each of these parameters sets the value (ATR value) of the address translation table corresponding to each of slave 1 to slave 32 on first FSSB line (first optical connector).

The slave is a generic term for servo amplifiers, spindle amplifiers and separate detector interface units connected via an FSSB optical cable to the CNC. Numbers 1 to 32 are assigned to slaves, with younger numbers sequentially assigned to slaves closer to the CNC.

A 2-axis amplifier consists of two slaves, and a 3-axis amplifier consists of three slaves. In each of these parameters, set a value as described below, depending on whether the slave is an amplifier, separate detector interface unit, or nonexistent.

- When the slave is a servo amplifier:
  Set the axis number of a servo amplifier to allocate (value set with parameter No. 1023) plus 1000.
- When the slave is a spindle amplifier:
  Set the spindle number of a spindle to allocate (value set with parameter No. 3717) plus 2000.
- When the slave is a separate detector interface unit:
  Set 3001, 3002, 3003, and 3004, respectively, for the first (one connected nearest to the CNC), second, third, and fourth separate detector interface units.
- When the slave is nonexistent:
  Set 1000.

> **NOTE**
> 1 When Electronic gear box (EGB) function is used
> Although an amplifier is not actually required for an EGB dummy axis, set this parameter with assuming that a dummy amplifier is connected. To put it another way, specify this parameter with a value set in the EGB dummy axis parameter No. 1023 plus 1000, instead of “1000”, as an address translation table value for one of non-existent slaves.
> 2 When the FSSB is set to the automatic setting mode (when the bit 0 (FMD) of parameter No. 1902 is set to 0), parameter Nos. 24000 to 24031 are automatically set as data is input on the FSSB setting screen. When the manual setting 2 mode is set (when the bit 0 (FMD) of parameter No. 1902 is set to 1), be sure to directly set values in parameter Nos. 24000 to 24031.

Example of axis configuration and parameter settings

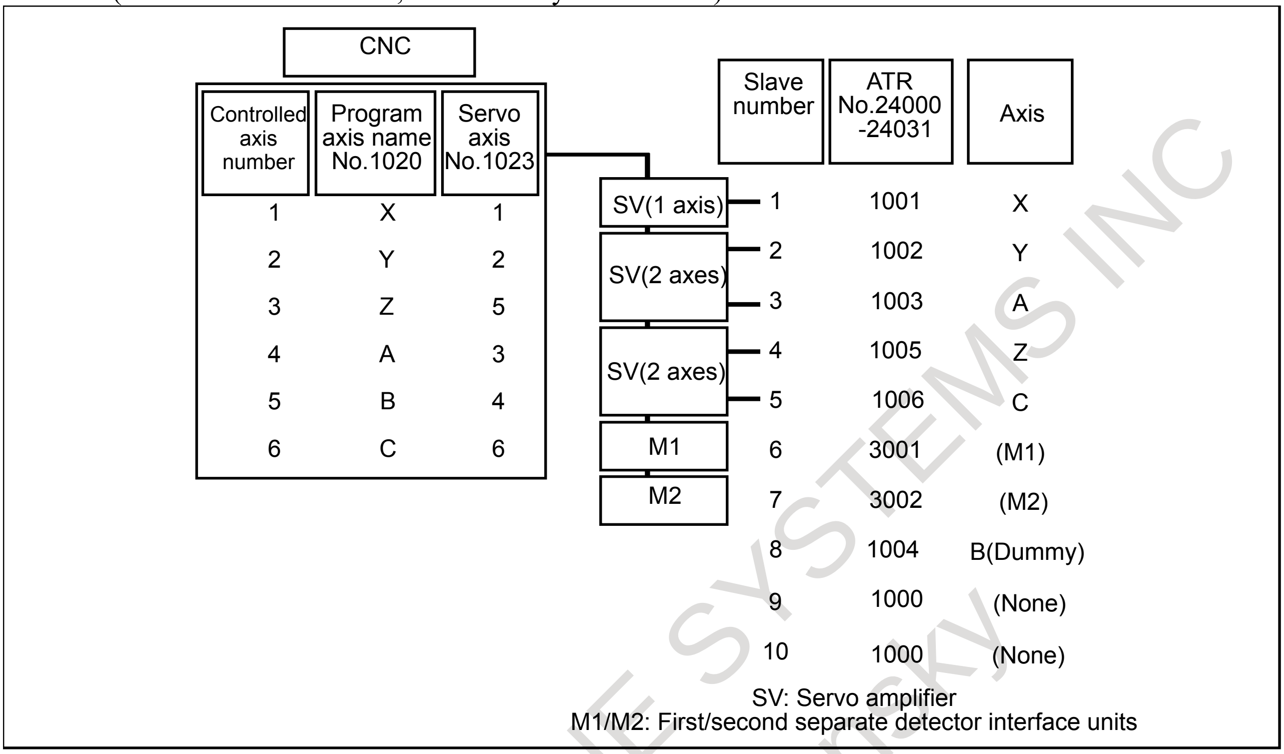
- Example 2 Setting with a dummy axis in use

Example of axis configuration and parameter settings when the electronic gear box (EGB) function is used
(EGB slave axis: A-axis, EGB dummy axis: B-axis)



24032	ATR value corresponding to slave 01 on second FSSB line
24033	ATR value corresponding to slave 02 on second FSSB line
to	to
24063	ATR value corresponding to slave 32 on second FSSB line

> **NOTE**
> When these parameters are set, the power must be turned off before operation is continued.

[Input type] Parameter input
[Data type] Word
[Valid data range] 1001 to 1046, 2001 to 2016, 3005 to 3008, 1000

Each of these parameters sets the value (ATR value) of the address translation table corresponding to each of slave 1 to slave 32 on second FSSB line (second optical connector). Set these parameters only when a servo axis control card with two optical connectors (FSSB lines) is used.

To specify these parameters, follow the same procedure as for the first FSSB line (parameters Nos. 24000 to 24031). Note, however, that the valid data range varies depending on the separate detector interface unit used.

- When the slave is a separate detector interface unit:
  Set 3005, 3006, 3007, and 3008, respectively, for the first (one connected nearest to the CNC), second, third, and fourth separate detector interface units.

24096	Connector number for the first separate detector interface unit

to	to
24159	ATR value corresponding to connector 8 on the seventh separate detector interface unit

24160	ATR value corresponding to connector 1 on the eighth separate detector interface unit
to	to
24167	ATR value corresponding to connector 8 on the eighth separate detector interface unit

NOTE

When these parameters are set, the power must be turned off before operation is continued.

[Input type] Parameter input
[Data type] Word
[Valid data range] 1000 to 1046

Each of these parameters sets the value (ATR value) of the address translation table corresponding to each connector on a separate detector interface unit.
The first to fourth separate detector interface units are connected to first FSSB line, and the fifth and eighth separate detector interface units are connected to second FSSB line.
Specify each parameter with a value set in parameter No. 1023 (axis connected to a separate detector interface unit connector) plus 1000.

If a connector attached to a separate detector interface unit is not in use, set 1000 for the connector.

> **NOTE**
> 1 Specify these parameters if one separate detector interface unit connector is shared among two or more axes. They need not be specified if one connector is used by one axis.
> 2 Using these parameters requires setting bit 5 (SSC) of parameter No. 14476 to 1.

Special setting for a separate detector 1

If you want to use one connector of a separate detector for multiple axes, set bit 5 (SSC) of parameter No. 14476 to 1 and parameter Nos. 24104 to 24199.

- Example of special setting for a separate detector 1

For two EGB pairs and common master axis
(EGB slave axis 1 : A axis, EGB dummy axis 1 : C1 axis)
(EGB slave axis 2 : B axis, EGB dummy axis 2 : C2 axis)

No.	14476#5 SSC

Alarm and message

Number	Message	Description
SV0456	ILLEGAL CURRENT LOOP	An attempt was made to set the current loop that could not be set. The amplifier pulse module in use does not comply with HIGH SPEED HRV. Or, requirements to control are not satisfied in the system.
SV0458	CURRENT LOOP ERROR	The specified current loop differs from the actual current loop.
SV0459	HI HRV SETTING ERROR	For two axes whose servo axis numbers (parameter No. 1023) are consecutively even and odd numbers, HIGH SPEED HRV control is possible for one axis and impossible for the other.
SV0462	SEND CNC DATA FAILED	The correct data could not be received on a slave side because of the FSSB communication error.
SV0463	SEND SLAVE DATA FAILED	The correct data could not be received in the servo software because of the FSSB communication error.
SV0465	READ ID DATA FAILED	A read of the ID information for the amplifier has failed at power-on.
SV0466	MOTOR/AMP. COMBINATION	The maximum current of an amplifier is different to that of a motor. Or, the connection command for an amplifier is incorrect. The parameter setting is incorrect
SV0468	HI HRV SETTING ERROR(AMP)	An attempt was made to set up HIGH SPEED HRV control for use when the controlled axis of an amplifier for which HIGH SPEED HRV control could not be used.
SV1067	FSSB:CONFIGURATION ERROR(SOFT)	An FSSB configuration error occurred (detected by software). The connected amplifier type is incompatible with the FSSB setting value.
SV5134	FSSB:OPEN READY TIME OUT	In the initialization, the FSSB could not be in an open ready sate. The axis card is thought to be defective.
SV5136	FSSB:NUMBER OF AMP. IS INSUFFICIENT	The number of amplifier identified by the FSSB is insufficient than the number of control axes. Or, the setting of the number of axes or the amplifier connection is in error.
SV5137	FSSB:CONFIGURATION ERROR	An FSSB configuration error occurred. The connecting amplifier type is incompatible with the FSSB setting value.
SV5139	FSSB:ERROR	Servo initialization has not completed successfully. It is probable that an optical cable failed or a connection between the amplifier and another module failed.
SV5197	FSSB:OPEN TIME OUT	The initialization of the FSSB was completed, but it could not be opened. Or, the connection between the CNC and the amplifier is inccorrect.
SV5311	FSSB:ILLEGAL CONNECTION	Different current loops (HRV) are set for FSSB lines. Specify the same current loop for the FSSB lines.
SP1220	NO SPINDLE AMP.	Either the cable connected to a serial spindle amplifier is broken, or the serial spindle amplifier is not connected.
SP1996	ILLEGAL SPINDLE PARAMETER SETTING	The spindle was assigned incorrectly. Check to see the following parameter. (No.3716 or 3717)

Reference item

Manual name	Item name
CONNECTION MANUAL (HARDWARE) (B-64693EN)	Connection to the amplifiers
CONNECTION MANUAL (FUNCTION) (this manual)	Spindle serial output

Diagnosis data

3510	FSSB alarm number

[Data type] Word

Information is output for identifying the location (parameter) and cause of an FSSB-related alarm which has been issued. For the displayed detail numbers and corresponding causes and actions, see the table below.

Detail alarm No.	Parameter number	Cause	Action
120 451 452	-	The FSSB internal status did not change to open.	Check the connection between the CNC and each amplifier. Alternatively, the servo card may be faulty.
140 450	24000 to 24095	The ATR value is inconsistent with the connected slave (servo, spindle, or separate detector).	Set the ATR value corresponding to the connected slave.
271	3717 24000 to 24095	The spindle amplifier number corresponding to the ATR value setting is not set.	Make the spindle amplifier number consistent with the ATR value setting.
272	24000 to 24031 24064 to 24095	The fifth to eighth separate detector is set for the first FSSB line (third FSSB line).	Do not set the fifth to eighth separate detectors for the first FSSB line (third FSSB line).
273	24032 to 24063	The first to fourth (ninth to twelfth) separate detector is set for the second FSSB line.	Do not set the first to fourth (ninth to twelfth) separate detectors for the second FSSB line.
276	24000 to 24095	The setting for a separate detector is made more than once.	Make the setting for each separate detector only once in the servo card.
290	24000 to 24095	The maximum number of slaves per FSSB line is exceeded for an FSSB line of servo HRV2 control.	Reduce the number of slaves to 32 (maximum number of slaves per FSSB line of servo HRV2 control) or less.
291	24000 to 24095	The maximum number of slaves per FSSB line is exceeded for an FSSB line of servo HRV3 control.	Reduce the number of slaves to 15 (maximum number of slaves per FSSB line of servo HRV3 control) or less.
310	1023 24104 to 24199	The servo axis number corresponding to the ATR value setting of a separate detector is not set for parameter No. 1023.	Set the value corresponding to the ATR value setting for parameter No. 1023.
313	1023 14476#5 24104 to 24199	The servo axis number corresponding to the ATR value setting of a separate detector is not set for parameter No. 1023.	Set the value corresponding to the ATR value setting for parameter No. 1023.
314	1023 14476#5 24104 to 24199	The ATR value setting of a separate detector is invalid.	Correct the settings of parameters Nos. 24104 to 24199.
383	-	Manual setting 1 cannot be performed when a separate detector is used.	Disconnect the separate detector. Alternatively, perform manual setting or automatic setting.

Detail alarm No.	Parameter number	Cause	Action
453	-	Servo initialization has not completed successfully.	An optical cable may be faulty or the connection between the amplifier and another module may be incorrect.
454	-	Alarm No. 550 to 556 of diagnosis data No. 3511 occurred.	Check diagnosis data No. 3511.
460	24000 to 24095	The ATR value of a spindle or separate detector is set for a slave which is not connected.	Set the ATR value corresponding to the connected slave.
471	24000 to 24095	Although a separate detector is connected, the separate detector setting is not made.	Set the value for the separate detector in the corresponding parameter.
480	24000 to 24095	In ATR value setting, a servo axis number exceeds 80.	Make settings so that any servo axis number does not exceed 80.

3511	FSSB alarm number

[Data type] Word axis

Information is output for identifying the location (parameter) and cause of an FSSB-related alarm which has been issued. For the displayed detail numbers and corresponding causes and actions, see the table below.

Detail alarm No.	Parameter number	Cause	Action
210	24096 to 24103	Although a separate detector is not set, a value is set in parameter No. 24096 to 24103.	Set parameter Nos. 24096 to 24103 to all 0.
220	1023	An unavailable servo axis number is set.	Change the servo axis number.
221	1023	A servo axis number is set more than once.	Change the servo axis number.
250	24096 to 24103	For a specific servo axis, two or more separate detectors are used and the paired separate detectors are two of the first, third, fifth, and seventh units or the second, fourth, sixth, and eighth units.	To use two separate detectors for a specific servo axis, one separate detector must have an odd number and the other must have an even number. Three or more separate detectors cannot be used.
270	1023 24000 to 24095	・ The servo axis number corresponding to the ATR value setting is not set for parameter No. 1023. ・ An unavailable servo axis number is set. ・ A servo axis number is set more than once.	Check the conditions on the left.
292	1023 2013#0	For an FSSB line of servo HRV3 control, only the following servo axis numbers can be used: (1 + 8n, 2 + 8n, 3 + 8n, 4 + 8n (n = 0, 1, ···, 9))	For the FSSB line of servo HRV3 control, set the servo axis numbers on the left.
311	24096 to 24103	A connector number is invalid.	Specify a value between 0 and 8.
314	24096 to 24103	A connector number is set more than once.	Make setting so that each connector number is used only once for one separate detector.
350	2013#0 2014#0	Different current loops (HRV) are used for FSSB lines.	Set the same current loop (HRV) for the FSSB lines.

Detail alarm No.	Parameter number	Cause	Action
360	1023 2013#0 2014#0	Different current loops (HRV) are set for the first and second FSSB lines and parameter No. 1023 setting is invalid.	Set servo axis numbers so that each set of (1 to 6), (9 to 14), (17 to 22), (25 to 30), (33 to 38), and (41 to 46) is set for the same FSSB line.
370	1902#0 1902#1 2013#0 2014#0	When servo HRV3 control is set, manual setting 1 cannot be performed.	To set servo HRV3 control, perform manual setting or automatic setting.
380	1023	When a servo axis number is skipped, manual setting 1 cannot be performed.	Set servo axis numbers without skipping any number.
382	1023	An attempt was made to perform manual setting 1 though the maximum number of controlled axes per FSSB line is exceeded.	Reduce the number of connected servo axes to the maximum number of controlled axes or less.
470	24000 to 24095	An ATR value is set more than once.	Set each ATR value only once.
481	1023 24000 to 24095	A servo axis number is inconsistent with the ATR value setting or the servo motor having a servo axis number is not connected.	Check whether the value set in parameter No. 1023 is consistent with ATR value setting and whether the servo motor corresponding to each servo axis number is connected.
520	2165	At power-on, amplifier ID information could not be read.	Check the connection between the CNC and each amplifier. Alternatively, an amplifier may be faulty.
550	1023 24000 to 24095	The ATR value setting is inconsistent with the servo axis number setting.	Make the value set in parameter No. 1023 consistent with the ATR value setting.
551	24000 to 24095	The number of ATR value settings exceeds the number of slaves connected to the CNC.	Make as many settings as the number of slaves connected to the CNC.
552	1023	An unavailable servo axis number is set.	Change the servo axis number.
553	1023	A servo axis number is set more than once.	Change the servo axis number.
554	24096 to 24103	A value is set in parameters Nos. 24096 to 24103 though no separate detector is connected.	Set parameters Nos. 24096 to 24103 to all 0.
555 557 558	2165	The maximum current of an amplifier (parameter No. 2165) differs from that of a motor.	Set the maximum current of the amplifier (parameter No. 2165) to that of the motor.
1023	1023	An invalid servo axis number is set.	Set a correct servo axis number.

3513	FSSB alarm number (spindle axis)

[Data type] Word spindle

Information is output for identifying the location (parameter) and cause of an FSSB-related alarm which has been issued.

For the displayed detail numbers and corresponding causes and actions, see the table below.

Detail alarm No.	Parameter number	Cause	Action
271	3717 24000 to 24095	An ATR value is set more than once.	Make each spindle amplifier consistent with the ATR value setting.

Detail alarm No.	Parameter number	Cause	Action
381	3717	When a spindle amplifier number is skipped, manual setting 1 cannot be performed.	Set spindle amplifier numbers without skipping any number.

1.4.4 Temporary Absolute Coordinate Setting

Overview

In the full closed system with an inner absolute position Pulsecoder (serial Pulsecoder) and an incremental scale, the position is set by using absolute position data from the inner absolute position Pulsecoder at the power on sequence. After that, the position is controlled with incremental data from the incremental scale. The position just after power on sequence is rough, and the manual reference position return is required to get the accurate position.
With this function, the position at the power on is rough, but the following functions are available before the reference position return.
- Stroke limit check
- Position switch

Please be careful this function does not make an incremental scale work as an absolute position detector.

Also in using the linear-scale with distance-coded reference marks (serial), these function are not available.

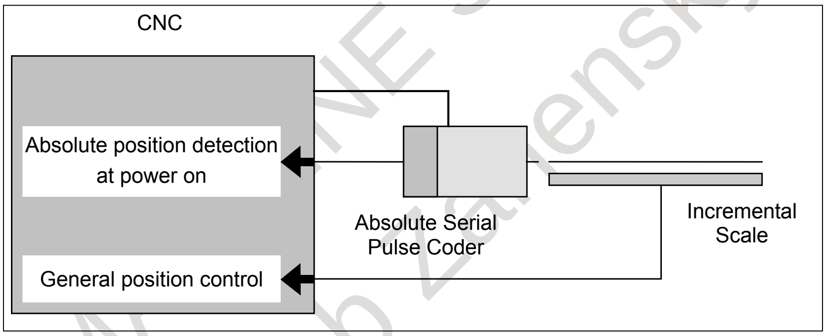

Fig. 1.4.4 (a) The system with the Temporary Absolute Coordinate Setting

In using the temporary absolute coordinate, the coordinate is same as the reference position return has not been performed.
The reference position return is required to get the accurate position after the power on sequence.

The reference position establishment signals ZRF1 to ZRF8<Fn120> are not set to 1 until the manual reference point return is performed.
The diagnosis data No.304 (reference counter value) are also not displayed until the manual reference point return is performed.

- Parameter setting

1 Please set the following parameters to the axis that uses this function.
  - The bit 1 (OPTx) of parameter No. 1815 = 1.
  - The bit 5 (APCx) of parameter No. 1815 = 1.
  - The bit 7 (XIAx) of parameter No. 2011 = 1.

2 Please set the flexible feed gear for the built-in position detector (parameters Nos. 1874 and 1875).

- Setting of the temporary absolute coordinate

Please set the temporary absolute coordinate according to the following procedures.

1 Perform the reference position return and move the reference position.

2 Turn off the power then turn on the power.
3 In MDI mode, bit 4 (APZx) of parameter No. 1815 is set to 1.

> **NOTE**
> In the above operations from 1 to 3, please do not move the axis from the reference position. If the axis is moved from the reference position, the temporary absolute coordinate is not correctly set.

- On the Difference of specifications with FS16*i*/FS18*i*/FS21*i*

With the FS16*i*/FS18*i*/FS21*i*, when bit 1 (XZF) of parameter No. 1807 is set to 0, the coordinate system is established.
At this time, the reference position establishment signals <Fn120> are set to 1, which indicates that the reference position has been established.
Diagnosis data No. 304 (reference counter value) is also displayed.

With the FS0*i*, the built-in absolute Pulsecoder is used to roughly determine the coordinate position without establishing the coordinate system.
At this time, the reference position establishment signals <Fn120> are set to 0, which indicates that the reference position has not been established.
Diagnosis data No. 304 (reference counter value) is not also displayed.

When manual reference position return by the scale of the full closed system is completed, the accurate coordinate system is established.
At this time, the reference position establishment signals <Fn120> are set to 1, which indicates that the reference position has been established.
Diagnosis data No. 304 (reference counter value) is also displayed.

With the FS0*i*, bit 1 (XZF) of parameter No. 1807 is not provided.

- Axis synchronous control

In case of the synchronization establishment of the axis synchronous control, when the position is set by this function, the synchronization establishment is executed.

Signal

Reference position establishment signal ZRF1 to ZRF8<Fn120>

[Classification] Output signal

[Function] Notify the system that the reference position has been established.
A reference position establishment signal is provided for each axis. The number appended to each signal indicates the number of the controlled axis.
ZRFx
x : 1 : 1st-axis reference position establishment signal
2 : 2nd-axis reference position establishment signal
3 : 3rd-axis reference position establishment signal
:
:

[Output cond.] The signals are set to 1 in the following case:
- When the reference position is established after manual reference position return
- When the reference position is established using the absolute-position detector at initial power-on

When the reference position is lost, the signals are set to “0”.

Signal address

	#7	#6	#5	#4	#3	#2	#1	#0
Fn120	ZRF8	ZRF7	ZRF6	ZRF5	ZRF4	ZRF3	ZRF2	ZRF1

Parameters

	#7	#6	#5	#4	#3	#2	#1	#0
1815			APCx	APZx			OPTx	

[Input type] Parameter input
[Data type] Bit axis

> **NOTE**
> When at least one of these parameters is set, the power must be turned off before operation is continued.

#1 OPTx The separate position detector is:
0: Not to be used (semi-closed system)
1: To be used (full-closed system)

> **NOTE**
> 1 In case of using the absolute position detector (bit 5 (APCx) of parameter No.1815 is set to 1), please set the following parameters that correspond to the absolute position detector which is actually used.
> - parameter No.1815#6, No.1815#0, No.1817#3, No.1868, No.2275#1, No.2394
>
> If these parameters are not set correctly, the machine coordinates are not correctly established at power-on.
> 2 In case of using this function, this parameter is set to 1.

#4 APZx Machine position and position on absolute position detector when the absolute position detector is used
0 : Not corresponding
1 : Corresponding

> **NOTE**
> 1 If the following parameters are modified, the bit 4 (APZ) of parameter No. 1815 will be changed to 0.
> No. 1803#7, No. 1815#1, No. 1820, No. 1821, No. 1822, No. 1823, No. 1874, No. 1875, No. 2022, No. 2084, No. 2085
> 2 The bit 4 (APZ) of parameter No. 1815 is kept value 1 even if the grid shift value is modified.

#5 APCx Position detector is
0 : Other than an absolute position detector.
1 : An absolute position detector (absolute Pulsecoder).

NOTE
1 In case of using this function, this parameter is set to 1.
2 When the servo axis is disabled (bit 4 (KSVx) of parameter No. 11802 is set to 1), an absolute position detector cannot be used (bit 5 (APCx) of parameter No. 1815 cannot be set to 1). If an absolute position detector is used, alarm SV0301, "APC ALARM; COMMUNICATION ERROR" is issued.

1874	Numerator of the flexible feed gear for the built-in position detector
1875	Denominator of the flexible feed gear for the built-in position detector

NOTE
When these parameters are set, the power must be turned off before operation is continued.

[Input type] Parameter input
[Data type] Word axis
[Valid data range] 1 to 32767

When using temporary absolute coordinate setting, set the flexible feed gear for the built-in position detector on each axis. The settings are as follows:

$$\frac{\text{No.1874}}{\text{No.1875}} = \frac{\text{Number of position feedback pulses per motor revolution}}{1{,}000{,}000}$$

NOTE
When parameter No. 1874 or 1875 is set to 0, both parameters are assumed to be 1.

	#7	#6	#5	#4	#3	#2	#1	#0
2011	XIAx							

[Input type] Parameter input
[Data type] Bit axis

#7 **XIAx** Temporary absolute coordinate setting is:
0: Not used.
1: Used.

NOTE
1 When temporary absolute coordinate setting is used, bit 1 (OPTx) of parameter No. 1815, bit 5 (APCx) of parameter No. 1815, parameter No. 1874, and parameter No. 1875 must be set.
2 The setting of this parameter becomes effective after the power is turned off then back on.

1.4.5 Diagnosis data display of detection unit

Explanation

Diagnosis data No.3740 displays detection unit of each axis. Diagnosis data No.3741 displays machine unit of each axis.

(Example 1)
If detection unit of X axis which is linear axis (metric system machine) is 0.0001[mm], diagnosis data No.3740 displays 0.0001.
Bit 0 (MM) of diagnosis data No.3741 is set to 1 because machine unit of X axis is [mm] (Fig. 1.4.5 (a)).
(Example 2)
If detection unit of C axis which is rotary axis is 0.001[degree], diagnosis data No.3740 displays 0.001.
Bit 2 (DEG) of diagnosis data No.3741 is set to 1 because machine unit of C axis is [degree] (Fig. 1.4.5 (a)).

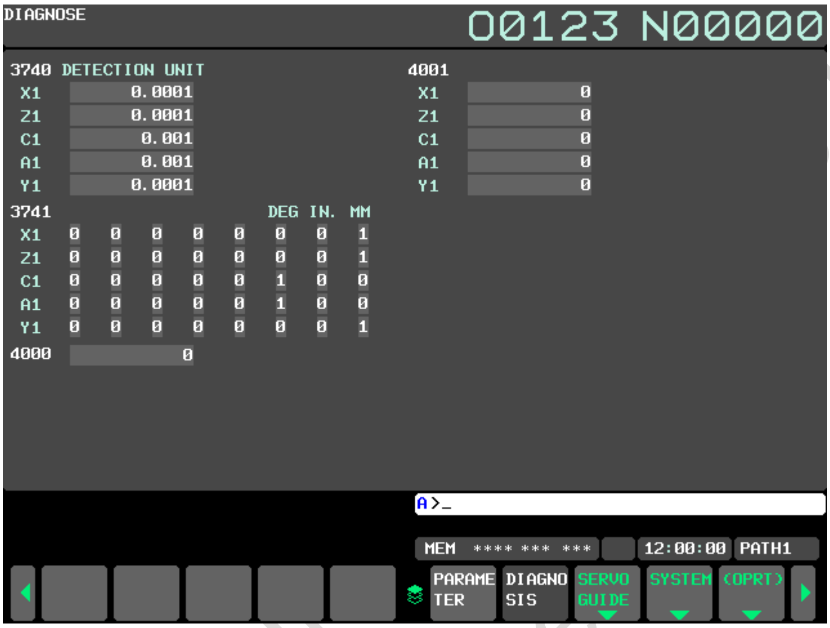

Fig. 1.4.5 (a) Diagnosis screen (metric system machine) (10.4” display unit)

(Example 3)
If detection unit of X axis which is linear axis (inch system machine) is 0.00001[inch], diagnosis data No.3740 displays 0.00001.
Bit 1 (IN.) of diagnosis data No.3741 is set to 1 because machine unit of X axis is [inch] (Fig. 1.4.5 (b)).

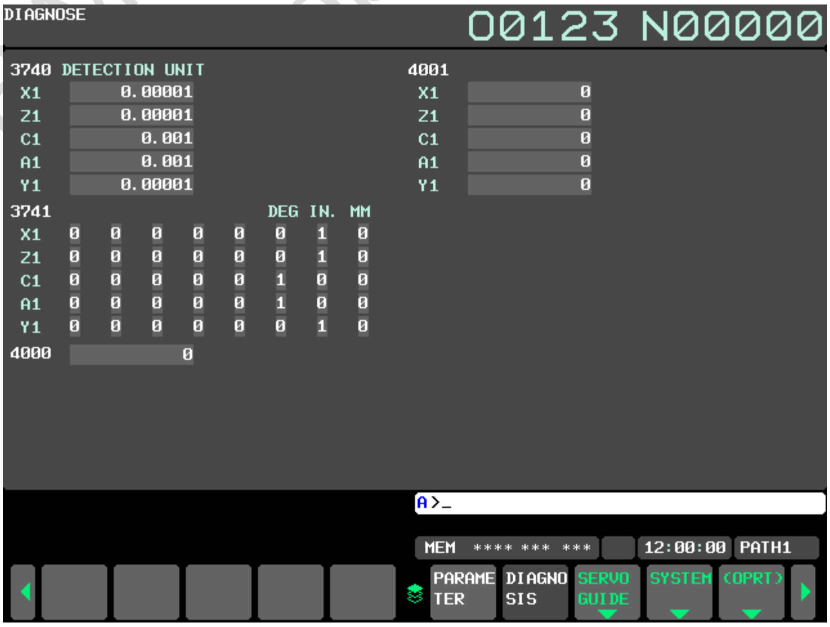

Fig. 1.4.5 (b) Diagnosis screen (inch system machine) (10.4” display unit)

- Servo axis

Diagnosis data No.3740 displays detection unit which is calculated by the following equation.

Detection unit = Least command increment / CMR

- Cs contour control axis

Detection unit of Cs contour control axis is set by bit 0 (CS360M) of parameter No.4005. Diagnosis data No.3740 displays the following value. Diagnosis data No.3740 is displayed 0.0 by the hypothetical Cs axis (bit 7 (CDMx) of parameter No.3740 = 1).

Table 1.4.5 (a) Detection unit of Cs contour control axis

Bit 0 (CS360M) of parameter No.4005	Diagnosis data No.3740
0	0.001
1	0.0001

- Spindle positioning axis

Detection unit of spindle positioning axis is set by gear ratio between spindle and position coder (parameter Nos.3721, 3722). Diagnosis data No.3740 displays the following value.

Table 1.4.5 (b) Detection unit of spindle positioning axis

Gear ratio of spindle to position coder	Diagnosis data No.3740
1:1	0.088 (1x360/4096)
1:2	0.176 (2x360/4096)
1:4	0.352 (4x360/4096)
1:8	0.703 (8x360/4096)
…	…
1:N	(Nx360/4096)

Diagnosis data

3740	Detection unit

[Data type] Real axis

1: degree.

1.5 SETTINGS RELATED WITH COORDINATE SYSTEMS

1.5.1 Machine Coordinate System

Overview

The point that is specific to a machine and serves as the reference of the machine is referred to as the machine zero point. A machine tool builder sets a machine zero point for each machine.
A coordinate system with a machine zero point set as its origin is referred to as a machine coordinate system.
A machine coordinate system is set by performing manual reference position return after power-on. A machine coordinate system, once set, remains unchanged until the power is turned off.

Format

M

(G90)G53 IP _ P1;
IP_ : Absolute command dimension word
P1 : Enables the high-speed G53 function.

(G90)G53.2 G01 IP__F__;
IP_ : Absolute command dimension word
F_ : Feedrate

T

G53 IP _ P1;
IP_ : Absolute command dimension word
P1 : Enables the high-speed G53 function.

G53.2 G01 IP__F__;
IP_ : Absolute command dimension word
F_ : Feedrate

Explanation

- Selecting a machine coordinate system (G53)

When a command is specified the position on a machine coordinate system, the tool moves to the position by rapid traverse. G53, which is used to select a machine coordinate system, is a one-shot G code; that is, it is valid only in the block in which it is specified on a machine coordinate system. Specify an absolute command for G53. When an incremental command is specified, the G53 command is ignored. When the tool is to be moved to a machine-specific position such as a tool change position, program the movement in a machine coordinate system based on G53.

- High-speed G53 function

The high-speed G53 function enables the rapid traverse block overlap function between the machine coordinate system selection command (G53) block and positioning (rapid traverse) command (G00) block, which allows the next rapid traverse command (G00) to be executed without decelerating and stopping the tool at the end of the machine coordinate system selection command (G53). This function enables high-speed positioning even when the machine coordinate system selection command (G53) is used.
The high-speed G53 function is enabled by specifying P1 in the G53 block.

- Selecting a machine coordinate system with feedrate (G53.2)

Positioning of machine coordinate system at a feed rate is available with the command of G53.2. The feed rate can be used in the modal of G01.

> **NOTE**
> The selecting a machine coordinate system with feedrate (G53.2) is an option. To use this function, an option of the selecting a machine coordinate system with feedrate is required.

G53.2 is one shot G code. Moreover, the tool offset value is temporarily canceled by G53.2 command like G53.
As for the time constant, a usual feed rate are used. At the point of G53.2 command, the axis decelerates to a stop once like G53 command.
Feed per minute, feed per revolution, and inverse time feed of G codes of 05 group are available.
When group 01 G-code except G00/G01 is commanded with G53.2, the alarm PS5372, "IMPROPER MODAL G-CODE" is generated. And, when G53.2 is commanded while group 01 Modal G-code is the one except G00/G01, the alarm PS5372 is generated.

Limitation

- Cancel of the compensation function

When the G53 command is specified, cancel the compensation functions such as the cutter compensation, tool length offset, tool-nose radius compensation, and tool offset.

- G53 specification immediately after power-on

Since the machine coordinate system must be set before the G53 command is specified, at least one manual reference position return or automatic reference position return by the G28 command must be performed after the power is turned on. This is not necessary when an absolute-position detector is attached.

Specification in the same block

M

Commands G50/G51, G50.1/G51.1, and G68/G69 cannot be specified in the same block where the G53 command is specified.

T

Commands G50/G51 (except for G code system A), G50.1/G51.1, and G68.1/G69.1 cannot be specified in the same block where the G53 command is specified.

Reference

- Setting a machine coordinate system

When manual reference position return is performed after power-on, a machine coordinate system is set so that the reference position is at the coordinate values of (α, β) set using parameter No.1240.

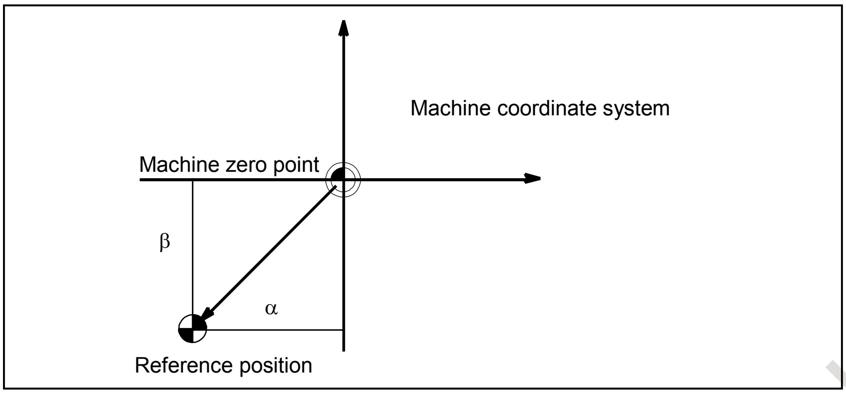

Fig. 1.5.1 (a)

Example (selecting a machine coordinate system with feedrate)

N1 G90 G01 ;
N2 G53.2 X50.0 Y100.0 F1000 ; Absolute command with feedrate F1000
N3 G53.2 X150.0 F500 ; Absolute command with feedrate F500

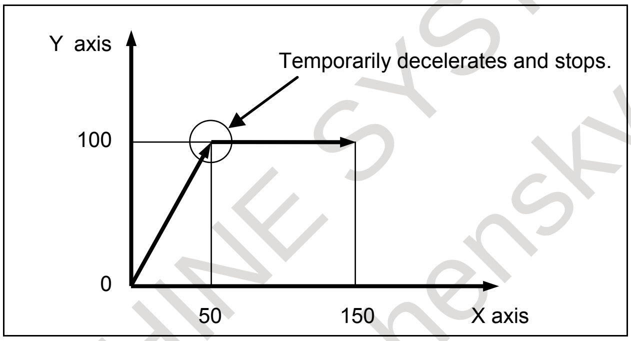

Fig. 1.5.1 (b)

Parameter

1240	Coordinate value of the reference position in the machine coordinate system

NOTE
When this parameter is set, the power must be turned off before operation is continued.

[Input type] Parameter input
[Data type] Real axis
[Unit of data] mm, inch, deg (machine unit)
[Min. unit of data] Depend on the increment system of the applied axis
[Valid data range] 9 digit of minimum unit of data (refer to standard parameter setting table (A))
(When the increment system is IS-B, -999999.999 to +999999.999)
Set the coordinate values of the reference position in the machine coordinate system.

Alarm and message

Number	Message	Description
PS5372	IMPROPER MODAL G-CODE (G53.2)	In the G53.2 block, a G code in group 01 other than G00 or G01 is specified. Alternatively, G53.2 is specified when the modal G code in group 01 is other than G00 or G01.

Manual name	Item name
OPERATOR'S MANUAL (B-64694EN)	Machine coordinate system

1.5.2 Workpiece Coordinate System/Addition of Workpiece Coordinate System Pair

Overview

A coordinate system used for machining a workpiece is referred to as a workpiece coordinate system. A workpiece coordinate system is to be set with the CNC beforehand (setting a workpiece coordinate system).
A machining program sets a workpiece coordinate system (selecting a workpiece coordinate system).
A set workpiece coordinate system can be changed by shifting its origin (changing a workpiece coordinate system).

1.5.2.1 Workpiece coordinate system

> **NOTE**
> To use the workpiece coordinate system, set 0 in bit 0 (NWZ) of parameter No.8136.

- Setting a workpiece coordinate system

A workpiece coordinate system can be set using one of three methods:

(1) Method using a workpiece coordinate system setting G code
A workpiece coordinate system is set by specifying a value in the program after a workpiece coordinate system setting G code.

(2) Automatic setting
If bit 0 (ZPR) of parameter No. 1201 is set to 1, a workpiece coordinate system is automatically set when manual reference position return is performed.
This function is, however, disabled when the workpiece coordinate system is being used.

(3) Method using a workpiece coordinate system selection G code
Six workpiece coordinate systems can be set beforehand using the MDI unit. Program commands G54 to G59 can be used to select the work axis to be used.

When using an absolute command, establish the workpiece coordinate system in any of the above ways.

> ⚠ **CAUTION**
> The established workpiece coordinate system depends on diameter programming or radius programming.

- Selecting a workpiece coordinate system

The user can choose from set workpiece coordinate systems as described below.

(1) Selecting a workpiece coordinate system set by workpiece coordinate system setting G code (G92, G50) or automatic workpiece coordinate system setting
Once a workpiece coordinate system is selected, absolute commands work with the workpiece coordinate system.

(2) Choosing from six workpiece coordinate systems set using the MDI unit
By specifying a G code from G54 to G59, one of the workpiece coordinate systems 1 to 6 can be selected.

G54.....Workpiece coordinate system 1   G55..... Workpiece coordinate system 2
G56.....Workpiece coordinate system 3   G57..... Workpiece coordinate system 4
G58.....Workpiece coordinate system 5   G59..... Workpiece coordinate system 6

Workpiece coordinate systems 1 to 6 are established after reference position return after the power is turned on. When the power is turned on, G54 coordinate system is selected as default.

When bit 2 (G92) of parameter No. 1202 is set to 1, executing the G code command for coordinate system setting (G92 <M series>, G50 <Tseries> (G92 with G code system B/C for T series)) results in the issue of alarm PS0010, “IMPROPER G-CODE”. This is designed to prevent the user from confusing coordinate systems.

> ⚠ **CAUTION**
> The set workpiece zero point offset value depends on diameter programming or radius programming.

- Changing workpiece coordinate system

The six workpiece coordinate systems specified with G54 to G59 can be changed by changing an external workpiece zero point offset value or workpiece zero point offset value.
Three methods are available to change an external workpiece zero point offset value or workpiece zero point offset value.

(1) Inputting from the MDI unit
(2) Programming (using a programmable data input G code or a workpiece coordinate system setting G code)
(3) Using the external data input function
An external workpiece zero point offset value can be changed by input signal to CNC. Refer to machine tool builder's manual for details.

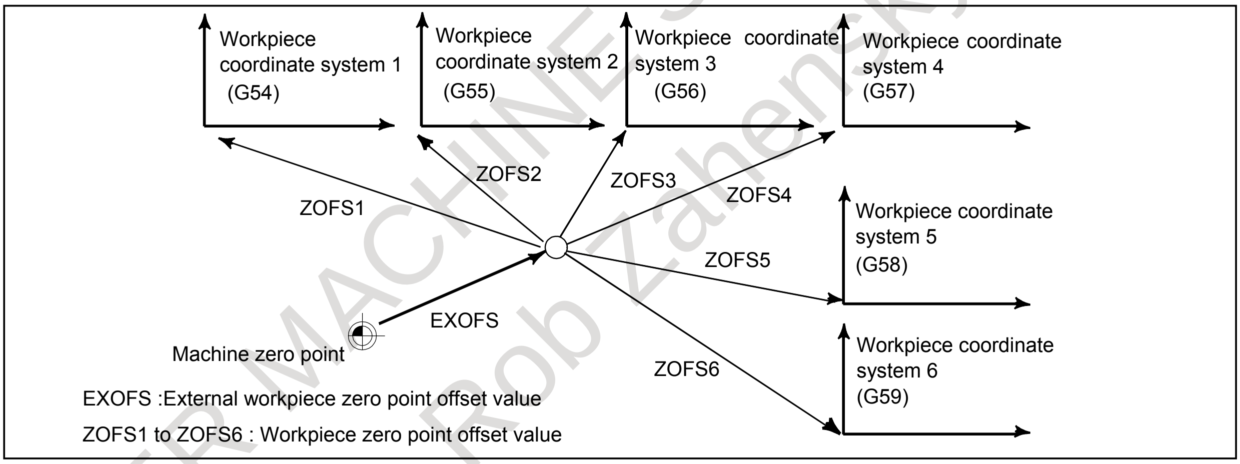

Fig. 1.5.2.1 (a) Changing an external workpiece zero point offset value or workpiece zero point offset value

Format

- Changing by inputting programmable data

G10 L2 Pp IP_;
p=0 : External workpiece zero point offset value
p=1 to 6: Workpiece zero point offset value correspond to workpiece coordinate system 1 to 6
IP_: For an absolute command, workpiece zero point offset for each axis.
For an incremental command, value to be added to the set workpiece zero point offset for each axis (the result of addition becomes the new workpiece zero point offset).

- Changing by setting a workpiece coordinate system

M

G92 IP_;

T

G50 IP_;

Explanation

- Changing by inputting programmable data

By specifying a programmable data input G code, the workpiece zero point offset value can be changed for each workpiece coordinate system.

- Changing by setting a workpiece coordinate system

By specifying a workpiece coordinate system setting G code, the workpiece coordinate system (selected with a code from G54 to G59) is shifted to set a new workpiece coordinate system so that the current tool position matches the specified coordinates (IP_).
Then, the amount of coordinate system shift is added to all the workpiece zero point offset values. This means that all the workpiece coordinate systems are shifted by the same amount.

> ⚠ **CAUTION**
> When a coordinate system is set with G code command for workpiece coordinate system setting after an external workpiece zero point offset value is set, the coordinate system is not affected by the external workpiece zero point offset value. When G92X100.0Z80.0; is specified, for example, the coordinate system having its current tool reference position at X = 100.0 and Z = 80.0 is set.

T

If IP is an incremental command value, the work coordinate system is defined so that the current tool position coincides with the result of adding the specified incremental value to the coordinates of the previous tool position. (Coordinate system shift)
When bit 0 (WAB) of parameter No. 11279 is set to 1, the setting of the workpiece coordinate system is executed with absolute value even if the work coordinate system setting (G92) is commanded during the incremental mode (G91) in the G-code system B/C of the lathe system.

Notes

- Manual reference position return

When the manual reference position return is performed, the value of the workpiece coordinate system set by G code (G92, or G50 for the lathe system G-code system A) is cleared to 0. And when the automatic reference position return (G28) is performed, this workpiece coordinate system is not cleared to 0 but stored.

Parameter

	#7	#6	#5	#4	#3	#2	#1	#0
11279								WAB

[Input type] Parameter input
[Data type] Bit

#0 WAB When the incremental mode (G91) is selected in the G-code system B/C of the lathe system, if the setting of the workpiece coordinate system (G92) is commanded, the setting of the workpiece coordinate system is executed with:

0: Incremental value.
1: Absolute value.

1.5.2.2 Workpiece coordinate system preset

NOTE

To use the workpiece coordinate system preset function, set 0 in bit 1 (NWC) of parameter No. 8136.

Explanation

In reset state, execute Manual reference position return, a workpiece coordinate system is shifted by the workpiece zero point offset value from the machine coordinate system zero point. Suppose that the manual reference position return operation is performed when a workpiece coordinate system is selected with G54. In this case, a workpiece coordinate system is automatically set which has its zero point displaced from the machine zero point by the G54 workpiece zero point offset value; the distance from the zero point of the workpiece coordinate system to the reference position represents the current position in the workpiece coordinate system.

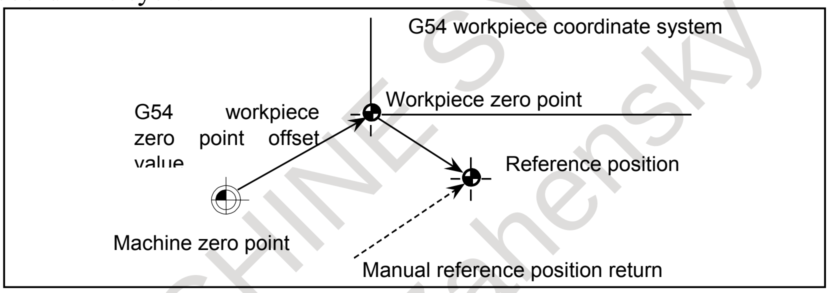

Fig. 1.5.2.2 (a)

If an absolute position detector is provided, the workpiece coordinate system automatically set at power-up has its zero point displaced from the machine zero point by the G54 workpiece zero point offset value. The machine position at the time of power-up is read from the absolute position detector and the current position in the workpiece coordinate system is set by subtracting the G54 workpiece zero point offset value from this machine position. The workpiece coordinate system set by these operations is shifted from the machine coordinate system using the commands and operations listed below.

(a) Manual intervention performed when the manual absolute signal is off
(b) Move command executed in the machine lock state
(c) Movement by handle interrupt
(d) Operation using the mirror image function
(e) Shifting the workpiece coordinate system by setting the local coordinate system or workpiece coordinate system

In the case of (a) above, the workpiece coordinate system is shifted by the amount of movement during manual intervention.

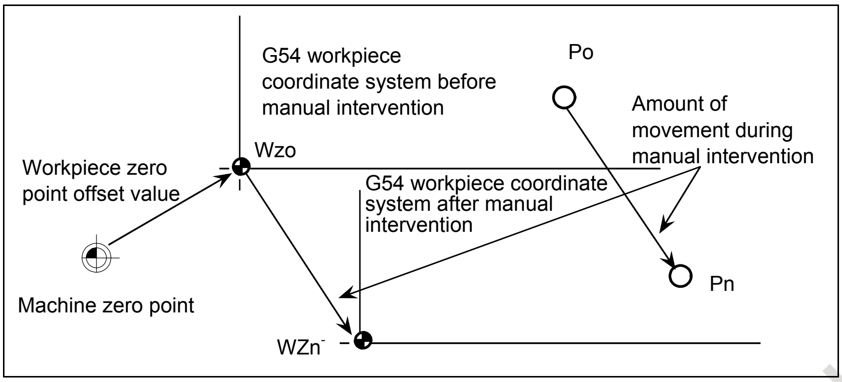

Fig.1.5.2.2 (b)

In the operation above, like execute Manual reference position return, a workpiece coordinate system once shifted can be preset using G code specification (G92.1/G50.3 (G code system A (T series))) or MDI operation (Refer to OPERATOR'S MANUAL (Common to Lathe System / Machining Center System) (B-64694EN) "Workpiece Coordinate System Preset" in "SETTING AND DISPLAYING DATA") to a workpiece coordinate system displaced by a workpiece zero point offset value from the machine zero point.
Bit 3 (PPD) of parameter No. 3104 specifies whether to preset relative coordinates as well as absolute coordinates.
When no workpiece coordinate system option (G54 to G59) is not provided (1 is set in bit 0 (NWZ) of parameter No. 8136), the workpiece coordinate system is preset to the coordinate system with its zero point placed at the reference position.

Limitation

M

- Cutter compensation, tool length compensation, tool offset

When using the workpiece coordinate system preset function, cancel compensation modes: cutter compensation, tool length compensation, and tool offset. If the function is executed without cancelling these modes, compensation vectors are cancelled.

T

- Tool-nose radius compensation, tool offset

When using the workpiece coordinate system preset function, cancel compensation modes: tool-nose radius compensation and tool offset. If the function is executed without cancelling these modes, compensation vectors are cancelled.

- Program restart

The workpiece coordinate system preset function is not executed during program restart.

- Prohibited modes

Do not use the workpiece coordinate system preset function when the scaling, coordinate system rotation, programmable mirror image, or drawing copy mode is set.

1.5.2.3 Adding workpiece coordinate systems (G54.1 or G54)

M

Besides the six workpiece coordinate systems (standard workpiece coordinate systems) selectable with G54 to G59, 48 or 300 additional workpiece coordinate systems (additional workpiece coordinate systems) can be used.

> **NOTE**
> 1 To use the additional workpiece coordinate systems (48 pairs), set 0 in bit 0 (NWZ) of parameter No. 8136 and 0 in bit 2 (NWN) of parameter No. 8136.
> 2 The additional workpiece coordinate systems (300 pairs) is an option. To use this function, an option of the additional workpiece coordinate systems (300 pairs) is required.

Explanation

- Selecting the additional workpiece coordinate systems

When a P code is specified together with G54.1 (G54), the corresponding coordinate system is selected from the additional workpiece coordinate systems (1 to 48 or 1 to 300).
A workpiece coordinate system, once selected, is valid until another workpiece coordinate system is selected. Standard workpiece coordinate system 1 (selectable with G54) is selected at power-on.

G54.1 P1.........Additional workpiece coordinate system 1
G54.1 P2.........Additional workpiece coordinate system 2
:
G54.1 P48.......Additional workpiece coordinate system 48
:
G54.1 P300.....Additional workpiece coordinate system 300

As with the standard workpiece coordinate systems, the following operations can be performed for a workpiece zero point offset in an additional workpiece coordinate system:

(1) The workpiece zero point offset value setting screen can be used to display and set a workpiece zero point offset value.
(2) The G10 function enables a workpiece zero point offset value to be set by programming.
(3) A custom macro allows a workpiece zero point offset value to be handled as a system variable.
(4) Workpiece zero point offset data can be entered or output as external data.
(5) The PMC window function enables workpiece zero point offset data to be read as program command modal data.

- Setting the workpiece zero point offset value in the additional coordinate systems (G10)

When a workpiece zero point offset value is specified using an absolute value, the specified value is the new offset value. When it is specified using an incremental value, the specified value is added to the current offset value to obtain a new offset value.

Limitation

- Specifying P codes

A P code must be specified after G54.1 (G54). If G54.1 is not followed by a P code in the same block, additional workpiece coordinate system 1 (G54.1P1) is assumed.
If a value not within the specifiable range is specified in a P code, an alarm PS0030, “ILLEGAL OFFSET NUMBER” is issued.
P codes other than workpiece offset numbers cannot be specified in a G54.1 (G54) block.

Example 1) G54.1G04P1000;
Example 2) G54.1M98P48;

1.5.2.4 Automatic coordinate system setting

When bit 0 (ZPR) of parameter No. 1201 for automatic coordinate system setting is 1, a coordinate system is automatically determined when manual reference position return is performed.
Once α, β, and γ are set with parameter No. 1250, a workpiece coordinate system is set upon reference position return so that the base point on the tool holder or the tip of the basic tool is positioned at X = α, Y = β, and Z = γ.
This processing occurs as if the following are specified at the reference position:
Note that this cannot be used when the workpiece coordinate system is provided (when 0 is set in bit 0 (NWZ) of parameter No. 8136).

M

G92 X<u>α</u> Y<u>β</u> Z<u>γ</u> ;

T

G50 X<u>α</u> Z<u>γ</u> ;

When the setting of a workpiece coordinate system shift amount is other than 0, a workpiece coordinate system shifted by the amount is set.

1.5.2.5 Workpiece coordinate system shift

T

Explanation

When the coordinate system actually set by the G50 command or the automatic system setting deviates from the programmed workpiece coordinate system, the set coordinate system can be shifted. Set the desired shift amount in the work coordinate system shift memory.

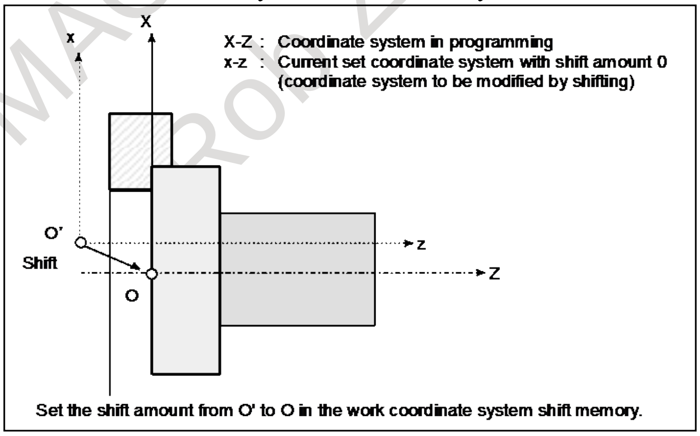

Fig. 1.5.2.5 (a) Workpiece coordinate system shift

Format

- Changing the workpiece coordinate system shift amount

G10 P0 IP_;
IP : Settings of an axis address and a workpiece coordinate system shift amount

⚠ CAUTION

1. A single block can contain a combination of X, Y, Z, C, U, V, W, and H (in G-code system A). In this case, if commands are specified for the same axis, whichever appears later becomes valid.
2. Be sure not to specify other G codes for the same block. When specified, only modal information is updated.
3. Be sure not to specify any auxiliary functions / spindle speed functions / tool functions or 2nd auxiliary functions for the same block. When specified, alarm PS1144 "G10 FORMAT ERROR" is issued.
4. When it commanded with bit 6 (NWS) of parameter No. 1201 is set to 1, alarm PS0010, "IMPROPER G-CODE" is issued.

Limitation

- Shift amount and coordinate system setting command

Specifying a coordinate system setting command (G50 or G92) invalidates the shift amount that has already been set.

Example)

When G50X100.0Z80.0; is specified, a coordinate system is set so that the current base position of the tool is at X =100.0 and Z = 80.0, regardless of which value has been set for the workpiece coordinate system shift amount.

- Shift amount and coordinate system setting

After a shift amount is set, when automatic coordinate system setting is performed upon manual reference position return, the set coordinate system is immediately shifted by the set amount.

- Diameter and radius values

The workpiece coordinate system shift amount depends on diameter programming or radius programming.

Example)

Although the base point should be positioned at X = ϕ120.0 (diameter value) and Z = 70.0 from the workpiece zero point, the actual position is at X = ϕ121.0 and Z = 69.0 from the zero point. Set a shift amount as shown below:

X=1.0, Z=-1.0

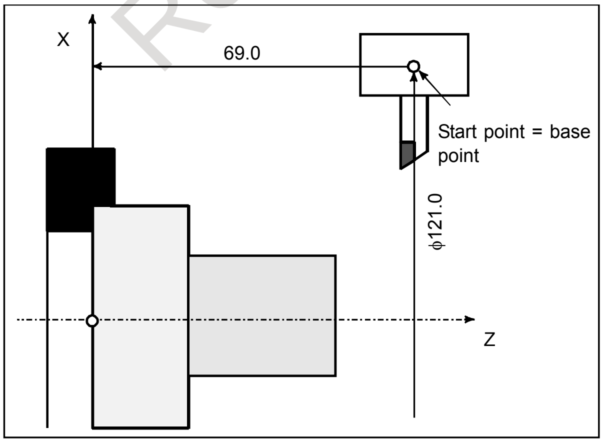

Fig. 1.5.2.5 (b)

Parameter

	#7	#6	#5	#4	#3	#2	#1	#0
1201	WZR	NWS						ZPR
	WZR							ZPR

[Input type] Parameter input
[Data type] Bit path

#0 ZPR Automatic setting of a coordinate system when the manual reference position return is performed
0: Not set automatically
1: Set automatically

> **NOTE**
> ZPR is valid while a workpiece coordinate system function is not provided (bit 0 (NWZ) of parameter No.8136 is 1). If a workpiece coordinate system function is provided, making a manual reference position return always causes the workpiece coordinate system to be established on the basis of the workpiece zero point offset (parameters Nos. 1220 to 1226), irrespective of this parameter setting.

#6 NWS The workpiece coordinate system shift amount setting screen is:
0: Displayed
1: Not displayed

> **NOTE**
> When workpiece coordinate system shift amount setting screen is not displayed, a workpiece coordinate system shift amount modification using G10P0 cannot be made. If G10P0 is commanded, alarm PS0010, "IMPROPER G-CODE" is issued.

#7 WZR If the CNC is reset by the reset key on the MDI unit, external reset signal, reset and rewind signal, or emergency stop signal when bit 6 (CLR) of parameter No. 3402 is set to 0, the G code of group number 14 (workpiece coordinate system) is:
0: Placed in the reset state (not returned to G54).
1: Placed in the cleared state (returned to G54).

> **NOTE**
> 1 When the 3-dimensional conversion mode is set, and bit 2 (D3R) of parameter No. 5400 is set to 1, the G code is placed in the reset state, regardless of the setting of this parameter.
> 2 When bit 6 (CLR) of parameter No. 3402 is set to 1, whether to place the G code in the reset state depends on bit 6 (C14) of parameter No. 3407.

	#7	#6	#5	#4	#3	#2	#1	#0
1202						G92	EWS	EWD
						G92		EWD

[Input type] Parameter input
[Data type] Bit path

#0 EWD The shift direction of the workpiece coordinate system is:
0: The direction specified by the external workpiece zero point offset value
1: In the opposite direction to that specified by the external workpiece zero point offset value

#1 EWS The external workpiece zero point offset is made:
0: Valid
1: Invalid

NOTE
When the external workpiece zero point offset is made invalid, the following operation results:
1 As the external workpiece zero point offset on the workpiece zero point offset setting screen, a workpiece coordinate system shift amount is displayed.
2 Data keyed through the MDI unit for the workpiece coordinate system shift amount and external workpiece zero point offset is loaded into the memory for the workpiece coordinate system shift amount.
3 A write to or read from the workpiece coordinate system shift amount and external workpiece zero point offset with a macro variable is performed using the respective memory.
4 A write to or read from the workpiece coordinate system shift amount and external workpiece zero point offset with the window function is performed using the respective memory.

#2 G92 When the workpiece coordinate system is used (when bit 0 (NWZ) of parameter No. 8136 is 0), if the G command for setting a coordinate system (G92 for M series, G50 for T series (or the G92 command in G command system B or C)) is specified,
0: G command is executed and no alarm is issued.
1: G command is not executed and an alarm PS0010, "IMPROPER G-CODE" is issued.

1220	External workpiece zero point offset value in each axis

[Input type] Setting input
[Data type] Real axis
[Unit of data] mm, inch, deg (input unit)
[Min. unit of data] Depend on the increment system of the applied axis
[Valid data range] 9 digit of minimum unit of data (refer to standard parameter setting table (A))
(When the increment system is IS-B, -999999.999 to +999999.999)

This is one of the parameters that give the position of the zero point of workpiece coordinate system (G54 to G59). It gives an offset of the workpiece zero point common to all workpiece coordinate systems. In general, the offset varies depending on the workpiece coordinate systems. The value can be set from the PMC using the external data input function.

1221	Workpiece zero point offset value in workpiece coordinate system 1 (G54)

0: Not disabled.
1: Disabled.

1.5.2.6 Direct input of coordinate system shift

T

Explanation

If the tool position assumed at programming is inputted when the coordinate system actually set is different from the workpiece coordinate system assumed at programming, shift length of the coordinate system actually set and the workpiece coordinate system assumed at programming is set in the workpiece coordinate system shift value.
The procedure leading up to inputting coordinate system position depend on the setting made for bit 2 (PRC) of parameter No.5005.
The procedure in which the coordinate system position of workpiece end face is specified is as follows.

When bit 2 (PRC) of parameter No.5005 is set to 0

1 Cut the workpiece end face tentatively.
2 Display the workpiece coordinate system shift amount setting screen with touching tool to the workpiece end face.
3 Move the cursor to Z axis of MEASUREMENT.
4 Input the workpiece end face position on workpiece coordinate system assumed at programming and press soft key [INPUT].

When bit 2 (PRC) of parameter No.5005 is set to 1

1 Cut the workpiece end face tentatively.
2 Set the position record signal PRC to "1" with touching tool to the workpiece end face.
3 Remove a tool from the workpiece end face.
4 Display the workpiece coordinate system shift amount setting screen.
5 Move the cursor to Z axis of MEASUREMENT.
6 Input the workpiece end face position on workpiece coordinate system assumed at programming and press soft key [INPUT].

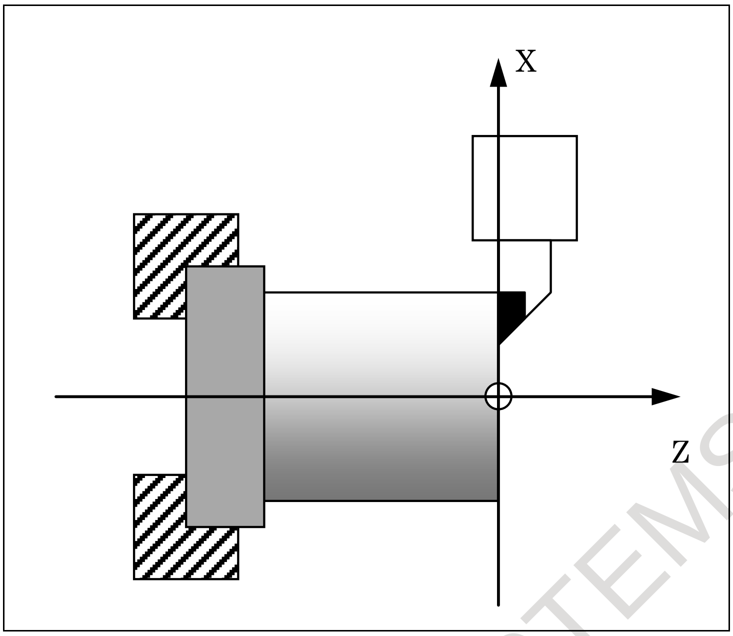

Fig. 1.5.2.6 (a) Direct input of coordinate system shift

Relationship between the input of measurement value and the diameter/radius specification

Whether the measured value input and set value use a diameter value or radius value on the setting of bit 3 (DIAx) of parameter No.1006.

Signal

Position record signal PRC <Gn040.6>

[Classification] Input signal

[Function] This signal is prepared for the function of direct input of tool offset value measured or direct input of coordinate system shift.
It is used to store the data on the positions of the tool for tentative cutting in the control unit. After measuring the workpiece position, input the measured value by the specified manual operation. The difference of the coordinate system actually set and the workpiece coordinate system assumed at programming is set in the workpiece coordinate system shift value.

[Operation] The control unit stores the current position along X and Z axes when the signal turns to "1".

> ⚠ **CAUTION**
> To use this signal, set bit 2 (PRC) of parameter No.5005 to 1.

1.5.2.7 Each axis workpiece coordinate system preset signals

Overview

The each axis workpiece coordinate system preset signals are function for presetting a workpiece coordinate system shifted due to manual intervention, a machine lock, etc. to a workpiece coordinate system offset from the pre-shift machine zero point by a workpiece origin offset value, using an input signal.
Each axis workpiece coordinate system preset signals become effective by setting bit 6 (WPS) of parameter No. 3006 to 1.
If actual tool length offset need to be considered when workpiece coordinate system preset is done, bit 7 (WTC) of parameter No. 1205 need to be set to 1.

Signal

Each axis workpiece coordinate system preset signals
WPRST1 to WPRST8 <Gn358>

[Classification] Input signal

[Function] These signals are used to preset a workpiece coordinate system shifted due to manual intervention, a machine lock, etc.

[Operation] By changing the signal for the axis for which to perform a workpiece coordinate system preset from "0" to "1", the workpiece coordinate system preset is performed. This cancels the shift amount for the workpiece coordinate system that is due to any of the items below, so that the workpiece coordinate system can be preset to a workpiece coordinate system preset from the pre-shift machine zero point by the workpiece origin offset value.

(a) Manual intervention performed when the manual absolute signal is off
(b) Move command executed in the machine lock state
(c) Movement by handle interruption
(d) Operation using the mirror image function
(e) Setting of a local coordinate system with G52 or shift of a workpiece coordinate system with G92/G50 (for the T series)

NOTE
1 If performing workpiece coordinate system preset with an each axis workpiece coordinate system preset signal during automatic operation, specify it with the M code set in parameters Nos. 11275 and 11276 or perform it during a single block stop.
2 If preset is to be performed with an each axis workpiece coordinate system preset signal during automatic operation, the state must be that in which all axes on the path including the axis on which to perform each axis workpiece coordinate system preset are stopped and no commands are in execution. If not all axes are stopped or if a command is in execution, alarm PS1820, "ILLEGAL DI SIGNAL STATE" is issued.

NOTE

3 When an M code for performing each axis workpiece coordinate system preset is issued during automatic operation, if the corresponding each axis workpiece coordinate system preset signal is not set to 1, alarm PS1820 is issued. It is possible to suppress the alarm by setting bit 0 (WPA) of parameter No. 11277 to 1. In this case, axis workpiece coordinate system preset is not performed.

4 During a reset (RST<Fn001.1> = "1"), preset with an each axis workpiece coordinate system preset signal is disabled. Preset is performed at the point the reset is canceled.

5 During an auxiliary function lock, this function is disabled.

6 In general, if preset is to be performed with an each axis workpiece coordinate system preset signal, the state must be that in which all axes on the path including the axis on which to perform each axis workpiece coordinate system preset are stopped. However, when bit 1 (EAX) of parameter No. 10410 is set to 1 and the axis moves by the PMC axis control, it is possible to exclude the axis from this condition. That is, the preset can be performed without stopping the axis that moves by the PMC axis control. However, when you move the axis that moved by the PMC axis control by the NC commands, it is necessary to stop the axis, and to reflect the amount of movement by PMC axis control to the program coordinate system by the manual return to the reference position etc.

7 Be sure to specify an M code used to turn on each axis workpiece coordinate system preset signal in an independent block.

Each axis workpiece coordinate system preset completion signals WPSF1 to WPSF8<Fn358>

[Classification] Output signal

[Function] These signals notify the PMC of the each axis workpiece coordinate system preset status.

[Output cond.] These signals become "1" in the following case:

- When workpiece coordinate system preset is completed with the corresponding each axis workpiece coordinate system preset signals.

They become "0" in the following cases:

- When the corresponding each axis workpiece coordinate system preset signals change from "1" to "0".
- When a reset is performed.

- Timing chart

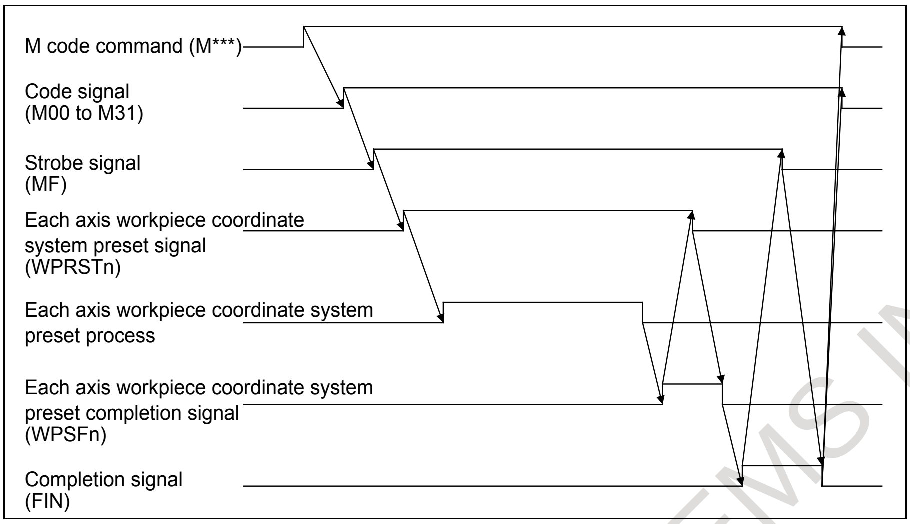

Fig. 1.5.2.7 (a)

[Input type] Parameter input
[Data type] Bit axis

#1 EAX When other axis is preset with the workpiece coordinate system preset signal while this axis is moving under the PMC axis control:
0: The alarm PS1820, “ILLEGAL DI SIGNAL STATE” occurs.
1: An alarm doesn’t occur.

11275	The top number of M code used to turn on each axis workpiece coordinate system preset signal

[Input type] Parameter input
[Data type] 2-word path
[Valid data range] 1 to 999999999

Specify the top number of M code for turning “1” each axis workpiece coordinate system preset signal <Gn358.*> during automatic operation.
When the specified M codes are within the range specified with this parameter and parameter No.11276, each axis workpiece coordinate system preset signal is checked and preset workpiece coordinate system for axis that the signal is turned “1”.
The specified M codes prevent buffering.

> **NOTE**
> When each axis workpiece coordinate system preset signals are turned “1“ more than two signals by an M code, please turn “1“ the signals of all axis at the same timing. If the timing is different, only the axis of the first signal turned “1“ is preset.
> If you want to turn “1“ the signals at the different timing, please specify M code separately.

11276	The number of M code used to turn on each axis workpiece coordinate system preset signal

[Input type] Parameter input
[Data type] Word path
[Valid data range] 1 to 999

Specify the number of M code for turning “1” each axis workpiece coordinate system preset signal <Gn358.*> during automatic operation.
For example, when parameter No.11275 = 100 and parameter No.11276 = 10 are set, From M100 to M109 are used for turning “1” each axis workpiece coordinate system preset signal.
When 0 is set, the number of M code is assumed to be 1.

> **NOTE**
> Set only M code that is not used for another function.
> (M00 to 05, 30, 98, 99, M code used to call the subprogram, etc.)

	#7	#6	#5	#4	#3	#2	#1	#0

[Input type] Parameter input
[Data type] Bit path

#0 WPA When an M code for turning on the workpiece coordinate system preset signal for an axis is specified, but the signal is not turned on, or an auxiliary function lock is provided:
0: An alarm PS1820, “ILLEGAL DI SIGNAL STATE” is issued.
1: An alarm is not issued.

When bit 6 (PGS) of parameter No. 3001 is set to 0 (M, S, T, and B codes are not output in the high speed program check mode), if an M code for turning on the workpiece coordinate system preset signal for an axis is specified, the system follows the setting of this parameter.

Alarm and message

Number	Message	Description
PS1820	ILLEGAL DI SIGNAL STATE	1. An each axis workpiece coordinate system preset signal was turned on in the state in which all axes on the path including the axis on which to perform preset with the each axis workpiece coordinate system were not stopped or in which a command was in execution. 2. When an M code for performing preset with an each axis workpiece coordinate system preset signal was specified, the each axis workpiece coordinate system preset signal was not turned on. 3. The auxiliary function lock is enabled. 4. When bit 6 (PGS) of parameter No. 3001 was set to 0 (M, S, T, and B codes are not output in the high speed program check mode), an M code for turning on an each axis workpiece coordinate system preset signal in the high speed program check mode was specified.

Notes

> **NOTE**
> The limitations are the same as those for the workpiece coordinate system preset using a program command (G92.1 or G50.3 (for G code system A (T series) or using MDI operation. Thus, before performing preset with this function, cancel each compensation mode (cutter compensation, tool offset, and tool length compensation). Otherwise, the compensation vector will be canceled. If this occurs, specify each compensation mode again. For details, refer to the OPERATOR'S MANUAL (Common to Lathe System/Machining Center System) (B-64694 EN).

1.5.3 Local Coordinate System

Overview

When a program is created in a workpiece coordinate system, a child workpiece coordinate system can be set for easier programming. Such a child coordinate system is referred to as a local coordinate system.

Format

G52 IP _; Setting the local coordinate system
:
G52 IP 0 ; Canceling the local coordinate system
IP_ : Origin of the local coordinate system

Explanation

By specifying G52 IP_;, a local coordinate system can be set in all the workpiece coordinate systems (G54 to G59). The origin of each local coordinate system is set at the position specified by IP_ in the workpiece coordinate system.
Once a local coordinate system is established, the coordinates in the local coordinate system are used in an axis shift command. The local coordinate system can be changed by specifying the G52 command with the zero point of a new local coordinate system in the workpiece coordinate system.
To cancel the local coordinate system and specify the coordinate value in the workpiece coordinate system, match the zero point of the local coordinate system with that of the workpiece coordinate system.

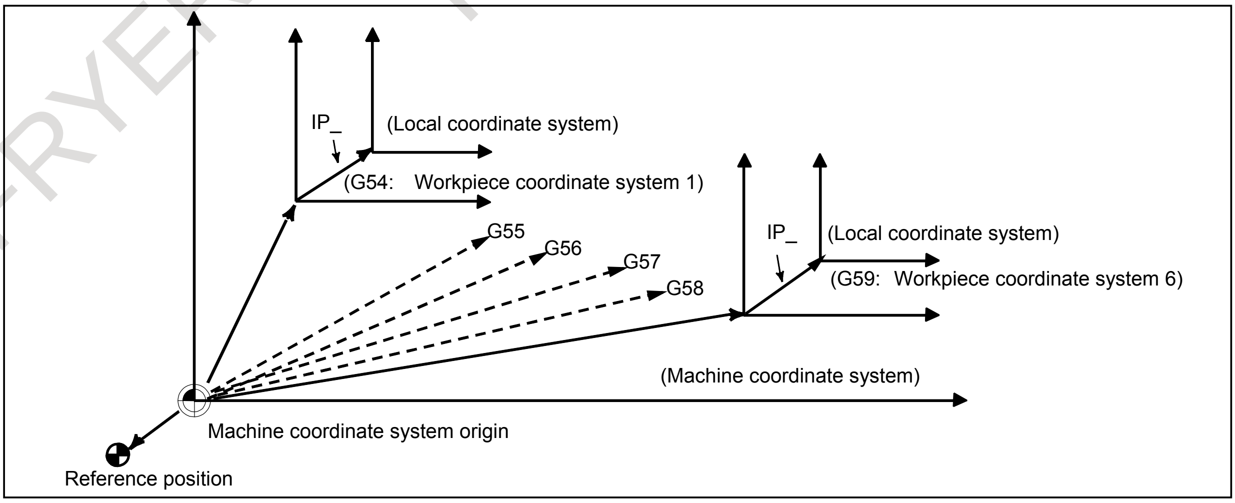

Fig. 1.5.3 (a) Setting the local coordinate system

> ⚠ **CAUTION**
> 1 When bit 2 (ZCL) of parameter No. 1201 is set to 1 and an axis returns to the reference point by the manual reference point return function, the zero point of the local coordinate system of the axis matches that of the work coordinate system.
> The same is true when the following command is issued:
> G52α0;
> α: Axis which returns to the reference point
> 2 The local coordinate system setting does not change the workpiece and machine coordinate systems.
> 3 Whether the local coordinate system is canceled upon reset depends on the specified parameters. The local coordinate system is canceled upon reset when bit 6 (CLR) of parameter No. 3402 or bit 3 (RLC) of parameter No. 1202 is set to 1. In 3-dimensional coordinate conversion mode, however, the local coordinate system is not canceled when bit 2 (D3R) of parameter No. 5400 is set to 1.
> 4 When a workpiece coordinate system is set with the G code command for coordinate system setting (G92 <M series>, G50 <T series> (G92 with G code system B/C for T series)), the local coordinate system is canceled. However, the local coordinate system of an axis for which no coordinate system is specified in a G code block for coordinate system setting remains unchanged.
> 5 G52 cancels the offset temporarily in cutter or tool-nose radius compensation.
> 6 Command a move command immediately after the G52 block in the absolute mode.

Parameter

	#7	#6	#5	#4	#3	#2	#1	#0
1201						ZCL		

[Input type] Parameter input
[Data type] Bit path

#2 ZCL Local coordinate system when the manual reference position return is performed
0: The local coordinate system is not canceled.
1: The local coordinate system is canceled.

> ⚠ **CAUTION**
> ZCL is valid when the workpiece coordinate system is provided (when 0 is set in bit 0 (NWZ) of parameter No. 8136). In order to use the local coordinate system (G52), the workpiece coordinate system option is required.

	#7	#6	#5	#4	#3	#2	#1	#0
1202					RLC			

[Input type] Parameter input
[Data type] Bit path

#3 RLC Local coordinate system is
0: Not cancelled by reset.
1: Cancelled by reset.

> ⚠ **CAUTION**
> 1 When bit 6 (CLR) of parameter No. 3402 is set to 0, and bit 7 (WZR) of parameter No. 1201 is set to 1, the local coordinate system is cancelled, regardless of the setting of this parameter.
> 2 When bit 6 (CLR) of parameter No. 3402 is set to 1, and bit 6 (C14) of parameter No. 3407 is set to 0, the local coordinate system is cancelled, regardless of the setting of this parameter.
> 3 When the 3-dimensional coordinate conversion mode is set, and bit 2 (D3R) of parameter No. 5400 is set to 1, the local coordinate system is not cancelled, regardless of the setting of this parameter.

	#7	#6	#5	#4	#3	#2	#1	#0
5400						D3R		

[Input type] Parameter input
[Data type] Bit path

#2 D3R When reset is done by reset operation or reset signal from PMC, 3-dimensional coordinate system conversion mode, tilted working plane command mode and workpiece setting error compensation mode is:
0: Canceled.
1: Not canceled.

1.5.4 Rotary Axis Roll-Over

Overview

The roll-over function of the rotary axis prevents coordinates for the rotary axis from overflowing. The roll-over function of the rotary axis is enabled by setting bit 0 (ROAx) of parameter No. 1008 to 1.
For an incremental command, the tool moves the angle specified in the command. For an absolute command, the coordinates after the tool has moved are values rounded by the angle corresponding to one rotation set in parameter No. 1260. The tool moves in the direction in which the final coordinates are closest when bit 1 (RABx) of parameter No. 1008 is set to 0. Displayed values for relative coordinates are also rounded by the angle corresponding to one rotation when bit 2 (RRLx) of parameter No. 1008 is set to 1.

Parameter

	#7	#6	#5	#4	#3	#2	#1	#0
1006							ROSx	ROTx

[Input type] Parameter input
[Data type] Bit axis

> **NOTE**
> When at least one of these parameters is set, the power must be turned off before operation is continued.

#0 ROTx
#1 ROSx Setting linear or rotary axis.

ROSx	ROTx	Meaning
0	0	Linear axis (1) Inch/metric conversion is done. (2) All coordinate values are linear axis type. (Is not rounded in 0 to 360°) (3) Stored pitch error compensation is linear axis type (Refer to parameter No.3624)
0	1	Rotary axis (A type) (1) Inch/metric conversion is not done. (2) Machine coordinate values are rounded in 0 to 360°. Absolute coordinate values are rounded or not rounded by bits 0 (ROAx) and 2 (RRLx) of parameter No.1008. (3) Stored pitch error compensation is the rotation type. (Refer to parameter No.3624) (4) Automatic reference position return (G28, G30) is done in the reference position return direction and the move amount does not exceed one rotation.
1	1	Rotary axis (B type) (1) Inch/metric conversion is not done. (2) Machine coordinate values, absolute coordinate values and relative coordinate values are linear axis type. (Is not rounded in 0 to 360°). (3) Stored pitch error compensation is linear axis type (Refer to parameter No.3624) (4) Cannot be used with the rotary axis roll-over and the index table indexing function (M series)
Except for the above.		Setting is invalid (unused)

	#7	#6	#5	#4	#3	#2	#1	#0
1008						RRLx	RABx	ROAx

[Input type] Parameter input
[Data type] Bit axis

> **NOTE**
> When at least one of these parameters is set, the power must be turned off before operation is continued.

#0 ROAx The rotary axis roll-over is
0: Invalid.
1: Valid.

> **NOTE**
> ROAx specifies the function only for a rotary axis (for which bit 0 (ROTx) of parameter No.1006 is set to 1)

#1 RABx In the absolute commands, the axis rotates in the direction
0: In which the distance to the target is shorter.
1: Specified by the sign of command value.

> **NOTE**
> RABx is valid only when ROAx is 1.

#2 RRLx Relative coordinates are
0: Not rounded by the amount of the shift per one rotation.
1: Rounded by the amount of the shift per one rotation.

> **NOTE**
> 1 RRLx is valid only when ROAx is 1.
> 2 Assign the amount of the shift per one rotation in parameter No.1260.

1260	The shift amount per one rotation of a rotary axis

> **NOTE**
> When this parameter is set, the power must be turned off before operation is continued.

[Input type] Parameter input
[Data type] Real axis
[Unit of data] Deg
[Min. unit of data] Depend on the increment system of the applied axis
[Valid data range] 0 or positive 9 digit of minimum unit of data (refer to the standard parameter setting table (B))
(When the increment system is IS-B, 0.0 to +999999.999)
Set the shift amount per one rotation of a rotary axis.
For the rotary axis used for cylindrical interpolation, set the standard value.

Note

> **NOTE**
> This function cannot be used together with the indexing function of the index table (machining center system).

1.6 AXIS SYNCHRONOUS CONTROL

Overview

When a movement is made along one axis by using multiple servo motors as in the case of a large gantry machine, a command for one axis can drive the multiple motors by synchronizing one motor with the other. An axis used as the reference for axis synchronous control is called a master axis (M-axis), and an axis along which a movement is made in synchronism with the master axis is called a slave axis (S-axis).

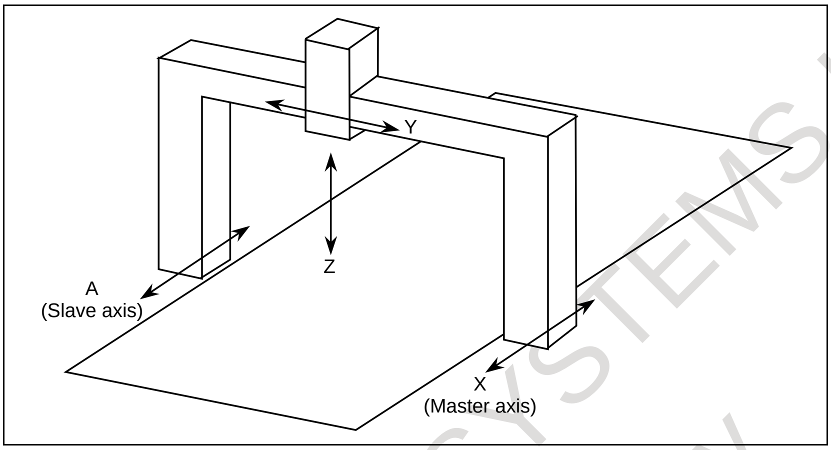

Fig. 1.6 (a) Example of machine with X and A being synchronous axes

Upon power-up or after emergency stop cancellation, the machine position on the slave with that on the master axis can be adjusted by the synchronization establishment function. And a synchronization error amount of the master axis and slave axis is monitored. If the error amount exceeds a certain limit, an alarm is issued and the movement along the axis can be stopped.

1.6.1 Example of Usage

Explanation

- Function to drive multiple axes by command of one axis

In the function to drive multiple axes by command of one axis, there are other functions except the axis synchronous control. The axis synchronous control might be unsuitable depending on the machine. Please select the proper function referring to Table 1.6.1 (a) and Fig. 1.6.1 (a).

Table 1.6.1 (a) Function to drive multiple axes by command of one axis

Function name	Functional overview
Axis synchronous control	• Multiple axes in same path can be drive in synchronism. • Synchronization establishment, Synchronization error check, and Synchronization error compensation can be used. • This function can be used on the large gantry machine. The slave axis can be driven with stability.
Synchronous control	• Multiple axes in all paths can be drive in synchronism. • Parking can be used. • This function can be used on the combined machine, etc.
Tandem control	• Two motors in same path can be drive one axis. • Position is controlled only for the master axis. The slave axis is used only to output torque same as master axis. • This function can be used as follows. Two motors drive one ball screw. Motor having two windings is driven.

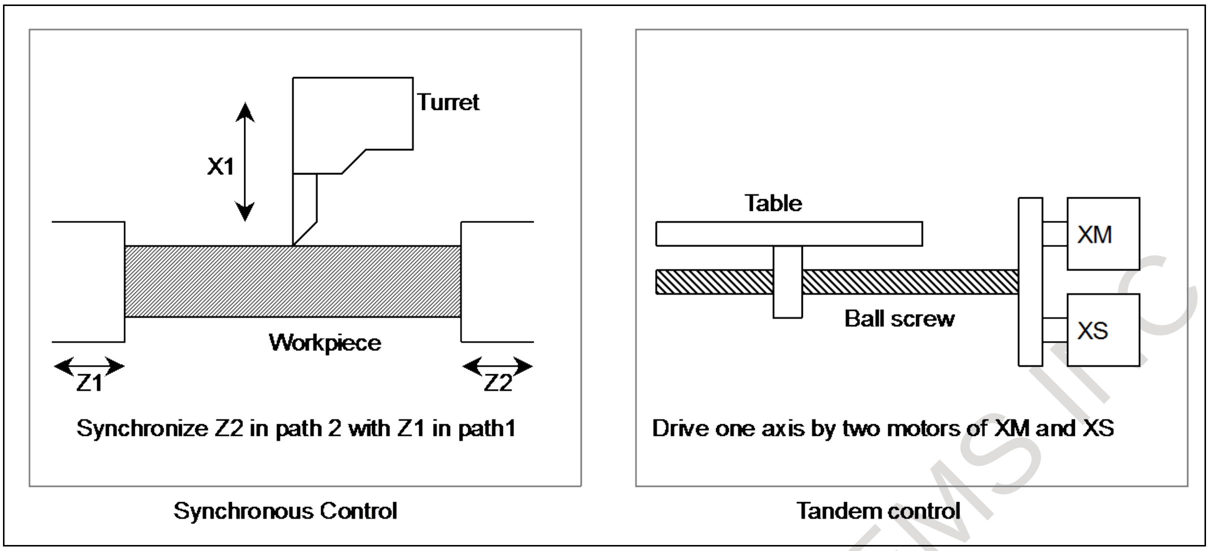

Fig. 1.6.1 (a) Application example

- Axis synchronous control

The axis synchronous control can drive multiple motors in synchronism by the command for one axis. The functions specific to axis synchronous control are as listed below.

Table1.6.1 (b) Functions of axis synchronous control

Function name	Overview
Automatic Setting for Grid Position Matching	The reference counters (grid positions) difference between the master axis and slave axis can be automatically set to a parameter. The CNC automatically adjusts reference positions (grid positions) of the master axis and the slave axis.
Synchronization establishment	Upon power-up or after emergency stop cancellation, the machine position on the slave axis with that on the master axis can be adjusted.
Synchronization error check	The synchronization error amount is monitored. If the error amount exceeds a certain limit, an alarm is issued and the movement along the axis can be stopped.
Axis Synchronous Control Torque Difference Alarm	The torque command difference between the master axis and the slave axis is observed. If the difference exceeds certain limit, a servo alarm can be issued.
Synchronous axes automatic compensation	If there is the torque difference according to a mechanical error (the pitch error of the scale, the expansion difference of the ball screw, etc.) between the master axis and the slave axis, servo control can automatically compensate the position of the slave axis to decrease torque difference. Overheat of the motor can be prevented when the conflicting torque is output from a master axis and a slave axis. (Note)
Integrator copy function	The main component of the torque command is copied from a master axis to a slave axis, and it shares. This function is similar to the tandem control. However, a movement that is more stable than the tandem control can be expected. Because the velocity damping control is executed on each motor. In case that the position control is executed on two motors independently, when the torque commands have the offset by the interference between axes, this function works appropriately. (Note)
Synchronization error compensation	When the synchronization error of the positional deviation value is larger than the parameter value, compensation pulses can be output to a slave axis for decreasing the synchronization error. If the positional deviation corresponding to the load were generated like a past analog servo, this function was effective for decreasing the synchronization error. When a current digital servo is applied, positional deviation corresponding to the load are not generated. Therefore, the function need not be applied.

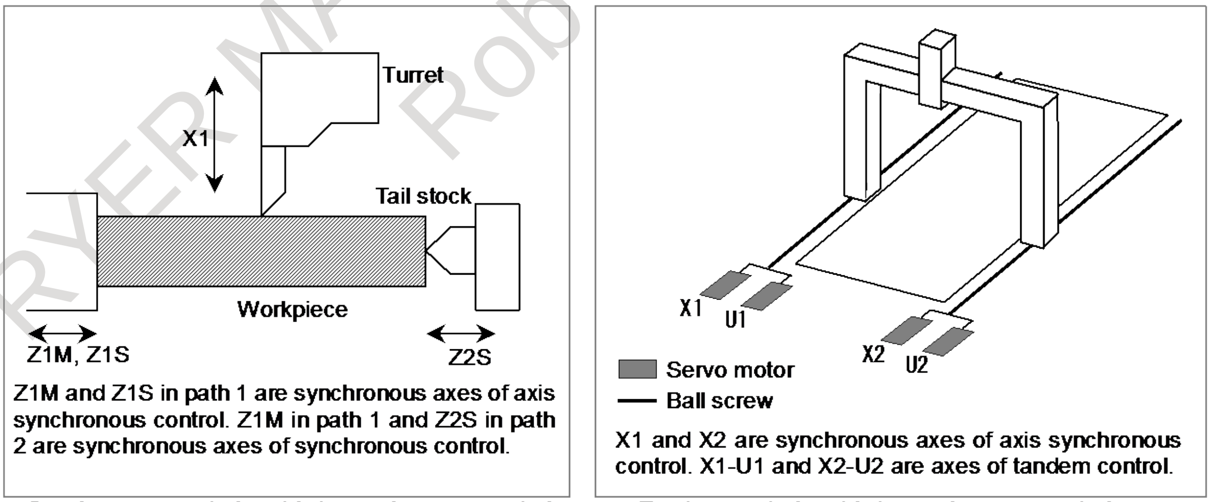
> **NOTE**
> This function is servo function. For details of this function, refer to "FANUC AC SERVO MOTOR α*i*/β*i* series, LINEAR MOTOR LiS series, SYNCHRONOUS BUILT-IN SERVO MOTOR DiS series PARAMETER MANUAL (B-65270EN)".

- Use with other functions

There are the functions to drive multiple axes by command of one axis, and the axis synchronous control can be used together with the following functions.

Table 1.6.1 (c) Use with other functions

Function name	Use with axis synchronous control
Synchronous control	The master axis of the axis synchronous control can be also set to the master axis of the synchronous Control. (Example) Path 1 X1M (Master of axis synchronous control and synchronous control) X1S (Slave of axis synchronous control) Path 2 X2S (Slave of synchronous control)
Tandem control	Tandem control can be used with each of the master axis and the slave axis of axis synchronous control respectively. The same restriction on axis arrangement as imposed in the case of normal tandem control is imposed. No particular restriction is imposed on axis synchronous control.
Flexible synchronization control	The slave axis of flexible synchronization control can be set to the master axis of axis synchronous control by setting bit 0 (FSS) of parameter No. 8307 to 1. Then, it is necessary to execute beginning and the end of flexible synchronization control while axis synchronous control.
Superimposed control	The slave axis of superimposed control can be set to the master axis of axis synchronous control by setting bit 0 (FSS) of parameter No. 8307 to 1. Then, it is necessary to execute beginning and the end of superimposed control while axis synchronous control. It is necessary to set superimposed ahead signals OVLN <Gn531.4> to "1" during superimposed control is begun.



Synchronous control and Axis synchronous control   Tandem control and Axis synchronous control

Fig. 1.6.1 (b) Use with other functions

When the axis of large gantry machine is driven by two motors, please apply the axis synchronous control. (See the left side of the below Fig. 1.6.1 (c).) The stability and the accuracy increase more than the tandem control because the velocity control is executed in the slave axis.

In the above gantry machine, if two motors drive the one ball screw, please apply the tandem control. (See the right side of the Fig. 1.6.1 (b).)

- Example of using axis synchronous control

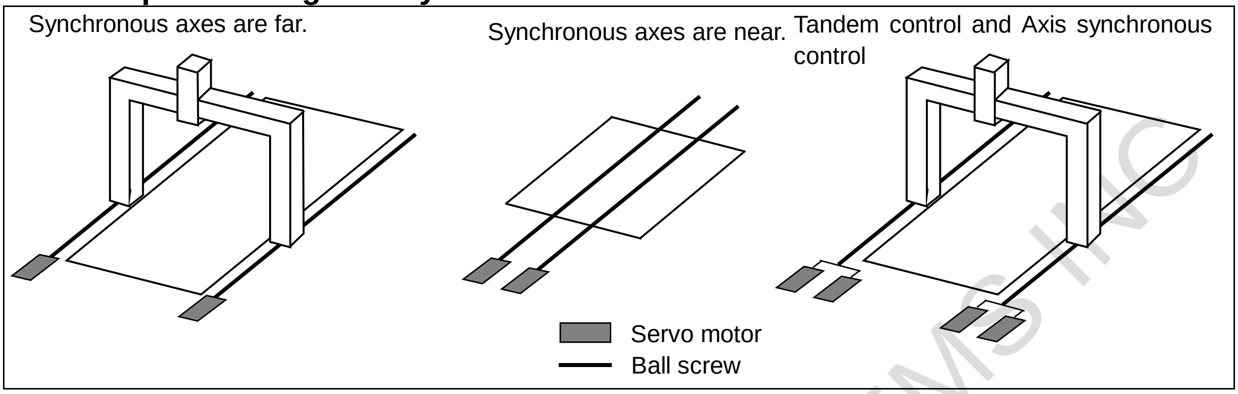


Fig. 1.6.1 (c) Example of using axis synchronous control

If there is the torque difference between a master axis and a slave axis, please apply the synchronous axes automatic compensation or the Integrator copy function.

1.6.2 Procedure to Start-Up

Explanation

The procedure to start-up the axis synchronous control is as follows.

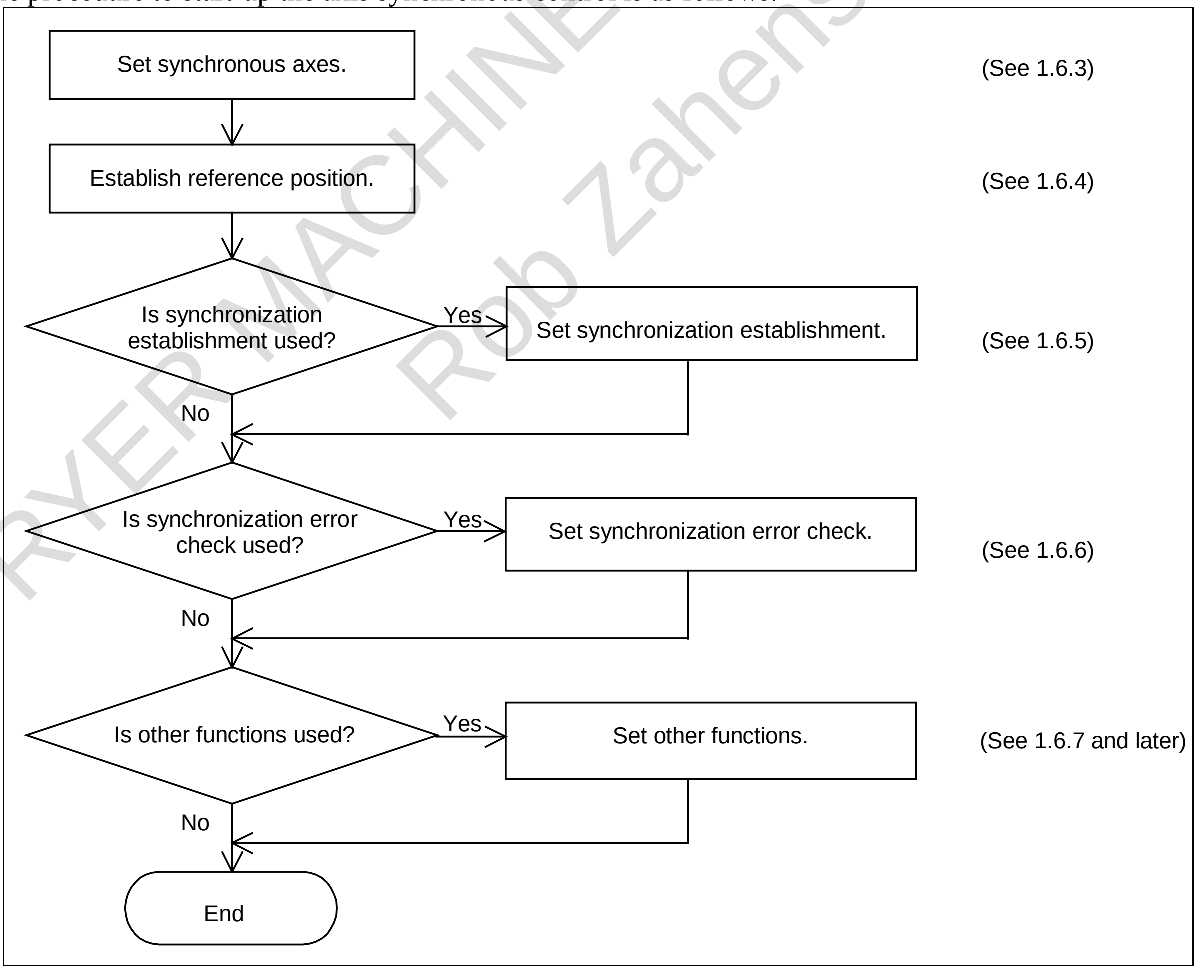

Fig. 1.6.2 (a)

1.6.3 Setting of Synchronous Axes

Explanation

- Master axis and slave axis for axis synchronous control

An axis used as the reference for axis synchronous control is called a master axis (M-axis), and an axis along which a movement is made in synchronism with the master axis is called a slave axis (S-axis).
By setting the axis number of a master axis within a path to the parameter No. 8311 of the slave axis, the axis configuration for axis synchronous control is set. The multiple slave axes can set within the range of the maximum controlled axes of a path. The slave axis cannot be set as the master axis of other synchronous axes.

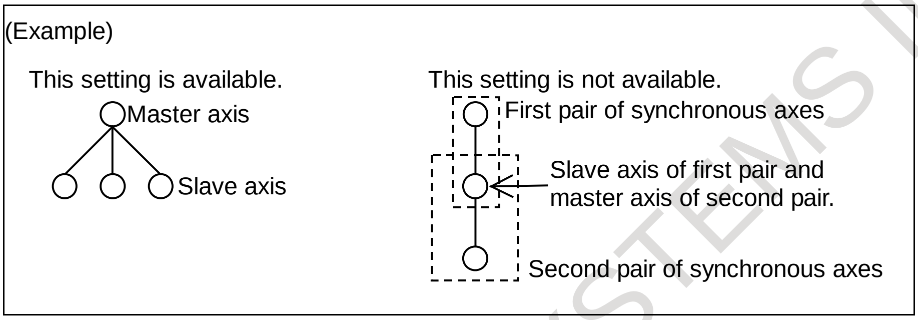

Fig. 1.6.3 (a)

- Maximum pairs of synchronous axes

Maximum pairs of synchronous axes (maximum number of combinations for master axis and slave axis) are 4 pairs.

- Synchronous operation and normal operation

Operation where axis synchronous control is turned on (enabled) to make a movement along the slave axis in synchronism with the master axis is called a synchronous operation. Operation where axis synchronous control is turned off (disabled) to move a master axis and a slave axis independently is called a normal operation.

(Example)

Automatic operation when the master axis is the X-axis and the slave axis is the A-axis:
In synchronous operation, both the X-axis and the A-axis are moved according to the programmed command Xxxxx for the master axis.
In normal operation, the master axis and the slave axis are moved independently as in the case of normal CNC control. The programmed command Xxxxx makes a movement along the X-axis. The programmed command Aaaaa makes a movement along the A-axis. The programmed command Xxxxx Aaaaa makes movements along the X-axis and A-axis at the same time.

The mode of operation can be switched between synchronous operation and normal operation by an input signal, or synchronous operation can be performed at all times. Which mode to use can be set using bit 5 (SCAx) of parameter No. 8304.

Switching between synchronous operation and normal operation by using an input signal

When bit 5 (SCAx) of parameter No. 8304 is set to 0 for the slave axis, the signals for selecting the axis for axis synchronous control SYNC1 to SYNC8<Gn138> / signals for selecting the manual feed axis for axis synchronous control SYNCJ1 to SYNCJ8<Gn140> is used to switch between synchronous operation and normal operation. When SYNC/SYNCJ = 1, synchronous operation is selected. When SYNC/SYNCJ = 0, normal operation is selected.
Synchronization error compensation cannot be used when the mode of operation is switched between synchronous operation and normal operation.

> ⚠ **CAUTION**
> To switch between synchronous operation and normal operation, command the relevant M code (set to the parameter No. 8337 or 8338).

The synchronous operation and the normal operation can be changed by setting each signal SYNC / SYNCJ by each operation of automatic operation and manual operation.

Setting for using synchronous operation at all times

When bit 5 (SCAx) of parameter No. 8304 for the slave axis is set to 1, synchronous operation is performed at all times, regardless of the setting of the signal SYNC/SYNCJ.

- Axis synchronous control status signals

During axis synchronous control, the axis synchronous control status signals SYNO1 to SYNO8<Fn532> becomes 1. However, this signal might not be the same as the status of signal SYNC / SYNCJ or bit 5 (SCAx) of parameter No. 8304. For instance, this signal is “0” during emergency stop, servo alarm, servo off, and controlled axes detach.

- Synchronous control axis name

There is no problem whether the name of a master axis and the name of a slave axis is the same or not.

Restrictions on using the same name for the master axis and slave axis

If the same axis name is assigned to the master axis and slave axis, manual operation only is allowed in normal operation. Automatic operation cannot be performed.

Axis name subscript and extended axis name

If the axis name of synchronous axis is set by using the axis name subscript or the extended axis name, the axes can be distinguished from each other on the screen display, or which of those axes issued an alarm can be identified.
The axis name subscript is set by the parameter No. 3131, and the extended axis name is set by the bit 0 (EEA) of parameter No.1000, parameter No.1025, and parameter No.1026.

- Current position display screen

On a screen such as the current position display screen, a slave axis is also displayed. The display of a slave axis can be disabled by the following parameter settings.

- Set the last to the slave axis of parameter No.3130 (axis display order for current position display screens).
- Set 1 to bit 0 (NDPx) of parameter No.3115 and bit 1 (NDAx) of parameter No.3115.

Example

In the example below, movements along the X1-axis and X2-axis are made in synchronism with the XM-axis.

Table 1.6.3 (a)

Axis name indication	Controlled axis number	Axis name No. 1020	Subscript No.3131	Master axis number No.8311	Operation
XM	1	88	77	0	
Y	2	89	0	0	
X1	3	88	49	1	A movement is made in synchronism with the XM-axis.
X2	4	88	50	1	A movement is made in synchronism with the XM-axis.

When one master axis has multiple slave axes, synchronization error compensation, synchronization establishment, and synchronization error check are performed for each slave axis independently.

- Slave axis mirror image

By setting parameter No. 8312, a mirror image can be applied to a slave axis placed in synchronous operation. When the mirror image function is enabled, the direction in which the absolute and relative coordinates change is the same as for the machine coordinates.
At this time, synchronization error compensation, synchronization establishment, synchronization error check, and correction mode cannot be used.
The mirror image set by bit 0 (MIRx) of parameter No. 0012 cannot be applied to the slave axis. Because this mirror image differs from the mirror image set by bit 0 (MIRx) of parameter No. 0012, it does not affect mirror image signals MI1 to MI8 <Gn106> or mirror image check signals MMI1 to MMI8 <Fn108>.

- Automatic slave axis parameter setting

Axis synchronous control involves parameters which must be set to the same values for the master axis and slave axis. (See the parameter list in "Parameters which must be set to the same value for the master and slave axes" to appear later. If bit 4 (SYPx) of parameter No. 8303 is 1, setting values for these parameters for the master axis causes the same values to be set to the parameters for the slave axis. For details, see Subsection “Automatic Slave Axis Parameter Setting”.

1.6.4 Reference Position Establishment

1.6.4.1 Procedure of reference position establishment

The procedure of reference position establishment using grid points is as follows.

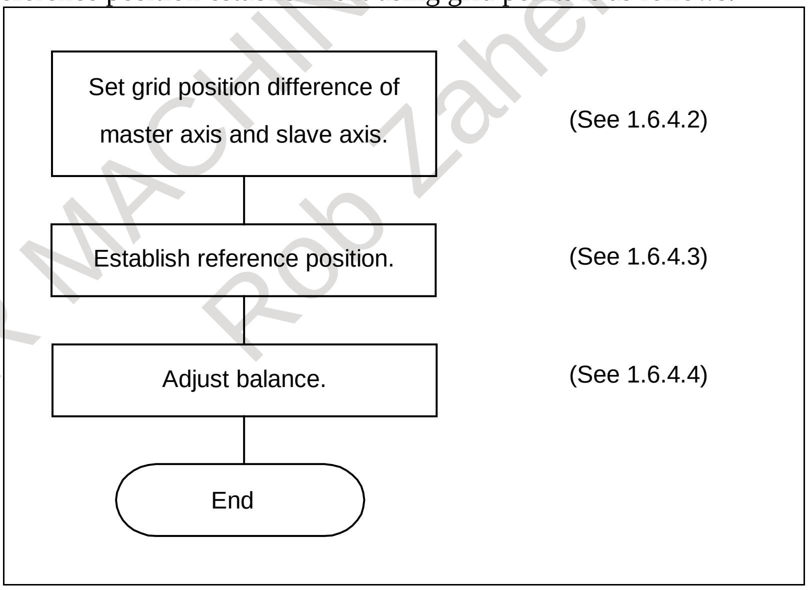

Fig. 1.6.4.1 (a)

- Absolute position detection

When the absolute position detection is used, do not execute the setting the zero point using MDI operation that sets bit 4 (APZ) of parameter No.1815 directly for the re-setting of the reference point establishment in the maintenance work. After setting up the deceleration dog or clarifying the start position for reference position establishment, perform the setting the zero point of the absolute position detector.
By setting bit 7 (SMA) of parameter No. 8302 is set to 1, when the bit 4 (APZx) of parameter No. 1815 for an axis in synchronous operation is set to 0, and APZx of the pairing axis in synchronous operation is also set to 0.

- Reference point setting with mechanical stopper

If the reference point setting with mechanical stopper is used, see Subsection “Reference point setting with mechanical stopper”.

- Distance coded linear scale interface, Linear scale with distance-coded reference marks (serial)

If the distance coded linear scale interface or the linear scale with distance-coded reference marks (serial) is used, see Subsection “Distance coded linear scale interface, Linear scale with distance-coded reference marks (serial)”.

- Normal operation

The reference point establishment by the normal operation is the same as a usual axis.

1.6.4.2 Setting of grid position

When manual reference position return operation is performed along axes under axis synchronous control, the machine is placed at the reference position on the master axis and slave axis according to the same sequence as for normal reference position return operation.
The sequence is the same as the grid method for one axis only. However, only the deceleration signal for the master axis is used. When the deceleration signal is set to 0, the machine gradually stops along the master axis and slave axis, and then an FL feedrate is set. When the deceleration signal is set to “1”, the machine moves to a grid position along each of the master axis and slave axis, then stops.

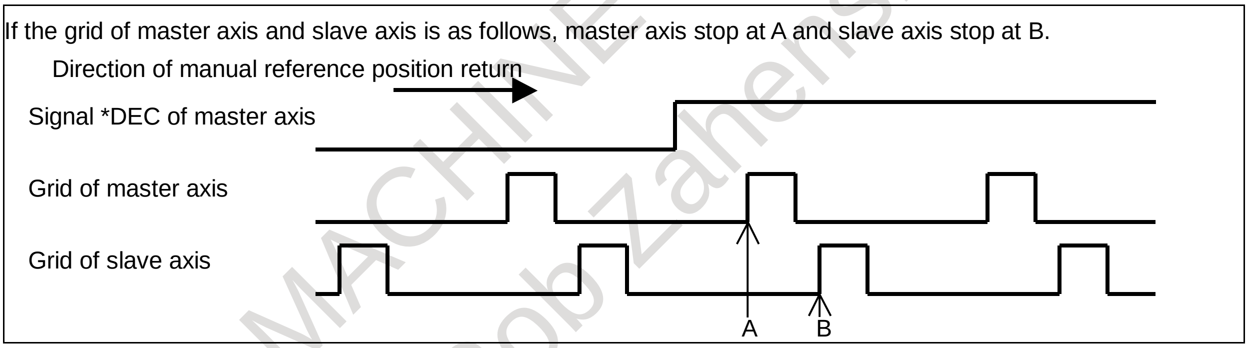

Fig. 1.6.4.2 (a)

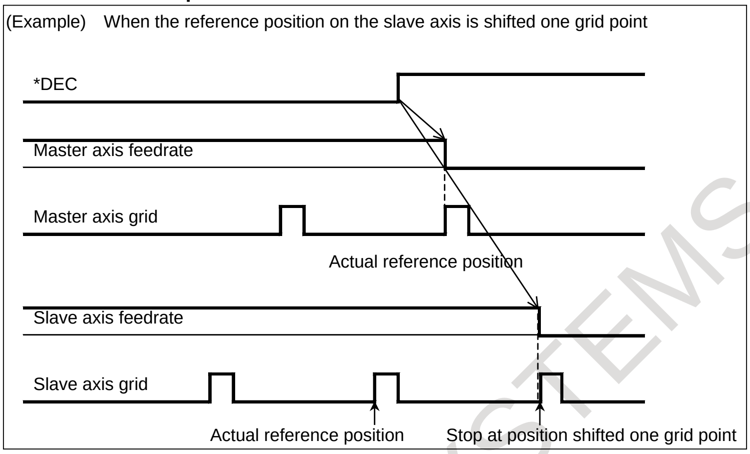
NOTE

When the grid position difference between the master axis and slave axis is large, a reference position shift may occur, depending on the timing of the *DEC signal set to “1”. In the example below, the shift along the slave axis is so large that the position shifted one grid point from the actual reference position is regarded as the reference position.



Before axis synchronous control can be performed, the reference position (grid position) on the slave axis must be adjusted to the reference position on the master axis.
If the grid position difference of the master axis and the slave axis is set to the parameter by either of the following methods, the master axis and the slave axis can be stopped at the grid position of the master axis.

- Automatic setting for grid position matching
- Reference position shift function

- Automatic setting for grid position matching

The automatic setting for grid position matching can be automatically set the reference counters (grid positions) difference in parameter No.8326, and the CNC automatically adjusts the reference positions (grid positions) of the master axis and slave axis. The operation procedure is as follows.

1. Select the synchronous operation.
2. Set the following parameters.

No.1844=0	: Distance to the first grid point	(NOTE 1)
No.1850=0	: Amount of grid shift and reference position shift	(NOTE 1)
Bit4 (SFDx) of No.1008 =0	: Reference position shift functions is disabled.	(NOTE 1)
Bit0 (ATEx) of No.8303 =1	: Automatic setting for grid positioning is enabled.	(NOTE 2)
Bit1 (ATSx) of No.8303 =1	: Automatic setting for grid positioning is started.	(NOTE 2)

   If bit 5 (APCx) of No.1815 =1, bit 4 (APZx) of No.1815 =0
3. Turn off the power then turn on the power.
4. Set the REF mode (or JOG mode in the case of reference position setting without dogs), and make movements in the reference position return direction along the master axis and slave axis.
5. The movements along the master axis and slave axis automatically stop, and a grid difference value is set in parameter No. 8326. At this time, bit 1 (ATSx) of parameter No. 8303 is set to 0, and the power-off request alarm PW0000, “POWER MUST BE OFF” is issued. Turn off the power then turn on the power again.

> **NOTE**
> 1 This parameter is set to the all synchronous axes.
> 2 This parameter is set to the slave axis.
> 3 Parameter setting
> When bit 1 (ATSx) of parameter No. 8303 is set, bit 4 (APZx) of parameter No. 1815 and parameter No. 8326 for the master axis and slave axis are set to 0. When the operator sets parameter No. 8326 (MDI, G10L50), bit 0 (ATEx) of parameter No. 8303 is set to 0.
> 4 This function cannot be used together with the reference position shift function.

- Reference position shift function

If the reference position shift function is used, set the following parameters after the parameter No.8326 is set automatically by the operation procedure of the automatic setting for grid position matching.

Bit4 (SFDx) of No.1008 = 1 : Reference position shift function is enabled. (NOTE 1)
No.1850 = Amount of parameter No.8326: Amount of reference position shift (NOTE 2)
No.8326 = 0 : Reference counters difference between synchronous axes (NOTE 2)

> **NOTE**
> 1 This parameter is set to the all synchronous axes.
> 2 This parameter is set to the slave axis.

1.6.4.3 Reference position establishment

The procedure of reference position establishment is as follows.

1. Select the synchronous operation.
2. When the reference position is shifted, add the shift amount to parameter No.1850 (Amount of grid shift and reference position shift) of the all synchronous axes.
3. If bit 5 (APCx) of parameter No.1815 is set to 1, set 0 to bit4 (APZx) of parameter No.1815.
4. Turn off the power then turn on the power.
5. Perform the manual reference position return.

- Reference position return operation of low-speed type

When bit 4 (SLR) of parameter No. 8305 is set to 1, if G28 is specified for an axis under axis synchronous control for which the reference position is not established, reference position return operation of low-speed type is performed.

1.6.4.4 Balance adjustment

The synchronous axes should be adjusted the balance because multiple motors are cooperatively driven. The procedure of balance adjustment is as follows.

1. Stop the synchronous axes at one side (See Fig. 1.6.4.4 (a) Measuring position 1), and record the absolute coordinate of slave axis. This coordinate value is assumed the coordinate value A.
2. Terminate synchronous status, and select the normal operation.
3. Move the slave axis by manual handle feed so that the actual current value in the servo tuning screen may become near.
4. Straightness of synchronous axes is adjusted if necessary. Adjust the position of slave axis by manual handle feed while confirming the measured straightness and the actual current value in the servo tuning screen. The aim of actual current value in the servo tuning screen is 5%-10% of the rated current value.
5. Select the synchronous operation. The following procedures are performed by synchronous operation.

6. Record the absolute coordinate of slave axis. This coordinate value is assumed the coordinate value B. (See Fig. 1.6.4.4 (b)) Add the value of “coordinate value B - coordinate value A” to parameter No.1850 of slave axis.
7. If bit 5 (APCx) of parameter No.1815 is set to 1, set 0 to bit4 (APZx) of parameter No.1815.
8. Turn off the power then turn on the power.
9. Perform the manual reference position return.
10. Stop the synchronous axes at other side (See Fig. 1.6.4.4 (a) Measuring position 2), and confirm the actual current value in the servo tuning screen. If the value is different, adjust the position of the slave axis by using the pitch error compensation, the straightness compensation, and the external machine coordinate system shift, etc.
11. Move the synchronous axes to the center (See Fig. 1.6.4.4 (a) Measuring position 3), and confirm the actual current value in the servo tuning screen. If the value is different, adjust the position of the slave axis by using the pitch error compensation, the straightness compensation, and the external machine coordinate system shift, etc.

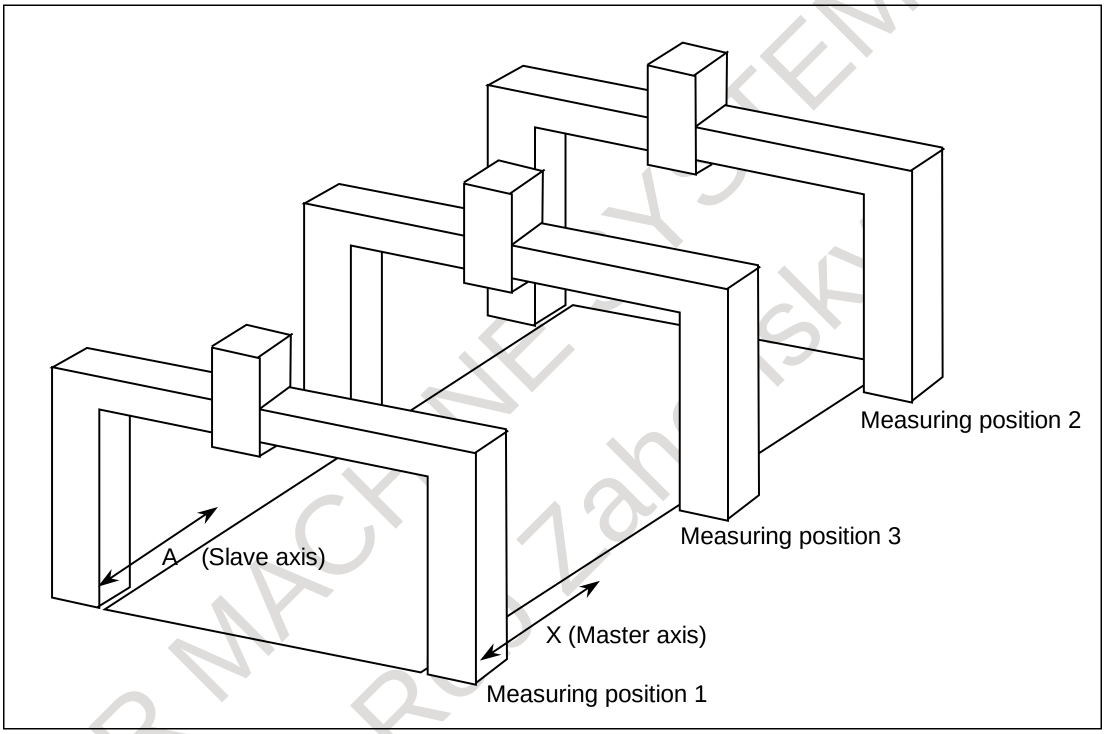


Fig. 1.6.4.4 (a) Measuring position

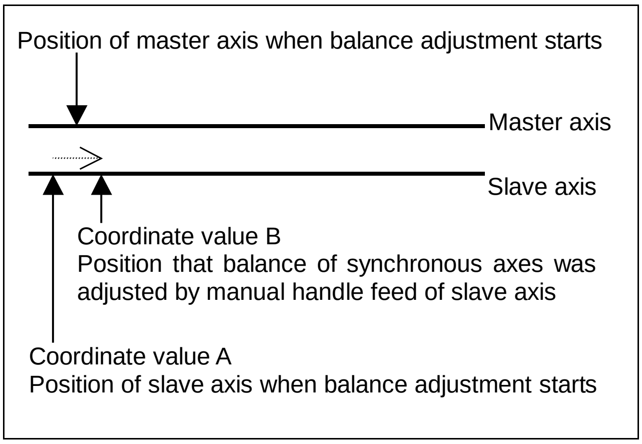

Fig. 1.6.4.4 (b) Position of balance adjustment

- Pitch error compensation and straightness compensation

The pitch error compensation and the straightness compensation are executed independently on the master axis and the slave axis.

- External machine coordinate system shift

By setting bit 7 (SYEx) of parameter No. 8304 to 1 to the slave axis, the slave axis can be shifted by the same amount as specified for the master axis when external machine coordinate system shift is specified by external data input/output for the master axis in synchronous control. When bit 7 (SYEx) of parameter No. 8304 is set to 0, the external machine coordinate system shift is executed independently on the master axis and the slave axis.

1.6.4.5 Maintenance

When motor is exchanged, perform the recovery operation from setting of grid position.
When the parameter is lost by an unexpected situation, restore the backup data of the parameter and perform only reference position establishment again. Thus, the reference position becomes the same position of last time.

1.6.4.6 Reference point setting with mechanical stopper

The procedure of reference position establishment by the reference point setting with mechanical stopper is as follows.

1. If the balance adjustment is necessary, execute the balance adjustment by the procedure 2-4 in Subsection "Balance adjustment". If the balance adjustment is completed, select the synchronous operation.
2. Perform the reference position establishment by the reference point setting with mechanical stopper.

1.6.4.7 Distance coded linear scale interface and linear scale with distance-coded reference marks (serial)

The procedure of reference position establishment by the distance coded linear scale interface or the linear scale with distance-coded reference marks (serial) is as follows.

1. If the balance adjustment is necessary, execute the balance adjustment by the procedure 2-4 in Subsection "Balance adjustment". If the balance adjustment is completed, select the synchronous operation.
2. Perform the reference position establishment by the distance coded linear scale interface or the linear scale with distance-coded reference marks (serial).
3. If the reference position of the master axis and the slave axis shifts, add the shift amount to parameter No.1883 and No.1884. Thus, the reference position of the master axis and slave axis becomes the same position.

NOTE

1 It is also possible to use the master axis or the slave axis in the opposite direction, in the distance coded linear scale interface and the linear scale with distance-coded reference marks (serial).

2 To use the distance coded linear scale interface and the linear scale with distance-coded reference marks (serial), the option "Linear scale I/F with absolute address reference mark" is required.

1.6.5 Synchronization Establishment

Explanation

Upon power-up or after emergency stop cancellation, the machine positions on the master axis and slave axis under axis synchronous control are not always the same. In such a case, the synchronization establishment function adjusts the machine position on the slave to that on the master axis.

- Synchronization establishment method

The method of synchronization establishment differs whether the synchronization error compensation is performed or not. For the synchronization establishment when synchronous error compensation is performed, see Subsection “Synchronization Error Compensation”.

- Synchronization establishment based on machine coordinates

To perform synchronization establishment, enable synchronization establishment based on machine coordinates by setting bit 7 (SOFx) of parameter No. 8303 to 1.
This synchronization establishment is performed by outputting the machine coordinate difference between the master axis and slave axis as command pulses for the slave axis. Thus, the position of the master axis and the slave axis become the same. A maximum allowable compensation value to be used for synchronization establishment is the value in parameter No. 8325. As a maximum allowable compensation value, set a maximum allowable value by which the machine may move abruptly.
If a compensation value is larger than the value set in this parameter, an alarm SV0001, “SYNC ALIGNMENT ERR” is issued, and synchronization establishment is not performed. Moreover, when parameter No. 8325 is set to 0, synchronization establishment is not performed.
The result of comparing the positional difference between the master axis and slave axis with a maximum allowable compensation value for synchronization establishment can be checked using the synchronization establishment enable state output signals SYNOF1 to SYNOF8 <Fn211>.

- First synchronization establishment after power-up

In the first synchronization establishment after power-up, there are a method by the manual reference position return and other methods.

Synchronization establishment based on manual reference position return operation

When manual reference position return operation is performed along axes under axis synchronous control, the machine is placed at the reference position on the master axis and slave axis according to the same sequence as for normal reference position return operation. Therefore, when the grid position of the master axis and the slave axis shifts and the shift amount is not set to parameter No.8326, the master axis and the slave axis stop at each grid position. For details, see Subsection “Setting of grid position”.

Synchronization establishment except manual reference position return

In case of synchronization establishment by absolute position detection or except manual reference position return, when the reference position is established, the synchronization establishment is performed automatically.
When the position is set by the following functions, the synchronization establishment is executed.
- Temporary absolute coordinate setting
- Checking the stored stroke during the time from power–on to the reference position establishment

- Synchronization establishment after emergency stop cancellation, etc.

Synchronization establishment is also performed when servo position control is turned on, for example, at emergency stop cancellation, servo alarm cancellation, or servo-off cancellation .
However, when the controlled axes detach is canceled, the synchronization establishment is not performed until the reference position is established by the manual reference position return etc.

- One-direction synchronization establishment

The synchronization establishment can be performed by setting bit 0 (SSO) of parameter No. 8305 to 1 to move the machine in one direction along the master axis and slave axis. The move direction depends on the reference position setting based on bit 0 (SSAx) of parameter No. 8304. When bit 0 (SSAx) of parameter No. 8304 = 0, for example, the machine coordinate on the master axis or slave axis, whichever larger, is used as the reference point. So, the machine moves in the + direction along the axes.
When bit 1 (SSE) of parameter No. 8305 is set to 1, normal synchronization establishment is performed instead of one-direction synchronization establishment after an emergency stop.

- Axis movement in synchronization establishment

A machine coordinate difference between the master axis and slave axis is output at a time as command pulses, when bit 0 (SJR) of parameter No. 8306 is 0. So, if the compensation value is large, the machine abruptly makes a large movement.
When bit 0 (SJR) of parameter No. 8306 = 1 and one-direction synchronization establishment is invalid (bit 0 (SSO) of parameter No. 8305 = 0), the axis movement of the synchronization establishment in the axis synchronous control can be executed with the feedrate of manual rapid traverse and acceleration/deceleration after interpolation in rapid traverse. In the synchronization establishment using this function, the setting values used for manual rapid traverse and acceleration/deceleration after interpolation in rapid traverse are the parameter values set with slave axis.
The followings are the parameters related to this function.

- No.1424 :Manual rapid traverse rate for each axis (When 0 is set, the rate set in parameter No. 1420)
- No.1620 :Time constant used for linear acceleration/deceleration for each axis
- No.1621 :Time constant T2 used for bell-shaped acc./dec. in rapid traverse for each axis
- No.1401#1 :Positioning (G00) is performed with non-linear or linear interpolation
- No.1603#4 :Acceleration/deceleration used for positioning of linear interpolation type is acceleration fixed or time fixed type

⚠WARNING

1 Do not execute automatic or manual operation while the axes are moving for the synchronization establishment.
2 Do not use other function while the axes are moving for the synchronization establishment.
3 Do not change operation mode while the axes are moving for the synchronization establishment.

NOTE

1 For the axes engaged in the synchronization establishment, the signals below are invalid:
- Rapid traverse override
- External deceleration
- Dry run
- Interlock

2 When the one-direction synchronization establishment function under axis synchronous control is valid (bit 0 (SSO) of parameter No.8305 is set to 1), this function is disabled, regardless of bit 0 (SJR) of parameter No. 8306

3 When the reference position has not been established, the synchronization establishment based on machine coordinates is not executed.

4 When the stored stroke limit check immediately after power-on is enabled (Bit 0 (DOT) of parameter No. 1311 = 1), the synchronization establishment based on machine coordinates is executed as follows.
- Bit 6 (LZR) of parameter No. 1300 = 0 : It is executed after power-on.
- Bit 6 (LZR) of parameter No. 1300 = 1 : It is executed after reference position establishment.

1.6.6 Synchronization Error Check

1.6.6.1 Synchronization error check

A synchronization error amount is monitored at all times. If the error amount exceeds a certain limit, an alarm is issued and the movement along the axis is stopped. For the synchronization error check when synchronous error compensation is performed, see Subsection “Synchronization Error Compensation”.

- Synchronization error check based on machine coordinates

When the value other than 0 is set in parameter No.8314, a synchronization error check based on machine coordinates is enabled.
The machine coordinate on the master axis is compared with that on the slave axis. When the error between the machine coordinates exceeds the value set in parameter No. 8314, the alarm SV0005, “SYNC EXCESS ERR (MCN)” is issued, and the motor is stopped immediately. The alarm SV0005 is output to both the master axis and the slave axis.
This synchronization error check can also be made in the emergency stop, servo-off, and servo alarm state.
If a synchronization error check is made when the mode of operation is switched between synchronous operation and normal operation with an input signal, an error check is made even in normal operation. So, even if the axis synchronous control selection signal (SYNC) or the axis synchronous control manual feed selection signal (SYNCJ) is set to “0” by mistake during synchronous operation, damage to the machine can be prevented.
The machine coordinates on the master axis and slave axis can be checked using the machine coordinate match state output signals SYNMT1 to SYNMT8 <Fn210>.

- Synchronization error check based on a positional deviation value

When the value other than 0 is set in parameter No.8323, a synchronization error check based on a positional deviation value is enabled. The servo positional deviation value of the master axis and slave axis is monitored during axis synchronous control. When the positional deviation value exceeds the limit value set in parameter No. 8323, the alarm DS0001, “SYNC EXCESS ERR (POS DEV)” is issued, and the axis synchronous control positional deviation error alarm signal SYNER<Fn403.0> is output.
The alarm DS0001 is issued to the master axis and slave axis.

When bit 4 (SYA) of parameter No. 8301 is set to 0, the positional deviation limit value of the master axis and slave axis is checked even if a servo-off occurs during axis synchronous control.

1.6.6.2 Methods of alarm recovery by synchronization error check

To recover from an alarm issued as a result of synchronization error check, the method is different by setting parameter of bit 5 (SCAx) of parameter No.8304.

- When the bit 5 (SCAx) of parameter No.8304 is set to 1

When the bit 5 (SCAx) of parameter No.8304 is set to 1 (synchronous operation is used at all times), a synchronization error can be decreased by using the correction mode. When the correction mode is used, synchronization error check can be temporarily disabled, and a movement can be made along the master axis or slave axis to correct a synchronization error.
In the correction mode, synchronization error compensation and error check are not performed, so that an alarm DS0003, "SYNCHRONIZE ADJUST MODE" is issued as a warning.

1. Select the correction mode, and select an axis along which a movement is to be made by manual feed of a master axis . Set bit 2 (ADJx) of parameter No. 8304 of the master axis or slave axis to 1 to select the correction mode. Thus, by manual feed of a master axis , a movement can be made along the axis with this parameter set to 1.
   When this parameter is set to 1, the alarm DS0003 is issued.
2. Reset the synchronization error excessive alarm.
   In this state, synchronization error compensation and error check are not performed. Be careful.
3. Select the manual mode (jog, incremental feed, or handle).
4. While checking the synchronization error amount, make a movement along the master axis or slave axis in the direction that reduces the error.
   If one master axis has multiple slave axes, an attempt to reduce the synchronization error of one slave axis by master axis movement may increase the synchronization error of another slave axis, thus a movement in any direction is disabled. In such a case, by setting bit 4 (MVBx) of parameter No. 8304 to 1, a movement can be made in the direction that increases the synchronization error.
5. When the synchronization error is reduced to within the allowable value for suppressing the alarm, reset the value of bit 2 (ADJx) of parameter No. 8304 to the original value to switch from the correction mode to the normal synchronization mode.
   Synchronization error compensation and synchronization error check are restarted.
6. Reset the correction mode alarm.

- When the bit 5 (SCAx) of parameter No.8304 is set to 0

When the bit 5 (SCAx) of parameter No.8304 is set to 0 (synchronous operation and normal operation are switched by using an input signal), a synchronization error can be decreased by using the normal operation. Use the procedure below for recovery from alarm SV0005.

1. Set signal SYNC/SYNCJ to "0" to select normal operation.
2. Set a value greater than the current value in the parameter No. 8314 for specifying a maximum allowable synchronization error, then reset the alarm.
3. Make a movement along the master axis or slave axis by using the manual handle so that the machine coordinates of the master axis and slave axis becomes almost the same.
4. Return the value of parameter No. 8314 for specifying a maximum allowable synchronization error to the original value.

1.6.7 Axis Synchronous Control Torque Difference Alarm

Explanation

If a movement made along the master axis differs from a movement made along the slave axis during axis synchronous control, the machine can be damaged. To prevent such damage, the torque command difference between the two axes is observed. If the difference exceeds certain limit, a servo alarm SV0420, " SYNC TORQUE EXCESS" can be issued.

[System configuration]

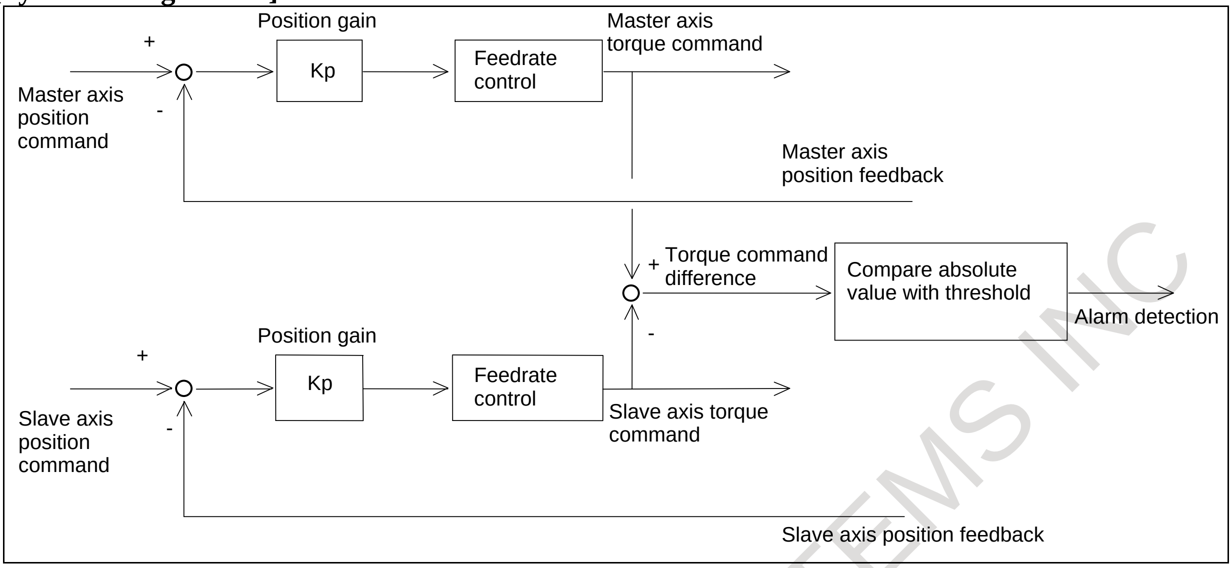

Fig. 1.6.7 (a) System configuration

[Method of use]

Specify the threshold parameter No. 2031 according to the procedure below.

1. Set 14564 in parameter No. 2031.
2. Display the diagnostic screen by pressing the function key then the soft key [DIAGNOSIS].
   Diagnosis data No. 3506 indicates the absolute value of the torque difference between the two axes.
3. Read the absolute torque difference value presented when normal operation is being performed. In the threshold parameter No. 2031, set a value obtained by adding some margin to the read absolute value.
   An absolute torque difference value can be read using SERVO GUIDE Mate.

- Enabling/disabling of alarm detection

Alarm detection is enabled when the time set in parameter No. 8327 has elapsed after the servo ready signal SA <Fn000.6> is set to "1". When the signal for disabling torque difference alarm detection for axis synchronous control NSYNCA <Gn059.7> is set to "1", alarm detection is disabled.

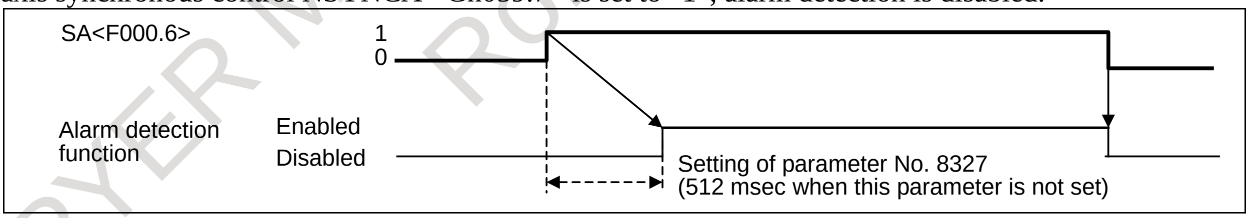

Fig.1 .6.7 (b) Timing chart

When the servo ready signal SA <Fn000.6>is set to "0", torque difference alarm detection is disabled.

> **NOTE**
> The servo axis number combination of the master axis and slave axis synchronized with each other must be such that an odd servo axis number is assigned to the master axis and the next servo axis number is assigned to the slave axis like (1,2) or (3,4).

Parameter

2031	Torque command difference threshold of torque difference alarm

[Input type] Parameter input
[Data type] Word axis
[Valid data range] 0 to 14564

If the absolute value of the torque command difference between two axes exceeds the value set in this parameter, an alarm is issued.
Set the same value for two axes that are placed under axis synchronous control.
The servo axis numbers of the synchronized master axis and slave axis must be assigned so that an odd number is assigned to the master axis and the next axis number is assigned to the slave axis. Examples are (1,2) and (3,4).

Diagnosis data

3506	SYNC TORQUE DIFFERENCE

[Data type] Word axis
[Valid data range] 0 to 32767

The absolute torque difference value between the master axis and the slave axis in the axis synchronous control is displayed.

1.6.8 Synchronization Error Compensation

Explanation

When a synchronization error amount exceeding the zero width set in parameter No. 8333 is detected, compensation pulses for synchronization error reduction are calculated and added onto the command pulses output for the slave axis. This compensation is not performed in servo-off state, servo alarm state, follow-up operation, and correction mode.
Compensation pulses are calculated by multiplying the synchronization error amount between master and slave axes by a compensation gain.

Compensation pulses = synchronization error × (Ci/1024)
Ci: Compensation gain (parameter No. 8334)

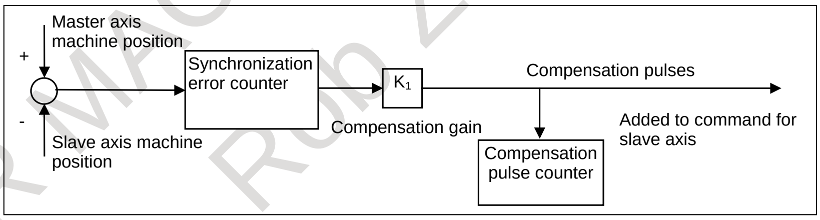

Fig. 1.6.8 (a) Compensation pulses

In case that the following parameters are set, after the reference position establishment had been completed and the first synchronization establishment after power-up was performed, the synchronization error counter is reset and the synchronization error compensation is started.

- Bit3 (CLPx) of parameter No.8304 is set to 1.
- Bit5 (SCAx) of parameter No.8304 is set to 1.
- The value other than 0 is set in parameter No.8334

NOTE
If the positional deviation corresponding to the load were generated like a past analog servo, this function was effective for decreasing the synchronization error. When a current digital servo is applied, positional deviation corresponding to the load are not generated. Therefore, the function need not be applied.

- Synchronization error compensation smooth suppress function

When bit 6 (SMSx) of parameter No. 8304 is set to 1, the synchronization error compensation smooth suppress function is enabled. With this function, another set of parameters for a synchronization error zero width and synchronization error compensation gain (B and Ks in the Fig.1.6.8 (b)) can be set. So, even a small synchronization error can be reduced smoothly as shown below.

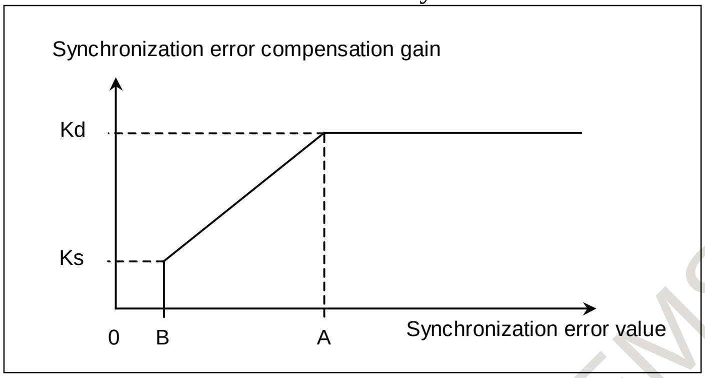

Fig. 1.6.8 (b) Smooth suppress function

A: Synchronization error zero width (parameter No. 8333)
B: Synchronization error zero width 2 (parameter No. 8335) (0 < B < A)
Kd: Synchronization error compensation gain (parameter No. 8334)
Ks: Synchronization error compensation gain 2 (parameter No. 8336) (0 < Ks < Kd)
Er: Synchronization error amount between the current master axis and slave axis
K: Current synchronization error compensation gain for Er

1. When Er < B, compensation is not performed. (K = 0)
2. When B < Er < A
   Compensation is performed with the following gain:
   $$K = Ks + \frac{(Er - B)(Kd - Ks)}{A - B}$$
3. When Er > A, compensation is performed with a gain of K = Kd.

- Synchronization establishment

When synchronization error compensation is performed , synchronization establishment is performed in the same way as synchronization error compensation. This means that the positional difference between the master axis and slave axis is regarded as a synchronization error, and pulses produced by multiplying the positional difference by a synchronization error compensation gain are output for the slave axis. So, the parameter No. 8334 for specifying a synchronization error compensation gain must be set before synchronization establishment can be performed.
If the parameter No. 8333 for specifying a synchronization error compensation zero width is set, no further synchronization establishment is performed after the positional difference between the master axis and slave axis becomes the zero width or below.
For “first synchronization establishment after power-up” and “synchronization establishment after emergency stop cancellation, etc.”, see Subsection “Synchronization Establishment”.

- Synchronization error check

When synchronization error compensation is performed, the synchronization error check is performed the check considering a positional deviation. The actual machine position shift considering a servo positional deviation as well is checked. Depending on the value of a synchronization error, one of two alarms is issued: an alarm (DS alarm) for deceleration stop, and an alarm (SV alarm) for turning off the servo system immediately. This check is enabled when a value other than 0 is set in the parameters Nos. 8331 and 8332 for specifying a maximum allowable synchronization error. When using this method of checking a synchronization error amount, disable "Synchronization error check based on machine coordinates" in Subsection by setting parameter No. 8314 to 0.

Synchronization error excessive alarm 1 (DS0002)

When a synchronization error exceeding the value set in parameter No. 8331 is detected, synchronization error excessive alarm 1 is issued. When synchronization error excessive alarm 1 is issued, the motor gradually stops. At this time, synchronization error compensation remains enabled, so that the synchronization error is reduced by compensation. Accordingly, as the synchronization error amount becomes smaller than the maximum allowable value, the alarm can be reset. If the alarm cannot be reset, the synchronization error needs to be manually corrected by selecting the correction mode in Subsection.

Synchronization error excessive alarm 2 (SV0002)

When a synchronization error exceeding the value set in parameter No. 8332 is detected, synchronization error excessive alarm 2 is issued. Before synchronization establishment is performed at power-up time, a value obtained by multiplying the value set in parameter No. 8332 by the coefficient set in parameter No. 8330 is used for judgment. When synchronization error excessive alarm 2 is issued, the motor immediately stops as in the case of other servo alarms. Accordingly, the positional difference between the master axis and slave axis remains uncorrected, so that the alarm cannot be reset usually. In this case, the synchronization error needs to be manually corrected by selecting the correction mode in Subsection.

1.6.9 Combination with other functions

Explanation

Notes on setting parameters for each axis

Parameters to be set for each axis can be divided into the following four types when they are set for an axis under axis synchronous control:

(1) Parameter which must be set the same value to the master and slave axes
(2) Parameter which needs to be set only to the master axis (data to the slave axis is not used.)
(3) Parameter which may be set different values to the master and slave axes
(4) Parameter which needs to be set only to the slave axis (data to the master axis is not used.)

Parameters are listed for each type below. If a parameter is not listed in any table below, assume that the parameter is of type (1) and set the same value to the master and slave axes.

> ⚠ **CAUTION**
> 1 If different values are set in a parameter of type (1) for the master and slave axes, these axes may not operate as axes under axis synchronous control.
> 2 When a signal is used to switch between synchronous and normal operation, in a parameter of type (2), also set a value for each of the master and slave axes.

(1) Parameters which must be set to the same value for the master and slave axes

Parameter number	Description
12#7	Releasing the assignment of the controlled axis for each axis
1005#0	Whether reference position return has been performed
1005#1	Enabling setting the reference position without dogs
1005#4	Enabling the external deceleration signal for the positive direction in cutting feed for each axis
1005#5	Enabling the external deceleration signal for the negative direction in cutting feed for each axis
1005#6	Turning off MCC signal of the servo amplifier in axis detach
1005#7	Enabling the controlled axis detach signal for each axis
1006#0,#1	Setting a rotary axis
1006#3	Specifying move commands for each axis using diameter programming
1006#5	Direction of manual reference position return
1007#1	Using the same method as for manual reference position return to perform automatic reference position return (G28)
1007#3	The rotary axis command in an absolute command is the absolute position of the specified value for the end point coordinates and the sign of the specified value for the direction of rotation.

Parameter number	Description
1007#4	Method of setting the reference position without dogs
1008#0	Enabling rotary axis roll-over
1008#1	Not making a short cut in an absolute command
1008#2	Rounding relative coordinates with the travel distance of one rotation.
1240	Coordinate value of the reference position in the machine coordinate system
1241	Coordinate value of the second reference position in the machine coordinate system
1242	Coordinate value of the third reference position in the machine coordinate system
1243	Coordinate value of the fourth reference position in the machine coordinate system
1260	Amount of a shift per one rotation of a rotary axis
1310#0,#1	Enabling stored stroke check 2, 3
1320	Coordinate value I of stored stroke check 1 in the positive direction on each axis
1321	Coordinate value I of stored stroke check 1 in the negative direction on each axis
1322	Coordinate value of stored stroke check 2 in the positive direction on each axis
1323	Coordinate value of stored stroke check 2 in the negative direction on each axis
1324	Coordinate value of stored stroke check 3 in the positive direction on each axis
1325	Coordinate value of stored stroke check 3 in the negative direction on each axis
1326	Coordinate value II of stored stroke check 1 in the positive direction on each axis
1327	Coordinate value II of stored stroke check 1 in the negative direction on each axis
1420	Rapid traverse rate for each axis
1424	Manual rapid traverse rate for each axis (bit 0 of (SJR) parameter No.8306 = 1)
1610#0,#1	Acceleration type of cutting feed or dry run during cutting feed
1610#4	Acceleration type of jog feed
1620	Time constant used for linear acceleration/deceleration for each axis
1621	Time constant T2 used for bell-shaped acceleration/deceleration in rapid traverse for each axis
1622	Time constant of acceleration/deceleration in cutting feed for each axis
1623	FL rate of acceleration/deceleration in cutting feed for each axis
1624	Time constant of acceleration/deceleration in jog feed for each axis.
1625	FL rate of exponential acceleration/deceleration in jog feed for each axis
1626	Time constant of acceleration/deceleration during thread cutting cycle
1627	FL rate of acceleration/deceleration during thread cutting cycle
1671	Maximum permissible acceleration of acceleration/deceleration before interpolation for linear rapid traverse for each axis or permissible reference acceleration of optimum torque acceleration/deceleration
1763	FL rate acceleration/deceleration after cutting feed interpolation for each axis in the acceleration/deceleration before interpolation mode
1769	Time constant of acceleration/deceleration after cutting feed interpolation in the acceleration/deceleration before interpolation mode
1815#2	Using a linear scale with reference marks
1818#0,#1,#3, 1819#2	Related to the linear scale with absolute addressing reference marks/linear scale with an absolute addressing origin
1819#0	Follow-up in the servo off state
1819#1	Reference position establishment state at the time of a servo alarm
1821	Reference counter capacity
1825	Servo loop gain
1881	Group number when an unexpected disturbance torque is detected
1882	Intervals of mark 2 of a linear scale with absolute address reference marks.
1885	Maximum allowable value for total travel during torque control
1886	Positional deviation when torque control is canceled
2028	Limit speed for enabling position gain switching
2031	Torque-command-difference threshold for a torque-difference alarm
2060	Torque limit
2068	Feed forward coefficient
2092	Advanced preview feed forward coefficient
2144	Position feed forward coefficient for cutting

Parameter number	Description
2178	Position gain for rapid traverse
2179	Reference counter (denominator)
3605#0	Using bidirectional pitch error compensation
3605#1	Using interpolation type pitch error compensation
3605#2	Using interpolated straightness compensation
3624	Interval between pitch error compensation positions for each axis
3625	Travel distance per revolution in pitch error compensation of rotary axis type
7310	Order of axes to move to with dry run after a program restart (in the case of not switching between synchronous operation and normal operation with signals)
8304#0	Setting the reference position for the one direction synchronization compensation function
11242	Time constant of acceleration/deceleration after interpolation of acceleration/deceleration before interpolation in rapid traverse
11248	Time constant 1 of acceleration/deceleration after interpolation in Smart overlap for each axis
11249	Time constant 2 of acceleration/deceleration after interpolation in Smart overlap for each axis
11814	The second servo loop gain for each axis
13622	Time constant for acceleration/deceleration after interpolation when AI contour control is used (precision level 1)
13623	Time constant for acceleration/deceleration after interpolation when AI contour control is used (precision level 10)

(2) Parameters which need to be set only for the master axis

Parameter number	Description
1005#3	Operation to be performed during a manual reference position return when a reference position is established
1012#0	Method of setting the reference position without dogs
1250	Coordinates of the reference position when automatic coordinate system setting is performed
1408#0	The rotary axis feedrate control method is to convert the rotation speed on the circumference of a virtual circle.
1421	F0 rate of rapid traverse override for each axis
1423	Feedrate in manual continuous feed (jog feed) for each axis
1424	Manual rapid traverse rate for each axis (bit 0 of (SJR) parameter No.8306 = 1)
1425	FL rate of the reference position return for each axis
1427	External deceleration rate of rapid traverse for each axis
1428	Reference position return speed for each axis
1430	Maximum cutting feedrate for each axis
1432	Maximum cutting feedrate for each axis in the mode of acceleration/deceleration before interpolation
1465	Radius of the virtual circle in a rotary axis virtual circle velocity command
1660	Maximum permissible acceleration of acceleration/deceleration before interpolation for each axis
1735	Permissible acceleration for each axis in the deceleration function with the acceleration in circular interpolation
1737	Permissible acceleration for each axis in the deceleration function with the acceleration in AI contour control
1783	Permissible speed difference in speed determination with the speed difference at a corner
1788	Permissible acceleration change amount in speed determination with the acceleration change on each axis
1789	Permissible acceleration change amount in speed determination with the acceleration change on each axis (linear interpolation)
3455#0	When the decimal point is omitted, mm, inch, sec units (calculator-type decimal point input)
5022	Distance (L) from reference tool tip position to the reference measurement surface
5401#0	Enabling scaling
5421	Scaling magnification for each axis
5440	Positioning direction and overrun distance in single directional positioning
7181	First retract distance at reference point setting with mechanical stopper

Parameter number	Description
7182	Second retract distance at reference point setting with mechanical stopper
7183	First retract speed at reference point setting with mechanical stopper
7184	Second retract speed at reference point setting with mechanical stopper
7185	Retract speed at reference point setting with mechanical stopper (common to the first and second retractions)
7741	Retract amount
8410	Allowable feedrate difference used for feedrate determination, based on a corner feedrate difference
19541 to 19544	Optimum torque acceleration/deceleration (speed)
19545 to 19568	Optimum torque acceleration/deceleration (acceleration)
19667	Control point shift vector

(3) Parameters which may be set to different values for the master and slave axes

Parameter number	Description
1020	Program axis name for each axis
1023	Number of the servo axis for each axis
18XX 2XXX	Parameters related to servo (other than those listed in (1), (2), or (4))
3115#0	Not displaying the current position
3115#1	Not displaying the absolute and relative coordinates
3115#3	Not adding axis moving to actual cutting feedrate display
3131	Subscript of axis name of synchronous controlled axis and tandem control axis
3620	Number of the pitch error compensation position for the reference position for each axis
3621	Number of the pitch error compensation position at extremely negative position for each axis
3622	Number of the pitch error compensation position at extremely positive position for each axis
3623	Magnification for pitch error compensation for each axis
3626	Number of the both-direction pitch error compensation position at extremely negative position (for movement in the negative direction)
3627	Pitch error compensation at reference position when a movement to the reference position is made from the direction opposite to the direction of reference position return
5861 to 5864	Inclination compensation : Compensation point number for each axis
5871 to 5874	Inclination compensation : Compensation at compensation point number for each axis
7186	Torque limit value in reference point setting with mechanical stopper (for 0% to 39%)
7187	Torque limit value in reference point setting with mechanical stopper (for 0 to 100%)
7310	Order of axes to move to with dry run after a program restart (in the case of switching between synchronous operation and normal operation with signals (SYNC1 to SYNC8<Gn138> and SYNCJ1 to SYNCJ8<Gn140>))
24096	Connector number for the first separate detector interface unit
24097	Connector number for the second separate detector interface unit
24098	Connector number for the third separate detector interface unit
24099	Connector number for the fourth separate detector interface unit
24100	Connector number for the fifth separate detector interface unit
24101	Connector number for the sixth separate detector interface unit
24102	Connector number for the seventh separate detector interface unit
24103	Connector number for the eighth separate detector interface unit

(4) Parameters which need to be set only for the slave axis

Parameter number	Description
1817#6	Performing tandem control for the axis
8303#0	Enabling automatic setting of grid positioning
8303#1	Setting the start of automatic setting of grid positioning
8303#2	Adding data for the slave axis for actual cutting feedrate display

Parameter number	Description
8303#7	Using the synchronization compensation function based on machine coordinates for the axis synchronous control function
8304#3	Enabling synchronization error compensation
8304#5	Always performing axis synchronous control
8304#6	Enabling the synchronization error smooth suppress function
8304#7	Enabling external machine coordinate system shift
8311	Axis number of master axis in axis synchronous control
8312	Enabling/disabling mirror image in axis synchronous control
8314	Maximum allowable error in synchronization error check based on machine coordinates
8323	Limit in positional deviation check in axis synchronous control
8325	Maximum compensation value in synchronization establishment based on machine coordinates
8326	Difference between master axis and slave axis reference counters
8327	Torque difference alarm detection timer
8331	Maximum allowable synchronization error for synchronization error excessive alarm 1
8332	Maximum allowable synchronization error for synchronization error excessive alarm 2
8333	Synchronization error zero width for each axis
8334	Synchronization error compensation gain for each axis
8335	Synchronization error zero width 2 for each axis
8336	Synchronization error compensation gain 2 for each axis

- How signals for each axis are handled

Some signals for each axis are input or output to both the master and slave axes and others are input or output to only the master axis. The following table lists the type of each signal.

- Input signals

Address	Bit	Symbol	Signal name	Master and slave axes	Master axis only
Gn100	0	+Jx	Feed axis direction select signals		O
Gn102	0	-Jx	Feed axis direction select signals		O
Gn104	0	+EXLx	Stored stroke limit 1 switching signals in axis direction	O	
Gn105	0	-EXLx	Stored stroke limit 1 switching signals in axis direction	O	
Gn106	0	MIx	Mirror image signals		O
Gn108	0	MLKx	Machine lock signal in each axis		O
Gn110	0	+LMx	Stroke limit external setting signals	O	
Gn112	0	-LMx	Stroke limit external setting signals	O	
Gn114	0	*+Lx	Over travel signals		O
Gn116	0	*-Lx	Over travel signals		O
Gn118	0	*+Edx	External deceleration signals		O
Gn120	0	*-Edx	External deceleration signals		O
Gn124	0	DTCHx	Controlled axes detach signals	O *1	
Gn126	0	*SVFx	Servo-off signals	O *1	
Gn130	0	*ITx	Interlock signals in each axis		O
Gn138	0	SYNCx	Signals for selecting the axis for axis synchronous control	O	
Gn140	0	SYNCJx	Signals for selecting the manual feed axis for axis synchronous control	O	
Gn192	0	IGVRYx	VRDY off alarm ignore signal in each axis	O *1	
X009	0	*DECx	Deceleration signals for reference position return		O

- Output signals

Address	Bit	Symbol	Signal name	Master and slave axes	Master axis only
Fn094	0	ZPx	Reference position return completion signals	O	
Fn096	0	ZP2x	2nd reference position return completion signals	O	

Address	Bit	Symbol	Signal name	Master and slave axes	Master axis only
Fn098	0	ZP3x	3rd reference position return completion signals	O	
Fn100	0	ZP4x	4th reference position return completion signals	O	
Fn102	0	MVx	Axis moving signals	O	
Fn104	0	INPx	In-position signals	O	
Fn106	0	MVDx	Axis moving direction signals	O	
Fn108	0	MMIx	Mirror image check signals	O	
Fn110	0	MDTCHx	Controlled axis detach status signals	O	
Fn120	0	ZRFx	Reference position establishment signals	O	

NOTE

1. Turn the signal marked with *1 on or off simultaneously for the master and slave axes in the synchronization mode.
2. In the above table, the address only for the 1st axis is listed. For the addresses of the 2nd and subsequent axes, see Appendix, "INTERFACE BETWEEN CNC AND PMC" in this manual.

- Axis selection in actual cutting feedrate display

The slave axis of the axis synchronous control does not execute the calculation of the actual cutting feedrate display during the synchronous operation.
By setting bit 2 (SAFx) of parameter No. 8303 to 1 for a slave axis, the slave axis can be included in an actual cutting feedrate display calculation during synchronous operation.

- Program restart

If an operation mode is not switched between synchronous operation and normal operation with signals (SYNC1 to SYNC8<Gn138> and SYNCJ1 to SYNCJ8<Gn140>) (to be in the synchronous state at all times), set the same data for the master axis and slave axis in parameter No.7310.
If an operation mode is switched between synchronous operation and normal operation with signals, the same data need not be set for the master axis and slave axis, but data (1 to the number of controlled axes) must be set for both the master axis and slave axis.

- Flexible synchronization/Superimposed control

The slave axis of flexible synchronization control or the slave axis of superimposed control can be set to the master axis of axis synchronous control by setting bit 0 (FSS) of parameter No. 8307 to 1. Then, it is necessary to execute beginning and the end of flexible synchronization control or superimposed control while axis synchronous control. The example of machining program is shown as follows.

Example of the machining program)

```
:
:
M50;      : Beginning of axis synchronous control
M210;     : Turning Superimposed ahead signals on (In case of superimposed control)
M16;      : Beginning of flexible synchronization control or superimposed control
:
:
M17;      : End of flexible synchronization control or superimposed control
M211;     : Turning Superimposed ahead signals off (In case of superimposed control)
M51;      : End of axis synchronous control
```

- Reference position return of axis synchronous control

It is necessary to perform reference position return before flexible synchronization control or superimposed control is begun.

- Synchronization Establishment of axis synchronous control

It is necessary to perform synchronization Establishment before flexible synchronization control or superimposed control is begun.

- When using slave axis of superimposed control as master axis of axis synchronous control

It is necessary to set superimposed ahead signals OVLN <Gn531.4> to "1" during superimposed control is begun.

Note

1) Please turn on the mode of axis synchronous control before turning on the mode of flexible synchronization control or superimposed control when the slave axis of flexible synchronization control or the slave axis of superimposed control is used as the master axis of axis synchronous control.
2) It is not possible to instruct the workpiece coordinate system setting command (G92) and local coordinate system setting command (G52) while the master axis of axis synchronous control is mode of flexible synchronization control or superimposed control.
3) When bit 0 (FSS) of parameter No. 8307 is set to 1, the display of slave axis of axis synchronous control is updated with the amount of travel after acceleration/deceleration and, therefore, the display may appear not to be in synchronization.
4) When the slave axis of flexible synchronization control or the slave axis of superimposed control is used as the master axis of axis synchronous control, slave axis of axis synchronous control checks the state of stopping state by positioning deviation limit in movement.
5) The output of the in-position signals INP1 to INP8 <Fn104> and the axis moving signals MV1 to MV8 <Fn102> follows each specification of flexible synchronization control or superimposed control.
6) At the correction mode inside (bit 2 (ADJ) of parameter No. 8304 = 1), the movement instruction cannot be done to the master axis of flexible synchronization control or the master axis of superimposed control.
7) Use an M code preventing buffering as the M code for turning the superimposed ahead signals on or off.

limitation

When bit 0 (FSS) of parameter No. 8307 is set to 1, the following parameters become invalid for the master axis and the slave axis of axis synchronous control.

Parameter number	Description
12255	Maximum servo motor speed
12256	Maximum servo motor acceleration rate

When bit 0 (FSS) of parameter No. 8307 is set to 1, please set the same value to master axis and slave axis of axis synchronous control about the following parameters.

Parameter number	Description
1013	Parameter of increment system
18xx	Parameter related to servo
2xxx	

Flexible synchronization control / superimposed control

When this function is effective(bit 0 (FSS) of parameter No. 8307 = 1), slave axis of axis synchronous control cannot be made the axis of flexible synchronization control or the axis of superimposed control.

General purpose retract

If general purpose retract is used in flexible synchronization control, general purpose retract can be set only to the master axis. General purpose retract can not be used in superimposed control. Because of this, general purpose retract cannot be used in the master axis of axis synchronous control while using this function.

Tandem control

When this function is effective(bit 0 (FSS) of parameter No. 8307 = 1), tandem control cannot be used with a related axis of axis synchronous control.

1.6.10 Automatic Slave Axis Parameter Setting

Explanation

Axis synchronous control involves parameters which must be set to the same values for the master axis and slave axis. (See the parameter list previously described in "Parameters which must be set to the same value for the master and slave axes"). If bit 4 (SYPx) of parameter No. 8303 is 1, setting values for these parameters for the master axis causes the same values to be set to the parameters for the slave axis.
This function is enabled when parameters are set with the following methods:

- MDI key input
- Parameter file input
- Input with a program command
  (1) Programmable data input (parameter)
  (2) Stored stroke check 2 on (parameters Nos. 1322, 1323)
  (3) Cutting condition selection function (parameters Nos. 1769, 13622, and 13623)
- Input with a signal
  Stroke limit external setting (parameters Nos. 1320, 1321)
- Input with the FOCAS function and the window function

- Prohibition of writing for the slave axis

If bit 4 (SYPx) of parameter No. 8303 is 1, it is prohibited to set values to the parameters for the slave axis previously described in "Parameters which must be set to the same value for the master and slave axes". Even if values are set, they will be invalid.
If any parameter other than the BIT parameter is set with the methods below, either an alarm or a warning will be output.
MDI key input
A "WRITE PROTECT" warning is issued.
Programmable data input, stored stroke check 2 on
The alarm PS5379, " WRITE PROTECTED TO SLAVE AXIS" is issued.
Input with the FOCAS function and the window function
The return value is 7 (write protect error).

1.6.11 Torque Difference of Axis Synchronous

Explanation

By acquiring and comparing information with this system variable at multiple points, can be detected balanced synchronous position in master axis and slave axis.
This function can read information of toque difference of master axis and slave axis in Axis synchronous control with system variable (#180801 to #180850).

Information of torque difference of master axis and slave axis

System variable number	System variable name	Attribute	Description
#180801 to #180850	[#_SYNTD[n]]	R	Torque difference of master axis and slave axis in Axis synchronous control Range：-32768 to 32767 Unit：Unit in which the set value corresponding to Nominal current limit of Amplifier [Ap] is 6554. (Note) Subscript n represents a compensation number (1 to 50).

R is attribute of a variable and indicate read-only.

Parameter (No.8311) determines the combination of master axis and slave axis, and torque difference of master axis and slave axis is output to system variable of slave axis during synchronous operation and normal operation.
The output torque difference is the value obtained by subtracting torque value of slave axis from the torque value of master axis.
System value is read “0” in master axis. The case of axis more than the number of axis in a path is read “0” as with master axis.
When value of parameter (No.8311) is incorrect, data of system variable cannot be read and becomes alarm (PS5580) “CANNOT GET SYSTEM VARIABLE”.

Application example

When setting Pitch error compensation of Axis synchronous control using this function. Acquiring torque difference master axis and slave axis from system variable, detecting the position where torque difference of master axis and slave axis is the minimum, it is possible to set more optimal Pitch error compensation.

Example)

Setting procedure of Pitch error compensation value in slave axis with this system variable (#180801 to #180850) is as follows.

In using this function, enable synchronization establishment of Axis synchronous control in NC parameter.

1 Set synchronization establishment of maser axis using Laser measuring instrument.
2 In synchronous operation, move master axis to the first observation point.
3 After cancel synchronous operation, move slave axis only while acquiring torque difference by system variable (#180801 to #180850), find position where torque difference of master axis and slave axis is the smallest
4 After save coordinate difference of master axis and slave axis to work variable, set synchronous operation.
5 Operate “3” to “4” in all master axis of observation point.
6 Calculate pitch data amount of movement of slave axis and set to Pitch error compensation of slave axis.

Limitation

- Real time custom macro

System variables (#180801 to #180850) can’t use in real time custom macro. Value is read “0” in Real time custom macro.

- Flexible path axis assignment

System variable (#180801 to #180850) corresponds to Flexible path axis assignment if axis configuration is changed while maintaining parameter (No.8311) and axis configuration.
Correspondence example of Flexible path axis assignment is as follows.

Basic configuration

Axis name	Axis number	Parameter(No.8311)	Description
Xm	1	0	Master axis of Xs-axis
Xs	2	1	Slave axis of Xm-axis

(Example1 : Add Y-axis after Xm-axis to basic configuration.)

When setting value of Parameter No.8311) and axis configuration are in the same states by Flexible path axis assignment, system variable is read torque difference of master axis and slave axis.

Xm	1	0	Master axis of Xs-axis
Y	- →2	0	Add axis
Xs	2→3	1	Slave axis of Xm-axis (Axis number and Parameter(No.8311) is match)

(Example2 : Add Y-axis before Xm-axis to basic configuration.)

When setting value of Parameter No.8311) and axis configuration are in different states by Flexible path axis assignment, system variable is read “0”.

Y	- →1	0	Add axis
Xm	1→2	0	Master axis of Xs-axis (Axis number of master axis changes)
Xs	2→3	1	Slave axis of Xm-axis (Axis number and Parameter(No.8311) don’t match)

in the case where axis of synchronization relationship moves to another path, system variable is read “0”.

- Background operation

System variables (#180801 to #180850) can’t use in Background operation. Value is “0” in Background operation.

1.6.12 Signal

Signals for selecting the axis for axis synchronous control
SYNC1 to SYNC8<Gn138>

[Classification] Input signal

[Function] Axis synchronous control is performed during memory or DNC or MDI operation.
This signal is provided for each controlled axis. The number at the end of the signal name represents the number of the controlled axis.

SYNC<u>x</u>

x : 1 .....The first axis becomes the slave axis for axis synchronous control.
2 .....The second axis becomes the slave axis for axis synchronous control.
3 .....The third axis becomes the slave axis for axis synchronous control.
: :

[Operation] When this signal is set to “1”, the control unit operates as described below:

- During memory or DNC or MDI operation, the control unit issues the move command specified for the master axis to both the master axis and slave axis of axis synchronous control.

The master axis is specified with a parameter.

See the following timing charts about the sequence that changes the synchronous operation and the normal operation.

Signals for selecting the manual feed axis for axis synchronous control SYNCJ1 to SYNCJ8<Gn140>

[Classification] Input signal

[Function] Axis synchronous control is performed in jog, handle, or incremental feed mode, or manual reference position return. This signal is provided for each controlled axis. The number at the end of the signal name represents the number of the controlled axis.

SYNCJx

x : 1 .....The first axis becomes the slave axis for axis synchronous control.
2 .....The second axis becomes the slave axis for axis synchronous control.
3 .....The third axis becomes the slave axis for axis synchronous control.
: :

[Operation] When this signal is set to “1”, the control unit operates as described below:

- In jog, handle, or incremental feed mode, the control unit issues the move command specified for the master axis to both the master axis and slave axis of axis synchronous control.

The master axis is specified with a parameter.

See the following timing charts about the sequence that changes the synchronous operation and the normal operation.

Signal for disabling torque difference alarm detection for axis synchronous control NSYNCA<Gn059.7>

[Classification] Input signal

[Function] When the torque difference alarm function for axis synchronous control is used, this signal can be used to disable alarm detection.

[Operation] When this signal is set to “1”, torque difference alarm detection for axis synchronous control is disabled.

Machine coordinate match state output signals SYNMT1 to SYNMT8<Fn210>

[Classification] Output signal

[Function] When master/slave axis pairs are set for axis synchronous control, this signal notifies an external unit that the machine coordinates of the master axis is adjusted to those of the slave axis for each pair, regardless of the synchronous operation on or off state and servo ready state.

[Operation] When this signal is set to “1”, the machine coordinates of the master axis is adjusted to those of the slave axis. The signal corresponding to the pair of a master axis and the slave axis with the lowest axis number is output first and the machine coordinate status of up to eight pairs can be checked.

Synchronization compensation enable state output signals SYNOF1 to SYNOF8<Fn211>

[Classification] Output signal

[Function] When master/slave axis pairs are set for axis synchronous control, this signal notifies an external unit that the machine coordinates difference between the master and slave axes is less than or equal to the maximum compensation for synchronization for each pair, regardless of the synchronous operation on or off state.

[Operation] When this signal is set to “1”, the machine coordinates difference between the master and slave axes is less than or equal to the maximum compensation for synchronization. When the servo ready signal SA<Fn000.6> is set to "0", this signal is set to "0". The signal corresponding to the pair of a master axis and the slave axis with the lowest axis number is output first and whether to enable synchronization compensation can be checked for up to eight pairs. This signal is not output for each axis.

Signal for indicating a positional deviation error alarm for axis synchronous control SYNER<Fn403.0>

[Classification] Output signal

[Function] When the positional deviation check function is used for axis synchronous control, this signal notifies an external unit that the alarm is issued.

[Operation] When axis synchronous control is applied, the servo positional deviation of the master axis and that of the slave axis are monitored. If the limit set in parameter No. 8323 is exceeded, alarm DS0001 is issued and the signal for indicating a positional deviation error alarm for axis synchronous control <Fn403.0> is set to “1”.
This signal is set to “0” when the alarm is cleared by a reset. This signal is not output for each signal.

Axis synchronous control status signals SYNO1 to SYNO8<Fn532>

[Classification] Output signal

[Function] These signals notify that axis synchronous control is in progress.

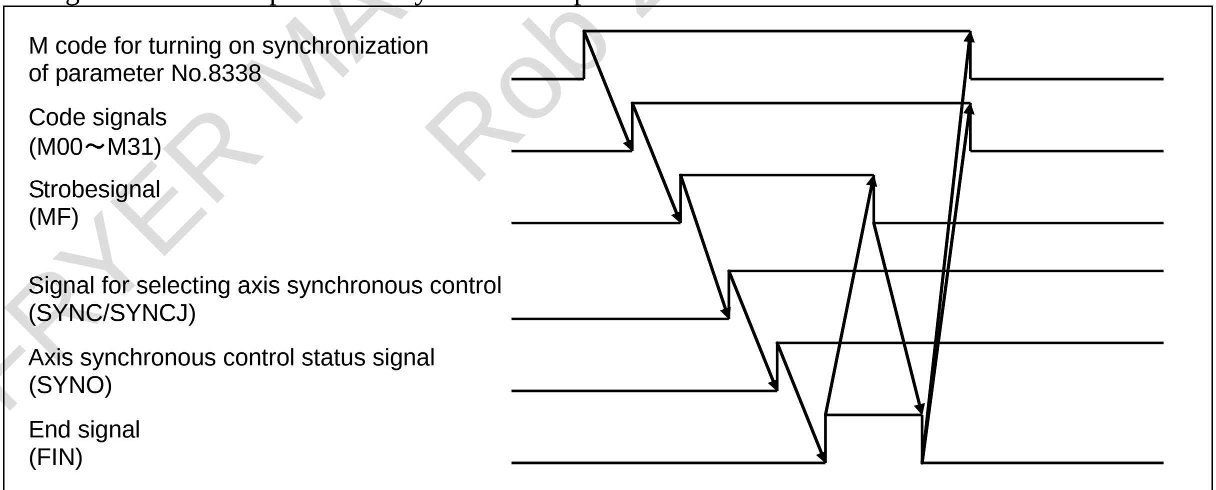
[Operation] These signals become “1” in the following case:
- When the corresponding axis is in axis synchronous control.

They become “0” in the following case:
- When the corresponding axis is not in the axis synchronous control.

> **NOTE**
> Whether axis synchronous control is in progress does not necessarily correspond to individual selection signals/parameters (axis synchronous control selection signal, axis synchronous control manual feed selection signal, bit 5 (SCAx) of parameter No. 8304). This signal is 0 in the emergency stop, servo alarm, serve off, and axis detach states.

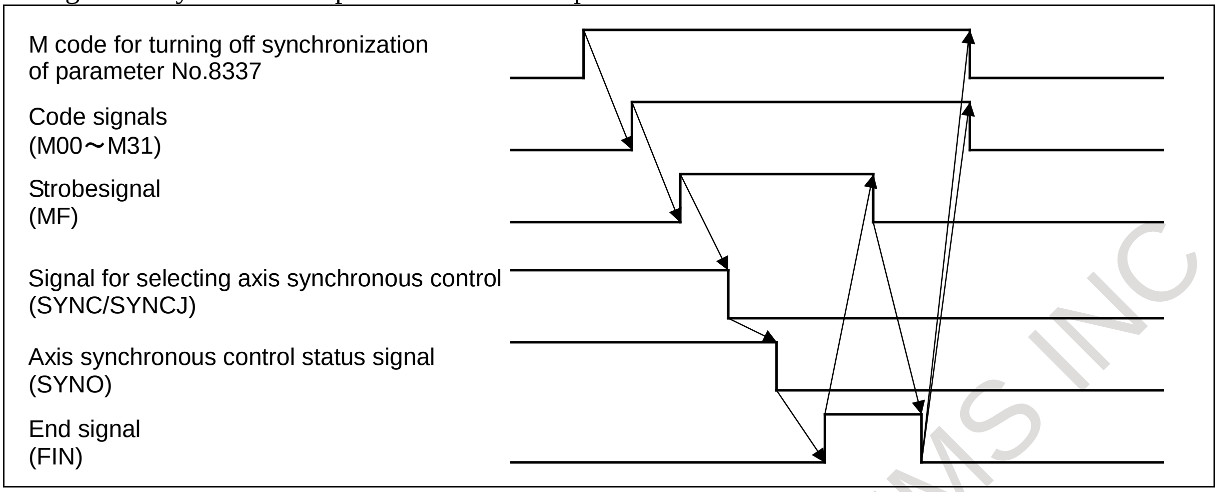
- Timing charts

Change from normal operation to synchronous operation



Supplement : Synchronization compensation enable state output signal SYNOF and machine coordinate match state output signals SYNMT can be check before signal SYNC/SYNCJ is set to “1”.

Change from synchronous operation to normal operation



Signal address

	#7	#6	#5	#4	#3	#2	#1	#0
Gn059	NSYNCA							
Gn138	SYNC8	SYNC7	SYNC6	SYNC5	SYNC4	SYNC3	SYNC2	SYNC1
Gn140	SYNCJ8	SYNCJ7	SYNCJ6	SYNCJ5	SYNCJ4	SYNCJ3	SYNCJ2	SYNCJ1

	#7	#6	#5	#4	#3	#2	#1	#0
Fn210	SYNMT8	SYNMT7	SYNMT6	SYNMT5	SYNMT4	SYNMT3	SYNMT2	SYNMT1
Fn211	SYNOF8	SYNOF7	SYNOF6	SYNOF5	SYNOF4	SYNOF3	SYNOF2	SYNOF1
Fn403								SYNER
Fn532	SYNO8	SYNO7	SYNO6	SYNO5	SYNO4	SYNO3	SYNO2	SYNO1

1.6.13 Parameter

	#7	#6	#5	#4	#3	#2	#1	#0
1000								EEA

[Input type] Parameter input
[Data type] Bit

#0 EEA An extended axis name and extended spindle name are:
0: Invalid
1: Valid

	#7	#6	#5	#4	#3	#2	#1	#0
1008				SFDx				

[Input type] Parameter input
[Data type] Bit axis

NOTE
When at least one of these parameters is set, the power must be turned off before operation is continued.

#4 SFDx In reference position return based on the grid method, the reference position shift function is:
0: Disabled
1: Enabled

1025	Program axis name 2 for each axis
1026	Program axis name 3 for each axis

[Input type] Parameter input
[Data type] Byte axis
[Valid data range] 48 to 57, 65 to 90
When axis name extension is enabled (when bit 0 (EEA) of parameter No. 1000 is set to 1), the length of an axis name can be extended to a maximum of three characters by setting axis name 2 and axis name 3.

NOTE
If program axis name 2 is not set, program axis name 3 is invalid.

	#7	#6	#5	#4	#3	#2	#1	#0
1401							LRP	

[Input type] Parameter input
[Data type] Bit path

#1 LRP Positioning (G00)
0: Positioning is performed with non-linear type positioning so that the tool moves along each axis independently at rapid traverse.
1: Positioning is performed with linear interpolation so that the tool moves in a straight line.
When using 3-dimensional coordinate system conversion, set this parameter to 1.

1420	Rapid traverse rate for each axis

[Input type] Parameter input
[Data type] Real axis
[Unit of data] mm/min, inch/min, deg/min (machine unit)
[Min. unit of data] Depend on the increment system of the applied axis
[Valid data range] Refer to the standard parameter setting table (C)
(When the increment system is IS-B, 0.0 to +999000.0)
Set the rapid traverse rate when the rapid traverse override is 100% for each axis.

1424	Manual rapid traverse rate for each axis

[Input type] Parameter input
[Data type] Real axis
[Unit of data] mm/min, inch/min, deg/min (machine unit)
[Min. unit of data] Depend on the increment system of the applied axis
[Valid data range] Refer to the standard parameter setting table (C)
(When the increment system is IS-B, 0.0 to +999000.0)
Set the rate of manual rapid traverse when the rapid traverse override is 100% for each axis.

NOTE
1. If 0 is set, the rate set in parameter No. 1420 (rapid traverse rate for each axis) is assumed.
2. When manual rapid traverse is selected (bit 0 (RPD) of parameter No. 1401 is set to 1), manual feed is performed at the feedrate set in this parameter, regardless of the setting of bit 4 (JRV) of parameter No. 1402.

	#7	#6	#5	#4	#3	#2	#1	#0
1603				**PRT**				

[Input type] Parameter input
[Data type] Bit path

#4 PRT For positioning of linear interpolation type:
0: Acceleration/deceleration of acceleration fixed type is used.
1: Acceleration/deceleration of time fixed type is used.

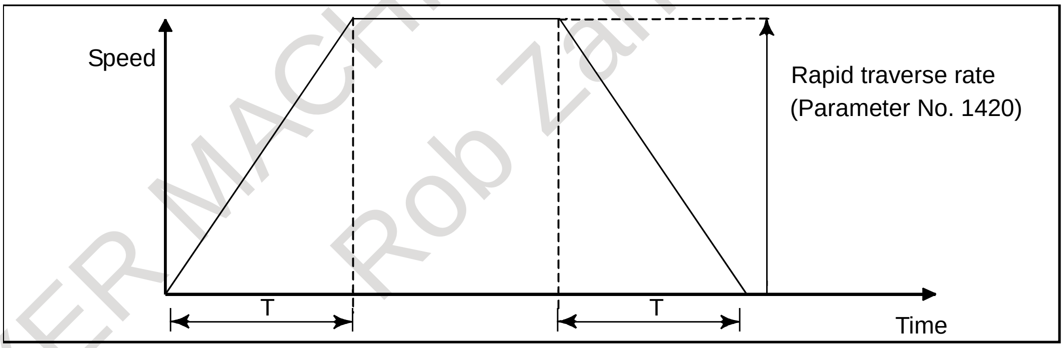
1620	**Time constant T or T1 used for linear acceleration/deceleration or bell-shaped acceleration/deceleration in rapid traverse for each axis**

[Input type] Parameter input
[Data type] Word axis
[Unit of data] msec
[Valid data range] 0 to 4000

Specify a time constant used for acceleration/deceleration in rapid traverse.

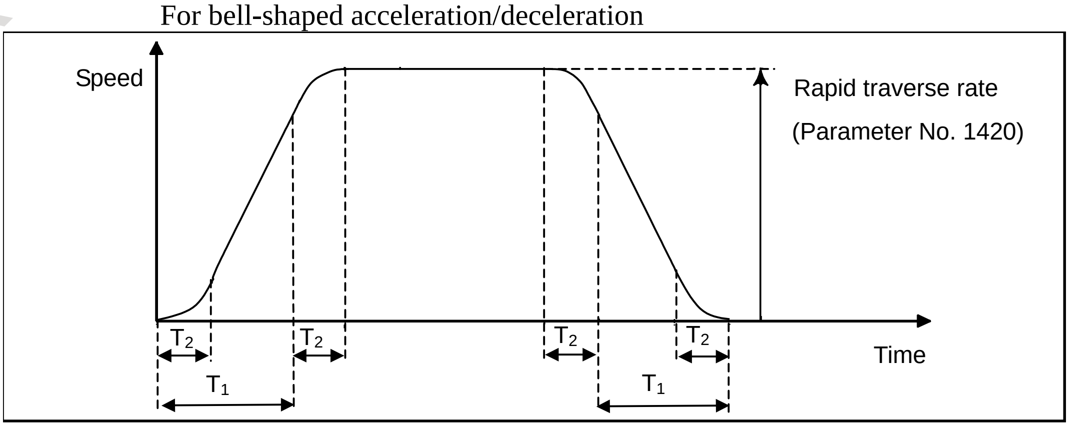
[Example]

For linear acceleration/deceleration



T : Setting of parameter No. 1620

For bell-shaped acceleration/deceleration



T_1 : Setting of parameter No. 1620
T_2 : Setting of parameter No. 1621

(However, $T_1 \geq T_2$ must be satisfied.)

Total acceleration (deceleration) time : $T_1 + T_2$
Time for linear portion : $T_1 - T_2$
Time for curve portion : $T_2 \times 2$

1621	Time constant T_2 used for bell-shaped acceleration/deceleration in rapid traverse for each axis

[Input type] Parameter input
[Data type] Word axis
[Unit of data] msec
[Valid data range] 0 to 512

Specify time constant T_2 used for bell-shaped acceleration/ deceleration in rapid traverse for each axis.

1844	Distance to the first grid point when the reference position shift amount in the reference position shift function is 0 or when a reference position return is made by grid shift

NOTE
When this parameter is set, the power must be turned off before operation is continued.

[Input type] Parameter input
[Data type] 2-word axis
[Unit of data] Detection unit
[Valid data range] -999999999 to 999999999

(1) When the reference position shift function is enabled (when bit 4 (SFDx) of parameter No. 1008 is set to 1)
Set the distance (detection unit) to the first grid point from a point at which the deceleration dog is released when the reference position shift (parameter No. 1850) is set to 0.

(2) When a reference position return is made by grid shift with a setting not to use reference position setting without dogs (when bit 4 (SFDx) of parameter No. 1008 is set to 0, and bit 1 (DLZx) of parameter No. 1005 is set to 0)
Set the distance to the first grid point from a point at which the deceleration dog is released. (Detection unit)

(3) When a reference position return is made by grid shift with a setting to use reference position setting without dogs (when bit 4 (SFDx) of parameter No. 1008 is set to 0, and bit 1 (DLZx) of parameter No. 1005 is set to 1)
Set the distance from the start position for reference position setting without dogs to the first grid point. (Detection unit)

NOTE
1 When the reference position shift function is enabled (when bit 4 (SFDx) of parameter No. 1008 is set to 1)
When bit 4 (SFDx) of parameter No. 1008 is set to 1, the distance from a point at which the deceleration dog is released to the first grid point (parameter No. 1844) is set to 0, and reference position shift (parameter No. 1850) is set to 0, a manual reference position return allows this parameter to be set automatically. Do not change an automatically set value.

NOTE

2 When a reference position return is made by grid shift with a setting not to use reference position setting without dogs (when bit 4 (SFDx) of parameter No. 1008 is set to 0, and bit 1 (DLZx) of parameter No. 1005 is set to 0)
When a manual reference position return using deceleration dogs is made, this parameter is set automatically.

3 When a reference position return is made by grid shift with a setting to use reference position setting without dogs (when bit 4 (SFDx) of parameter No. 1008 is set to 0, and bit 1 (DLZx) of parameter No. 1005 is set to 1)
When a reference position setting without dogs is made, this parameter is set automatically.

1850	Grid shift and reference position shift for each axis

NOTE

When this parameter is set, the power must be turned off before operation is continued.

[Input type] Parameter input
[Data type] 2-word axis
[Unit of data] Detection unit
[Valid data range] -99999999 to 99999999

To shift the reference position, the grid can be shifted by the amount set in this parameter. Up to the maximum value counted by the reference counter can be specified as the grid shift.
In case of bit 4 (SFDx) of parameter No. 1008 is 0: Grid shift
In case of bit 4 (SFDx) of parameter No. 1008 is 1: Reference point shift

NOTE

For setting the reference position without dogs, only the grid shift function can be used.
(The reference position shift function cannot be used.)

2031	Torque command difference threshold of torque difference alarm

[Input type] Parameter input
[Data type] Word axis
[Valid data range] 0 to 14564

If the absolute value of the torque command difference between two axes exceeds the value set in this parameter, an alarm is issued.
Set the same value for two axes that are placed under axis synchronous control.
The servo axis numbers of the synchronized master axis and slave axis must be assigned so that an odd number is assigned to the master axis and the next axis number is assigned to the slave axis. Examples are (1,2) and (3,4).

3115							NDAx	NDPx

[Input type] Parameter input
[Data type] Bit axis

#0 NDPx The current position is:
0: Displayed.
1: Not displayed.

#1 NDAx The current position and the amount of the movement to be made in absolute and relative coordinates are:
0: Displayed.
1: Not displayed.

3130	Axis display order for current position display screens

[Input type] Parameter input
[Data type] Byte axis
[Valid data range] 0 to 32

Set the order in which axes are displayed on current position display screens (absolute, relative overall, and handle interrupt screens).

3131	Subscript of axis name

[Input type] Parameter input
[Data type] Byte axis
[Valid data range] 0 to 9, 65 to 90

In order to distinguish axes under synchronization control and tandem control, specify a subscript for each axis name.

Setting value	Meaning
0	Each axis is set as an axis other than a synchronization control axis and tandem control axis.
1 to 9	A set value is used as a subscript.
65 to 90	A set letter (ASCII code) is used as a subscript.

[Example] When the axis name is X, a subscript is added as indicated below.

Setting value	Axis name displayed on a screen such as the position display screen
0	X
1	X1
77	XM
83	XS

If a multi-path system is used, no extended axis name is used within a path, and no subscript is set for the axis names, then the path number is automatically used as the subscript for the axis names. To disable the display of axis name subscripts, set a blank (32) of ASCII code in the parameter for specifying an axis name subscript.

> **NOTE**
> If even one axis in a path uses an extended axis name when bit 2 (EAS) of parameter No. 11308 is set to 0, subscripts cannot be used for axis names in the path.

	#7	#6	#5	#4	#3	#2	#1	#0
8301				SYA				

[Input type] Parameter input
[Data type] Bit path

#4 SYA In the servo-off state in axis synchronous control, the limit of the difference between the positioning deviation of the master axis and that of the slave axis is:
0: Checked.
1: Not checked.

	#7	#6	#5	#4	#3	#2	#1	#0
8302	SMA							

[Input type] Parameter input
[Data type] Bit path

> **NOTE**
> When this parameter is set, the power must be turned off before operation is continued.

#7 SMA When an absolute position detector is attached, and bit 4 (APZx) of parameter No. 1815 for an axis in synchronous operation is set to 0, APZx of the pairing axis in synchronous operation is:
0: Not set to 0.
1: Set to 0.

	#7	#6	#5	#4	#3	#2	#1	#0
8303	SOFx			SYPx		SAFx	ATSx	ATEx

[Input type] Parameter input
[Data type] Bit axis

> **NOTE**
> When at least one of these parameters is set, the power must be turned off before operation is continued.

#0 ATEx In axis synchronous control, automatic setting for grid positioning is:
0: Disabled
1: Enabled
The setting for the slave axis is available.

#1 ATSx In axis synchronous control, automatic setting for grid positioning is:
0: Not started
1: Started
The setting for the slave axis is available.

> **NOTE**
> When starting automatic setting for grid positioning, set ATS to 1. Upon the completion of setting, ATS is automatically set to 0.

#2 SAFx In axis synchronous control, a movement along a slave axis is:
0: Not added to actual feedrate display.
1: Added to actual feedrate display.
The setting for the slave axis is available.

#4 SYPx In axis synchronous control, some parameters must be set to the same value for the master and slave axes. When a value is set in such a parameter for the master axis:
0: The same value is not automatically set in the parameter for the slave axis.
1: The same value is automatically set in the parameter for the slave axis.

> **NOTE**
> 1 The parameters that are automatically set are found previously described in "Parameters which must be set to the same value for the master and slave axes".
> 2 Set this parameter to the same value for both the master and slave axes.

#7 SOFx In axis synchronous control, the synchronization establishment function based on machine coordinates is:
0: Disabled.
1: Enabled.
The setting for the slave axis is available.When using synchronization error compensation, set this parameter to 0.

	#7	#6	#5	#4	#3	#2	#1	#0
8304	SYEx	SMSx	SCAx	MVBx	CLPx	ADJx		SSAx

[Input type] Parameter input
[Data type] Bit axis

#0 SSAx When the one-direction synchronization establishment function under axis synchronous control is used:
0: The axis with a larger machine coordinate is used as the reference.
1: The axis with a smaller machine coordinate is used as the reference.

> **NOTE**
> 1 When this parameter is set, the power must be turned off before operation is continued.
> 2 Set this parameter to the same value for both the master and slave axes.

#2 ADJx In axis synchronous control, this parameter specifies an axis along which a movement is made in the correction mode.
0: A movement is not made in the correction mode along the axis.
1: A movement is made in the correction mode along the axis.
When this parameter is set to 1, the correction mode is set.
Along an axis with this parameter set to 1, a movement is made by a move command for the master axis.
Set this parameter for one of the master and slave axes.
When there are multiple slave axes for one master axis, set this parameter to 1 for an axis with which a synchronization error excessive alarm is issued for recovery. If an alarm is issued with multiple axes, modify this parameter after recovery of one axis to recover another axis.

#3 CLPx In axis feed synchronous control, synchronization error compensation is:
0: Disabled.
1: Enabled.
The setting for the slave axis is available.

#4 MVBx In the correction mode, a move command in a direction that increases a synchronization error is:
0: Ignored.
1: Valid.
When there are multiple slave axes for one master axis, an attempt to reduce the synchronous error of a slave axis by a movement along the master axis can increase the synchronization error of another slave axis. If this parameter is set to 0 in such a case, a movement can be made in neither direction along the master axis. In this case, set bit 2 (ADJx) of parameter No. 8304 to make a movement along a slave axis to perform a corrective operation.

#5 SCAx In axis synchronous control:
0: Synchronous operation is performed when the axis synchronous control manual feed selection signal SYNCJ <Gn140> or the axis synchronous control selection signal SYNC <Gn138> for slave axes is set to 1.
1: Synchronous operation is performed at all times.
The setting for the slave axis is available.

#6 SMSx The synchronization error smooth suppress function is:
0: Disabled.
1: Enabled.
The setting for the slave axis is available.

#7 SYEx When external machine coordinate system shift is specified by external data input/output for the master axis in synchronous control, the slave axis is:
0: Not shifted.
1: Shifted by the same amount as specified for the master axis.
The setting for the slave axis is available.
This function is disabled during normal operation.

	#7	#6	#5	#4	#3	#2	#1	#0
8305				SLR		SRF	SSE	SSO

[Input type] Parameter input
[Data type] Bit path

#0 SSO One-direction synchronization establishment function under axis synchronous control in axis synchronous control is:
0: Disabled.
1: Enabled.

#1 SSE After emergency stop, one-direction synchronization establishment function under axis synchronous control in axis synchronous control is:
0: Enabled.
1: Disabled.

#2 SRF In axis synchronous control, G28, G30, and G53:
0: Make the same movement along the slave axis as a movement along the master axis.
1: Make movements along the slave axis and master axis independently to specified positions.

#4 SLR When G28 is specified for an axis under axis synchronous control for which the reference position is not established:
0: Alarm PS0213, “ILLEGAL COMMAND IN SYNCHRO-MODE” is issued.

1: Reference position return operation of low-speed type is performed.

	#7	#6	#5	#4	#3	#2	#1	#0
8306								SJR

[Input type] Parameter input
[Data type] Bit path

#0 SJR In synchronization establishment,
0: A machine coordinate difference between the master axis and slave axis is output at a time as command pulses (axis movements are performed without acceleration/deceleration).
1: Axis movements are executed with the feedrate of manual rapid traverse and the acceleration/deceleration after interpolation in rapid traverse.

> **NOTE**
> When the one-direction synchronization establishment function under axis synchronous control is used (bit 0 (SSO) of parameter No.8305 is set to 1), the machine coordinate difference for synchronization establishment is output as command pulses at a time, regardless of the setting of this parameter. Acceleration/deceleration is not applied to the axis movements in the one-direction synchronization establishment.

	#7	#6	#5	#4	#3	#2	#1	#0
8307								FSS

[Input type] Parameter input
[Data type] Bit type

> **NOTE**
> When this parameter is set, the power must be turned off before operation is continued.

#0 FSS The slave axis of flexible synchronization control or the slave axis of superimposed control is:
0: Not used as the master axis of axis synchronous control.
1: Used as the master axis of axis synchronous control.

8311	Axis number of master axis in axis synchronous control

> **NOTE**
> When this parameter is set, the power must be turned off before operation is continued.

[Input type] Parameter input
[Data type] Byte axis
[Valid data range] 0 to Number of controlled axes

Select a master axis in axis synchronous control. In the parameter for the slave axis, set the axis number of the master axis.

Example 1)
When one set of axis synchronous control is used:

When the master axis is the first axis (X-axis), and the slave axis is the third axis (Z-axis), set parameter No. 8311 as follows:

Parameter No.8311	X (first axis)	= 0
Parameter No.8311	Y (second axis)	= 0
Parameter No.8311	Z (third axis)	= 1
Parameter No.8311	A (fourth axis)	= 0

Example 2)

When three sets of axis synchronous control is used:
When the master axes are the first axis, second axis, and third axis, and the slave axes are the sixth axis, fifth axis, and fourth axis, set parameter No. 8311 as follows:

Parameter No.8311	X (first axis)	= 0
Parameter No.8311	Y (second axis)	= 0
Parameter No.8311	Z (third axis)	= 0
Parameter No.8311	A (fourth axis)	= 3
Parameter No.8311	B (fifth axis)	= 2
Parameter No.8311	C (sixth axis)	= 1

Example 3)

When the multiple slave axes of axis synchronous control are used in each path:
When the master axes are the first axis of the each path, and the slave axes are the fourth axis and fifth axis of the each path, set parameter No. 8311 as follows:

	Path-1		Path-2	
Parameter No.8311	X (first axis)	= 0	X (first axis)	= 0
Parameter No.8311	Y (second axis)	= 0	Y (second axis)	= 0
Parameter No.8311	Z (third axis)	= 0	Z (third axis)	= 0
Parameter No.8311	A (fourth axis)	= 1	A (fourth axis)	= 1
Parameter No.8311	B (fifth axis)	= 1	B (fifth axis)	= 1

8312	Enabling/disabling slave axis mirror image

[Input type] Parameter input
[Data type] Word axis
[Valid data range] 0, 100

When the slave axis mirror image is enabled on axis synchronous control, set this parameter to 100. If 0 is set in this parameter, the slave axis mirror image is disabled. The setting for the slave axis is available.

Example)

For reverse synchronization with the master axis being the third axis and the slave axis being the fourth axis, set parameter No. 8312 as follows:

Parameter No.8312	X (first axis)	= 0
Parameter No.8312	Y (second axis)	= 0
Parameter No.8312	Z (third axis)	= 0
Parameter No.8312	A (fourth axis)	= 100

NOTE

In synchronous operation with mirror image applied, synchronization error compensation, synchronization establishment, synchronization error checking, and correction mode cannot be used.

8314	Maximum allowable error in synchronization error check based on machine coordinates

[Input type] Parameter input
[Data type] Real axis
[Unit of data] mm, inch, deg (machine unit)

[Min. unit of data] Depend on the increment system of the applied axis
[Valid data range] 0 or positive 9 digit of minimum unit of data (refer to the standard parameter setting table (B))
(When the increment system is IS-B, 0.0 to +999999.999)
This parameter sets a maximum allowable error in a synchronization error check based on machine coordinates. When the error between the master and slave axes in machine coordinates exceeds the value set in this parameter, the machine stops with the servo alarm SV0005, "SYNC EXCESS ERROR (MCN)".
The setting for the slave axis is available.

> **NOTE**
> Set 0 in this parameter when a synchronization error check is not made.

8323	Limit in positional deviation check in axis synchronous control

[Input type] Parameter input
[Data type] 2-word axis
[Unit of data] Detection unit
[Valid data range] 0 to 999999999
This parameter sets the maximum allowable difference between the master axis and slave axis position deviations. When the absolute value of a positional deviation difference exceeds the value set in this parameter in axis synchronous control, the alarm DS0001, "SYNC EXCESS ERROR (POS DEV)" is issued.
The setting for the slave axis is available. If 0 is specified in this parameter, no position deviation difference check is made.

8325	Maximum compensation value in synchronization establishment based on machine coordinates

[Input type] Parameter input
[Data type] Real axis
[Unit of data] mm, inch, deg (machine unit)
[Min. unit of data] Depend on the increment system of the applied axis
[Valid data range] 0 or positive 9 digit of minimum unit of data (refer to the standard parameter setting table (B))
(When the increment system is IS-B, 0.0 to +999999.999)
This parameter sets the maximum compensation value for synchronization. When a compensation value exceeding the value set in this parameter is detected, the servo alarm SV0001, "SYNC ALIGNMENT ERROR" is issued, and the synchronization establishment is not performed.
The setting for the slave axis is available. To enable this parameter, set the bit 7 (SOF) of parameter No.8303 to 1. When 0 is set in this parameter, synchronization establishment is not performed.

8326	Difference between master axis and slave axis reference counters

[Input type] Parameter input
[Data type] 2-word axis
[Unit of data] Detection unit
[Valid data range] 0 to 999999999

The difference between the master axis reference counter and slave axis reference counter (master axis and slave axis grid shift) is automatically set when automatic setting for grid positioning is performed. Then, the difference is transferred together with an ordinary grid shift value to the servo system when the power is turned on. This parameter is set with a slave axis.

8327	Torque difference alarm detection timer

[Input type] Parameter input
[Data type] 2-word axis
[Unit of data] msec
[Valid data range] 0 to 4000

This parameter sets a time from the servo preparation completion signal, SA <Fn000.6>, being set to “1” until torque difference alarm detection is started in axis synchronous control.
When 0 is set in this parameter, the specification of 512 msec is assumed.
The setting for the slave axis is available.

8330	Multiplier for a maximum allowable synchronization error immediately after power-up

NOTE
When this parameter is set, the power must be turned off before operation is continued.

[Input type] Parameter input
[Data type] Word path
[Valid data range] 1 to 100

Until synchronization establishment is completed immediately after power-up, synchronization error excessive alarm 2 is checked using the maximum allowable error (parameter No. 8332) multiplied by the value set in this parameter.
If the result produced by multiplying the value of parameter No. 8332 by the value of this parameter exceeds 32767, the value is clamped to 32767.

8331	Maximum allowable synchronization error for synchronization error excessive alarm 1

[Input type] Parameter input
[Data type] 2-word axis
[Unit of data] Detection unit
[Valid data range] 1 to 32767

This parameter sets a maximum allowable synchronization error for synchronization error excessive alarm 1.
The setting for the slave axis is available.

8332	Maximum allowable synchronization error for synchronization error excessive alarm 2

NOTE
When this parameter is set, the power must be turned off before operation is continued.

[Input type] Parameter input
[Data type] 2-word axis
[Unit of data] Detection unit
[Valid data range] 1 to 32767

This parameter sets a maximum allowable synchronization error for synchronization error excessive alarm 2.
The setting for the slave axis is available.

8333	Synchronization error zero width for each axis

[Input type] Parameter input
[Data type] 2-word axis
[Unit of data] Detection unit
[Valid data range] 1 to 32767

When a synchronization error below the value set in this parameter is detected, synchronization error compensation is not performed.
The setting for the slave axis is available.

8334	Synchronization error compensation gain for each axis

[Input type] Parameter input
[Data type] Word axis
[Valid data range] 1 to 1024

This parameter sets a synchronization error compensation gain.
Compensation pulses found by the following expression are output for the slave axis:

Compensation pulses = Synchronization error × (Ci/1024)

Ci: Compensation gain

The setting for the slave axis is available.

8335	Synchronization error zero width 2 for each axis

[Input type] Parameter input
[Data type] 2-word axis
[Unit of data] Detection unit
[Valid data range] 0 to 32767

This parameter sets synchronization error zero width 2 for synchronization error smooth suppression.
The setting for the slave axis is available.

> **NOTE**
> Set a value less than the value set in parameter No. 8333.

8336	Synchronization error compensation gain 2 for each axis

[Input type] Parameter input
[Data type] Word axis
[Valid data range] 0 to 1024

This parameter sets synchronization error compensation gain 2 for synchronization error smooth suppression.
The setting for the slave axis is available.

> **NOTE**
> Set a value less than the value set in parameter No. 8334.

8337	M code for turning off synchronization in axis synchronous control
8338	M code for turning on synchronization in axis synchronous control

[Input type] Parameter input
[Data type] 2-word path
[Valid data range] 1 to 999999999

This parameter specifies an M code for switching between synchronous operation and normal operation.
The M code set in this parameter is not buffered.

> ⚠ **CAUTION**
> To switch between synchronous operation and normal operation, specify the M code set in parameter No. 8337 or 8338.

1.6.14 Diagnosis Data

The synchronization error and compensation are displayed on the diagnostic screen.

3500	Synchronization error for each axis

[Unit of data] Detection unit
[Description] The difference between the positions of the master and slave axes (synchronization error) is displayed.
It is displayed for the axis number of the slave axis.

3501	Synchronization error compensation for each axis

[Unit of data] Detection unit
[Description] The total number of compensation pulses output to the slave axis (synchronization error compensation) is displayed. This number is displayed for the axis number of the slave axis.

1.6.15 Alarm and Message

Number	Message	Description
PS0213	ILLEGAL COMMAND IN SYNCHRO-MODE	In axis synchronous control, the following errors occurred during the synchronous operation. 1) The program issued the move command to the slave axis. 2) The manual operation (jog feed or incremental feed) is performed to the slave axis. 3) The program issued the automatic reference position return command without specifying the manual reference position return after the power was turned on.
PS5379	WRITE PROTECTED TO SLAVE AXIS	It is not possible to directly set the parameters for the slave axis under axis synchronous control.
PS5580	CANNOT GET SYSTEM VARIABLE	System variable (#180801 to #180850) cannot be read when parameter No.8311 is incorrect value. Confirm the setting of parameter No.8311.
DS0001	SYNC EXCESS ERROR (POS DEV)	In axis synchronous control, the difference in the amount of positional deviation between the master and slave axes exceeded the parameter No. 8323 setting value. This alarm occurs for the master or slave axis.

Number	Message	Description
DS0002	SYNC EXCESS ERROR ALARM 1	In axis synchronous control, the difference in the amount of synchronization between the master and slave axes exceeded the parameter No. 8331 setting value. This alarm occurs only for the slave axis.
DS0003	SYNCHRONIZE ADJUST MODE	The system is in the synchronize adjust mode.
SV0001	SYNC ALIGNMENT ERROR	In axis synchronous control, the amount of compensation for synchronization exceeded the parameter No. 8325 setting value. This alarm occurs for the master or slave axis.
SV0002	SYNC EXCESS ERROR ALARM 2	In axis synchronous control, the amount of synchronization error exceeded the parameter No. 8332 setting value. When the synchronization is not completed after power-up, the determination is made by the parameter value No. 8332 multiplied by the parameter No. 8330 multiplier. This alarm occurs only for a slave axis only.
SV0005	SYNC EXCESS ERROR (MCN)	In axis synchronous control, for synchronization, the difference value of the machine coordinate between a master and slave axes exceeded the parameter No. 8314 setting value. This alarm occurs for a master or slave axis.
SV0420	SYNC TORQUE EXCESS	In axis synchronous control, for synchronization, the difference value of torque between a master and slave axes exceeded the parameter No. 2031 setting value. This alarm occurs for a master axis.

1.6.16 Caution

Caution

⚠ **CAUTION**

1. When making a synchronization error check, ensure that the reference position on the master axis and the reference position on the slave axis must be at the same position.
2. In manual reference position return operation, the same operation is performed along the master axis and slave axis until a deceleration operation starts. After a deceleration operation starts, grid detection is performed for the master axis and slave axis independently of each other.
3. Pitch error compensation and backlash compensation are performed for the master axis and slave axis independently of each other.

Note

NOTE

1 During axis synchronous control, a movement based on the reference position return check (G27), automatic reference position return (G28), 2nd/3rd/4th reference position return (G30), or machine coordinate system selection (G53) command is made as described below according to the setting of bit 2 (SRF) of parameter No. 8305.
   <1> When SRF = 0, the same movement as made along the master axis is made along the slave axis.
   <2> When SRF = 1, a movement is made along the slave axis to the specified position independently of a movement made along the master axis to the specified position.

2 A command not involving a movement along an axis such as the workpiece coordinate system setting command (G92) and local coordinate system setting command (G52) is set with the master axis according to the master axis programming.

3 During synchronous operation, the axis-by-axis signals such as for external deceleration, interlock, and machine lock are enabled for the master axis only. During synchronous operation, those signals for the slave axis are ignored.

4 When switching the synchronization state in a program, be sure to specify M codes (parameters Nos. 8337 and 8338) for turning synchronization on and off. By switching between the input signals SYNC <Gn138> and SYNCJ <Gn140> from the PMC with the M codes, the synchronization state can be switched in the program.

5 When controlled axis detach is performed, the synchronization state is cancelled. When performing controlled axis detach, perform detach for the master axis and slave axis at the same time.

6 If a programmed command is specified for the slave axis during synchronous operation, an alarm PS0213, “ILLEGAL COMMAND IN SYN-CHRO-MODE” is issued.
   A programmed command can be specified for the slave axis when switching between synchronous operation and normal operation is set to 0 (with bit 5 (SCAx) of parameter No. 8304 set to 0) and the signal SYNC/SYNCJ select normal operation.

7 Axis synchronous control and PMC axis control cannot be used at the same time.

8 When bit 4 (SYPx) of parameter No. 8303 is changed from 0 to 1 to use automatic slave axis parameter setting, those slave axis parameters that have already been set are not automatically set. Automatic slave axis parameter setting is enabled after parameter No. 8311 and bit 4 (SYPx) of parameter No. 8303 are set.

9 If inputting a parameter file after enabling automatic slave axis parameter setting, set parameter No. 8311 and bit 4 (SYPx) of parameter No. 8303 for both the CNC and the parameter file before inputting it.

10 If the manual handle interrupt and the tool retract and recover is performed on the axes of axis synchronous control, set “1” to signal SYNCJ.

> **NOTE**
> 11 When the machine lock is effective, the coordinate of master axis is as follows.
> - The absolute and relative coordinate are updated.
> - The machine coordinate is not updated.
>
> And, the absolute, relative and machine coordinate of slave axis are not updated.

Manual name	Item name
OPERATOR'S MANUAL (B-64694EN)	Axis synchronous control

1.7 TANDEM CONTROL

Overview

If a single motor cannot produce sufficient torque to move a large table, for example, this function allows two motors to be used. By means of this function, two motors can be used to perform movement along a single axis.

Positioning is carried out only for the master axis. The slave axis is used only to produce a torque. By means of this function, double the amount of torque can be obtained.

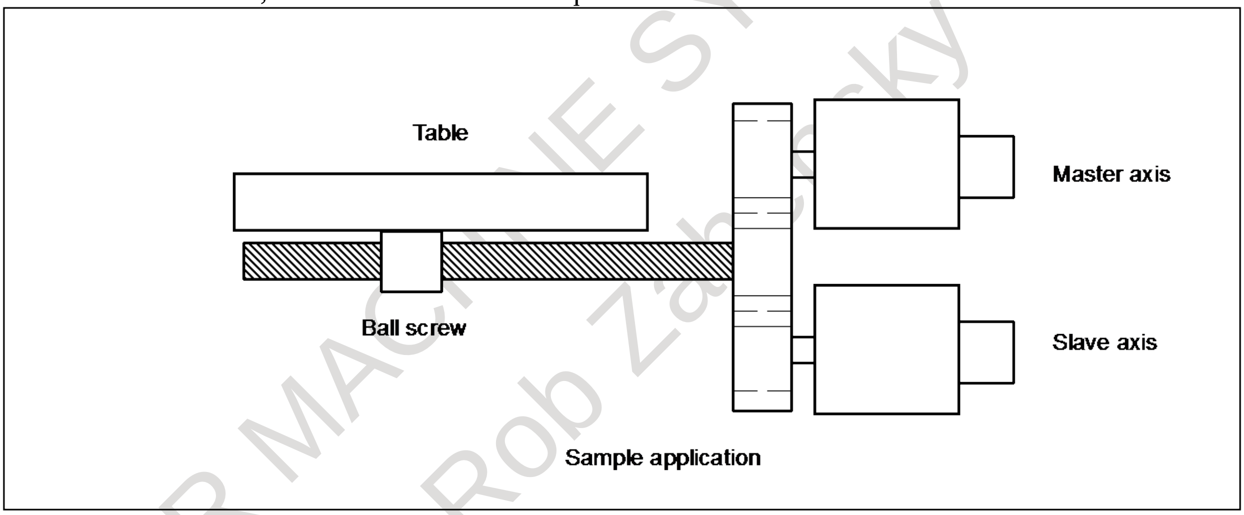

Fig. 1.7 (a)

The CNC generally processes the two axes of tandem control as a single axis. In the management of servo parameters and the monitoring of servo alarms, however, the two axes are handled individually.

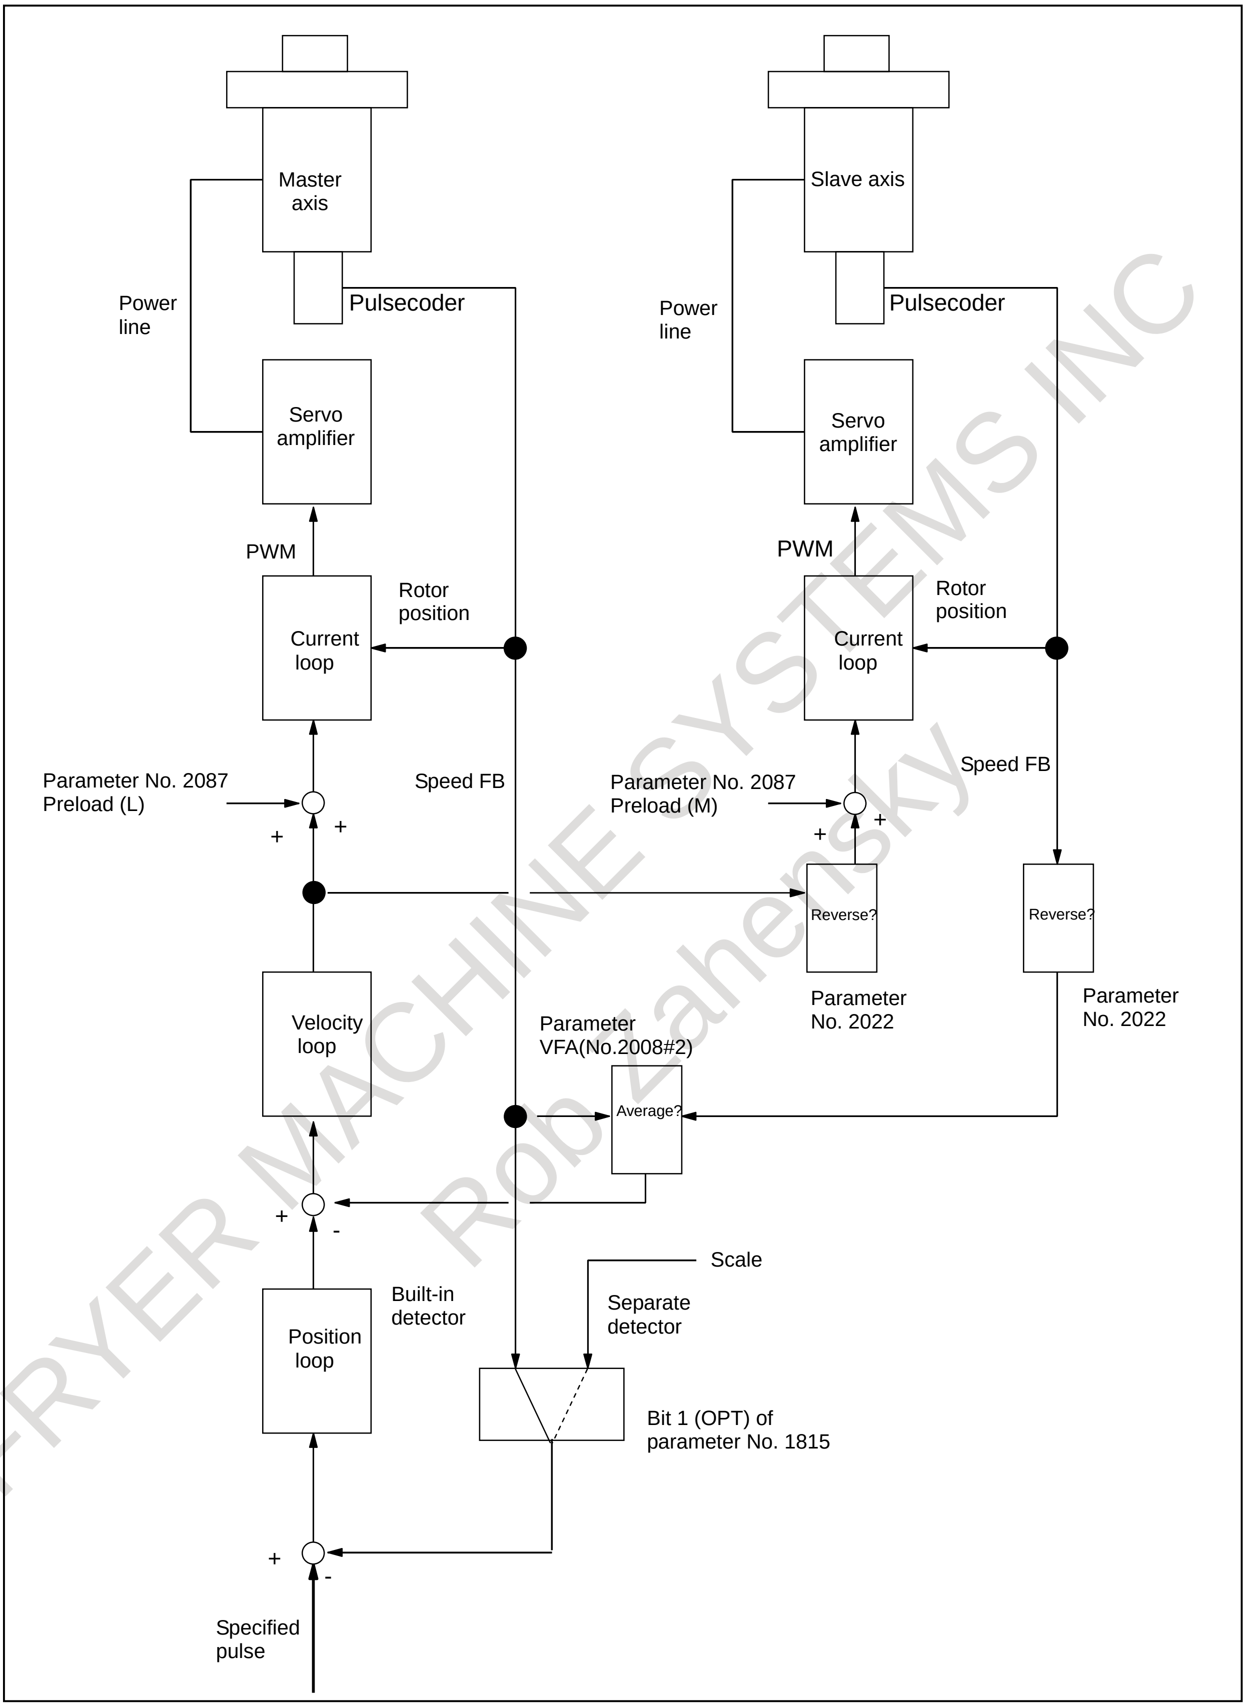

Fig. 1.7 (b) Block Diagram of Tandem Control

Explanation

- Axis configuration in tandem control

To specify the axis configuration in tandem control, follow the procedure below:

(1) Tandem control can be performed for up to sixteen pairs of axes.
It can be performed for up to twelve pairs of axes for each path.

(2) In terms of controlled axes, the pair of axes is handled as two separate axes. For a programmed command or manual feed, the pair of axes is handled as a single axis.

(3) The pair of axes is handled as two separate axes in the management of servo parameters and the monitoring of servo alarms.

(4) Assign two consecutive numbers, that is one odd and one even number, to the master and slave axes as their servo axis numbers (parameter No. 1023). Assign the smaller number to the master axis.
(Example)
If the servo axis number of the master axis (parameter No. 1023) is set to 1, specify servo axis number 2 for the corresponding slave axis. If the servo axis number of the master axis is set to 3, specify servo axis number 4 for the corresponding slave axis.
In terms of controlled axis order, it is necessary to set master axis ahead of slave axis.

(5) The master and slave axes may have the same name or different names.

(6) A subscript can be attached to an axis name like X1, X2, XM, and XS. If the same axis name is used for multiple axes, and a unique subscript is assigned to each of those axes, the axes can be distinguished from each other on the screen display, or which of those axes issued an alarm can be identified.
Set a subscript in parameter No. 3131.

(7) The slave axis is handled as a controlled axis. Set bit 0 (NDPx) of parameter No. 3115 to 1 to suppress the position display.
The following sample axis configuration is for a machine with five axes X, Y, Z, A, and B. The X-axis and Y-axis are the master axes of tandem control.
Number of controlled axes = Seven

Table 1.7 (a)

Axis number	Displayed axis name	Axis name (No.1020)	Subscript (No.3131)	Servo axis number (No.1023)	Tandem axis (No.1817#6)	
1	XM	88	77	1	1	Master axis of tandem control
2	XS	88	83	2	1	Slave axis of tandem control
3	Z	90	0	5	0	
4	A	65	0	6	0	
5	B	66	0	9	0	
6	YM	89	77	3	1	Master axis of tandem control
7	YS	89	83	4	1	Slave axis of tandem control

(8) The master and slave axes must be included in the same path.

(9) Set an absolute position detector only on the master axis. If it is set on the slave axis, alarm SV0006 "ILLEGAL TANDEM AXIS" is issued.

- Preload function

By adding an offset to the torque controlled by the position (velocity) feedback device, the function can apply opposite torques to the master and slave axes so that equal and opposite movements are performed for both axes. This function can reduce the effect of backlash on the master and slave axes caused by the tandem connection of the two motors via a gear. This function, however, cannot reduce backlash between the ball screw and table or other backlash inherent to the machine.

If a preload of X is set for the master axis and -X for the slave axis, the opposing preload torques are continuously applied to the two axes, even at rest, as shown below (Fig. 1.7 (c)):

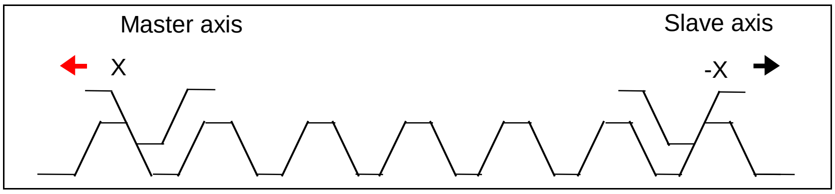

Fig. 1.7 (c)

> ⚠ **CAUTION**
> 1 Specify as low a preload as possible. Avoid specifying a preload higher than the rated torque. Too high a preload will trigger an overload alarm because the specified torques continue to be applied, even at rest. A preload that is only slightly higher than the frictional force is recommended. Thus, the recommended preload may be about one-third of the rated torque.
> 2 If the motors rotate in opposite directions (different signs are specified in parameter No. 2022), specify the preload values with the same sign.

- Velocity feedback average function

As shown in the block diagram of tandem control, the motor of the slave axis is not subject to velocity control. A machine with a large amount of backlash may become unstable if the motor of the slave axis vibrates as a result of backlash in the gear. This can be overcome by applying velocity control to the slave axis also. This velocity feedback average function is enabled when bit 2 of parameter No. 2008 is set to 1.

- Improved stability of a closed-loop system

The following two functions can increase the stability and position gain of a closed-loop system having a linear scale:

- Dual position feedback function
- Machine velocity feedback function

For details of these functions, refer to "FANUC AC SERVO MOTOR α*i*/β*i* series, LINEAR MOTOR L*i*S series, SYNCHRONOUS BUILT-IN SERVO MOTOR D*i*S series PARAMETER MANUAL (B-65270EN)".

- Notes on stability of tandem control

An important factor affecting stability in tandem control is the capability of back feed. Back feed is to cause movement along either the master or slave axis from the other axis, via the transmission mechanism connecting the two axes. A machine without this capability may be inclined to become unstable and require adjustments.

- Connection of axis signals

The DI/DO signals, generally connected to each axis, must be connected only to the master axis of two axes of tandem control. The signals need not be connected to the slave axis. The following signals, however, may have to be connected depending on the application.

i) Controlled axis detach signals DTCH1 to DTCH8<Gn124> and servo off signals SVF1 to SVF8<Gn126>
   Connect these signals so that the master and slave axis signals are simultaneously input.

ii) Overtravel signals *+L1 to *+L8<Gn114>, *-L1 to *-L8<Gn116>
   Connect the signal so that 1 is always output as the overtravel signal for the slave axis.

If the slave axis stroke limit must also be detected, connect the signals so that the signal detected on the slave axis is sent to the overtravel signal of the master axis.

- Connecting motors

Connect the motors according to the servo axis numbers. Connect the feedback cable of the slave axis.
(Sample connection for position feedback cable)

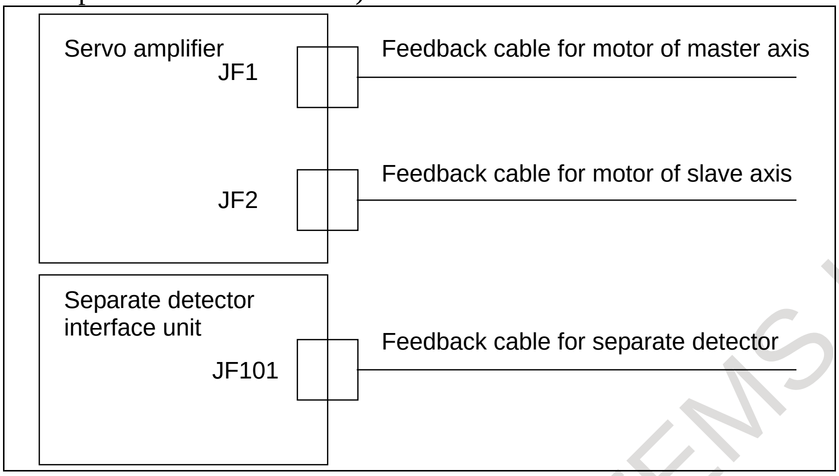

Fig. 1.7 (d)

- Servo alarms

Motor overload and other servo alarms are displayed separately for the master and slave axes.

- Servo off of slave axis

Specification of servo off of slave axis depends on the parameter TSF (No.11803#2) as follows.

- In case parameter TSF=0
  The servo of the slave axis is turned off together with that of the master axis.
- In case parameter TSF=1
  The servo of the slave axis is turned off independently of, rather than together with, that of the master axis.

NOTE

1. Use the parameter TSF for the slave axis.
2. Specify the parameter TSF when both the master and slave axes are at a stop.
3. Setting the parameter TSF to 1 requires consideration on the ladder side, because the servo of the slave axis is turned off independently of, rather than together with, that of the master axis.

Parameter

- Setting data (parameters)

The parameters that are generally set for each axis can, when set for axes under tandem control, be classified into the following three groups:

i) Parameters in which identical values must be set for the master and slave axes
ii) Parameters that must be specified only for the master axis (The corresponding parameter for the slave axis is not used.)
iii) Parameters for which different values may be set for the master and slave axes

The classifications of the parameters are described below. Any parameter that is not listed in the tables for the three classifications should be processed as a parameter of type i) and, specify identical values for the master and slave axes.

⚠ **CAUTION**

Note that, if different values are set for the master and slave axes in a parameter of type i), the operations for the two axes of tandem control will not be performed correctly.

- Care must be taken to specify the following two servo parameters, according to the directions of rotation around the master and slave axes.
  No. 2022 Direction of rotation of the motor
  No. 2087 Preload value
  In parameter No. 2022, specify 111 for forward rotation and -111 for the reverse rotation.
  In parameter No. 2087, specify values having identical signs when the motors of the master and slave axes rotate in opposite directions. Specify values having different signs when the motors of the master and slave axes rotate in the same direction.
- If a separate detector is used, use of the separate detector must be set for the master axis. For the slave axis, use of a built-in Pulsecoder must be set. Therefore, pay particular attention to setting the following parameters.
  No. 1815#1 Separate detector
  No. 2024 Number of position pulses (PPLS)
  No. 1821 Capacity of a reference counter
  No. 2084 Flexible feed gear ratio (numerator)
  No. 2085 Flexible feed gear ratio (denominator)

If, for example, a motor with αi Pulsecoder is used with a linear scale capable of detecting a position in 1-μm units, and if a single rotation of the motor produces a movement of 4 mm, specify the parameters as shown below:

	Master axis	Slave axis
No. 1815#1=	1	0
No. 2024 =	4000	12500
No. 1821 =	4000	4000
No. 2084 =	1	4
No. 2085 =	1	1000

- Parameters that should be set to the same values for the master and slave axes

Parameter No.	Meaning of parameters
1005#0	Reference position return
1005#1	Setting of the reference position without dogs
1006#0 to #1	Linear / rotary axis
1006#3	Diameter/radius specification
1006#5	Direction of manual reference position return
1013#0 to #3	Setting unit
1020	Program axis name
1025	Program axis name 2 for each axis
1026	Program axis name 3 for each axis
1240	Coordinate value on the 1st reference point of the machine coordinate system
1241	Coordinate value on the 2nd reference point of the machine coordinate system
1242	Coordinate value on the 3rd reference point of the machine coordinate system
1243	Coordinate value on the 4th reference point of the machine coordinate system
1260	Move distance per rotation of rotary axis
1420	Rapid traverse rate
1421	F0 speed of rapid traverse override
1620	Time constant of rapid traverse linear acceleration/deceleration
1621	Time constant of rapid traverse bell shaped acceleration/deceleration
1622	Time constant of acceleration/deceleration in cutting feed
1623	FL speed of acceleration/decelerati after interpolation in cutting feed
1624	Time constant acceleration/deceleration in jog feed
1625	FL speed of acceleration/deceleration in jog feed
1626	Time constant of during thread cutting cycle
1627	FL speed of acceleration/deceleration during thread cutting cycle
1820	Command multiplier (CMR)
18XX	Most of parameters related to digital servo
20XX	Most of parameters related to digital servo

- Parameters that should be set only for the master axes

Parameter No.	Meaning of parameters
0012#0	Mirror image
0012#7	Controlled axis detach
1004#7	Input unit 10 times
1005#4	External deceleration in positive direction
1005#5	External deceleration in negative direction
1005#7	Servo control off
1022	Basic / parallel axis specification
1220	External workpiece zero point offset
1221	Workpiece zero point offset of workpiece coordinate system 1 (G54)
1222	Workpiece zero point offset of workpiece coordinate system 2 (G55)
1223	Workpiece zero point offset of workpiece coordinate system 3 (G56)
1224	Workpiece zero point offset of workpiece coordinate system 4 (G57)
1225	Workpiece zero point offset of workpiece coordinate system 5 (G58)
1226	Workpiece zero point offset of workpiece coordinate system 6 (G59)
1423	Jog feedrate
1424	Manual rapid traverse
1425	FL rate in manual reference position return
1427	External deceleration rate at rapid traverse
1430	Maximum cutting feedrate
1815#5	Absolute Pulsecoder
2008#2	Velocity feedback average function
19655	Axis number of the linear axis to which a rotation axis belongs
19658	Angular displacement of a rotary axis
19659	Offset value for angular displacement of a rotation axis
19660	Origin offset value of a rotation axis
19667	Control point shift vector

- Parameters that may be set to different values for the master and slave axes

Parameter No.	Meaning of parameters
1023	Servo axis number
1310#0	Stored stroke check 2
1310#1	Stored stroke check 3
1320	Coordinate value I of stored stroke check 1 in the positive direction
1321	Coordinate value I of stored stroke check 1 in the negative direction
1322	Coordinate value of stored stroke check 2 in the positive direction
1323	Coordinate value of stored stroke check 2 in the negative direction
1324	Coordinate value of stored stroke check 3 in the positive direction
1325	Coordinate value of stored stroke check 3 in the negative direction
1326	Coordinate value II of stored stroke check 1 in the positive direction
1327	Coordinate value II of stored stroke check 1 in the negative direction
1815#1	Separatedetector
1821	Arbitrary reference counter capacity
2022	Motor rotation direction
2024	Number of position pulses (PPLS)
2084	Numerator of flexible feed gear ratio
2085	Denominator of flexible feed gear ratio
2087	Preload value
3115#0	Current position display

1020	Program axis name for each axis

[Input type] Parameter input
[Data type] Byte axis
[Valid data range] 65 to 67, 85 to 90

An axis name (axis name 1: parameter No. 1020) can be arbitrarily selected from A, B, C, U, V, W, X, Y, and Z. (When G code system A is used with the lathe system, however, U, V, and W are not selectable.) When bit 0 (EEA) of parameter No. 1000 is set to 1, the length of an axis name can be extended to three characters by setting axis name 2 (parameter No. 1025) and axis name 3 (parameter No. 1026) (extended axis name).
For axis names 2 and 3, a character from 0 to 9 and A to Z of ASCII code can be arbitrarily selected. However, the setting of axis name 3 for each axis is invalid if axis name 2 is not set. Moreover, if a character from 0 to 9 is set as axis name 2, do not use a character from A to Z as axis name 3.

(Tip) ASCII code

Axis name	X	Y	Z	A	B	C	U	V	W
Setting	88	89	90	65	66	67	85	86	87

When G code system A is used with the lathe system, and the character X, Y, Z, or C is used as axis name 1 of an axis, a command with U, V, W, or H specified for axis name 1 represents an incremental programming for the axis.

NOTE
1. When a multiple repetitive canned cycle for turning is used, no character other than X, Y, and Z can be used as the address of the axis.
2. When the custom macro function is enabled, the same extended axis name as a reserved word cannot be used. Such an extended axis name is regarded as a reserved word.
   Because of reserved words of custom macros, extended axis names that start with the following two characters cannot be used:
   AB, AC, AD, AN, AS, AT, AX, BC, BI, BP, CA, CL, CO, US, WH, WR, XO, ZD, ZE, ZO, ZW
3. In a macro call, no extended axis name can be used as an argument.

1023	Number of the servo axis for each axis

NOTE
When this parameter is set, the power must be turned off before operation is continued.

[Input type] Parameter input
[Data type] Byte axis
[Valid data range] 0 to 80

This parameter associates each control axis with a specific servo axis. Specify values 1+8n, 2+8n, 3+8n, 4+8n, 5+8n, and 6+8n (n = 0, 1, 2, …, 9) like 1, 2, 3, 4, 5, …, 77, and 78.
The control axis number is the order number that is used for setting the axis-type parameters or axis-type machine signals

- With an axis for which Cs contour control/spindle positioning is to be performed, set -(spindle number) as the servo axis number.
  Example)
  When exercising Cs contour control on the fourth controlled axis by using the first spindle, set -1.
- For tandem controlled axes or electronic gear box (EGB) controlled axes, two axes need to be specified as one pair. So, make a setting as described below.

Tandem axis: For a master axis, set an odd (1, 3, 5, 9, ...) servo axis number. For a slave axis to be paired, set a value obtained by adding 1 to the value set for the master axis.

EGB axis: For a slave axis, set an odd (1, 3, 5, 9, ...) servo axis number. For a dummy axis to be paired, set a value obtained by adding 1 to the value set for the slave axis.

	#7	#6	#5	#4	#3	#2	#1	#0
1815							OPTx	

[Input type] Parameter input
[Data type] Bit axis

> **NOTE**
> When at least one of these parameters is set, the power must be turned off before operation is continued.

#1 OPTx The separate position detector is:
0: Not to be used (semi-closed system)
1: To be used (full-closed system)

> **NOTE**
> 1 In case of using the absolute position detector (bit 5 (APCx) of parameter No.1815 is set to 1), please set the following parameters that correspond to the absolute position detector which is actually used.
> - parameter No.1815#6, No.1815#0, No.1817#3, No.1868, No.2275#1, No.2394
>
> If these parameters are not set correctly, the machine coordinates are not correctly established at power-on.
> 2 Set this parameter to 1 when using a linear scale with reference marks or a linear scale with distance-coded reference marks (serial) (full-closed system).

	#7	#6	#5	#4	#3	#2	#1	#0
1817		TANx						

[Input type] Parameter input
[Data type] Bit axis

> **NOTE**
> When this parameter is set, the power must be turned off before operation is continued.

#6 TANx Tandem control
0: Not used
1: Used

> **NOTE**
> Set this parameter to both master axis and slave axis.

1821	Reference counter size for each axis

> **NOTE**
> When this parameter is set, the power must be turned off before operation is continued.

[Input type] Parameter input
[Data type] 2-word axis
[Unit of data] Detection unit
[Valid data range] 0 to 999999999

Set a reference counter size.
As a reference counter size, specify a grid interval for reference position return based on the grid method.
When a value less than 0 is set, the specification of 10000 is assumed.
When a linear scale with absolute address reference marks is used, set the interval of mark 1.

	#7	#6	#5	#4	#3	#2	#1	#0
2008						VFA		

[Input type] Parameter input
[Data type] Bit axis

#2 VFA In tandem control, the speed feedback average function is:
0: Disabled.
1: Enabled.

2021	Load inertia ratio

[Input type] Parameter input
[Data type] Word axis
[Valid data range] 0 to 32767

(Load inertia)/(motor inertia) × 256

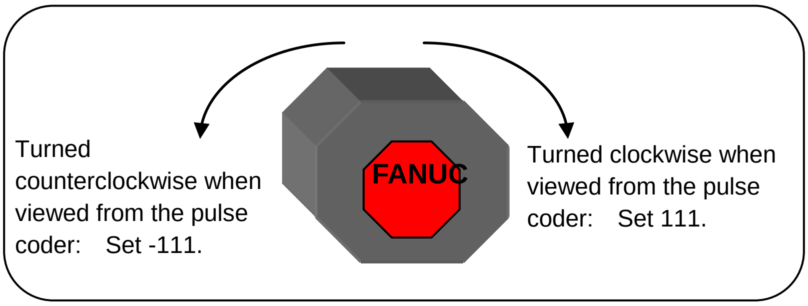
For tandem control:
(Load inertia)/(motor inertia) × 256/2
Set the same value for the master axis and slave axis.

2022	Direction of motor rotation

> **NOTE**
> When this parameter is set, the power must be turned off before operation is continued.

[Input type] Parameter input
[Data type] Word axis
[Valid data range] -111,111

Set the direction of motor rotation.
If the motor turns clockwise when viewed from the Pulsecoder side, set 111. If the motor turns counterclockwise when viewed from the Pulsecoder side, set -111.
When the master axis and slave axis rotate in opposite directions each other, this parameter is used for switching.



2087	Preload value for each axis (Tcmd offset)

[Input type] Parameter input
[Data type] Word axis
[Unit of data] (Ampere limit)/7282
[Valid data range] -1821 to 1821

An offset is applied to a torque command to suppress backlash.
Set a value much greater than the friction.
As a guideline, specify a value that is about one-third of the rated torque.

[Example] To set a torque equivalent to 3 A in the opposite directions:
When the ampere limit is 40 A

3/(40/7282) = 546
Master side = 546
Slave side = -546

	#7	#6	#5	#4	#3	#2	#1	#0
3115								NDPx

[Input type] Parameter input
[Data type] Bit axis

#0 NDPx The current position is:
0: Displayed.
1: Not displayed.

> **NOTE**
> When using the electronic gear box (EGB) function, set 1 for the EGB dummy axis to disable current position display.

3131	Subscript of axis name

[Input type] Parameter input
[Data type] Byte axis
[Valid data range] 0 to 9, 65 to 90

In order to distinguish axes under parallel operation, synchronization control, and tandem control, specify a subscript for each axis name.

Setting value	Meaning
0	Each axis is set as an axis other than a parallel axis, synchronization control axis, and tandem control axis.
1 to 9	A set value is used as a subscript.
65 to 90	A set letter (ASCII code) is used as a subscript.

[Example] When the axis name is X, a subscript is added as indicated below.

Setting value	Axis name displayed on a screen such as the position display screen
0	X
1	X1
77	XM
83	XS

If a multi-path system is used, no extended axis name is used within a path, and no subscript is set for the axis names, then the path number is automatically used as the subscript for the axis names. To disable the display of axis name subscripts, set a blank (32) of ASCII code in the parameter for specifying an axis name subscript.

NOTE

If even one axis in a path uses an extended axis name when bit 2 (EAS) of parameter No. 11308 is set to 0, subscripts cannot be used for axis names in the path.

	#7	#6	#5	#4	#3	#2	#1	#0
11803						TSF		

[Input type] Parameter input
[Data type] Bit axis

#2 TSF Under tandem control, the servo of the slave axis is turned off:
0: Together with that of the master axis.
1: Independently of that of the master axis.

NOTE

1 Use this parameter for the slave axis under tandem control.
2 Specify this parameter when both the master and slave axes under tandem control are at a stop.
3 Setting this parameter to 1 requires consideration on the ladder side, because the servo of the slave axis is turned off independently of, rather than together with, that of the master axis.

Alarm and message

Number	Message	Description
SV0006	ILLEGAL TANDEM AXIS	For the slave axis under tandem control, absolute position detection is set (bit 5 (APCx) of parameter No. 1815 = 1).
SV1055	ILLEGAL TANDEM AXIS	The setting of parameter No. 1023 and bit 6 (TDMx) of parameter No.1817 is invalid for tandem control.

NOTE

⚠ CAUTION

In case the names of the master axis and slave axis are different, be sure not to specify a programmed command for the slave axis.

Manual name	Item name
OPERATOR’S MANUAL (B-64694EN)	Tandem control

1.8 ANGULAR AXIS CONTROL

Overview

When the angular axis installed makes an angle other than 90° with the perpendicular axis, the angular axis control function controls the distance traveled along each axis according to the inclination angle as in the case where the angular axis makes 90° with the perpendicular axis.

Arbitrary axes can be specified as a set of an angular axis and perpendicular axis by parameter setting.

The actual distance traveled is controlled according to an inclination angle. However, a program, when created, assumes that the angular axis and perpendicular axis intersect at right angles. The coordinate system used at this time is referred to as the program coordinate system. (The program coordinate system may be referred to as the Cartesian coordinate system, and the actual move coordinate system may be referred to as the slanted coordinate system or machine coordinate system.)

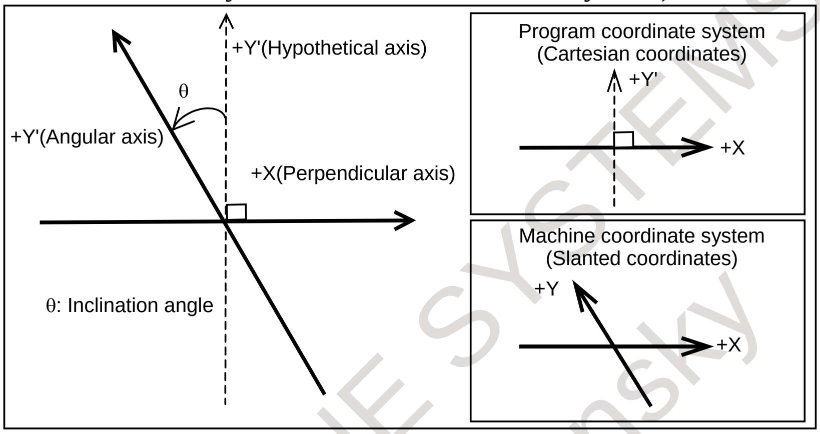

Fig. 1.8 (a)

Explanation

- Travel distance of each axis

When the amounts of travel along the angular axis and the perpendicular axis are Ya and Xa, respectively, the amounts are controlled according to the formulas shown below.

$$Ya = \frac{Yp}{\cos\theta}$$

Xa,*Ya*: Actual distance
Xp,*Yp*: Programmed distance

The amount of travel along the perpendicular axis is corrected by the influence of travel along the angular axis, and is determined by the following formula:

$$Xa = Xp - C \times Yp \times \tan\theta$$

> **NOTE**
> The coefficient C is 2 in the case of diameter specification for the perpendicular axis (X) or 1 in the case of radius specification.

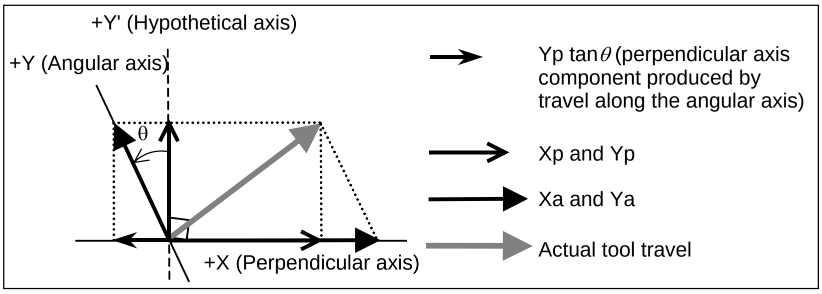

Fig. 1.8 (b)

- Feedrate

When the Y-axis is an angular axis, and the X-axis is a perpendicular axis, the feedrate along each axis is controlled as described below so that the feedrate in the tangent direction becomes Fp.
The feedrate component along the Y-axis is determined by the following expressions:

$$Fay = \frac{Fp}{\cos\theta}$$

Fa represents the actual feedrate.
Fp represents a programmed feedrate.

Fax = Fp – Fp × tanθ

- Absolute and relative position display

An absolute and a relative position are indicated in the programmed Cartesian coordinate system.

- Machine position display

A machine position indication is provided in the machine coordinate system where an actual movement is taking place according to an inclination angle.

Method of use

The angular and perpendicular axes for which angular axis control is to be applied must be specified beforehand, using parameters Nos. 8211 and 8212. When 0 is set in one of the parameters, the same number is specified in the parameters, or a number other than the controlled axis numbers is specified in a parameter, however, an angular axis and perpendicular axis are selected according to the Table 1.8 (a).

Table 1.8 (a)

	Angular axis	Perpendicular axis
M series	Y-axis of the basic three axes (axis with 2 set in parameter No. 1022)	Z-axis of the basic three axes (axis with 3 set in parameter No. 1022)
T series	X-axis of the basic three axes (axis with 1 set in parameter No. 1022)	Z-axis of the basic three axes (axis with 3 set in parameter No. 1022)

- Bit 0 (AAC) of parameter No. 8200 enables or disables the angular axis control. If the function is enabled, the distance traveled along each axis is controlled according to an angular angle parameter No. 8210.
- By using bit 2 (AZR) of parameter No. 8200, whether to make a movement along the perpendicular axis by a movement made along the angular axis when a manual reference position return operation is performed along the angular axis can be chosen. When a movement along the perpendicular axis is enabled (AZR = 1), a reference position return operation along the perpendicular axis can be performed by a movement made along the angular axis.
- Bit 3 (AZP) of parameter No. 8200 can be used to set reference position return end signals for the perpendicular axis ZP1 to ZP8<Fn094.0 to Fn094.7> to “0” when a movement is made along the perpendicular axis due to a movement along the angular axis.
- By setting the signal for disabling angular axis control for the perpendicular axis NOZAGC<Gn063.5> to “1”, slanted axis control only for the angular axis can be available. In this time the angular axis are converted to those along the slanted coordinate system without affecting commands to normal axis.
  Use this signal when operating each axis independently.

- Manual reference position return operation

A movement is made to the reference position (machine position) set in parameter No. 1240. By using bit 2 (AZR) of parameter No. 8200, whether to make a movement along the perpendicular axis when a reference position return operation is performed along the angular axis can be chosen.

- Automatic reference position return operation (G28, G30)

A movement to the middle point along the angular axis affects a movement along the perpendicular axis. It is possible to select between Cartesian coordinate system operation (compatible with FS16*i*) and

angular coordinate system operation as the movement along the angular axis from the intermediate position to the reference position, using bit 0 (ARF) of parameter No. 8209.
If manual reference position return operation is not performed even once after the power is turned on, operation is performed in the same sequence as for manual reference position return operation. So, specify commands first for the angular axis then for the perpendicular axis.
Example 1)
When the Y-axis is an angular axis and the X-axis is a perpendicular axis
(1) If the angular axis is first specified then the perpendicular axis is specified, reference position return operation is performed normally.
G28Y_;
G28X_;
(2) If the perpendicular axis is first specified then the angular axis is specified, or if the perpendicular axis and the angular axis are specified at the same time, alarm PS0372 is issued when a movement is made along the perpendicular axis.
G28X_; or G28X_Y_;
G28Y_;

Example 2)
Automatic reference position return example
(If the Y-axis is an angular axis, the X-axis is a perpendicular axis, and the angular angle is -30°)
<1> Automatic reference position return command on the X-axis from point P2
>G90G28X200.0
<2> Automatic reference position return command on the Y-axis from point P1
>G90G28Y100.0
(1) If bit 0 (ARF) of parameter No. 8209 is 1 (compatible with FS16*i*)
<1> Coordinates at P1

(Absolute coordinate)		(Machine coordinate)	
X	0.000	X	57.735
Y	100.000	Y	115.470

<2> Coordinates at P0

(Absolute coordinate)		(Machine coordinate)	
X	0.000	X	0.000
Y	0.000	Y	0.000

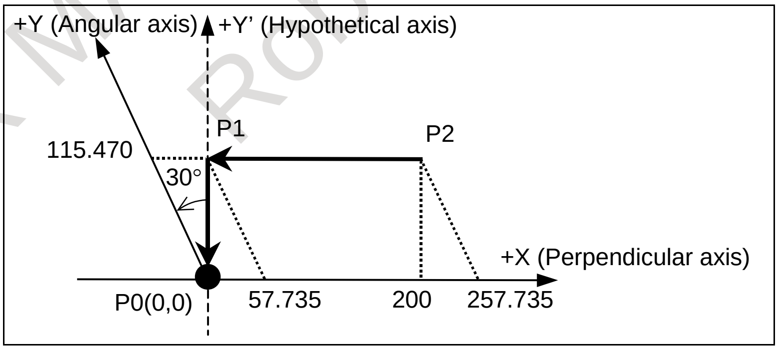

Fig. 1.8 (c)

(2) If bit 0 (ARF) of parameter No. 8209 is 0
<1> Coordinates at P1

(Absolute coordinate)		(Machine coordinate)	
X	0.000	X	0.000
Y	100.000	Y	115.470

<2> Coordinates at P0

(Absolute coordinate)		(Machine coordinate)	
X	0.000	X	0.000
Y	0.000	Y	0.000

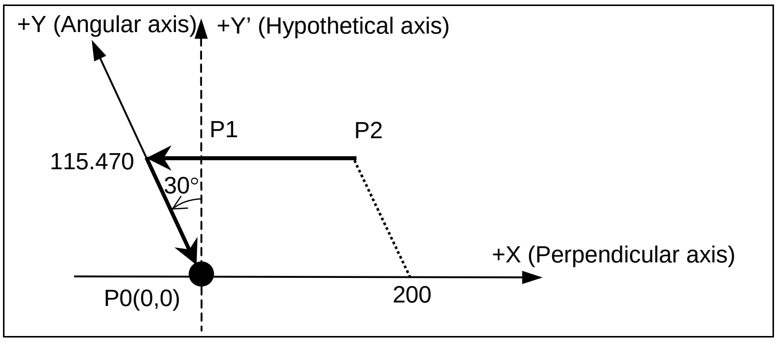

Fig. 1.8 (d)

- Reference position return operation of high-speed type

When a reference position is already established and a reference position return operation of high-speed type is to be performed, the reference position return operation need not be performed in the order from the angular axis to the perpendicular axis.

- Machine coordinate selection (G53)

By specifying (G90)G53X_Y_: (when the Y-axis is an angular axis, the X-axis is a perpendicular axis, and the inclination angle is -30°), a movement is made by rapid traverse.
However, a movement along the angular axis (G53 command) does not affect a movement along the perpendicular axis, regardless of whether the signal for disabling angular axis control for the perpendicular axis (NOZAGC) is turned on or off.
Example)

<1> Move command for movement from point P0 to point P1
>G90G53Y100.0

<2> Move command for movement from point P1 to point P2
>G90G53X200.0

<1> Coordinates of P1

(Absolute coordinate)		(Machine coordinate)	
X	-50.000	X	0.000
Y	86.603	Y	100.000

<2> Coordinates of P2

(Absolute coordinate)		(Machine coordinate)	
X	150.000	X	200.000
Y	86.603	Y	100.000

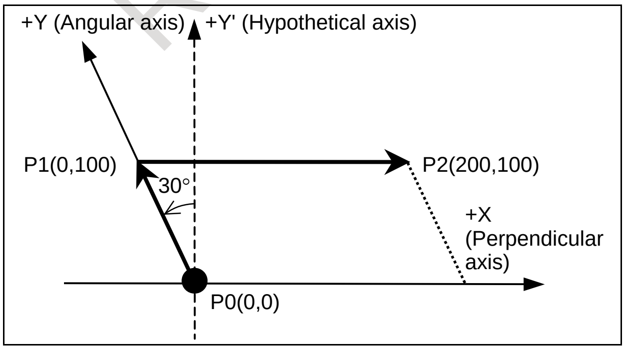

Fig. 1.8 (e)

- Commands for linear interpolation and positioning of linear interpolation type (G01, G00)

The tool moves to a specified position in the Cartesian coordinate system when the following is specified:
(G90)G00X_Y_; (when the Y-axis is an angular axis, the X-axis is a perpendicular axis, and the inclination angle is -30°)
or

(G90)G01X_Y_F_; (when the Y-axis is an angular axis, the X-axis is a perpendicular axis, and the inclination angle is -30°)

Example) Examples of positioning

<1> Move command for movement from point P0 to point P1

>G90G00Y100.0

<2> Move command for movement from P1 to P2

>G90G00X200.0

(1) When the signal for disabling angular axis control for the perpendicular axis (NOZAGC) is set to “0”

<1> Coordinates of P1

(Absolute coordinate)		(Machine coordinate)	
X	0.000	X	57.735
Y	100.000	Y	115.470

<2> Coordinates of P2

(Absolute coordinate)		(Machine coordinate)	
X	200.000	X	257.735
Y	100.000	Y	115.470

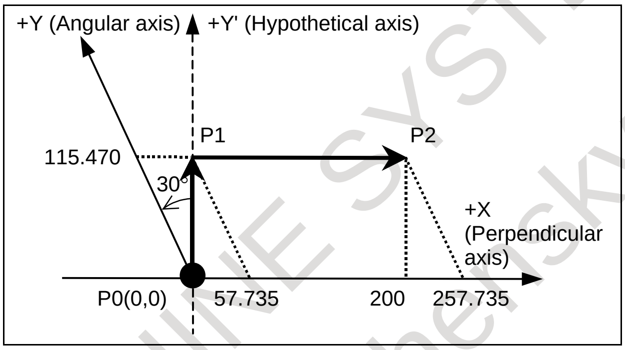

Fig. 1.8 (f)

(2) When the signal for disabling angular axis control for the perpendicular axis (NOZAGC) is set to “1”

<1> Coordinates of P1

(Absolute coordinate)		(Machine coordinate)	
X	0.000	X	0.000
Y	100.000	Y	115.470

<2> Coordinates of P2

(Absolute coordinate)		(Machine coordinate)	
X	200.000	X	200.000
Y	100.000	Y	115.470

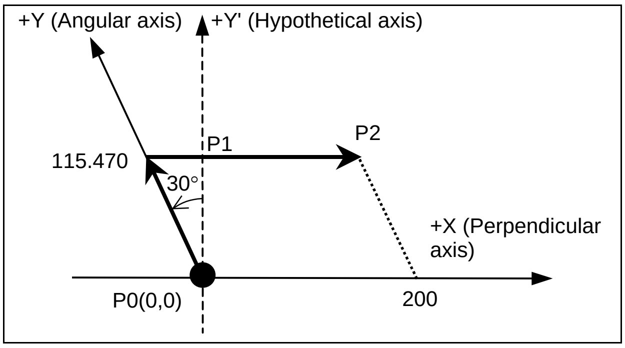

Fig. 1.8 (g)

- 3-dimensional coordinate conversion

In the 3-dimensional coordinate conversion mode, slanted coordinate system conversion is applied to the workpiece coordinate system that has undergone 3-dimensional coordinate conversion.

- Stored stroke limit

Stored stroke limits under angular axis control can be set not in a slanted coordinate system but in the Cartesian coordinate system by setting bits 0, 1, and 2 (AOT, AO2, and AO3) of parameter No. 8201.

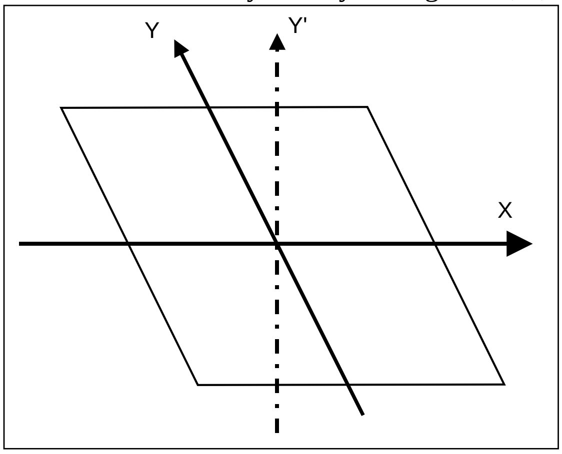

Fig. 1.8 (h) OT area in a slanted coordinate system

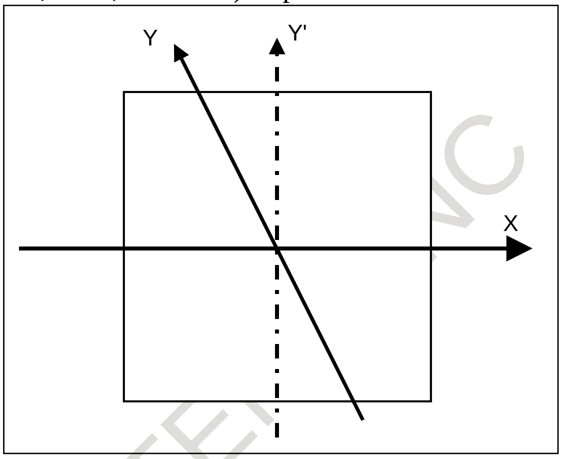

Fig. 1.8 (i) OT area in a Cartesian coordinate system

Machine coordinates include a value converted for the angular axis and a compensation value for the perpendicular axis, so that a slanted machine coordinate system as shown in Fig. 1.8 (h) results.
A stored stroke limit is checked in the machine coordinate system, so that the limit area is slanted to form a rhombus as shown in Fig. 1.8 (h). In this case, the area cannot be identified intuitively. So, stroke limits are checked not in an actual slanted machine coordinate system but in a virtual Cartesian machine coordinate system as shown in Fig. 1.8 (i).

The functions that operate in the Cartesian coordinate system are:
- Stored stroke limit 1 (Both of I and II)
- Stored stroke limit 2 (G22/G23)
- Stored stroke limit 3
- Pre-movement stroke check

The pre-movement stroke check function does not work in a slanted coordinate system. Unless this function is enabled, and the coordinate system is converted to the Cartesian coordinate system, no stroke check is made.
- Stored stroke external setting (function specific to the M series only and valid only for OT1)
- Bit 7 (BFA) of parameter No. 1300 for specifying whether to issue an alarm before or after a stroke limit is exceeded (valid for OT1 and OT3)

The stored stroke limit functions other than the above work in a slanted coordinate system.

- General purpose retract

When the angular axis control is valid the general purpose retract is retracted in the Cartesian coordinate system. Therefore the retracted distance (parameter No.7741) is set with the Cartesian coordinate system. Moreover, even if the command is the machine coordinate system (=the slanted coordinate system) such as G28, G30, G53 the general purpose retract is retracted in the Cartesian coordinate system.

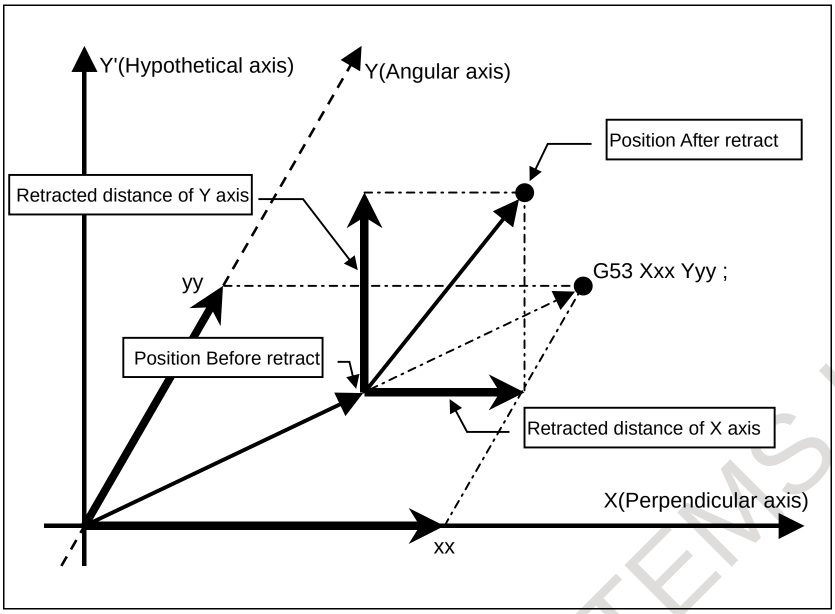

Fig.1.8 (j) Retract motion

- Relationships between this function and axis-by-axis input/output signals

The Table 1.8 (b) and Table 1.8 (c) indicates the relationships between this function and the meaning of each controlled axis signal.

The input/output signals are classified as signals valid for the program coordinate system (Cartesian coordinate system) and signals valid for the machine coordinate system (slanted coordinate system). In the "Classification" column, "Cartesian" is indicated for a signal that is valid for the Cartesian coordinate system, and "Slanted" is indicated for a signal that is valid for the slanted coordinate system.

A signal valid for the Cartesian coordinate system means a signal valid for a specified axis, and a signal valid for the slanted coordinate system is a signal valid for actual machine movement.

This means that when a movement is made along the perpendicular axis by a movement along the angular axis alone:

A signal valid for the Cartesian coordinate system is affected by a movement along the angular axis.

A signal valid for the slanted coordinate system is not affected by a movement along the angular axis.

Table 1.8 (b)

Input signal				
Signal name		**Address**	**Classification**	**Remarks**
Interlock signal for each axis	*ITx	G130	Cartesian	When a movement is made along the angular axis only, interlocking the perpendicular axis does not interlock a movement along the perpendicular axis made by a movement along the angular axis. Caution) When using the axis-by-axis interlock signal, make both of the angular axis and perpendicular axis are set to “1”.
Overtravel	*+Lx *-Lx	G114 G116	Slanted	This signal is applied to each axis independently. (If the perpendicular axis is made ”1”, no alarm is issued for the perpendicular axis even when an OT alarm is issued for the angular axis.)
Deceleration signal for reference position return	*DECx	X009	Slanted	This signal is applied to each axis independently.
Servo-off signal	SVFx	G126	Slanted	This signal is applied to each axis independently.

Input signal				
Signal name		**Address**	**Classification**	**Remarks**
Controlled axis removal signal	DTCHx	G124	Slanted	This signal is applied to each axis independently.
Feed axis direction selection signal	+Jx -Jx	G100 G102	Cartesian	A movement is made in the Cartesian coordinate system. (When the +J/-J signal for the angular axis is made "1", a movement is made also along the perpendicular axis.)
Mirror image	MIx	G106	Slanted	Mirror image is applied to the slanted coordinate system for each axis independently. Caution) Be sure to turn off the mirror image signal for the angular axis and perpendicular axis engaged in manual operation.
Interlock signal for each axis direction, Tool offset write signals	+MIT1, +MIT2	X004.2, 4	Cartesian	Set the tool compensation parameter in the Cartesian coordinate system.
Each-axis machine lock signal	MLKx	G108	Slanted	This signal is applied to each axis independently.

Table 1.8 (c)

Output signal				
Signal name		**Address**	**Classification**	**Remarks**
In-position signal	INPx	F104	Slanted	Applied to each axis independently.
Mirror image check signal	MMIx	F108	Slanted	Applied to each axis independently.
Controlled axis removal in-progress signal	MDTCHx	F110	Slanted	Applied to each axis independently.
Travel in-progress signal	MVx	F102	Slanted	Applied to each axis independently.
Reference position return completion signal	ZPx	F094	Cartesian	Applied to each axis independently. (A manual reference position return operation and the first automatic reference position return operation after power-up need to be performed first for the angular axis.)
2nd reference position return completion signal	ZP2x	F096	Cartesian	Applied to each axis independently.
3rd reference position return completion signal	ZP3x	F098	Cartesian	Applied to each axis independently.
4th reference position return completion signal	ZP4x	F100	Cartesian	Applied to each axis independently.

- Pitch Error Compensation

The pitch error compensation is applied in a slanted coordinate system.

Limitation

- 3-dimensional coordinate conversion

If the basic three axes in the 3-dimensional coordinate conversion mode do no include a perpendicular axis and angular axis for angular axis control, operation cannot be performed normally in a correct slanted coordinate system.

- Linear scale with an absolute address reference mark

- For both of the angular axis and perpendicular axis, a linear scale with an absolute address reference mark must be used.
- Reference position return operation must be first completed along the angular axis.

- Return operation cannot be performed along the perpendicular axis while return operation is being performed along the angular axis.

- Synchronous control

- To perform synchronous control over related axes under angular axis control, specify the angular axis and Cartesian axis on the master axis side and the angular axis and Cartesian axis on the slave axis side as the targets of synchronous control at the same time. In synchronous control, one angular axis must be paired with the other angular axis while one Cartesian axis must be paired with the other Cartesian axis.
  If synchronous control is performed in a way other than the above, alarm PS0375 is issued.
  Example)

Path 1		Path 2
X1 (Cartesian axis)	← Synchronous control pair	→ X2 (Cartesian axis)
Y1 (slanted axis)	← Synchronous control pair	→ Y2 (slanted axis)

- Composite control

- To perform composite control over related axes under angular axis control, specify the angular axis and Cartesian axis on the master axis side and the angular axis and Cartesian axis on the slave axis side as the targets of composite control at the same time. In composite control, one angular axis must be paired with the other angular axis while one Cartesian axis must be paired with the other Cartesian axis.
  If composite control is performed in a way other than the above, alarm PS0375 occurs.
  Example)

Path 1		Path 2
X1 (Cartesian axis)	← Composite control pair	→ X2 (Cartesian axis)
Y1 (slanted axis)	← Composite control pair	→ Y2 (slanted axis)

- Rigid tapping

- An angular axis cannot be used as a tapping axis for rigid tapping.

- Manual handle interrupt

- When machine coordinate system setting (G53) or return to reference position (G28, G30) is commanded to the perpendicular axis, the manual handle interrupt can not be used to the angular axis.

- Functions that cannot be used simultaneously

- Axis synchronous control, Hypothetical axis control, EGB function, PMC axis control, Superimposed control, Flexible synchronization Control, Flexible path axis assignment, High precision oscillation function, Reference position setting with mechanical stopper, Reference position setting with mechanical stopper by grid method

Caution

⚠ CAUTION

1 After angular axis control parameter setting, be sure to perform manual reference position return operation.
2 Before manual reference position return operation is performed along the perpendicular axis, reference position return operation along the angular axis must be completed (with the reference position return completion signal for the angular axis (ZPx) set to 1). If reference position return operation is performed along the perpendicular axis first, an alarm (PS0372) is issued.
3 When the setting is made so that the tool moves along the perpendicular axis during manual reference position return along the slanted axis (bit 2 (AZK) of parameter No. 8200 is set to 0), if once manual reference position return has been performed along the angular axis, also perform manual reference position return along the perpendicular axis immediately after the operation.
4 Before attempting to manually move the tool along the angular and perpendicular axes independently, set signal for disabling angular axis control for the perpendicular axis NOZAGC to “1”.
5 Once the tool has been moved along the angular axis when signal for disabling angular axis control for the perpendicular axis NOZAGC has been set to “1”, manual reference position return must be performed.
6 The same increment system must be used with the angular axis and perpendicular axis.
7 Before a perpendicular axis reference position return check can be made, angular axis reference position return operation must be completed.
8 No rotary axis must be set for the angular axis and perpendicular axis. A rotary axis may be specified only for a linear axis.
9 Set a position switch operation range (parameter Nos. 6930 to 6965) in a slanted coordinate system.

Signal

Signal for disabling angular axis control for the perpendicular axis NOZAGC<Gn063.5>

[Classification] Input signal
[Function] Disables angular axis control for the perpendicular axis.
[Operation] When this signal is set to “1”, the control unit operates as follows:
- Converts an angular axis move command to angular coordinates. The perpendicular axis is not affected by an angular axis move command, however.

Parameter

	#7	#6	#5	#4	#3	#2	#1	#0
8200					AZP	AZR		AAC

[Input type] Parameter input
[Data type] Bit path

NOTE
When at least one of these parameters is set, the power must be turned off before operation is continued.

#0 AAC

0: Does not perform angular axis control.
1: Performs inclined axis control.

#2 AZR

0: The machine tool is moved along the Cartesian axis during manual reference position return along the slanted axis under angular axis control.
1: The machine tool is not moved along the Cartesian axis during manual reference position return along the slanted axis under angular axis control.

#3 AZP When a movement is made along the Cartesian axis due to a movement along the slanted axis, reference position return end signals for the Cartesian axis ZP1 to ZP8 <Fn094.0 to Fn094.7> are:
0: Not cleared.
1: Cleared.

	#7	#6	#5	#4	#3	#2	#1	#0
8201	ADG	A53				AO3	AO2	AOT

[Input type] Parameter input
[Data type] Bit path

> **NOTE**
> When at least one of these parameters is set, the power must be turned off before operation is continued.

#0 AOT Stored stroke limit 1 under angular axis control is handled as:
0: Value in the slanted coordinate system.
1: Value in the Cartesian coordinate system.

#1 AO2 Stored stroke limit 2 under angular axis control is handled as:
0: Value in the slanted coordinate system.
1: Value in the Cartesian coordinate system.

#2 AO3 Stored stroke limit 3 under angular axis control is handled as:
0: Value in the slanted coordinate system.
1: Value in the Cartesian coordinate system.

#6 A53 So far, if a slanted axis is singly specified by a machine coordinate command (G53) in angular axis control, this parameter set to 0 specifies that "compensation is applied to the Cartesian axis", and this parameter set to 1 specifies that "a movement is made along the slanted axis only". However, the specification has been changed so that "a movement is made along the slanted axis only", regardless of whether this parameter is set to 0 or 1.

#7 ADG The contents of diagnostic data Nos. 306 and 307 are:
0: Not swapped. The slanted axis and Cartesian axis are displayed in this order.
1: Swapped. The Cartesian axis and slanted axis are displayed in this order.

	#7	#6	#5	#4	#3	#2	#1	#0
8209								ARF

[Input type] Parameter input
[Data type] Bit path

NOTE
When this parameter bit is set, the power must be turned off before operation is continued.

#0 ARF In angular axis control, a movement from an intermediate point to the reference position in the G28/G30 command is:
0: Made in the angular coordinate system.
1: Made in the Cartesian coordinate system.

8210	Slant angle of a slanted axis in angular axis control

[Input type] Parameter input
[Data type] Real path
[Unit of data] deg
[Min. unit of data] Depend on the increment system of the applied axis
[Valid data range] -180.000 to 180.000. However, angular axis control is disabled in the ranges -95.000 to -85.000 and 85.000 to 95.000 (in the case of IS-B).

8211	Axis number of a slanted axis subject to angular axis control
8212	Axis number of a Cartesian axis subject to slanted axis control

NOTE
When these parameters are set, the power must be turned off before operation is continued.

[Input type] Parameter input
[Data type] Word path
[Valid data range] 1 to number of controlled axes
When angular axis control is to be applied to an arbitrary axis, these parameters set the axis numbers of a slanted axis and Cartesian axis. If 0 is set in either of the two parameters, the same number is set in the two parameters, or a number other than the controlled axis numbers is set in either of the two parameters, a slanted axis and Cartesian axis are selected as indicated in the following table:

	Slanted axis	Cartesian axis
M series	Y-axis (axis with 2 set in parameter No. 1022) of the basic three axes	Z-axis (axis with 3 set in parameter No. 1022) of the basic three axes
T series	X-axis (axis with 1 set in parameter No. 1022) of the basic three axes	Z-axis (axis with 3 set in parameter No. 1022) of the basic three axes

Alarm and message

Number	Message	Description
PS0372	REFERENCE RETURN INCOMPLETE	An attempt was made to perform an automatic return to the reference position on the orthogonal axis before the completion of a return to the reference position on the angular axis. However, this attempt failed because a manual return to the reference position during angular axis control or an automatic return to the reference position after power-up was not commanded. First, return to the reference position on the angular axis, then return to the reference position on the orthogonal axis.

Number	Message	Description
PS0375	CAN NOT ANGULAR CONTROL(SYNC:MIX:OVL)	Angular axis control is disabled for this axis configuration. 1) When some related axes under angular axis control are not in synchronous control mode or when one angular axis is not paired with the other angular axis or one Cartesian axis is not paired with the other Cartesian axis in synchronous control 2) When some related axes under composite control are not in composite control mode or when one angular axis is not paired with the other angular axis or one Cartesian axis is not paired with the other Cartesian axis in composite control 3) When related axes under angular axis control is switched to superimposed control mode1)

Diagnosis

306	Machine coordinates on the angular axis in the Cartesian coordinate system
307	Machine coordinates on the perpendicular axis in the Cartesian coordinate system

[Data type] Real number
[Unit of data] Machine unit

Machine coordinates in the Cartesian coordinate system are displayed in angular axis control.
Bit 7 (ADG) of parameter No. 8201 can be used to change the display order.

1.9 ELECTRONIC GEAR BOX

1.9.1 Electronic Gear Box

Overview

This function enables fabrication of high-precision gears, screws, and other components by rotating the workpiece in synchronization with a rotating tool or by moving the tool in synchronization with a rotating workpiece. The rate of synchronization can be specified with a program. The synchronization of tool and workpiece axes with this function adopts a system in which the synchronization is directly controlled by digital servo, so that the workpiece axis can follow up the speed fluctuations on the tool axis with no error, thereby allowing fabrication of high-precision cogwheels. In the subsequent explanation, the Electronic Gear Box is called the EGB.

- Example of controlled axis configuration

Spindle : EGB master axis : Tool axis
1st axis : X axis
2nd axis : Y axis
3rd axis : C axis (EGB slave axis : Workpiece axis)
4th axis : C axis (EGB dummy axis : Cannot be used as a normal controlled axis.)

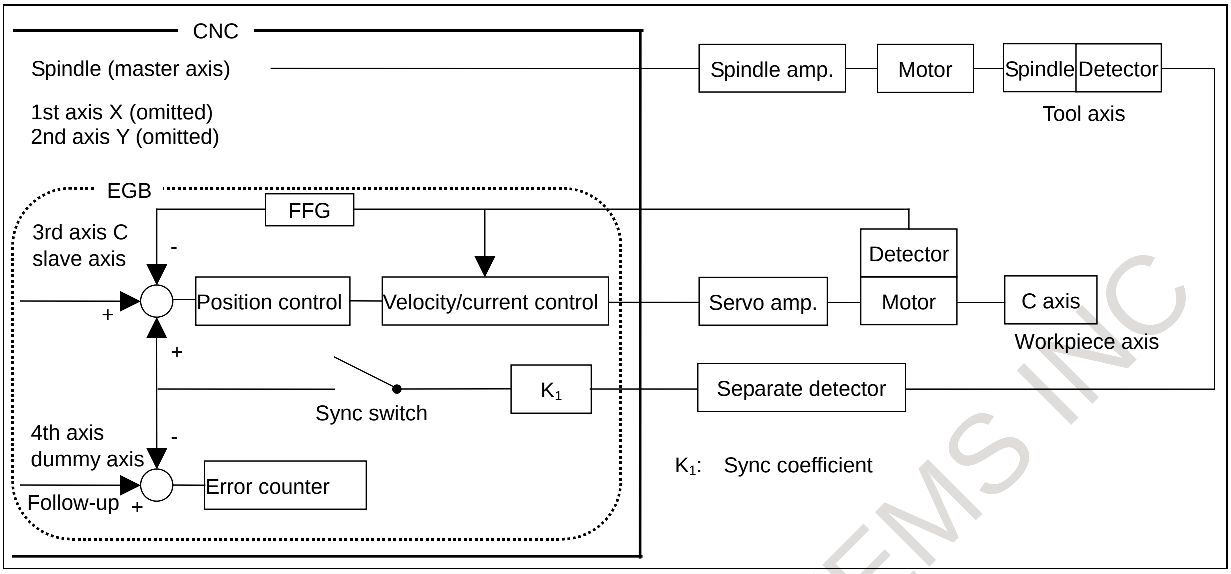

Fig. 1.9.1 (a)

For EGB axis configuration parameter setting examples, see the section on "FSSB setting".

Format

	Bit 0 (EFX) of parameter No.7731=0	Bit 0 (EFX) of parameter No.7731=1	
		Bit 5 (HBR) of parameter No.7731=1	Bit 5 (HBR) of parameter No.7731=0
Start of synchronization	**G81 T_ (L_) (Q_ P_) ;**	**G81.4 R_ (L_) (Q_ P_) ;**	**G81.4 T_ (L_) (Q_ P_) ;**
Cancellation of synchronization	**G80 ;**	**G80.4 ;**	**G80.4 ;**
	(*1) (*4)	**(*2) (*4)**	**(*3) (*4)**

T(or R) : Number of teeth (Specifiable range: 1 to 5000)
L : Number of hob threads (Specifiable range: -250 to 250)
The sign of L determines the direction of rotation for the workpiece axis.
When L is positive, the direction of rotation for the workpiece axis is positive (+ direction).
When L is negative, the direction of rotation for the workpiece axis is negative (- direction).
When L is 0, it follows the setting of bit 3 (LZR) of parameter No.7701.
If L is not specified, the number of hob threads is assumed 1.
Q : Module or diametral pitch
Specify a module in the case of metric input.
(Unit: 0.00001mm, Specifiable range: 0.01 to 25.0mm)
Specify a diametral pitch in the case of inch input.
(Unit: 0.00001inch^{-1}, Specifiable range: 0.01 to 254.0 inch^{-1})
P : Gear helix angle
(Unit: 0.0001deg, Specifiable range: -90.0 to 90.0deg)
*1 Use it for machining centers.
*2 Use it for lathes.
*3 Use it for machining centers.
This format enables specification of the same G codes as those for lathes.
*4 When specifying Q and P, the user can use a decimal point.

NOTE
Specify G81, G80, G81.4, and G80.4 in a single block.

Explanation

- Master axis, slave axis, and dummy axis

The synchronization reference axis is called the master axis, while the axis along which movement is performed in synchronization with the master axis is called the slave axis. For example, if the workpiece moves in synchronization with the rotating tool as in a hobbing machine, the tool axis is the master axis and the workpiece axis is the slave axis.
Which axes to become the master and slave axes depends on the configuration of the machine. For details, refer to the manual issued by the machine tool builder.
A single servo axis is used exclusively so that digital servo can directly read the rotation position of the master axis. (This axis is called the EGB dummy axis.)

- Synchronous control

(1) Start of synchronization

If G81 is issued so that the machine enters synchronization mode, the synch switch of the EGB function is closed, and the synchronization of the tool and workpiece axes is started. At this time, the EGB mode signal SYNMOD <Fn065.6> becomes “1”. During synchronization, the rotation about the tool and workpiece axes is controlled so that the relationship between T (number of teeth) and L (number of hob threads) is maintained. During synchronization, the synchronization relationship is maintained regardless of whether the operation is automatic or manual.
Specify P and Q to use helical gear compensation.
If only either P or Q is issued, alarm PS1594, “EGB FORMAT ERROR” is generated.
If, during synchronization, G81 is issued again without synchronization cancellation, alarm PS1595, “ILL-COMMAND IN EGB MODE” is generated if bit 3 (ECN) of parameter No. 7731 is 0. If bit 3 (ECN) of parameter No. 7731 is 1, helical gear compensation is conducted with the synchronization coefficient being changed to the one newly specified with T and L commands if T and L commands are issued, and if T and L commands are not issued and only P and Q commands are issued, helical gear compensation is conducted with the synchronization coefficient kept intact. This allows consecutive fabrication of helical gears and spur gears.

(2) Start of tool axis rotation

When the rotation of the tool axis starts, the rotation of the workpiece axis starts so that the synchronous relationship specified in the G81 block can be maintained.
The rotation direction of the workpiece axis depends on the rotation direction of the tool axis. That is, when the rotation direction of the tool axis is positive, the rotation direction of the workpiece axis is also positive; when the rotation direction of the tool axis is negative, the rotation direction of the workpiece axis is also negative. However, by specifying a negative value for L, the rotation direction of the workpiece axis can be made opposite to the rotation direction of the tool axis.
During synchronization, the machine coordinates of the workpiece axis and EGB axis are updated as synchronous motion proceeds. On the other hand, a synchronous move command has no effect on the absolute and relative coordinates.

(3) Termination of tool axis rotation

In synchronism with gradual stop of the tool axis, the workpiece axis is decelerated and stopped. By specifying the G80 command after the spindle stops, synchronization is canceled, and the EGB synchronization switch is opened. At this time, the EGB mode signal SYNMOD becomes “0”.

(4) Cancellation of synchronization

When cancellation of synchronization is issued, the absolute coordinate on the workpiece axis is updated in accordance with the amount of travel during synchronization. Subsequently, absolute commands for the workpiece axis will be enabled.
For a rotation axis, the amount of travel during synchronization, as rounded to 360-degree units is added to the absolute coordinate.
In the G80 block, only O and N addresses can be specified.
By setting bit 0 (HBR) of parameter No. 7700 to 0, it is possible to cancel synchronization with a reset.
Synchronization is automatically canceled under the following conditions:

<1> An emergency stop is applied.
<2> A servo alarm is generated.
<3> Alarm PW0000, “POWER MUST BE OFF” is generated.
<4> An IO alarm is generated.

⚠ CAUTION

1 Feed hold, interlock, and machine lock are invalid to a slave axis in EGB synchronization.
2 Even if an OT alarm is issued for a slave axis in EGB synchronization, synchronization will not be canceled.
3 During synchronization, it is possible to execute a move command for a slave axis and other axes, using a program. The move command for a slave command must be an incremental one.

NOTE

1 If bit 0 (HBR) of parameter No. 7700 is set to 1, EGB synchronization will not be canceled due to a reset. Usually, set this parameter bit to 1.
2 In synchronization mode, it is not possible to specify G27, G28, G29, G30, and G53 for a slave axis.
3 It is not possible to use controlled axis detach for a slave axis.
4 During synchronization, manual handle interruption can be performed on the slave and other axes.
5 In synchronization mode, no inch/metric conversion commands (G20 and G21) cannot be issued.
6 In synchronization mode, only the machine coordinates on a slave axis are updated.
7 If bit 0 (EFX) of parameter No. 7731 is 0, no canned cycle for drilling can be used. To use a canned cycle for drilling, set bit 0 (EFX) of parameter No. 7731 to 1 and use G81.4 instead of G81 and G80.4 instead of G80.
8 If bit 0 (TDP) of parameter No. 7702 is 1, the permissible range of T is 0.1 to 500 (1/10 of the specified value).
9 If, at the start of EGB synchronization (G81), L is specified as 0, synchronization starts with L assumed to be 1 if bit 3 (LZR) of parameter No.7701 is 0; if bit 3 (LZR) of parameter No.7701 is 1, synchronization is not started with L assumed to be 0. At this time, helical gear compensation is performed.
10 Feed per revolution is performed on the feedback pulses on the spindle. By setting bit 0 (ERV) of parameter No. 7703 to 1, feed per revolution can be performed based on the speed on the synchronous slave axis.
11 Actual cutting feedrate display does not take synchronization pulses into consideration.
12 For an EGB slave axis, synchronous and composite control cannot be executed.
13 In EGB synchronization mode, AI contour control mode is temporarily canceled.
14 Not advanced preview feed-forward but conventional feed-forward is enabled in the path where EGB synchronization mode is effective.

- Synchronization start/cancellation timing chart example

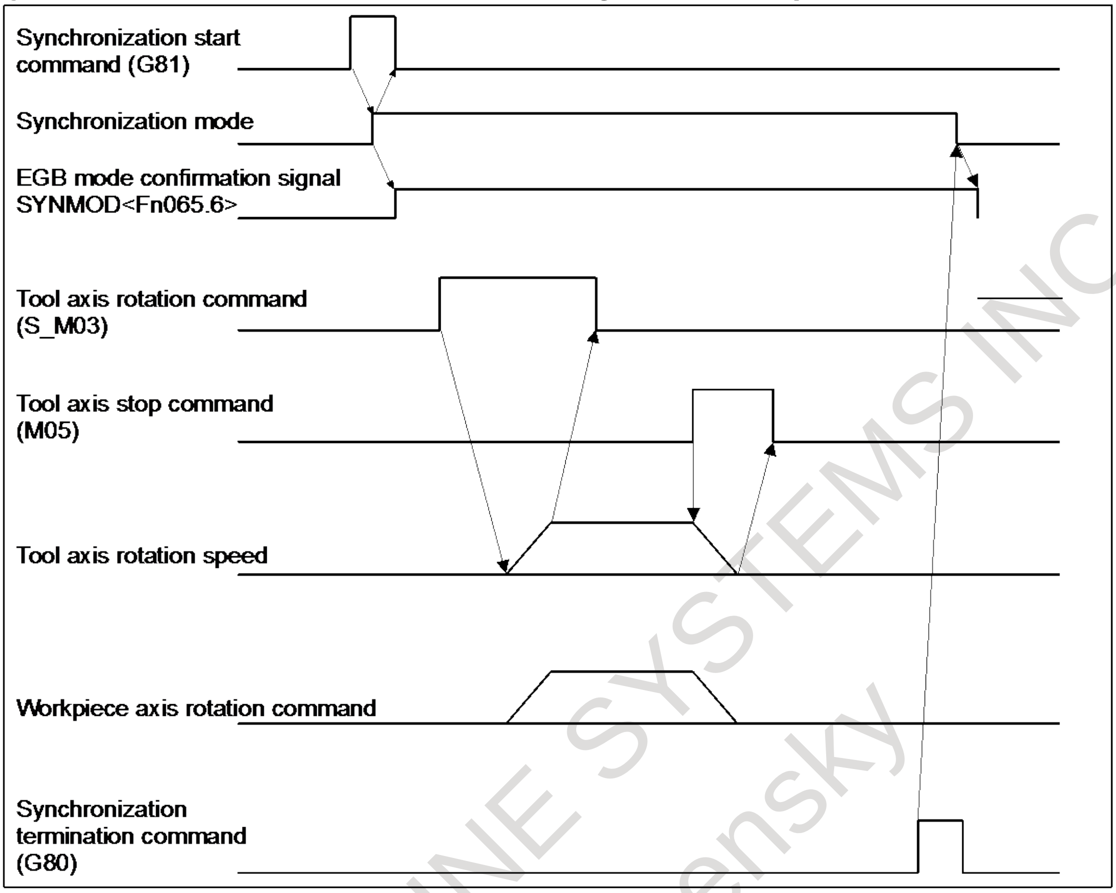

Fig. 1.9.1 (b)

- How to reduce the synchronous error

When you use the Electronic gear box function, to reduce the synchronous error, please apply feed-forward to the slave axis and set 100% to the parameter of feed-forward coefficient.
And please confirm the effectiveness of feed-forward by the following procedure.

[Procedure]

1. When the slave axis synchronizes only with the command from master axis (i.e. When the slave axis doesn't use helical gear compensation), the position error of slave axis is regarded as the synchronous error. Please check that the position error (DGN data No.300) of the slave axis becomes 0 or so.
2. And also please check the position error is near 0 even when the speed of the master axis is changed.

Please set the following parameters to use Feed-forward function with 100% coefficient.

[Setting parameters]

Bit 3 (PIEN) of parameter No. 2003 = 1 (Slave axis)	Use PI control in velocity control
Bit 1 (FEED) of parameter No. 2005 = 1 (Slave axis)	Use Feed-forward function
Bit 1 (FFALx) of parameter No. 2011 = 1 (Slave axis)	Use Feed-forward function irrespective of feed mode
Parameter No.2068 (FF coefficient) = 10000 (Slave axis)	Feed-forward coefficient is 100%.

Please refer to the chapter of “Feed-forward Function” in FANUC AC SERVO MOTOR α*i* series FANUC AC SERVO MOTOR β*i* series FANUC LINEAR MOTOR L*i*S series FANUC SYNCHRONOUS BUILT-IN SERVO MOTOR D*i*S series Parameter manual (B-65270EN) about the detail of Feed-forward function.

- How to reduce shock at the start of acc./dec.

If the shock of slave axis is large when the master axis accelerates or decelerates in velocity control mode, please apply “Soft start/stop” function to the master axis (spindle axis).
Please set the following parameters to use Soft start/stop function.

[Setting parameters]

Bit 2 (SOSALWs) of parameter No. 4399 = 1 Use Soft start/stop function even at emergency stop

Note) If the spindle axis is a sub axis of spindle switching control, please set bit 2 of parameter No. 4472 instead of bit 2 of parameter No. 4399.

Parameter No. 4030 Soft start/stop setting time
Parameter No. 4508 Rate of change in acceleration at soft start/stop

Note) Parameters Nos. 4030 and 4508 should be tuned according to the spindle characteristic to reduce the shock well.

[Signals]

Soft start/stop signal SOCNA <Gn071.4> : First spindle
Soft start/stop signal SOCNB <Gn075.4> : Second spindle
Soft start/stop signal SOCNC <Gn205.4> : Third spindle
Soft start/stop signal SOCND <Gn267.4> : Fourth spindle

Please refer to FANUC AC SPINDLE MOTOR α*i*/β*i* series BUILT-IN SPINDLE MOTOR B*i* series parameter manual (B-65280EN) about the detail of Soft start/stop function.

- Helical gear compensation

For a helical gear, the workpiece axis is compensated for the movement along the Z-axis (axial feed axis) based on the torsion angle of the gear.
Helical gear compensation is performed with the following formulas:

$$\text{Compensation angle} = \frac{Z \times \sin(P)}{\pi \times T \times Q} \times 360 \text{ (for metric input)}$$

$$\text{Compensation angle} = \frac{Z \times Q \times \sin(P)}{\pi \times T} \times 360 \text{ (for inch input)}$$

where

Compensation angle: Signed absolute value (deg)

Z : Amount of travel on the Z-axis after the specification of G81
P : Signed gear helix angle (deg)
π : Circular constant
T : Number of teeth
Q : Module (mm) or diametral pitch (inch^{-1})

Use P, T, and Q specified in the G81 block.

In helical gear compensation, the machine coordinates on the workpiece axis and the absolute coordinates are updated with helical gear compensation.
The updated timing is as follows.

<table>
<tr><th>Machine coordinates</th><th colspan="2">Absolute coordinates</th></tr>
<tr><td rowspan="3">During helical gear compensation</td><td colspan="2">Bit 7(HAD) of parameter No.7731</td></tr>
<tr><td>= 0</td><td>= 1</td></tr>
<tr><td>Synchronization cancel</td><td>During helical gear compensation</td></tr>
</table>

- Direction of helical gear compensation

The direction depends on bit 2 (HDR) of parameter No. 7700.

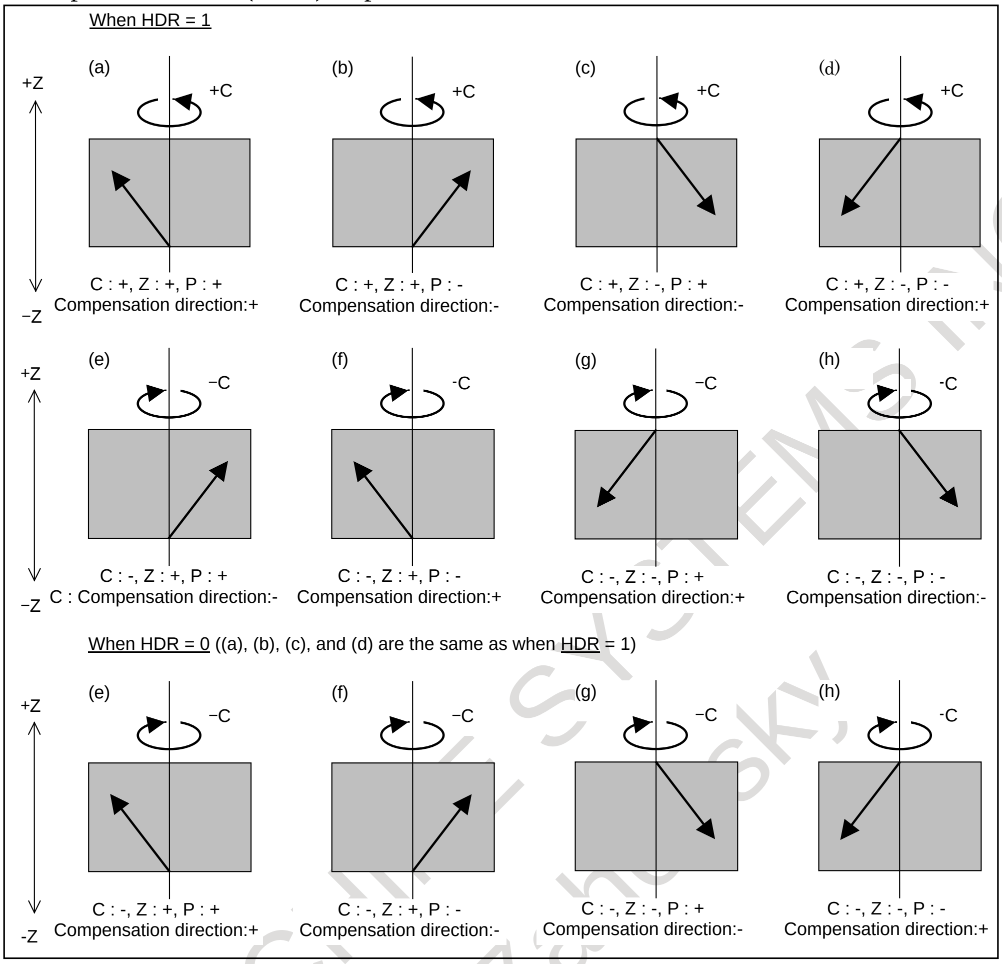

Fig. 1.9.1 (c) Direction of helical gear compensation

- Synchronization coefficient

A synchronization coefficient is internally represented using a fraction (Kn/Kd) to eliminate an error. The formula below is used for calculation.

$$\text{Synchronization coefficient} = \frac{K_n}{K_d} = \frac{L}{T} \times \frac{\beta}{\alpha}$$

where

L : Number of hob threads

T : Number of teeth

α : Number of pulses of the position detector per rotation about the master axis (parameter No. 7772)

β : Number of pulses of the position detector per rotation about the slave axis (parameter No. 7773)

Kn / Kd is a value resulting from reducing the right side of the above formula, but the result of reduction is subject to the following restrictions:

$-2147483648 \le K_n \le 2147483647$

$1 \le K_d \le 2147483647$

When this restriction is not satisfied, the alarm PS1596, “EGB OVERFLOW” is issued when G81 is specified.

- Retract function

(1) Retract function with an external signal

When the retract signal, RTRCT<Gn066.4>, becomes “1” (the rise of the signal is captured), retraction is performed with the retract amount set in parameter No. 7741 and the speed set in parameter No. 7740.
No movement is performed along an axis for which 0 is set as the retract amount.
After the end of retraction, the retract completion signal, RTRCTF<Fn065.4>, is output.

(2) Retract function with an alarm

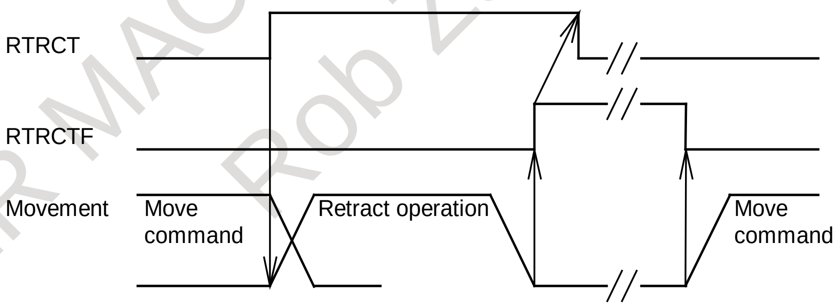
If, during EGB synchronization or automatic operation, a CNC alarm is issued, retraction is performed with the retract amount set in parameter No. 7741 and the speed set in parameter No. 7740.
This can prevent the tool and the object being machined from damage if a servo alarm is generated.
No movement is performed along an axis for which 0 is set as the retract amount.
After the end of retraction, the retract completion signal, RTRCTF, is output.

Conditions under the retract function with an alarm
The conditions under which the retract function with an alarm can be changed using the settings of bit 1 (ARE) of parameter No. 7703 and bit 2 (ARO) of parameter No. 7703.
The table below lists parameter settings and corresponding conditions.

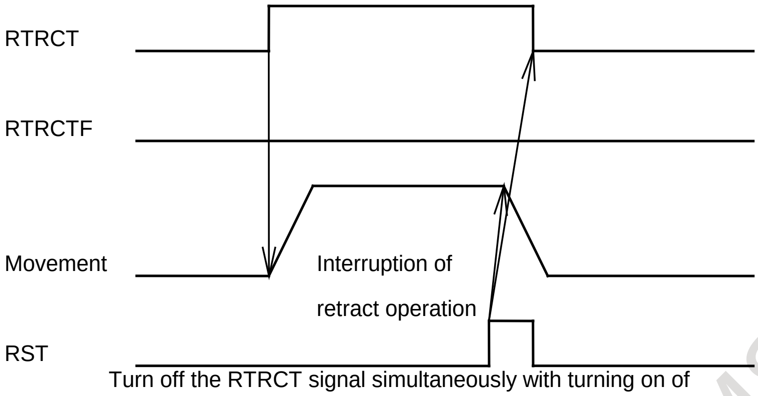
ARE	ARO	Condition
1	0	EGB synchronization is in progress.
1	1	Both EGB synchronization and automatic operation are in progress.
0	0	Either EGB synchronization or automatic operation is in progress.
0	1	

Timing chart

<1> On/off timing of RTRCT and RTRCTF

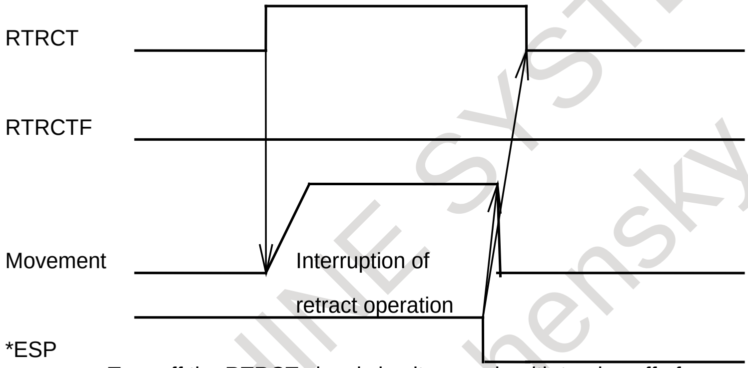


<2> Interruption of retraction with to a reset



Turn off the RTRCT signal simultaneously with turning on of the RST signal.

<3> Interruption of retraction due to an emergency stop



Turn off the RTRCT signal simultaneously with turning off of the *ESP signal.

> ⚠ **CAUTION**
> 1 Retraction is performed at the speed specified in parameter No. 7740.
> 2 Feed hold is not effective to movement during retraction.
> 3 Feedrate override is not effective to movement during retraction.

NOTE

1 During a retract operation, an interlock is effective to the retract axis.
2 During a retract operation, a machine lock is effective to the retract axis. The retract operation terminates in the machine lock state, and a retract completion signal is output.
3 The retraction direction depends on the movement direction of the machine, regardless of whether an mirror image (signal and setting) is enabled or disabled. (No mirror image can be applied to the updating of absolute coordinates.)
4 If retraction is performed during automatic operation, automatic operation is halted simultaneously with a retract operation, but it is at the end of the retract operation that the operation state switches to the automatic operation halt state.

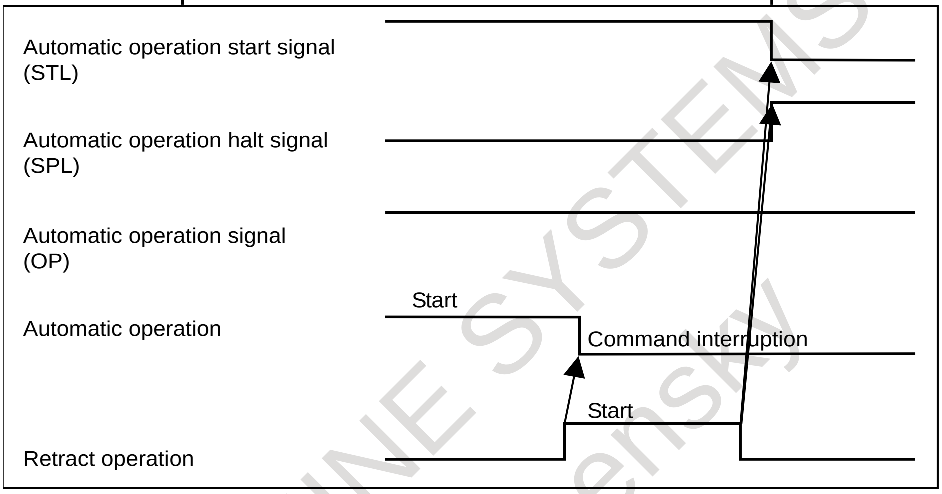


Fig. 1.9.1 (d)

5 It is not possible to perform automatic operation during retraction.
6 The acceleration/deceleration of a retract operation is in the acceleration/deceleration state at the start of retraction.
7 Retract movement is performed with non-linear type positioning.
8 If, during a retract operation, a reset or an emergency stop is made, the operation is interrupted. At this time, the retract completion signal does not become “1”.
9 To enable the retract function with an alarm, bit 3 (ART) of parameter No.7702 must be set.
10 The retract function with an alarm does not perform a retract operation on the retract axis if an overtravel alarm or a servo alarm is generated on the retract axis.
11 If a new alarm is issued during retraction with the retract function with an alarm, a retract operation is not performed.
12 After the end of retraction with a servo alarm, servo position control stops in 400 ms.
13 The retract completion signal RTRCTF <Fn065.4> becomes “0” when a move command is issued for any axis after retract operations on all axes are completed.

Example

O1000 ;	
N0010 M19 ;	Tool axis orientation
N0020 G28 G91 C0 ;	Reference position return on the work axis
N0030 G81 T20 L1 ;	Start of synchronization of the tool axis and the work axis (Rotation about the work axis by 18° per rotation about the tool axis)
N0040 S300 M03 ;	Rotation about the tool axis at 300min^{-1}
N0050 G01 X_ F_ ;	Movement along the X-axis (cutting)
N0060 G01 Z_ F_ ;	Movement along the Z-axis (machining)
;	If required, C, X, Z, and other axis command are possible.
;	
N0100 G01 X_ F_ ;	Movement along the X-axis (escape)
N0110 M05 ;	Stop on the tool axis
N0120 G80 ;	Cancellation of synchronization of the tool and work axes
N0130 M30 ;	

Signal

Retract signal RTRCT <Gn066.4>

[Classification] Input signal

[Function] Performs retraction for the axis specified with a parameter.

[Operation] When this signal becomes “1”, the CNC operates as follows:

The CNC can capture the rise of the signal and perform retraction for the axis for which the retract amount has been specified with parameter No. 7741. The retract amount and the retract speed will be the values previously set in parameters Nos. 7741 and 7740. After the end of retraction, the retract completion signal, RTRCTF, is output. The retract signal is effective both during automatic operation mode (MEM, MDI, etc.) and manual operation mode (HNDL, JOG, etc.). If, during automatic operation, the retract signal is set to “1”, a retract operation is performed and, at the same time, automatic operation is halted.

Retract completion signal RTRCTF <Fn065.4>

[Classification] Output signal

[Function] Posts notification of the completion of retraction.

[Operation] This signal is set to “1” in the following case:

- Upon the completion of retraction (at the end of movement)

This signal is set to “0” in the following case:

- When a move command is issued for any retract axis after the end of a retract operation.

> **NOTE**
> The retract signal is not accepted while the retract completion signal is set to “1”.

EGB mode signal SYNMOD <Fn065.6>

[Classification] Output signal

[Function] Posts notification that synchronization using the EGB is in progress.

[Operation] This signal is set to “1” in the following case:

- While synchronization using the EGB is in progress

This signal is set to “0” in the following case:

- Once synchronization using the EGB has terminated

Signal address

	#7	#6	#5	#4	#3	#2	#1	#0

Parameter

The table below gives parameters related to EGB.

Parameter number	Description
1006#0 1006#1	An EGB slave axis and an EGB dummy axis require that the setting of a rotary axis (type A) (bit 0 (ROT) of parameter No. 1006 be 1 and bit 1 (ROS) of parameter No. 1006 be 0.
1023	Set from the FSSB setting screen. For FSSB manual setting, be sure to set the EGB axis as described below: The slave axis must be set with an odd number, and the dummy axis with an even number. They must be consecutive. Example: If the servo axis number of the slave axis is 1, the servo axis number of the dummy axis must be set to 2. If the servo axis number of the slave axis is 3, the servo axis number of the dummy axis must be set to 4.
2011#0	Specify an axis to be synchronized. Specify 1 for both an EGB slave axis and EGB dummy axis.
3115#0	The current position is not indicated for an axis for which this parameter is set to 1.Since the current position for an EGB dummy axis has no meaning, set this parameter to 1 to delete the current position indication for the axis from the screen.
7700#0	The synchronization mode is canceled (0)/not canceled (1) by a reset.
7700#2	Compensation direction for helical gear compensation
7701#3	At the start of synchronization (G81), synchronization is started (0)/not started (1) if the number of hob threads L is specified as 0.
7702#0	The specifiable number of teeth, T, at the start of synchronization (G81) is not reduced to a 1/10 of a specified value (0)/reduced (1).
7702#3	The retract function with an alarm is disabled (0)/enabled (1).
7703#0	During synchronization (G81), feed per revolution is performed for feedback pulses (0)/pulses converted to the speed for the workpiece axis(1).
7703#1,#2	Specify when to perform a retract operation with the retract function with an alarm; during synchronization; during synchronization and automatic operation; or during synchronization or automatic operation.
7709	Number of the axial feed axis in helical gear compensation
7731#0	The EGB command is G80 and G81(0)/G80.4 and G81.4(1).
7731#3	When the automatic phase synchronization function for the electronic gear box is disabled, the G81 command cannot be issued again (an alarm is issued) (0)/can be issued again (1)during EGB synchronization.
7731#5	In EGB synchronization start command G81.4, the number of teeth is specified in T (0)/specified in R (1).
7740	Feedrate during retraction
7741	Retract amount
7772	Number of position detector pulses per rotation about tool axis
7773	Number of position detector pulses per rotation about workpiece axis

For FSSB settings, see the section on "FSSB settings".

If FSSB setting mode is automatic setting mode, setting is made automatically by inputting data to the FSSB setting screen. For the slave/dummy axes of EGB, set the value in the 'M/S' item in the FSSB axis setting screen same way of the tandem setting.

Note the following points when specifying parameters for the electronic gear box.

1 Specify an axis that is not used or the same name as that for a slave axis for the name of a dummy axis. Do not use a name which is usually not allowed to be used as an axis address, such as D.

2 Specify the same values for an EGB slave axis and an EGB dummy axis in the following parameters.

1013#0 to 3	Increment system
1004#7	Ten times minimum input increment
1006#0,1	Rotary axis setting
1006#3	Diameter/radius specification
1420	Rapid traverse rate
1421	Rapid-traverse override F0 speed
1820	Command multiplication
2000 and over, except 2022, 2084, 2085	Parameters related to digital servo

3 Specify the amount of travel per rotation about a rotation axis for a slave axis and dummy axis in a parameter No. 1260.

4 Make the specification for a dummy axis in the following way.

1815#1	Whether to use separate detectors. Although an EGB dummy axis uses the interface of a separate detector, set these parameters to 0.
2022	Motor rotation direction. Set the parameter to 111.
2084	Numerator of flexible feed gear ratio. Set the parameter to 1.
2085	Denominator of flexible feed gear ratio. Set the parameter to 1. When using a serial type position detector, set an appropriate value for the flexible feed gear. To set the Flexible Feed Gear to a value other than 1/1 with A/B phase type position detector, set parameter EGFx (bit6 of parameter No.2273) to 1.

5 Reducing synchronous errors requires enabling the feed-forward function for the slave axis. For details, see “How to reduce the synchronous error” in "Explanation" of this chapter.

6 Reducing shocks that may occur at the beginning of acceleration/deceleration requires enabling the soft start/stop function for the spindle axis. For details, see “How to reduce shock at the start of acc./dec.” in "Explanation" of this chapter.

1023	Number of the servo axis for each axis

> **NOTE**
> When this parameter is set, the power must be turned off before operation is continued.

[Input type] Parameter input
[Data type] Byte axis
[Valid data range] 0 to 80

This parameter associates each control axis with a specific servo axis. Specify values 1+8n, 2+8n, 3+8n, 4+8n, 5+8n, and 6+8n (n = 0, 1, 2, …, 9) like 1, 2, 3, 4, 5, …, 77, and 78.

The control axis number is the order number that is used for setting the axis-type parameters or axis-type machine signals

* For electronic gear box (EGB) controlled axes, two axes need to be specified as one pair. So, make a setting as described below.
EGB axis:
For a slave axis, set an odd (1, 3, 5, 7, 9, ...) servo axis number. For a dummy axis to be paired, set a value obtained by adding 1 to the value set for the slave axis.

	#7	#6	#5	#4	#3	#2	#1	#0
2011								SYNx

[Input type] Parameter input
[Data type] Bit axis

#0 SYNx When the electronic gear box function (EGB) is used, this bit sets the axis to be synchronized.

0: Axis not synchronized by EGB
1: Axis synchronized by EGB
Set 1 for both of the slave and dummy axes of EGB.

> **NOTE**
> The setting of this parameter becomes valid after the power is turned off then back on.

	#7	#6	#5	#4	#3	#2	#1	#0
3115								NDPx

[Input type] Parameter input
[Data type] Bit axis

#0 NDPx The current position is:
0: Displayed.
1: Not displayed.

> **NOTE**
> When using the electronic gear box (EGB) function, set 1 for the EGB dummy axis to disable current position display.

	#7	#6	#5	#4	#3	#2	#1	#0
7700						HDR		HBR

[Input type] Parameter input
[Data type] Bit path

#0 HBR When the electronic gear box (EGB) function is used, performing a reset:
0: Cancels the synchronization mode (G81 or G81.5).
1: Does not cancel the synchronization mode. The mode is canceled only by the G80 or G80.5 command.

#2 HDR Direction of helical gear compensation (usually, set 1.)
(Example) To cut a left-twisted helical gear when the direction of rotation about the C-axis is the negative (-) direction:
0: Set a negative (-) value in P.
1: Set a positive (+) value in P.

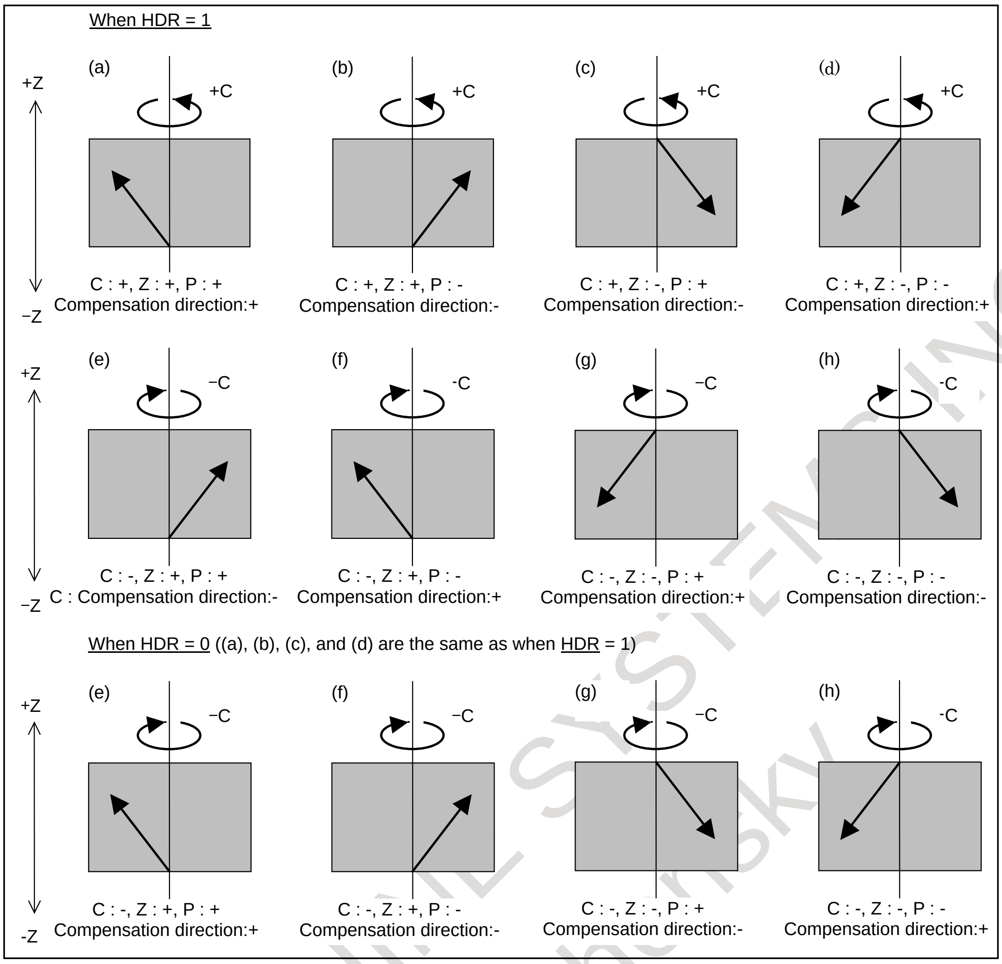

Fig. 1.9.1 (e) Direction of helical gear compensation

	#7	#6	#5	#4	#3	#2	#1	#0
7701					**LZR**			

[Input type] Parameter input
[Data type] Bit path

#3 LZR When L (number of hob threads) = 0 is specified at the start of EGB synchronization (G81):
0: Synchronization is started, assuming that L = 1 is specified.
1: Synchronization is not started, assuming that L = 0 is specified. However, helical gear compensation is performed.

	#7	#6	#5	#4	#3	#2	#1	#0
7702					**ART**			**TDP**

[Input type] Parameter input
[Data type] Bit path

#0 TDP The specifiable number of teeth, T, of the electronic gear box (G81) is:
0: 1 to 5000
1: 0.1 to 500 (1/10 of a specified value)

> **NOTE**
> In either case, a value from 1 to 5000 can be specified.

#3 ART The retract function executed when an alarm is issued is:
0: Disabled.
1: Enabled.
When an alarm is issued, a retract operation is performed with a set feedrate and travel distance (parameters Nos. 7740 and 7741).

NOTE
If a servo alarm is issued for other than the axis along which a retract operation is performed, the servo activating current is maintained until the retract operation is completed.

	#7	#6	#5	#4	#3	#2	#1	#0
7703						ARO	ARE	ERV

[Input type] Parameter input
[Data type] Bit path

#0 ERV During EGB synchronization (G81), feed per revolution is performed for:
0: Feedback pulses.
1: Pulses converted to the speed for the workpiece axis.

#1 ARE The retract function executed when an alarm is issued retracts the tool during:
0: EGB synchronization or automatic operation (automatic operation signal OP <Fn000.7> = “1”).
1: EGB synchronization.

#2 ARO The retract function executed when an alarm is issued retracts the tool during:
0: EGB synchronization.
1: EGB synchronization and automatic operation (automatic operation signal OP <Fn000.7> = “1”).

NOTE
This parameter is valid when bit 1 (ARE) of parameter No. 7703 is set to 1.

The table lists the parameter settings and corresponding operation.

ARE	ARO	Operation
1	0	During EGB synchronization
1	1	During EGB synchronization and automatic operation
0	0	During EGB synchronization or automatic operation
0	1	

NOTE
Parameters ARE and ARO are valid when bit 3 (ART) of parameter No. 7702 is set to 1 (when the retract function executed when an alarm is issued).

7709	Number of the axial feed axis for helical gear compensation

[Input type] Parameter input
[Data type] 2-word path
[Valid data range] 0 to Number of controlled axes
This parameter sets the number of the axial feed axis for a helical gear.

> **NOTE**
> When this parameter is set to 0 or a value outside the valid setting range, the Z-axis becomes the axial feed axis.

	#7	#6	#5	#4	#3	#2	#1	#0
7731	HAD		HBR		ECN			EFX

[Input type] Parameter input
[Data type] Bit path

#0 EFX As the EGB command:
0: G80 and G81 are used.
1: G80.4 and G81.4 are used.

> **NOTE**
> When this parameter is set to 0, no canned cycle for drilling can be used.

#3 ECN When the automatic phase synchronization function for the electronic gear box is disabled, during EGB synchronization, the G81 or G81.5 command:
0: Cannot be issued again. (The alarm PS1595, "ILL-COMMAND IN EGB MODE" is issued.)
1: Can be issued again.

#5 HBR In EGB synchronization start command G81.4, the number of teeth is:
0: Specified in T.
1: Specified in R.

> **NOTE**
> This parameter is valid when bit 0 (EFX) of parameter No. 7731 is set to 1.

#7 HAD In electronic gear box, the timing for reflecting helical gear compensation and travel distance of automatic phase synchronization to absolute coordinates is:
0: When synchronization is canceled.
1: During helical gear compensation and automatic phase synchronization.

7740	Feedrate during retraction

[Input type] Parameter input
[Data type] Real axis
[Unit of data] mm/min, inch/min, deg/min (machine unit)
[Min. unit of data] Depend on the increment system of the applied axis
[Valid data range] Refer to the standard parameter setting table (C)
(When the increment system is IS-B, 0.0 to +999000.0)
This parameter sets the feedrate during retraction for each axis.

7741	Retract amount

[Input type] Parameter input
[Data type] Real axis
[Unit of data] mm, inch, deg (machine unit)
[Min. unit of data] Depend on the increment system of the applied axis
[Valid data range] 9 digit of minimum unit of data (refer to standard parameter setting table (A))
(When the increment system is IS-B, -999999.999 to +999999.999)

This parameter sets the retract amount for each axis.

7772	Number of position detector pulses per rotation about the tool axis

[Input type] Parameter input
[Data type] 2-word path
[Unit of data] Detection unit
[Valid data range] 1 to 999999999

This parameter sets the number of pulses per rotation about the tool axis (master axis), for the position detector.
For an A/B phase detector, set this parameter with four pulses equaling one A/B phase cycle.

7773	Number of position detector pulses per rotation about the workpiece axis

[Input type] Parameter input
[Data type] 2-word path
[Unit of data] Detection unit
[Valid data range] 1 to 999999999

This parameter sets the number of pulses per rotation about the workpiece axis (slave axis), for the position detector.
Set the number of pulses output by the detection unit.
Set parameters Nos. 7772 and 7773 when using the G81 EGB synchronization command.

[Example 1] When the EGB master axis is the spindle and the EGB slave axis is the C-axis

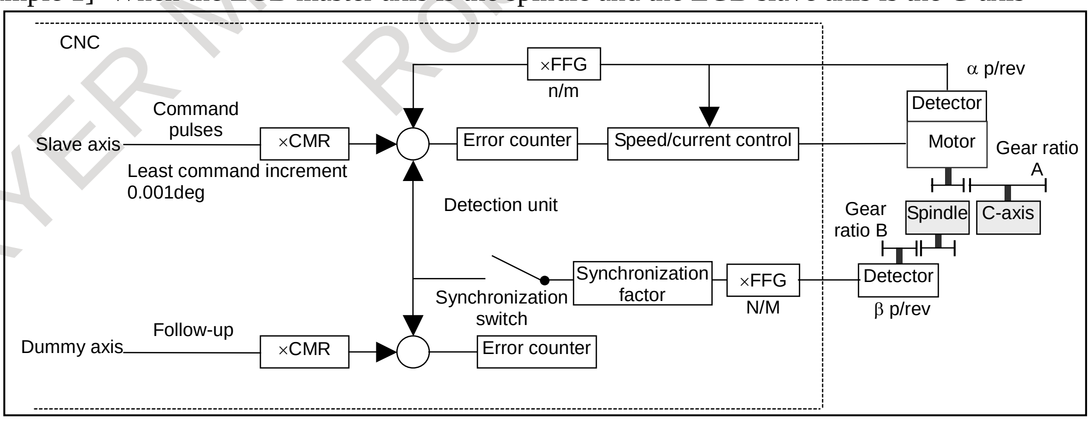

Fig. 1.9.1 (f)

Gear ratio of the spindle to the detector B:
1/1 (The spindle and detector are directly connected to each other.)
Number of detector pulses per spindle rotation β: 80,000 pulses/rev
(Calculated for four pulses for one A/B phase cycle)
FFG N/M of the EGB dummy axis : 1/1

Gear ratio of the C-axis A :1/36 (One rotation about the C-axis to 36 motor rotations)
Number of detector pulses per C-axis rotation α: 1,000,000 pulses/rev
C-axis CMR: 1
C-axis FFG n/m :1/100

In this case, the number of pulses per spindle rotation is:
$80000 \times 1/1 = 80000$
Therefore, set 80000 for parameter No. 7772.
The number of pulses per C-axis rotation in the detection unit is:

$$1000000 \div \frac{1}{36} \times \frac{1}{100} = 360000$$

Therefore, set 360000 for parameter No. 7773.

[Example 2] When the gear ratio of the spindle to the detector B is 2/3 for the above example (When the detector rotates twice for three spindle rotations)
In this case, the number of pulses per spindle rotation is:

$$80000 \times \frac{2}{3} = \frac{160000}{3}$$

160000 cannot be divided by 3 without a remainder. In this case, change the setting of parameter No. 7773 so that the ratio of the settings of parameters Nos. 7772 and 7773 indicates the value you want to set.

$$\frac{\text{No.7772}}{\text{No.7773}} = \frac{160000/3}{360000} = \frac{160000}{360000 \times 3} = \frac{160000}{1080000}$$

Therefore, set 160000 for parameter No. 7772 and 1080000 for parameter No. 7773.
As described above, all the settings of parameters Nos. 7772 and 7773 have to do is to indicate the ratio correctly. So, you can reduce the fraction indicated by the settings. For example, you may set 16 for parameter No. 7772 and 108 for parameter No. 7773 for this case.

	#7	#6	#5	#4	#3	#2	#1	#0
2273		EGFx						

[Input type] Parameter input
[Data type] Bit axis

#6 EGFx FFG is:
0: Not considered in the number of pulses of the position detector per rotation about the master axis.
1: Considered.
Set for the EGB dummy axis.

> **NOTE**
> EGFx is valid for A/B phase type position detector. In the case of using serial type position detector, FFG is always considered.

The synchronization coefficient is subject to the following restriction:

$$\text{Synchronization coefficient} = \frac{K_n}{K_d} = \frac{L}{T} \times \frac{\beta}{\alpha}$$

$-2147483648 \le K_n \le 2147483647$
$1 \le K_d \le 2147483647$

If above condition cannot be satisfied, set this parameter bit to 1. With this setting, FFG is considered in the number of pulses of the position detector per rotation about the master axis, and by selecting FFG appropriately, it is possible to be satisfied above condition without the change of synchronization coefficient. $\alpha[\text{New}] = \alpha[Old] \times \frac{N}{M}$

N: Numerator of FFG
M: Denominator of FFG

[Setting example]

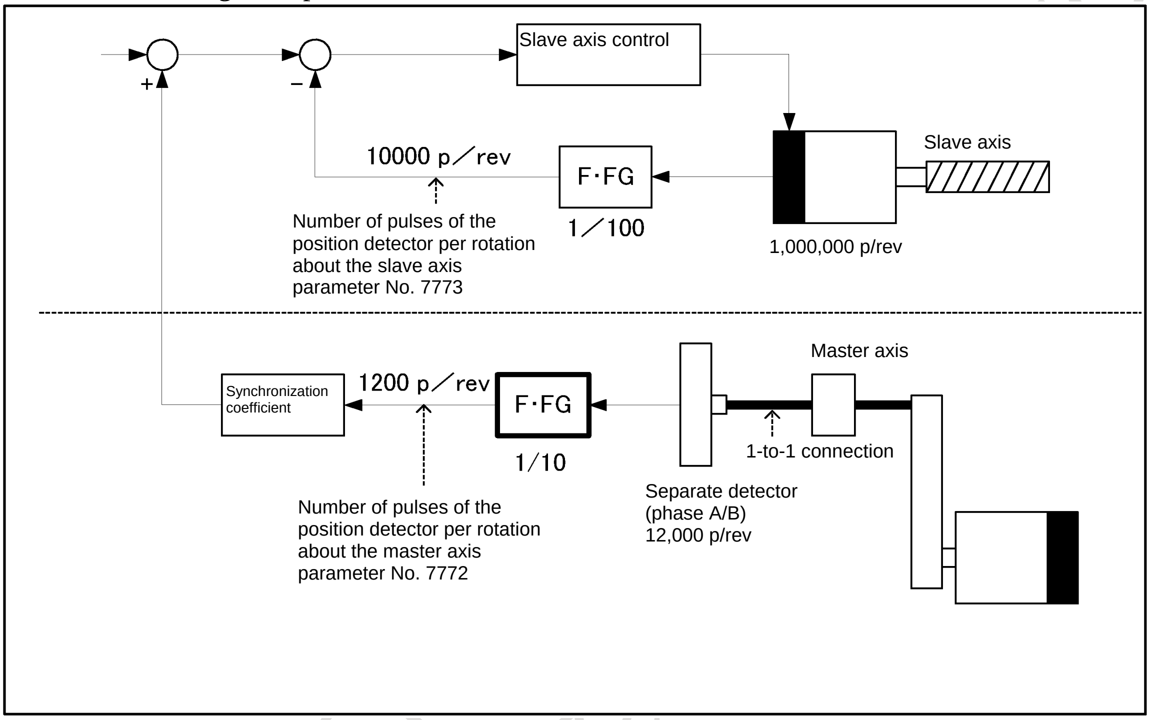

Fig. 1.9.1 (g)

Master axis conditions:
The separate detector must be 12000 p/rev.
The master axis and the separate detector must have a 1-to-1 connection.

In this example, EGFx (bit6 of parameter No.2273) is set to 1, FFG is set to 1/10, and the number of pulses of the position detector per rotation about the master axis is
$\alpha = 12000 \times \frac{1}{10} = 1200$

	#7	#6	#5	#4	#3	#2	#1	#0
4399						**SOSALWs**		

[Input type] Parameter input
[Data type] Bit spindle

#2 SOSALWs Soft start/stop function is:
0: Disabled if *ESP is ”0” (emergency stop) or if MRDY is ”0”.
1: Enabled also if *ESP is ”0” (emergency stop) or if MRDY is ”0”.

4030	**Soft start/stop setting time**

[Input type] Parameter input
[Data type] Word spindle

[Unit of data] 1min^{-1}/sec
[Valid data range] 0 to 32767

This parameter sets an acceleration (rate at which the speed changes) applied when the soft start/stop function is enabled (soft start/stop signal SOCNA <Gn071> is “1”).

4508	Rate of change in acceleration at soft start/stop

[Input type] Parameter input
[Data type] Word spindle
[Unit of data] 10min^{-1}/sec^{2}
[Valid data range] 0 to 32767

This parameter sets the rate of change of acceleration (rate at which the acceleration changes) applied when the soft start/stop function is enabled (soft start/stop signal SOCNA <Gn071> is “1”).

> **NOTE**
> If the setting is 0, speed commands are linear when the soft start/stop function is enabled.

	#7	#6	#5	#4	#3	#2	#1	#0
4472						SOSALWs		

[Input type] Parameter input
[Data type] Bit spindle

#2 SOSALWs Soft start/stop function(if the spindle axis is a sub axis of spindle switching control) is:
0: Disabled if *ESP is ”0” (emergency stop) or if MRDY is ”0”.
1: Enabled also if *ESP is ”0” (emergency stop) or if MRDY is ”0”.

Alarm and message

Number	Message	Description
PS1593	EGB PARAMETER SETTING ERROR	Error in setting a parameter related to the EGB (1) The setting of bit 0 (SYNx) of parameter No. 2011, is not correct. (2) The slave axis specified with G81 is not set as a rotation axis. (bit 0 (ROTx) of parameter No. 1006) (3) Number of pulses per rotation (parameter No. 7772 or 7773) is not set.
PS1594	EGB FORMAT ERROR	Error in the format of the block of an EGB command (1) T (number of teeth) is not specified in the G81 block. (2) In the G81 block, the data specified for one of T, L, P, and Q is out of its valid range. (3) In the G81 block, only one of P and Q is specified.
PS1595	ILL-COMMAND IN EGB MODE	During synchronization with the EGB, a command that must not be issued is issued. (1) Slave axis command using G27, G28, G29, G30, G33, G53, etc. (2) Inch/metric conversion command using G20, G21, etc. (3) Synchronization start specified by G81 when bit 3 (ECN) of parameter No. 7731 is set to 0
PS1596	EGB OVERFLOW	An overflow occurred in the calculation of the synchronization coefficient.

OPERATOR'S MANUAL (B-64694EN)	Electronic gear box

1.9.2 Spindle Electronic Gear Box

Overview

In a system in which two spindles are used as the tool axis and workpiece axis, a gear can be machined (ground or cut) by synchronizing the workpiece axis rotation with the tool axis (grinding wheel or hob) rotation.

To synchronize these two spindles, the spindle electronic gear box is used (the electronic gear box is hereinafter called the EGB). In the spindle EGB, synchronization pulses are generated based on feedback pulses from the position detector attached to the tool axis (master axis), and the workpiece axis (slave axis) rotates based on the synchronization pulses. Feedback pulses are transferred from the master axis to the slave axis by communication between amplifiers.

Specification

The specification of spindle EGB synchronization are as follows:

(1) Spindle EGB synchronization is started by specifying the T command (number of teeth) and L command (number of hob threads), which determine the synchronization coefficient, in the G81 block. The synchronization is canceled by specifying G80.
(2) The synchronization coefficient is calculated using the T command (number of teeth) and L command (number of hob threads) in the G81 block, and the number of position detector pulses per rotation about each of the tool and workpiece pulses (set in the relevant parameter).
(3) This function allows a retract operation.
(4) A helical gear can be cut by specifying the Q command (module or diametral pitch) and P command (gear helix angle) in the G81 block.
(5) During EGB synchronization, the synchronization relationship is maintained regardless of whether the operation is automatic or manual.
(6) Spindle amplifier SPM type B is required for both the master and slave axes. In addition, the spindle amplifiers can have a 1-to-1 connection only. For details, refer to "SPINDLE EGB (SPINDLE ELECTRONIC GEAR BOX)" in "FANUC AC SPINDLE MOTOR α*i* series, FANUC AC SPINDLE MOTOR β*i* series, FANUC BUILT-IN SPINDLE MOTOR β*i* series PARAMETER MANUAL (B-65280EN)".
(7) To turn the EGB synchronization mode on, the slave axis must be put in the Cs contour control mode, though the master axis may be in any control mode.

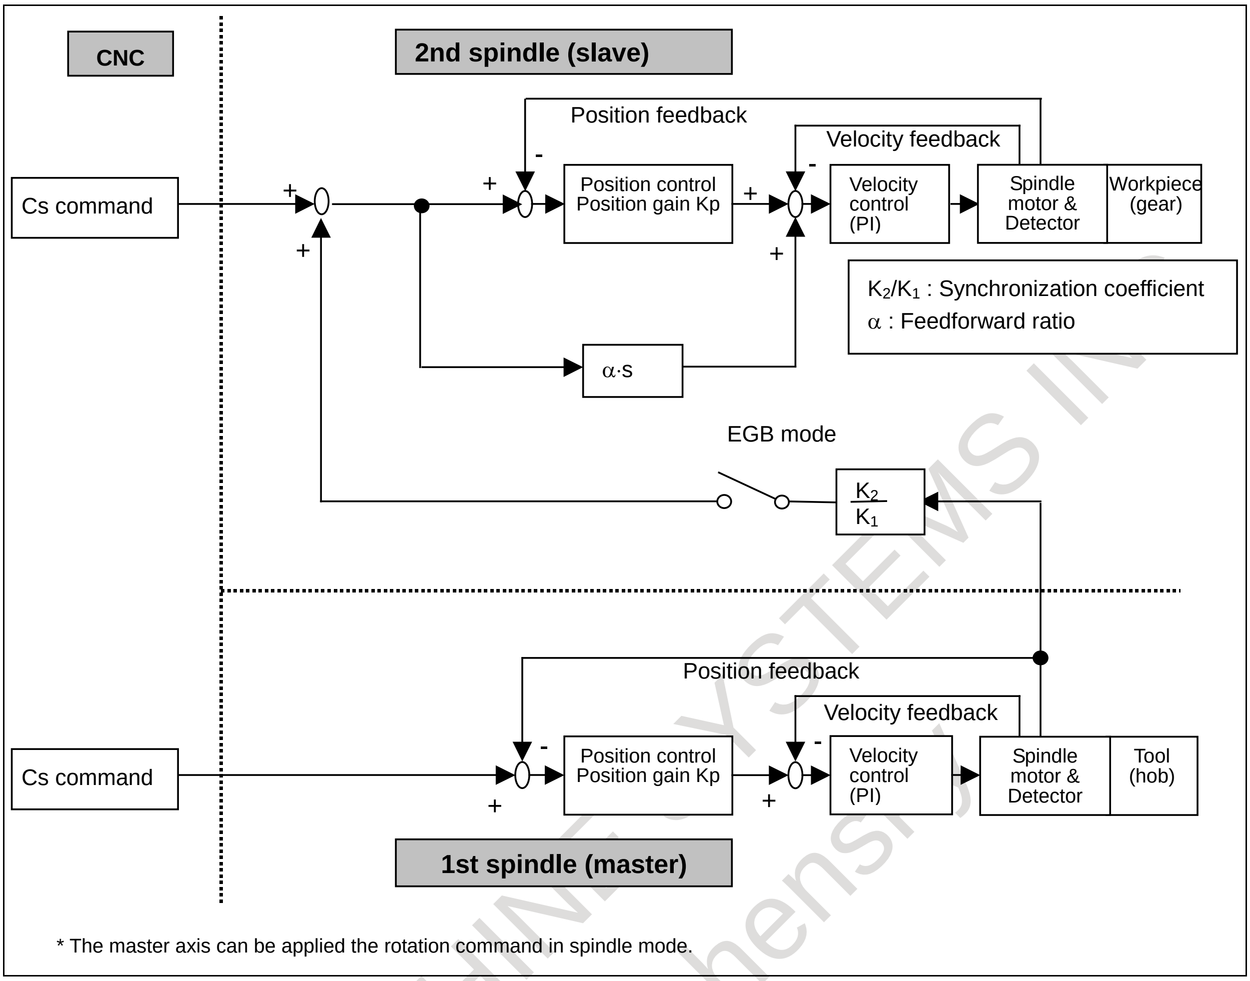

Fig. 1.9.2 (a) Block diagram of spindle EGB control

Format

	Bit 0 (EFX) of parameter No.7731=0	Bit 0 (EFX) of parameter No.7731=1	
		Bit 5 (HBR) of parameter No.7731=1	Bit 5 (HBR) of parameter No.7731=0
Start of synchronization	**G81 T_ (L_) (Q_ P_) ;**	**G81.4 R_ (L_) (Q_ P_) ;**	**G81.4 T_ (L_) (Q_ P_) ;**
Cancellation of synchronization	**G80 ;**	**G80.4 ;**	**G80.4 ;**
	(*1) (*4)	**(*2) (*4)**	**(*3) (*4)**

T(or R) : Number of teeth (Specifiable range: 1 to 5000)
L : Number of hob threads (Specifiable range: -250 to 250)
The sign of L determines the direction of rotation for the workpiece axis.
When L is positive, the direction of rotation for the workpiece axis is positive (+ direction).
When L is negative, the direction of rotation for the workpiece axis is negative (- direction).
When L is 0, it follows the setting of bit 3 (LZR) of parameter No.7701.
If L is not specified, the number of hob threads is assumed 1.
Q : Module or diametral pitch
Specify a module in the case of metric input.
(Unit: 0.00001mm, Specifiable range: 0.01 to 25.0mm)
Specify a diametral pitch in the case of inch input.
(Unit: $0.00001inch^{-1}$, Specifiable range: 0.01 to $254.0\ inch^{-1}$)
P : Gear helix angle
(Unit: 0.0001deg, Specifiable range: -90.0 to 90.0deg)
*1 Use it for machining centers.
*2 Use it for lathes.
*3 Use it for machining centers.
This format enables specification of the same G codes as those for lathes.
*4 When specifying Q and P, the user can use a decimal point.

NOTE
Specify G81, G80, G81.4, and G80.4 in a single block.

Explanation

- Parameter setting

For spindle EGB control, the following parameters must be set:

- Controlled axis number for the slave axis (parameter No. 7710)
- Number of position detector pulses per rotation about the tool axis (parameter No. 7772)
- Number of position detector pulses per rotation about the workpiece axis (parameter No. 7773)
- Spindle EGB master axis enable (bit 7 of parameter No. 4352)
- Spindle EGB slave axis enable (bit 6 of parameter No. 4352)
- Number of sinusoidal waves from the master spindle position detector (parameter No. 4386)

- Start/Cancellation of synchronization

When rotation about the tool axis (master axis) starts after G81 is specified, EGB synchronization starts according to the synchronization relationship specified in the G81 block, and rotation about the workpiece axis (slave axis) starts. When EGB synchronization starts, the EGB mode signal SYNMOD <Fn065.6> becomes “1”.

When rotation about the tool axis is stopped, rotation about the workpiece axis is also stopped. At this time, specifying G80 cancels EGB synchronization. When EGB synchronization is canceled, the EGB mode signal SYNMOD <Fn065.6> becomes 0.

Specify P and Q to use helical gear compensation.

If only either P or Q is specified, alarm PS1594 “EGB FORMAT ERROR” is issued.

G81 cannot be specified again during EGB synchronization. In addition, the specification of T, L, Q, and P cannot be modified during synchronization. Start and cancel synchronization when rotation about the tool axis (master axis) stops.

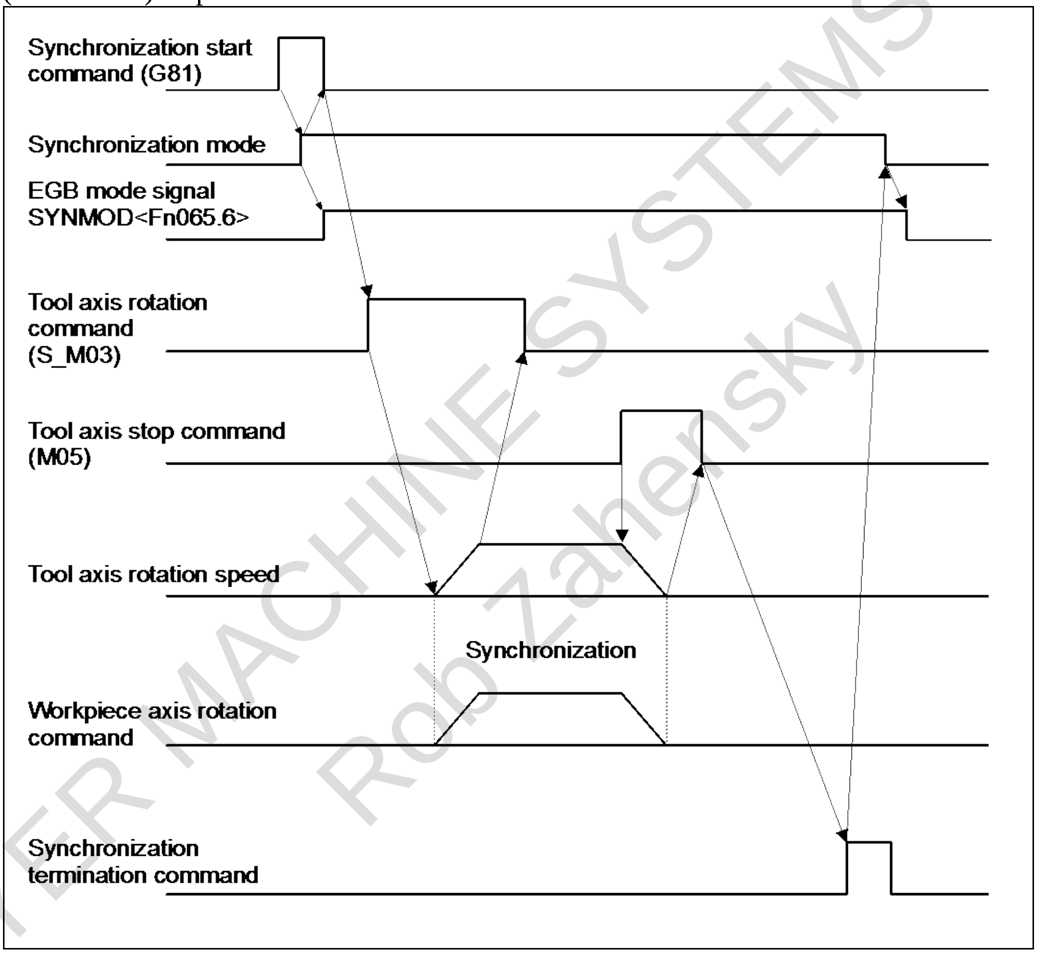

Fig. 1.9.2 (b) Synchronization start/cancellation timing chart

> ⚠ **CAUTION**
> 1 Feed hold, interlock, and machine lock are invalid to a slave axis in EGB synchronization.
> 2 Even if an OT alarm is issued for a slave axis in EGB synchronization, synchronization will not be canceled.
> 3 During synchronization, it is possible to execute a move command for a slave axis and other axes, using a program. The move command for a slave command must be an incremental one.

NOTE

1 If bit 0 (HBR) of parameter No. 7700 is set to 1, EGB synchronization will not be canceled due to a reset. Usually, set this parameter bit to 1.

2 Start and cancel EGB synchronization when rotation about the master and slave axes stops. It means that rotation about the master axis should be started while the EGB mode signal SYNMOD is “1” (see Fig. 1.10.2 (b), "Synchronization start/cancellation timing chart"). If the master axis starts rotating before the EGB mode signal SYNMOD becomes “1”, synchronization is not performed correctly.

3 Perform the reference position return of the Cs contour controlled axis for the master and slave axes before specifying G81. During synchronization, reference position return cannot be performed. Do not place the machine in the reference position return mode during synchronization.

4 If a parameter for axis setting (No. 7710 or 4352) is not set correctly, alarm PS1593, “EGB PARAMETER SETTING ERROR” is issued when G81 is specified.

5 In synchronization mode, it is not possible to specify G27, G28, G29, G30, and G53 for a slave axis.

6 In EGB synchronization mode, AI contour control mode is temporarily canceled.

7 The position display of the slave axis is updated based on synchronization pulses as follows:
   - During synchronization, only the machine coordinate is updated. The absolute and relative coordinates are not updated.
   - When synchronization is canceled, the amount of travel during synchronization, as rounded to 360-degree units is added to the absolute coordinate.

8 The direction of rotation about the slave axis depends on the direction of rotation about the master axis. When the direction of rotation about the master axis is positive, the direction of rotation about the slave axis is also positive; when the direction of rotation about the master axis is negative, the direction of rotation about the slave axis is also negative. A negative value can be specified for L to make the direction of rotation about the slave axis opposite to the direction of rotation about the master axis, however.

9 The synchronization mode is canceled by a servo alarm, spindle alarm, PW alarm, or emergency stop.

10 Synchronization is not maintained if the slave axis is in the servo off state.

11 During synchronization, manual handle interrupt can be performed on the workpiece and other axes.

12 In synchronization mode, no inch/metric conversion commands (G20 and G21) cannot be issued.

13 If bit 0 (EFX) of parameter No. 7731 is 0, no canned cycle for drilling can be used. To use a canned cycle for drilling, set bit 0 (EFX) of parameter No. 7731 to 1 and use G81.4 instead of G81 and G80.4 instead of G80.

14 If bit 0 (TDP) of parameter No. 7702 is 1, the permissible range of T is 0.1 to 500 (1/10 of the specified value).

15 If, at the start of EGB synchronization (G81), L is specified as 0, synchronization starts with L assumed to be 1 if bit 3 (LZR) of parameter No.7701 is 0; if bit 3 (LZR) of parameter No.7701 is 1, synchronization is not started with L assumed to be 0. At this time, helical gear compensation is performed.

NOTE

16 Feed per revolution is performed on the feedback pulses on the spindle. By setting bit 0 (ERV) of parameter No. 7703 to 1, feed per revolution can be performed based on the speed on the synchronous slave axis.
17 Actual cutting feedrate display does not take synchronization pulses into consideration.
18 For an EGB slave axis, synchronous and composite control cannot be executed.
19 The G81 command cannot be specified to use the servo EGB and spindle EGB together. To use them together, specify the G81 command for the spindle EGB and the G81.5 command for the servo EGB.
20 When the simple spindle EGB function is used, this function cannot be used. If the G81 command is specified for the slave axis of the simple spindle EGB, alarm PS1593 “EGB PARAMETER SETTING ERROR” is issued.
21 The master axis cannot be shared by the simple spindle EGB function and this function.
22 Not advanced preview feed-forward but conventional feed-forward is enabled in the path where EGB synchronization mode is effective.

- Program example

Axis configuration X, Y, Z, B (Cs axis: tool axis/master axis), C (Cs axis: workpiece axis/slave axis)

```
O1000 ;
N0010 G80 ;
N0020 G28 G91 B0 C0 ;   Performs reference position return for the tool and workpiece axes.
N0030 G81 T20 L1 ;      Starts synchronization.
N0040 Mxx ;             Rotates the tool axis by the constant speed command of PMC axis control.
N0050 G04 X1000 ;       Waits until rotation of the tool axis becomes constant.
N0060 G01 X_ F_ ;       Moves the tool along the X-axis (cutting).
N0070 G01 Z_ F_ ;       Moves the tool along the Z-axis (machining).
-------------------------
-------------------------
N0100 G01 X_ F_ ;       Moves the tool along the X-axis (retraction).
N0110 M05 ;             Stops rotation about the tool axis.
N0120 G80 ;             Cancels synchronization.
N0130 M30 ;
```

- Helical gear compensation

For a helical gear, the workpiece axis is compensated for the movement along the Z-axis (axial feed axis) based on the torsion angle of the gear.
Helical gear compensation is performed with the following formulas:
For a helical gear, the workpiece axis is compensated for the movement along the Z-axis (axial feed axis) based on the torsion angle of the gear.
Helical gear compensation is performed with the following formulas:

$$\text{Compensation angle} = \frac{Z \times \sin(P)}{\pi \times T \times Q} \times 360 \text{ (for metric input)}$$

$$\text{Compensation angle} = \frac{Z \times Q \times \sin(P)}{\pi \times T} \times 360 \text{ (for inch input)}$$

where

Compensation angle: Signed absolute value (deg)

- Z : Amount of travel on the Z-axis after the specification of G81
- P : Signed gear helix angle (deg)
- π : Circular constant
- T : Number of teeth
- Q : Module (mm) or diametral pitch ($inch^{-1}$)

Use P, T, and Q specified in the G81 block.
In helical gear compensation, the machine coordinates on the workpiece axis and the absolute coordinates are updated with helical gear compensation.
The updated timing is as follows.

<table>
<tr><th>Machine coordinates</th><th colspan="2">Absolute coordinates</th></tr>
<tr><td rowspan="3">During helical gear compensation</td><td colspan="2">Bit 7(HAD) of parameter No.7731</td></tr>
<tr><td>= 0</td><td>= 1</td></tr>
<tr><td>Synchronization cancel</td><td>During helical gear compensation</td></tr>
</table>

- Direction of helical gear compensation

The direction depends on bit 2 (HDR) of parameter No. 7700.

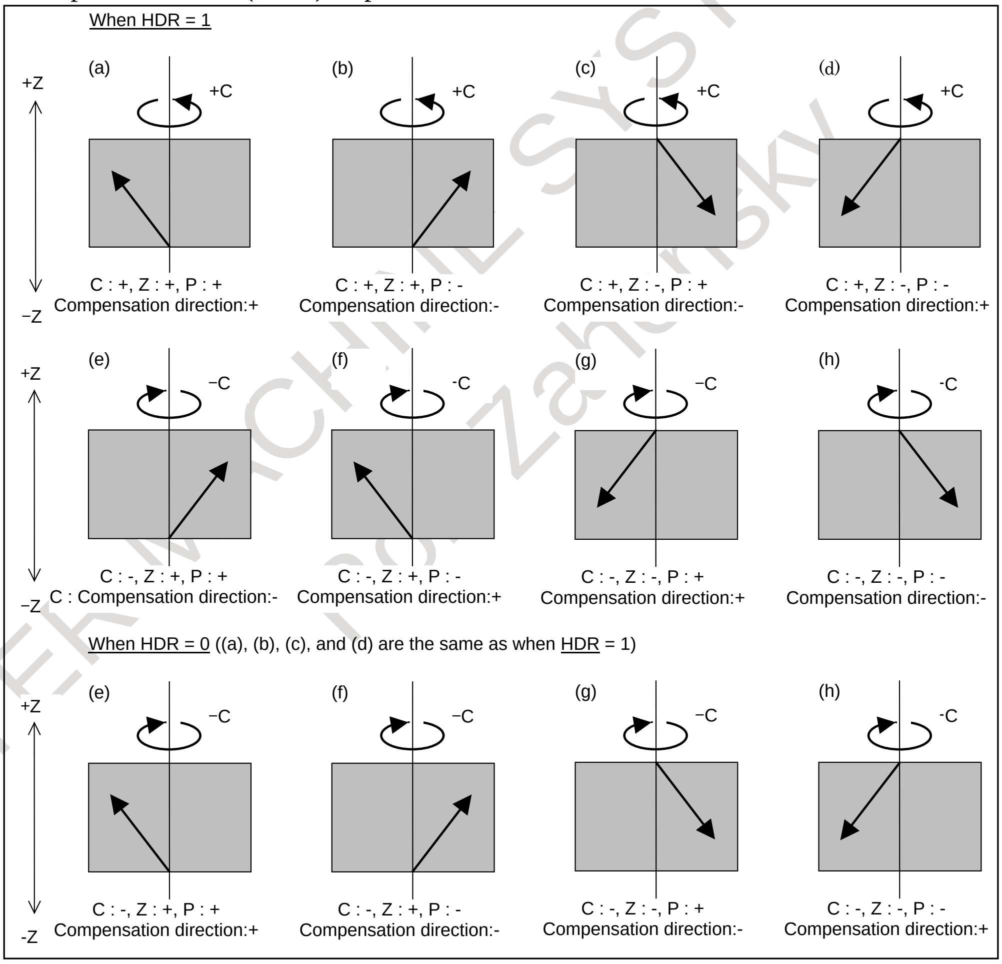

Fig. 1.9.2 (c) Direction of helical gear compensation

- Synchronization coefficient

A synchronization coefficient is internally represented using a fraction (K_2/K_1) to eliminate an error. The formula below is used for calculation.

$$\text{Synchronization coefficient} = \frac{K_2}{K_1} = \frac{L}{T} \times \frac{\beta}{\alpha}$$

where

L : Number of hob threads
T : Number of teeth
α : Number of pulses of the position detector per rotation about the master axis (parameter No. 7772)
β : Number of pulses of the position detector per rotation about the slave axis (parameter No. 7773)

K_2/K_1 is a value resulting from reducing the right side of the above formula, but the result of reduction is subject to the following restrictions:

$-32767 \le K_2 \le 32767$

$1 \le K_1 \le 32767$

When this restriction is not satisfied, the alarm PS1596 “EGB OVERFLOW” is issued when G81 is specified.

The values of K_2 and K_1 are set in parameters Nos. 4387 and 4388 automatically when G81 is specified. If T is not specified in the G81 block, alarm PS1594 “EGB FORMAT ERROR” is issued. If L is not specified in that block, the synchronization coefficient is calculated, assuming L = 1.

Example)

When the number of pulses that correspond to one rotation (360000) is specified for the tool axis (master axis) under the following conditions, the position command pulses are distributed as shown in Fig. 1.10.2 (d).

Number of hob threads L: 10
Number of teeth T: 100
Number of pulses of the position detector per rotation about the tool axis : 360000
Number of pulses of the position detector per rotation about the workpiece axis : 360000

$$\text{Synchronization coefficient} = \frac{K_2}{K_1} = \frac{L}{T} \times \frac{\beta}{\alpha} = \frac{10}{100} \times \frac{360000}{360000} = \frac{1}{10}$$

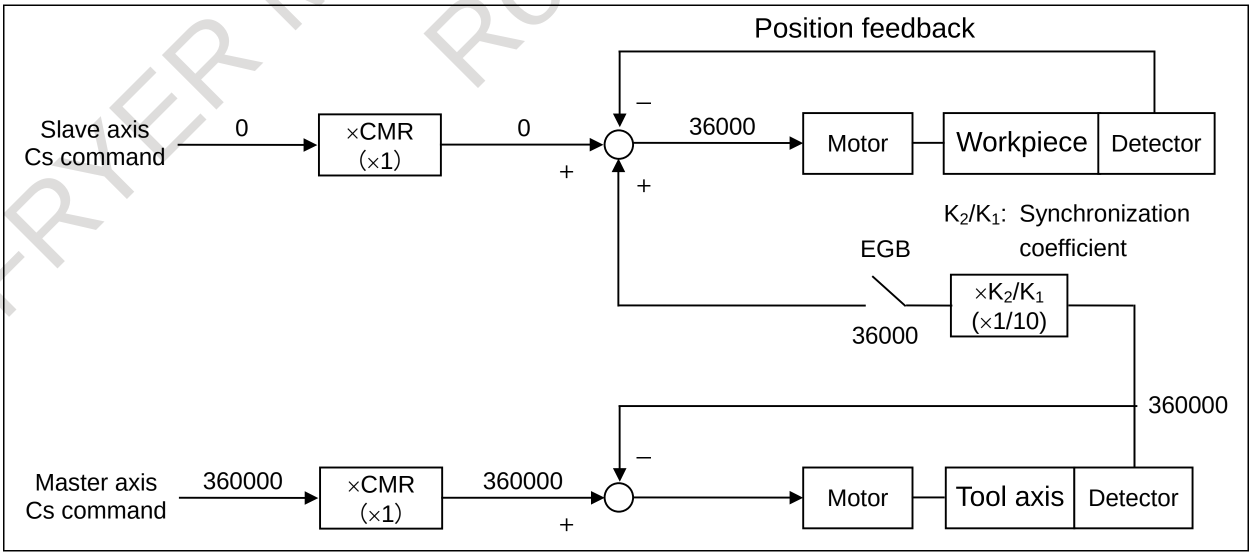

Fig. 1.9.2 (d) Command pulse distribution

As shown in Fig. 1.10.2 (d), when 360000 pulses (number of pulses required for one rotation about the master axis) are specified for the master axis, the value of the position command to the slave axis by EGB is obtained by multiplying the number of pulses required for one rotation about the slave axis by the ratio of the number of hob threads to the number of teeth (rotation ratio of the slave axis to the master axis):

360000 × 1/10 = 36000

・Retract function

See Item, “Retract function” in the Subsection “Electronic Gear Box”.

Signal

EGB mode signal SYNMOD <Fn065.6>

[Classification] Output signal

[Function] Posts notification that synchronization using the EGB is in progress.

[Operation] This signal is set to “1” in the following case:

- While synchronization using the EGB is in progress

This signal is set to “0” in the following case:

- Once synchronization using the EGB has terminated

Signal address

	#7	#6	#5	#4	#3	#2	#1	#0
Fn065		SYNMOD						

Parameter

The table below gives parameters related to spindle EGB.

Parameter number	Description
1006#0 1006#1	An EGB slave axis requires that the setting of a rotary axis (type A) (bit 0 (ROT) of parameter No. 1006 be 1 and bit 1 (ROS) of parameter No. 1006 be 0.
4036	Feed forward coefficient for serial spindle
4352#4	Feed forward setting
4352#6	Setting of the spindle EGB slave axis
4352#7	Setting of the spindle EGB master axis
4386	Number of sinusoidal waves from the master spindle position detector
4387	Numerator of synchronization coefficient
4388	Denominator of synchronization coefficient
7700#0	The synchronous mode is canceled (0)/not canceled (1) by a reset.
7700#2	Compensation direction for helical gear compensation
7701#3	At the start of synchronization (G81), synchronization is started (0)/not started (1) if the number of hob threads L is specified as 0.
7702#0	The specifiable number of teeth, T, at the start of synchronization (G81) is not reduced to a 1/10 of a specified value (0)/reduced (1).
7702#3	The retract function with an alarm is disabled (0)/enabled (1).
7703#0	During synchronization (G81), feed per revolution is performed for feedback pulses (0)/pulses converted to the speed for the workpiece axis(1).
7703#1,#2	Specify when to perform a retract operation with the retract function with an alarm; during synchronization; during synchronization and automatic operation; or during synchronization or automatic operation.
7709	Number of the axial feed axis in helical gear compensation
7710	The controlled axis number for the spindle EGB slave axis
7731#0	The EGB command is G80 and G81(0)/G80.4 and G81.4(1).
7731#5	In EGB synchronization start command G81.4, the number of teeth is specified in T (0)/specified in R (1).
7740	Retraction speed

Parameter number	Description
7741	Retract amount
7772	Number of position detector pulses per rotation about tool axis
7773	Number of position detector pulses per rotation about workpiece axis

4036	Feed forward coefficient for serial spindle

[Input type] Parameter input
[Data type] Word spindle
[Unit of data] 1%
[Valid data range] 0 to 10000

This parameter sets the feed forward coefficient in the Cs axis contour control mode.
When the setting is smaller than or equal to 100: In units of 1%
When the setting is greater than 100: In units of 0.01%
Set 100 for the slave spindle.

	#7	#6	#5	#4	#3	#2	#1	#0
4352	SPEGBM	SPEGBS		FFALWS				

[Input type] Parameter input
[Data type] Bit spindle

#4 FFALWS Feed forward setting
0: Feed forward is enabled only in cutting feed.
1: Feed forward is always enabled.
Set 1 for the slave spindle.

#6 SPEGBS The spindle EGB function for slave spindle is:
0: Disabled.
1: Enabled.
Set 1 for the slave spindle.

#7 SPEGBM The spindle EGB function for master spindle is:
0: Disabled.
1: Enabled.
Set 1 for the master spindle.

4386	Number of sinusoidal waves from the master spindle position detector

[Input type] Parameter input
[Data type] Word spindle
[Unit of data] 1λ/rev
[Valid data range] 0, 64 to 4096

This parameter sets the number of sinusoidal waves per spindle rotation from the master spindle position detector.
Set this parameter for the slave spindle amplifier.
Setting 0 in this parameter is equivalent to setting the synchronization coefficient to 0.

4387	Numerator of synchronization coefficient

[Input type] Parameter input
[Data type] Word spindle
[Valid data range] -32767 to 32767

The numerator of the synchronization coefficient is set in this parameter automatically when G81 is specified.

4388	Denominator of synchronization coefficient

[Input type] Parameter input
[Data type] Word spindle
[Valid data range] 1 to 32767

The denominator of the synchronization coefficient is set in this parameter automatically when G81 is specified.

	#7	#6	#5	#4	#3	#2	#1	#0
7700						HDR		HBR

[Input type] Parameter input
[Data type] Bit path

#0 HBR When the electronic gear box (EGB) function is used, performing a reset:
0: Cancels the synchronous mode (G81 or G81.5).
1: Does not cancel the synchronous mode. The mode is canceled only by the G80 or G80.5 command.

#2 HDR Direction of helical gear compensation (usually, set 1.)
(Example) To cut a left-twisted helical gear when the direction of rotation about the C-axis is the negative (-) direction:
0: Set a negative (-) value in P.
1: Set a positive (+) value in P.

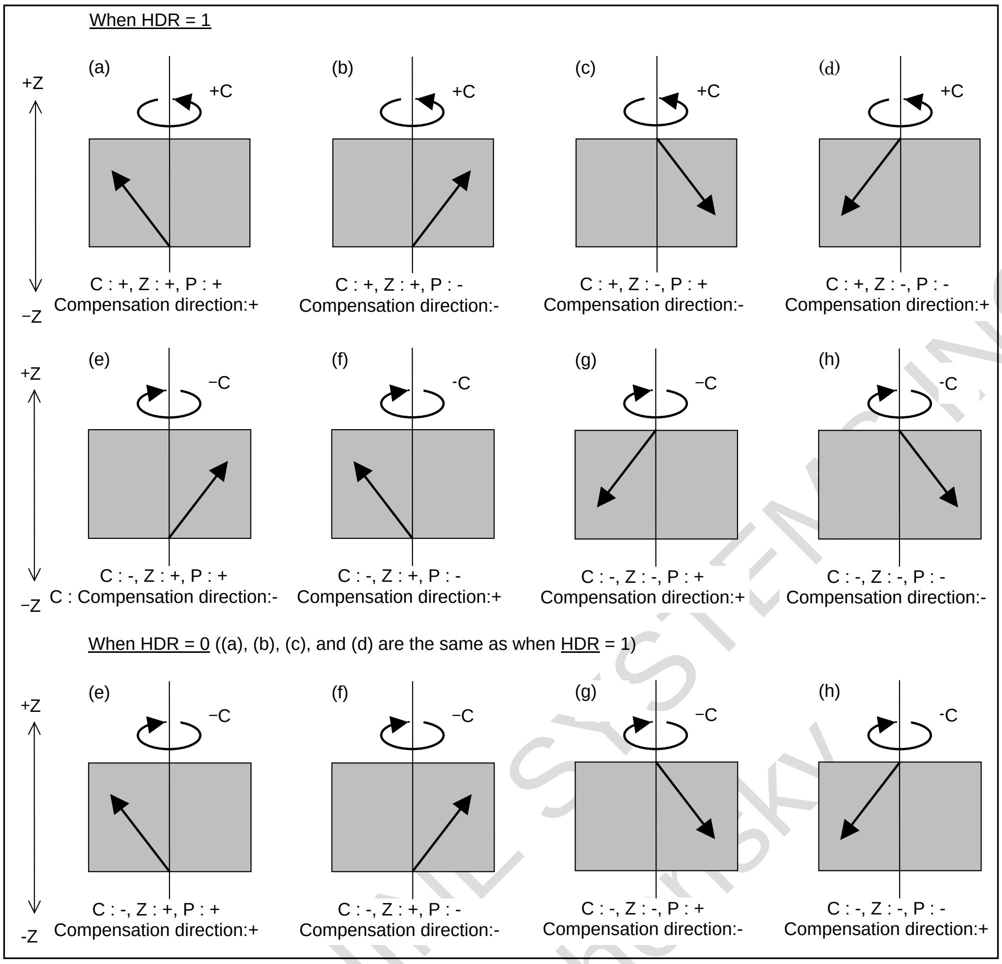

Fig. 1.9.2 (e) Direction of helical gear compensation

	#7	#6	#5	#4	#3	#2	#1	#0
7701					LZR			

[Input type] Parameter input
[Data type] Bit path

#3 LZR When L (number of hob threads) = 0 is specified at the start of EGB synchronization (G81):
0: Synchronization is started, assuming that L = 1 is specified.
1: Synchronization is not started, assuming that L = 0 is specified. However, helical gear compensation is performed.

	#7	#6	#5	#4	#3	#2	#1	#0
7702					ART			TDP

[Input type] Parameter input
[Data type] Bit path

#0 TDP The specifiable number of teeth, T, of the electronic gear box (G81) is:
0: 1 to 5000
1: 0.1 to 500 (1/10 of a specified value)

> **NOTE**
> In either case, a value from 1 to 5000 can be specified.

#3 ART The retract function executed when an alarm is issued is:
0: Disabled.
1: Enabled.
When an alarm is issued, a retract operation is performed with a set feedrate and travel distance (parameters Nos. 7740 and 7741).

> **NOTE**
> If a servo alarm is issued for other than the axis along which a retract operation is performed, the servo activating current is maintained until the retract operation is completed.

	#7	#6	#5	#4	#3	#2	#1	#0
7703						ARO	ARE	ERV

[Input type] Parameter input
[Data type] Bit path

#0 ERV During EGB synchronization (G81), feed per revolution is performed for:
0: Feedback pulses.
1: Pulses converted to the speed for the workpiece axis.

#1 ARE The retract function executed when an alarm is issued retracts the tool during:
0: EGB synchronization or automatic operation (automatic operation signal OP <Fn000.7> = “1”).
1: EGB synchronization.

#2 ARO The retract function executed when an alarm is issued retracts the tool during:
0: EGB synchronization.
1: EGB synchronization and automatic operation (automatic operation signal OP = “1”).

> **NOTE**
> This parameter is valid when bit 1 (ARE) of parameter No. 7703 is set to “1”.

The following table lists the parameter settings and corresponding operation.

<table>
<tr><th>ARE</th><th>ARO</th><th>Operation</th></tr>
<tr><td>1</td><td>0</td><td>During EGB synchronization</td></tr>
<tr><td>1</td><td>1</td><td>During EGB synchronization and automatic operation</td></tr>
<tr><td>0</td><td>0</td><td rowspan="2">During EGB synchronization or automatic operation</td></tr>
<tr><td>0</td><td>1</td></tr>
</table>

> **NOTE**
> Parameters ARE and ARO are valid when bit 3 (ART) of parameter No. 7702 is set to 1 (when the retract function executed when an alarm is issued).

7709	Number of the axial feed axis for helical gear compensation

[Input type] Parameter input
[Data type] 2-word path
[Valid data range] 0 to Number of controlled axes

This parameter sets the number of the axial feed axis for a helical gear.

> **NOTE**
> When this parameter is set to 0 or a value outside the valid setting range, the Z-axis becomes the axial feed axis.

7710	Controlled axis number for the spindle EGB slave axis

[Input type] Parameter input
[Data type] 2-word path
[Valid data range] 0 to Number of controlled axes

This parameters sets the controlled axis number for the spindle EGB slave axis.

> **NOTE**
> 1 Set this parameter when there are two or more groups of servo and spindle EGBs in the same path. Set 0 when there is one group of EGBs in the same path.
> 2 When there are two or more groups of servo and spindle EGBs in the same path, setting a value outside the valid data range in this parameter causes alarm PS1593 to be issued.
> 3 For Series 16*i*, when a value outside the valid data range is set in this parameter, the fourth axis is assumed according to the specifications.
> 4 The setting of this parameter becomes valid after the power is turned off then back on.

	#7	#6	#5	#4	#3	#2	#1	#0
7731	HAD		HBR					EFX

[Input type] Parameter input
[Data type] Bit path

#0 EFX As the EGB command:
0: G80 and G81 are used.
1: G80.4 and G81.4 are used.

> **NOTE**
> When this parameter is set to 0, no canned cycle for drilling can be used.

#5 HBR In EGB synchronization start command G81.4, the number of teeth is:
0: Specified in T.
1: Specified in R.

> **NOTE**
> This parameter is valid when bit 0 (EFX) of parameter No. 7731 is set to 1.

#7 HAD In electronic gear box, the timing for reflecting helical gear compensation and travel distance of automatic phase synchronization to absolute coordinates is:
0: When synchronization is canceled.
1: During helical gear compensation and automatic phase synchronization.

7740	Feedrate during retraction

[Input type] Parameter input
[Data type] Real axis
[Unit of data] mm/min, inch/min, deg/min (machine unit)
[Min. unit of data] Depend on the increment system of the applied axis
[Valid data range] Refer to the standard parameter setting table (C)
(When the increment system is IS-B, 0.0 to +999000.0)
This parameter sets the feedrate during retraction for each axis.

7741	Retract amount

[Input type] Parameter input
[Data type] Real axis
[Unit of data] mm, inch, deg (machine unit)
[Min. unit of data] Depend on the increment system of the applied axis
[Valid data range] 9 digit of minimum unit of data (refer to standard parameter setting table (A))
(When the increment system is IS-B, -999999.999 to +999999.999)
This parameter sets the retract amount for each axis.

7772	Number of position detector pulses per rotation about the tool axis

[Input type] Parameter input
[Data type] 2-word path
[Unit of data] Detection unit
[Valid data range] 1 to 999999999
This parameter sets the number of pulses per rotation about the tool axis (master axis), for the position detector.
When the increment system is IS-B, set 360000.

7773	Number of position detector pulses per rotation about the workpiece axis

[Input type] Parameter input
[Data type] 2-word path
[Unit of data] Detection unit
[Valid data range] 1 to 999999999
This parameter sets the number of pulses per rotation about the workpiece axis (slave axis), for the position detector.
When the increment system is IS-B, set 360000.

Alarm and message

Number	Message	Description
PS1593	EGB PARAMETER SETTING ERROR	Error in setting a parameter related to the EGB (1) The slave axis specified with G81 is not set as a rotation axis. (bit 0 (ROTx) of parameter No. 1006) (2) Number of pulses per rotation (parameter No. 7772 or 7773) is not set. (3) Although G81 is specified, a parameter such as parameter No. 7710 or 4352 is not set. (4) The slave axis specified in G81 is set as the slave axis of the simple spindle EGB.
PS1594	EGB FORMAT ERROR	Error in the format of the block of an EGB command (1) T (number of teeth) is not specified in the G81 block. (2) In the G81 block, the data specified for one of T, L, P, and Q is out of its valid range. (3) In the G81 block, only one of P and Q is specified.
PS1595	ILL-COMMAND IN EGB MODE	During synchronization with the EGB, a command that must not be issued is issued. (1) Slave axis command using G27, G28, G29, G30, G33, G53, etc. (2) Inch/metric conversion command using G20, G21, etc. (3) The Cs contour control mode is not selected for the slave axis.
PS1596	EGB OVERFLOW	An overflow occurred in the calculation of the synchronization coefficient.

1.9.3 Electronic Gear Box Automatic Phase Synchronization

Overview

In the electronic gear box (EGB), when the start or cancellation of synchronization is specified, the synchronizing state is changed gradually by applying acceleration/deceleration. This is because if synchronization is started or canceled immediately, a shock applies to the machine. Therefore, synchronization can be started or canceled while the spindle is rotating. Also, synchronization ratio can be changed while the spindle is rotating.

In addition, automatic phase synchronization is performed in such a way that, at the start of synchronization, the position of the machine coordinate origin for the workpiece axis matches the spindle position determined by the one-rotation signal. With this synchronization, the same operation is performed as synchronization start caused by a one-rotation signal in hobbing synchronization when using the functions of a hobbing machine.

The spindle corresponds to the EGB master axis and the workpiece axis corresponds to an EGB slave axis (servo axis or Cs contouring axis).

Format

M

- **Acceleration/deceleration type**

G81 T _ L _ R1 ;	Synchronization start
G80 R1 ;	Synchronization cancellation

T : Number of teeth (range of valid settings: 1-5000)
L : Number of hob threads (range of valid settings: -250 to 250, excluding 0)
When L is positive, the direction of rotation about the workpiece axis is positive (+ direction).
When L is negative, the direction of rotation about the workpiece axis is negative (- direction).

- **Acceleration/deceleration plus automatic phase synchronization type**

G81 T _ L _ R2 ;	Synchronization start
G80 R1 ;	Synchronization cancellation

T : Number of teeth (range of valid settings: 1-5000)
L : Number of hob threads (range of valid settings: -250 to 250, excluding 0)
When L is positive, the direction of rotation about the workpiece axis is positive (+ direction).
When L is negative, the direction of rotation about the workpiece axis is negative (- direction).

T

To use this function for the T series, set the following parameters.
Automatic phase synchronization is enabled in a command compatible with that for a hobbing machine used in the T series.
Bit 0 (EFX) of parameter No. 7731=1
Bit 5 (HBR) of parameter No. 7731=1
Bit 6 (PHS) of parameter No. 7702=1

- **Acceleration/deceleration plus automatic phase synchronization type**

G81.4 R _ L _ ;	Synchronization start
G80.4 ;	Synchronization cancellation

R : Number of teeth (range of valid settings: 1-5000)
L : Number of hob threads (range of valid settings: -250 to 250, excluding 0)
When L is positive, the direction of rotation about the workpiece axis is positive (+ direction).
When L is negative, the direction of rotation about the workpiece axis is negative (- direction).

Explanation

- Acceleration/deceleration type

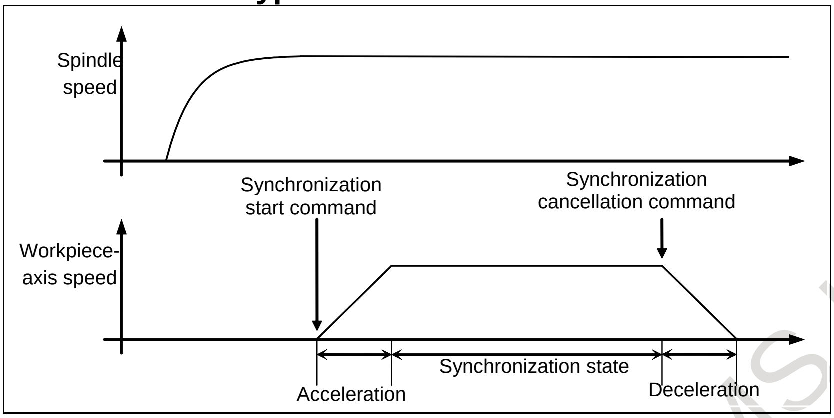

Fig. 1.9.3 (a)

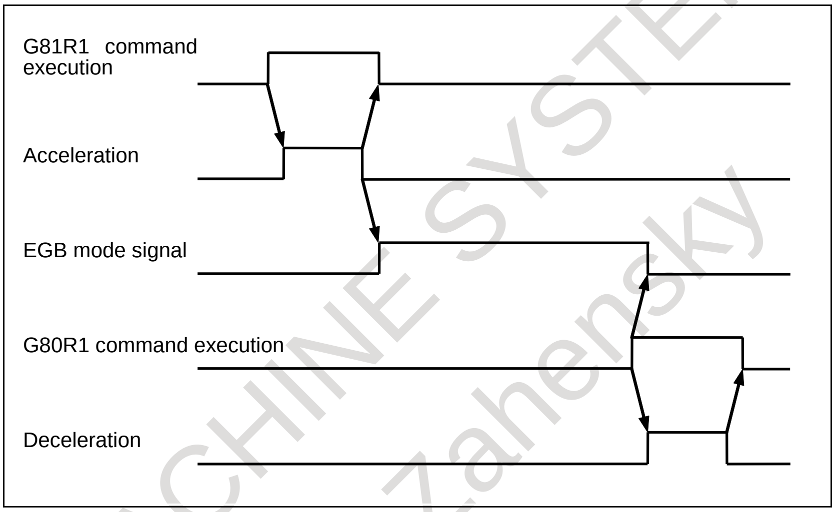

Fig. 1.9.3 (b)

1. Specify G81R1 to start synchronization.
   When G81R1 is specified, the workpiece axis (slave axis) is subject to acceleration at the acceleration rate set in parameter No. 7778. When the synchronization speed is reached, the EGB mode signal, SYNMOD<Fn065.6>, becomes 1 and the G81R1 block is terminated.
2. For cancellation, specify G80R1 while the tool is moved away from the workpiece.
3. When G80R1 is specified, the EGB mode signal SYNMOD<Fn065.6> becomes "0" and deceleration is started immediately at the acceleration rate set in parameter No. 7778.
   When the speed is reduced to 0, the G80R1 block is terminated.

NOTE
1 During synchronization start/cancellation, acceleration/deceleration is linear.
2 In the automatic cancellation of synchronization due to one of the following causes, deceleration is performed and synchronization is canceled:
<1> Reset
<2> PW0000, "POWER MUST BE OFF"
<3> IO alarm
3 If bit 0 (EFX) of parameter No. 7731 is 0, the canned cycle for drilling cannot be used. To use the canned cycle for drilling, set bit 0 (EFX) of parameter No. 7731 to 1 and use G81.4 instead of G81 and G80.4 instead of G80.

- Acceleration/deceleration plus automatic phase synchronization type

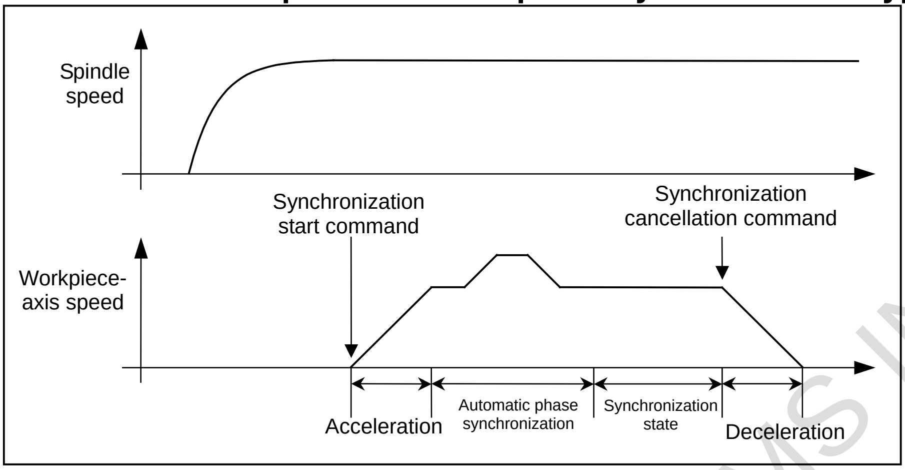

Fig. 1.9.3 (c)

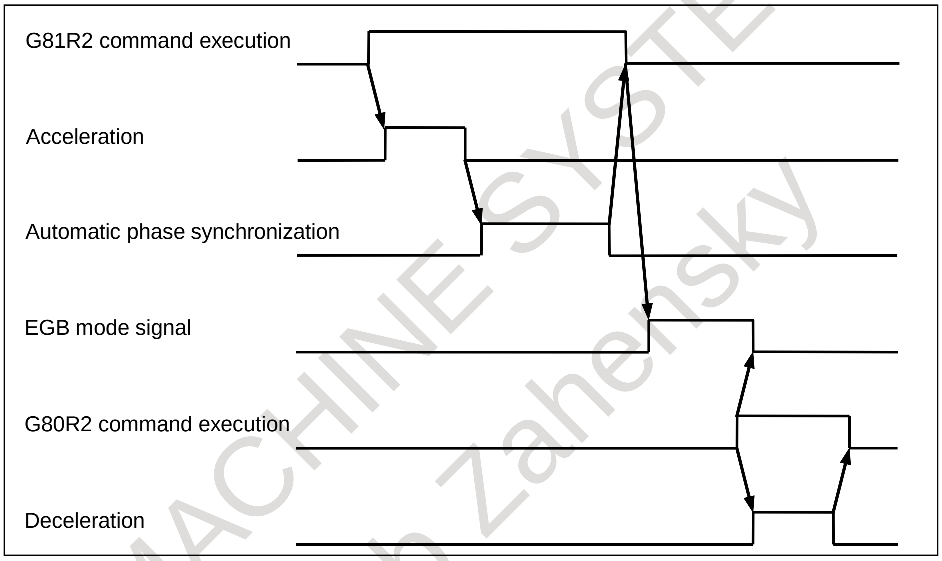

Fig. 1.9.3 (d)

1. Move the workpiece axis to the position that corresponds to that of the one-rotation signal of the spindle.
2. Specify G81R2 to start synchronization.
   When G81R2 is specified, the workpiece axis is accelerated with the acceleration according to the acceleration rate set in the parameter No.7778. Upon completion of phase synchronization, the EGB mode signal SYNMOD<Fn065.6> becomes “1” and the G81R2 block terminates.
3. For cancellation, specify G80R2 while the tool is moved away from the workpiece.
4. When G80R2 is issued, the EGB mode signal SYNMOD<Fn065.6> becomes “0” and deceleration is started immediately according to the acceleration rate set in parameter No. 7778. When the speed reaches 0, the G80R2 block terminates.

⚠ CAUTION

1 Set the automatic phase synchronization speed in parameter No. 7776 and the movement direction in bit 7 (PHD) of parameter No. 7702.

2 Phase synchronization acceleration/deceleration is performed with the rapid traverse linear acceleration/deceleration rate (time constant specified in parameter No. 1620).

⚠ CAUTION

3 The workpiece axis speed is the speed synchronized with spindle rotation with automatic phase synchronization speed being superposed. When setting the position deviation limit parameter No. 1828, take the superposition into consideration.

NOTE

1 The one-rotation signal used for automatic phase synchronization is issued not by the spindle position coder but by the separate Pulsecoder attached to the spindle and used to collect EGB feedback information. This means that the orientation position based on the one-rotation signal issued by the spindle position coder does not match the position used as the reference for the workpiece axis when establishing phase synchronization for automatic phase synchronization based on G81R2.
Moreover, the one-rotation signal of the separate Pulsecoder must be turned on for each rotation of the spindle.

2 With the use of parameter No.7777, the position at which the phase of the workpiece axis is matched can be shifted from the position corresponding to the one-rotation signal in automatic phase matching.

3 Setting bit 6 (EPA) of parameter No. 7731 to 1 can perform automatic phase synchronization in such a way that, at the start of synchronization, the position of the workpiece axis matches the spindle position set by the one-rotation signal.

4 If bit 6 (EPA) of parameter No. 7731 is set to 1 to cause a synchronization command to be issued again when synchronization is already established, automatic phase synchronization is performed to move the workpiece axis in such way that the position where the workpiece axis was when the G81R2 (synchronization command) was issued for the first time matches the spindle position set by the one-rotation signal.

5 In automatic phase synchronization, movement is performed about the workpiece axis from the current position to the nearest phase position in the phase synchronization movement direction specified by the parameter.

6 Linear acceleration/deceleration applies to synchronization start/cancellation.

7 The acceleration/deceleration plus automatic phase synchronization type can be executed by the bit 6 (PHS) of parameter No. 7702 without specifying an R2 command in a G81 or G80 block.

8 In the automatic cancellation of synchronization due to one of the following causes, deceleration is performed and synchronization canceled:
<1> Reset
<2> PW0000, “POWER MUST BE OFF”
<3> IO alarm

9 When EGB (Spindle EGB is excluded) is used, it is necessary to move the separate Pulsecoder attached to the spindle by one rotation or more before executing automatic phase synchronization.

10 When the spindle EGB is used and the master axis is in the speed control mode, perform position coder orientation before executing automatic phase synchronization. In this case, set bit 7 (RFCHK3) of parameter No. 4016 for the master axis to 0 to maintain the spindle one-rotation signal position in the speed control mode.

NOTE

11 When the spindle EGB is used and the master axis is in the Cs contour control mode, perform reference position return before executing automatic phase synchronization.

12 The acceleration rate parameter No.7778 must not be changed in the synchronization mode.

13 If the acceleration rate parameter No. 7778 is 0, alarm PS1598, “EGB AUTO PHASE PARAMETER SETTING ERROR” is issued when G81 is issued.

14 In the Series 16*i*, acceleration for automatic phase matching is set by specifying a feedrate and a time constant in parameters Nos. 2135 and 2136 (Nos. 4384 and 4385 in the case of spindle EGB) separately; in the Series 0*i*-F Plus, acceleration is directly set in parameter No. 7778.

15 If bit 0 (EFX) of parameter No. 7731 is 0, the canned cycle for drilling cannot be used. To use the canned cycle for drilling, set bit 0 (EFX) of parameter No. 7731 to 1 and use G81.4 instead of G81 and G80.4 instead of G80.

16 In the case of bit 7 (HAD) of parameter No.7731 is 0, travel distance of automatic phase synchronization is reflected to absolute coordinates when the synchronization is canceled. In the case of bit 7 (HAD) of parameter No.7731 is 1, travel distance of automatic phase synchronization is reflected to absolute coordinates during automatic phase synchronization.

Direction of rotation (for the spindle EGB)

The EGB automatic phase synchronization function assumes that the direction of rotation about the slave axis is the same as that of rotation about the master axis.

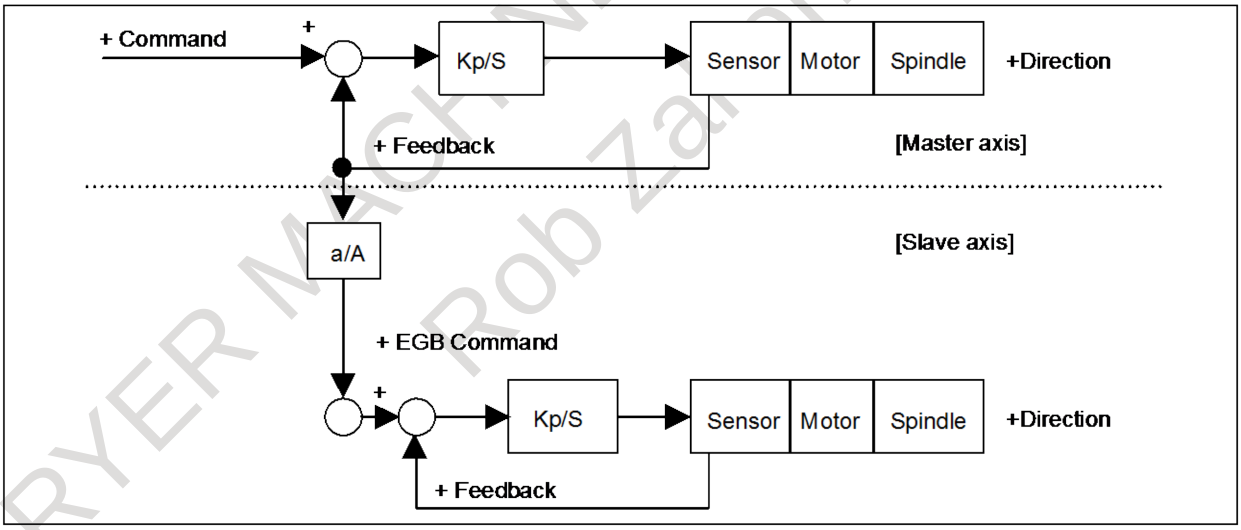

Fig. 1.9.3 (e)

When this function is used, the SFR/SRV function in the Cs contour mode (*) cannot be used.
If you want to change the direction of rotation about the master axis, change the sign of the master axis mode command.

* SFR/SRV function in the Cs contour mode
The SFR/SRV signal determines the direction of rotation of the spindle in the Cs contour mode.

Signal

EGB mode signal SYNMOD< Fn065.6>

[Classification] Output signal
[Function] Reports that synchronization with the EGB is in progress.
[Operation] This signal becomes "1" if:
- Synchronization with the EGB is in progress.

It becomes "0" if:
- Synchronization with the EGB is canceled.

Signal address

	#7	#6	#5	#4	#3	#2	#1	#0
Fn065		SYNMOD						

Parameter

	#7	#6	#5	#4	#3	#2	#1	#0
4016	RFCHK3							

[Input type] Parameter input
[Data type] Bit spindle

#6 RFCHK3 When the EGB master axis is in the speed control mode, if you want to execute automatic phase synchronization, be sure to set RFCHK3 for the master axis to 0.

	#7	#6	#5	#4	#3	#2	#1	#0
7702	PHD	PHS						

[Input type] Parameter input
[Data type] Bit path

#6 PHS When the G81/G80 block contains no R command:
0: Acceleration/deceleration is not performed at the start or cancellation of EGB synchronization.
1: Acceleration/deceleration is performed at the start or cancellation of EGB synchronization. After acceleration at the start of synchronization, phase synchronization is automatically performed.

#7 PHD The direction of movement for automatic phase synchronization is:
0: Positive (+).
1: Negative (-).

	#7	#6	#5	#4	#3	#2	#1	#0
7731	HAD	EPA	HBR					EFX

[Input type] Parameter input
[Data type] Bit path

#0 EFX As the EGB command:
0: G80 and G81 are used.
1: G80.4 and G81.4 are used.

NOTE
When this parameter is set to 0, no canned cycle for drilling can be used.

#5 HBR In EGB synchronization start command G81.4, the number of teeth is:
0: Specified in T.
1: Specified in R.

> **NOTE**
> This parameter is valid when bit 0 (EFX) of parameter No. 7731 is set to 1.

#6 EPA Automatic phase synchronization for the electronic gear box is performed in such a way that:
0: The machine coordinate 0 of the slave axis is aligned to the position of the master axis one-rotation signal.
1: The position of the slave axis at synchronization start is aligned to the position of the master axis one-rotation signal. (Specification of Series 16*i*)

#7 HAD In electronic gear box, the timing for reflecting helical gear compensation and travel distance of automatic phase synchronization to absolute coordinates is:
0: When synchronization is canceled.
1: During helical gear compensation and automatic phase synchronization.

7776	Feedrate during automatic phase synchronization for the workpiece axis

[Input type] Parameter input
[Data type] Real path
[Unit of data] deg/min
[Minimum unit of data] Depend on the increment system of the applied axis
[Valid data range] Refer to standard parameter setting table (C).
(When the increment system is IS-B, 0.0 to +999000.0)
This parameter sets the feedrate during automatic phase synchronization for the workpiece axis.
When this parameter is set to 0, the rapid traverse rate (parameter No. 1420) is used as the feedrate during automatic phase synchronization.

7777	Angle shifted from the spindle position (one-rotation signal position) the workpiece axis uses as the reference of phase synchronization

[Input type] Parameter input
[Data type] Real path
[Unit of data] deg
[Minimum unit of data] Depend on the increment system of the applied axis
[Valid data range] 0.000 to 360.000 (when the increment system is IS-B)
This parameter sets the angle shifted from the spindle position (one-rotation signal position) the workpiece axis uses as the reference of phase synchronization.

7778	Acceleration for acceleration/deceleration for the workpiece axis

[Input type] Parameter input
[Data type] Real axis
[Unit of data] deg/sec^2
[Minimum unit of data] Depend on the increment system of the applied axis
[Valid data range] Refer to the standard parameter setting table (D)
(For a millimeter machine, 0.0 to +100000.0, for an inch machine, 0.0 to +10000.0)
This parameter sets an acceleration for acceleration/deceleration for the workpiece axis.

> **NOTE**
> 1 In the Series 16*i*, acceleration for automatic phase matching is set by specifying a feedrate and a time constant in parameters Nos. 2135 and 2136 (Nos. 4384 and 4385 in the case of spindle EGB) separately; in the Series 0*i*-F Plus, acceleration is directly set in parameter No. 7778.
> 2 If this parameter is 0, alarm PS1598, “EGB AUTO PHASE PARAMETER SETTING ERROR” is issued when G81 is issued.

Alarm and message

Number	Message	Description
PS1597	EGB AUTO PHASE FORMAT ERROR	Format error in the G80 or G81 block in EGB automatic phase synchronization (1) R is outside the permissible range. (2) In the spindle EGB, reference position return is not performed for the master axis before G81R2 is specified.
PS1598	EGB AUTO PHASE PARAMETER SETTING ERROR	Error in the setting of a parameter related to EGB automatic phase synchronization (1) The acceleration/deceleration parameter is not correct. (2) The automatic phase synchronization parameter is not correct.

Manual name	Item name
OPERATOR’S MANUAL (B-64694EN)	Electronic gear box automatic phase synchronization

1.9.3.1 Arbitrary Gear Ratio for Master Axis in Electronic Gear Box Automatic Phase Synchronization

Overview

In electronic gear box automatic phase synchronization, the gear ratio between the master axis and the detector must be 1-to-1. Because the angle of the master axis is counted by number of pulses from one-rotation signal of detector.
This function considers the pulse from the detector and the gear ratio for calculating the angle of master axis. Therefore, EGB automatic phase synchronization can apply even if the gear ratio is not 1-to-1.
Moreover, the angle about the master axis can be reset by angle counter reset signal PREGB<Gn291.4>. An arbitrary angle of the master axis can be specified as the reference position of phase synchronization by this signal.

Explanation

1. To enable this function set bit 5 (EGEx) of parameter No.2273 to 1.
2. The value of counter per rotation for the master axis is set by 2 parameters. The parameters mean the fraction. Numerator is set to parameter No.1821, and denominator is set to parameter No.2179.
   For example, when the number of pulses from detector is 4096 and the gear ratio of the master axis to the detector is 1 : 7, the setting is as follows.
   No.1821 = 4096
   No.2179 = 7
3. To reset the angle about the master axis, set the angle counter reset signal PREGB<Gn291.4> to “1”. When angle counter reset signal PREGB is set to “1”, CNC resets the angle about the master axis. At this time, angle counter reset completion signal PREGBF<Fn291.4> is set to “1”.

- When the bit 6 (EPA) of parameter No.7731 = 0:
  In EGB automatic phase synchronization, the machine coordinate 0 for the slave axis is aligned to the position of angle 0 for the master axis.
- When the bit 6 (EPA) of parameter No.7731 = 1:
  In EGB automatic phase synchronization, the position for the slave axis at synchronization start is aligned to the position of angle 0 for the master axis.

NOTE

1. This function is the additional specification in EGB automatic phase synchronization for servo axis.
2. This function cannot be used in EGB automatic phase synchronization for spindle EGB.
3. If the serial type position detector , or A/B phase type position detector(FFG setting other than 1/1) are used in EGB automatic phase synchronization, this function must be made effective.
4. When bit 5 (EGEx) of parameter No.2273 is set to 0, parameters No.1821, No.2179, angle counter reset signal PREGB<Gn291.4> and angle counter reset completion signal PREGBF<Fn291.4> are invalid.
5. This function cannot be used in EGB (FSSB type)

Signal

Angle counter reset signal PREGB<Gn291.4>

[Classification] Input signal
[Function] Reset the angle about the master axis.
[Operation] When this signal is set to “1”, the angle about the master axis is reset.

Angle counter reset completion signal PREGBF<Fn291.4>

[Classification] Output signal
[Function] This signal indicates that the reset of angle about the master axis is completed.
[Operation] This signal becomes 1 under the following condition.
- Reset of the angle is completed.

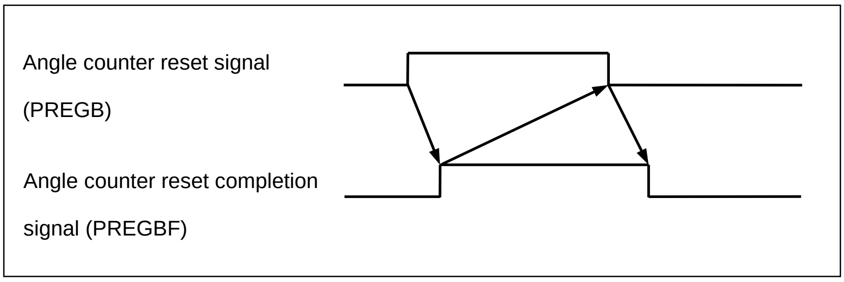
This signal becomes 0 under the following condition.
- Angle counter reset signal PREGB<Gn291.4> is set to “0”.

Signal address

	#7	#6	#5	#4	#3	#2	#1	#0
Gn291				PREGB				

	#7	#6	#5	#4	#3	#2	#1	#0
Fn291				PREGBF				

Timing chart



Parameter

Set the following parameters for the EGB dummy axis.

	#7	#6	#5	#4	#3	#2	#1	#0
2273		EGFx	EGEx					

[Input type] Parameter input
[Data type] Bit axis

#5 EGEx In electronic gear box automatic phase synchronization, the gear ratio of the master axis to the detector is:
0: 1-to-1.
1: Arbitrary.

#6 EGFx FFG is:
0: Not considered in the number of pulses per rotation about the master axis, for the position detector.
1: Considered in the number of pulses per rotation about the master axis, for the position detector.

> **NOTE**
> This parameter is valid for A/B phase type position detector. In the case of using serial type position detector, FFG is always considered.

In case of considering FFG, set the value which FFG is multiplied by the number of output pulses of detector to parameter No.7773. In case of bit 5 (EGEx) of parameter No.2273 is set to 1, set the value in which FFG is multiplied to the counter per rotation for the master axis.
N: Numerator of FFG (parameter No.2084)
M: Denominator of FFG (parameter No.2085)
α: Counter per rotation for the master axis (parameter No.1821 / parameter No.2179)
The value of new counter is the old one multiplied by FFG.

$$\alpha\,[\text{New}] = \alpha\,[\text{Old}] \times \frac{N}{M}$$

2084	Flexible feed gear (numerator) (N)

2085	Flexible feed gear (denominator) (M)

[Input type] Parameter input
[Data type] Word axis
In the case of serial type position detector or A/B phase type position detector and bit 6 (EGFx) of parameter No.2273 is set to 1, FFG is considered to the synchronization coefficient.

> **NOTE**
> If FFG is not using, be sure to set to 1 for both numerator and denominator parameter.

1821	Counter per rotation for the master axis (numerator)

[Input type] Parameter input
[Data type] 2-Word axis
[Valid data range] 1 to 2147483647

Set the counter per one rotation for the master axis with a fraction. (Numerator)

NOTE
When 0 or less is set to this parameter, the alarm PS1598, "EGB AUTO PHASE PARAMETER SETTING ERROR" occurs when G81 is issued.

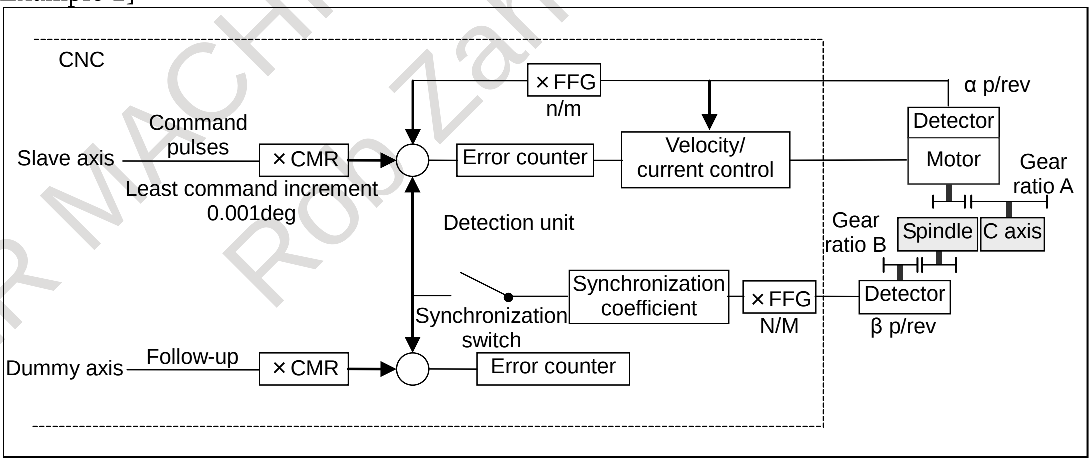
2179	Counter per rotation for the master axis (denominator)

[Input type] Parameter input
[Data type] Word axis
[Valid data range] 1 to 32767

Set the counter per one rotation for the master axis with a fraction. (Denominator)

NOTE
1 When 0 is set to this parameter, the alarm PS1598, "EGB AUTO PHASE PARAMETER SETTING ERROR" occurs when G81 is issued.
2 When negative value is set to this parameter, the alarm SV0417 "ILL DGTL SERVO PARAMETER" occurs.

[Example 1]



Gear ratio of the spindle to the detector B:
2/3 (When the detector rotates 2 for 3 spindle rotations)
Number of detector pulses per spindle rotation β:
80,000 pulses/rev (Calculated as 4 pulses for one A/B phase cycle)
FFG N/M of the EGB dummy axis : 1/1
Gear ratio of the C-axis A:
1/36 (One C-axis rotation corresponds to 36 motor rotations)
Number of detector pulses per C-axis rotation α:
1,000,000 pulses/rev
C-axis CMR : 1
C-axis FFG n/m : 1/100

Because the gear ratio of the spindle (master axis) to the detector is 2/3, enable this function by setting 1 to bit 5 (EGEx) of parameter No.2273.
The gear ratio of the spindle to the detector is 2/3 and the detector is 80,000 pulse/rev, so the angle counter is:

$$80000 \times \frac{2}{3} = \frac{160000}{3}$$

Set the parameter No.1821=160,000 and parameter No.2179=3.
The angle counter is not effective to synchronization ratio. The ordinary parameter No.7772 is used for calculation of synchronization ratio.
The number of pulses per spindle one-rotation is:

$$80000 \times \frac{2}{3} = \frac{160000}{3} \qquad <1>$$

It cannot be divided. It is impossible to set. In this case, the setting of the parameter No.7773 must be changed, and the ratio of the parameter No.7772 and the parameter No.7773 must be changed to the ratio that wants to be set.

Number of pulses per C-axis rotation by detection unit is:

$$1000000 \div 1/36 \times 1/100 = 360000 \qquad <2>$$

For <1>,<2>

$$\frac{\text{No.7772}}{\text{No.7773}} = \frac{160000/3}{360000} = \frac{160000}{360000 \times 3} = \frac{160000}{1080000}$$

Therefore, it is set as parameter No.7772 = 160,000 and parameter No.7773 = 1,080,000.
As described above, all the setting of parameter No.7772 and parameter No.7773 have to do is to indicate the ratio correctly. So, you can reduce the fraction indicated by the settings. For example, you may set 16 for parameter No.7772 and 108 for parameter No.7773 for this case.

[Example 2]
When the FFG of EGB dummy axis N/M is 1/10 for the above example, bit 6 (EGFx) of parameter No.2273 is set to 1 for making valid FFG.

The parameter No.7772 and parameter No.7773 is set to the new value that multiplies FFG for considering FFG.

$$\frac{\text{No.7772}}{\text{No.7773}} = \frac{160000}{1080000} \times \frac{1}{10} = \frac{16000}{1080000}$$

Set the parameter No.7772 = 16,000 and parameter No.7773 = 1,080,000.

And a new value that the angle counter similarly multiplied FFG is set.

$$\frac{\text{No.1821}}{\text{No.2179}} = \frac{160000}{3} \times \frac{1}{10} = \frac{16000}{3}$$

Set the parameter No.1821 = 16,000 and parameter No.2179 = 3.

Alarm and message

Number	Message	Description
PS1598	EGB AUTO PHASE PARAMETER SETTING ERROR	Error in the setting of a parameter related to EGB automatic phase synchronization (1) The acceleration/deceleration parameter is not correct. (2) The automatic phase synchronization parameter is not correct. (3) Bit 5 (EGE) of parameter No.2273 is set to 1 with the servo software that does not support this function,.

CONNECTION MANUAL (FUNCTION) (This manual)	Electronic Gear Box Automatic Phase Synchronization

1.9.3.2 Speed-up EGB Automatic Phase Synchronization

Overview

In electronic gear box automatic phase synchronization, the next block can be started without waiting for completion of phase synchronization.
It is possible to set M code for waiting for completion of EGB automatic phase synchronization in parameter No.7787. When the M code for waiting for completion of EGB automatic phase synchronization is commanded, execution of the next block is started after completion of EGB automatic phase synchronization.
This makes it possible to issue a program command during auto phase synchronization and acceleration of auto phase synchronization.
Also, by commanding the M code for waiting for completion of EGB automatic phase synchronization before the start of machining, it is possible to start machining with the EGB automatic phase synchronization completed.
It is possible to set M code for starting deceleration of EGB automatic phase synchronization in parameter No.7788. When the M code for starting deceleration of EGB automatic phase synchronization is commanded, deceleration of EGB automatic phase synchronization is started. The block of M code for starting deceleration of EGB automatic phase synchronization is immediately ended and the next block is started.
This makes it possible to issue a program command during deceleration of EGB automatic phase synchronization.

Format

- **Acceleration/deceleration plus speed-up automatic phase synchronization type**

G81 T_ L_ R3 ;	**Synchronization start**
G80 R3 ;	**Synchronization cancellation**

T : Number of teeth (range of valid settings: 1-5000)
L : Number of hob threads (range of valid settings: -250 to 250, excluding 0)
When L is positive, the direction of rotation about the workpiece axis is positive (+ direction).
When L is negative, the direction of rotation about the workpiece axis is negative (- direction).

Explanation

- Acceleration/deceleration plus speed-up automatic phase synchronization type

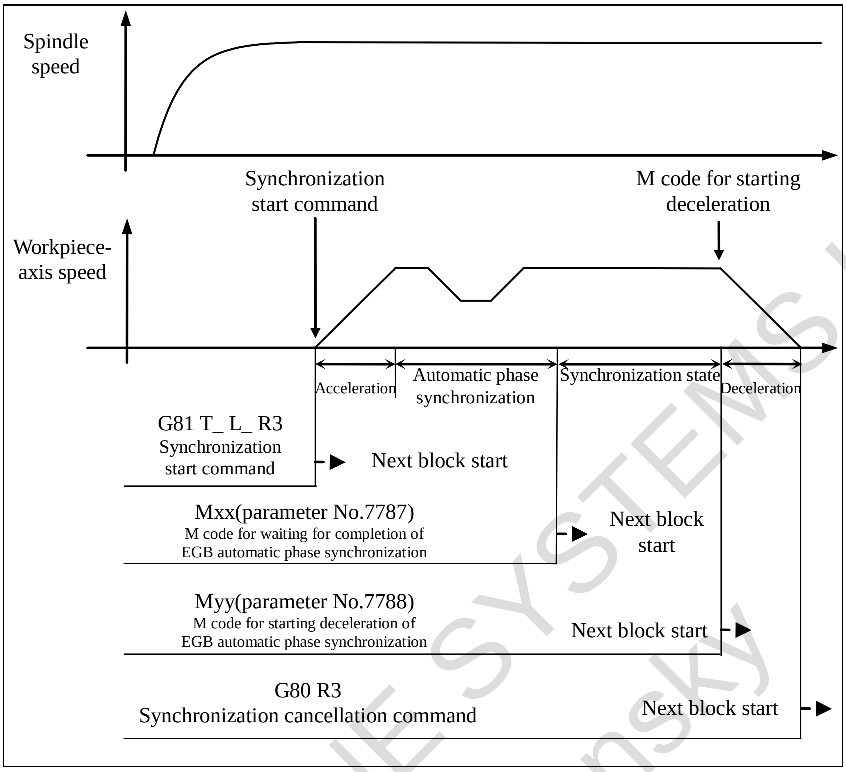

Fig. 1.9.3.2 (a) Acceleration/deceleration plus speed-up automatic phase synchronization type

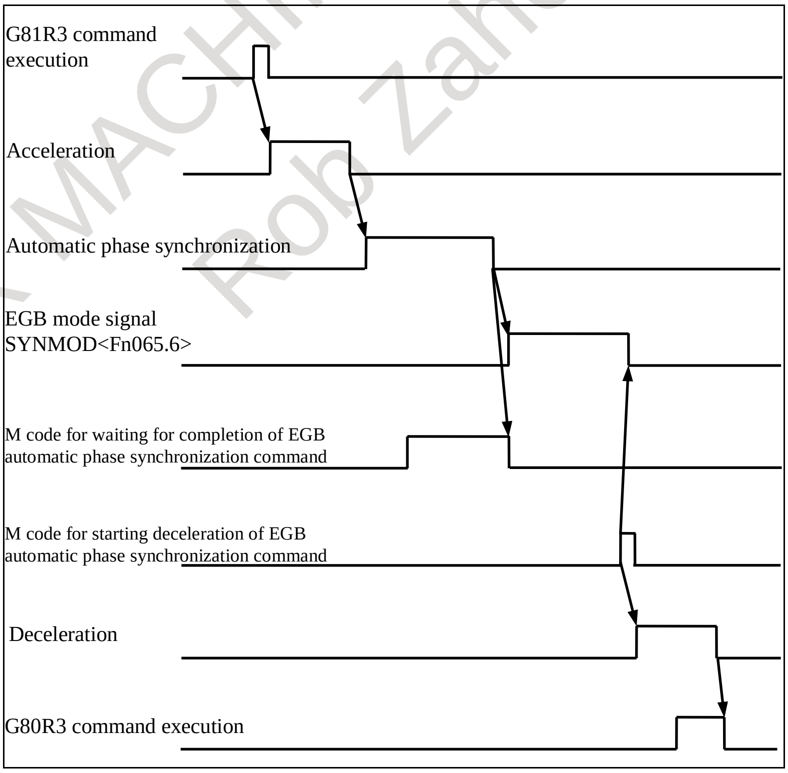

Fig. 1.9.3.2 (b) Timing chart of acceleration/deceleration plus speed-up automatic phase synchronization type

1. Move the workpiece axis to the position that corresponds to that of the one-rotation signal of the spindle.

2. Specify G81R3 to start synchronization. The block of G81R3 is immediately ended and the next block is started.
   When G81R3 is specified, the workpiece axis is accelerated with the acceleration according to the acceleration rate set in the parameter No.7778. Upon completion of phase synchronization, the EGB mode signal SYNMOD<Fn065.6> becomes “1”.
3. When the M code for waiting for completion of EGB automatic phase synchronization is commanded, the next block is not started until automatic phase synchronization is completed.
4. For cancellation, specify the M code for starting deceleration of EGB automatic phase synchronization while the tool is moved away from the workpiece. The block of M code for starting deceleration is immediately ended and the next block is started.
5. When M code for starting deceleration is issued, the EGB mode signal SYNMOD<Fn065.6> becomes “0” and deceleration is started immediately according to the acceleration rate set in parameter No.7778.
6. When G80R3 is issued, deceleration is continued. And the speed reaches 0, the G80R3 block terminates.

NOTE

1 Do not specify EGB synchronization (G81/G81.5) command before automatic phase synchronization is completed. If EGB synchronization command is issued, alarm (PS1595), “ILL-COMMAND IN EGB MODE” is generated. Even when an alarm (PS1595) occurs, automatic phase synchronization before the occurrence of an alarm is continued.

2 Confirm the completion of phase synchronization by M code (parameter No.7787) for waiting for completion of EGB automatic phase synchronization, then issue a movement command or machining to work axis. Also, in the case of helical gears, make sure that the phase synchronization is completed and then issue a movement command for the axial feed axis.

3 Specify M code (parameter No.7787) for waiting for completion of EGB automatic phase synchronization and M code (parameter No.7788) for starting deceleration of EGB automatic phase synchronization in a single block.

4 As for M code (parameter No.7787) for waiting for completion of EGB automatic phase synchronization and M code (parameter No.7788) for starting deceleration of EGB automatic phase synchronization, the function code signal and strobe signal are not output.

- Program example

```

  :
G81 T_ L_ R3;   Synchronization start command
G00 X_;         X-axis approach
Mxx;            M code for waiting for completion of EGB automatic phase synchronization command
G01 Z_ F_;      Machining start
  :
G00 X_;         Release work and tool
Myy;            M code for starting deceleration of EGB automatic phase synchronization command
G00 X_;         X-axis retraction
G80 R3;         Synchronization cancellation command
  :
M30;
```

Signal

EGB mode signal SYNMOD< Fn065.6>

[Classification] Output signal

[Function] Reports that synchronization with the EGB is in progress.

[Operation] This signal becomes “1” if:

- Synchronization with the EGB is in progress.

It becomes “0” if:

- Synchronization with the EGB is canceled.

Signal address

	#7	#6	#5	#4	#3	#2	#1	#0
Fn065		SYNMOD						

Parameter

7787	M code for waiting for completion of EGB automatic phase synchronization

[Input type] Parameter input

[Data type] 2-word path

[Valid data range] 0 to 99999999

Set M code for waiting for completion of EGB automatic phase synchronization.
When 0 is set in this parameter, this parameter is invalid.

7788	M code for starting deceleration of EGB automatic phase synchronization

[Input type] Parameter input

[Data type] 2-word path

[Valid data range] 0 to 99999999

Set M code for starting deceleration of EGB automatic phase synchronization.
When 0 is set in this parameter, this parameter is invalid.

1.9.4 Skip Function for EGB Axis

Overview

This function enables the skip or high-speed skip signal (these signals are collectively called skip signals in the remainder of this manual) for the EBG slave axis in synchronization mode with the EGB (electronic gear box).

This function has features such as the following:

1 If a skip signal is input while an EGB axis skip command block is being executed, this block does not terminate until the specified number of skip signals have been input.

2 If a skip signal is input while an EGB axis skip command block is being executed, the tool remains in synchronization mode and moves, not stopping on the EGB slave axis.

3 The machine coordinates assumed when skip signals are input and the number of input skip signals are stored in specified custom macro variables.

For an explanation of the electronic gear box, see the preceding Subsection, "Electronic Gear Box" in this manual.

Format

G81 T_ L_ ;	**EGB mode ON**
G31.8 G91 α0 P_ Q_ (R_) ;	**EGB skip command**

α: Specify an EGB slave axis. The specified value must always be 0.
P: Number of the first one of the custom macro variables used to store the machine coordinates assumed when skip signals are input.
Q: Number of skip signals that can be input during the execution of G31.8 (permissible range: 1 to 512).
R: Number of the custom macro variable used to store the number of input skip signals.
Specify it to check the number of input signals.

Explanation

G31.8 is a one-shot G code.
When G31.8 is executed, the machine coordinates assumed when skip signals are input are written in as many custom macro variables as the number specified in Q, starting with the one having the number specified in P, when the skip command block terminates.
Also, the number of input skip signals is written to the custom macro variable specified in R each time a skip signal is input.

Positional deviation

In skip function for EGB axis, when bit 5 (ESE) of parameter No.6216 is set to 1, positional deviation when the skip signal and the high-speed skip signal are input is considered and compensated.
As a result, the measurement with high accuracy becomes possible in skip function for EGB axis.

Example

The pitch of a gear can be measured.

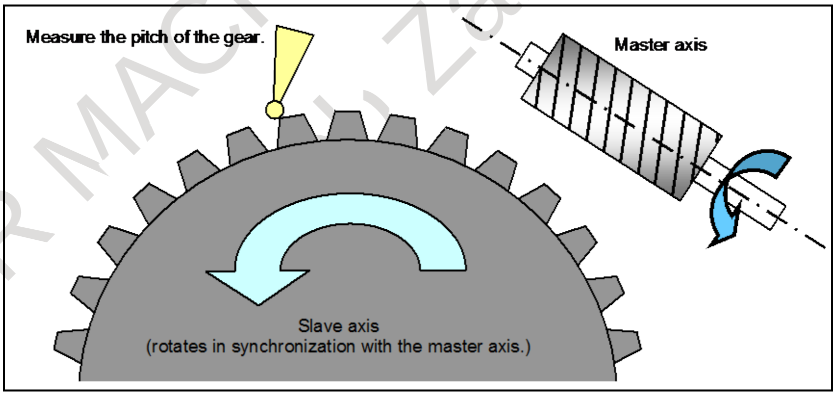

Fig. 1.9.4

G81 T200 L2 ; ....EGB mode ON
X_ ;
Z_ ;
G31.8 G91 C0 P500 Q200 R1 ;...........EGB skip command

After 200 skip signals have been input, the 200 skip positions on the C-axis that correspond to the respective skip signals are stored in custom macro variables #500 to #699.
Also, the number of input skip signals is stored in custom macro variable #1.

NOTE

1. When specifying this function, specify only a single EGB slave axis. If no axis is specified for two or more axes are specified, alarm PS1152, “G31.9/G31.8 FORMAT ERROR” is generated.
2. If P is not specified, alarm PS1152 is generated.
3. If R is not specified, the number of input skip signals is not written to a custom macro variable.
4. The custom macro variable numbers specified in P and R must be existing ones. If a non-existent variable number is specified, alarm PS0115, "VARIABLE NO. OUT OF RANGE" is generated.
   If a variable shortage occurs, alarm PS0115 is generated.
5. Whether to use conventional skip signals or high-speed skip signals with this function can be specified with HSS, bit 4 of parameter No. 6200. If deciding to use high-speed skip signals, specify which high-speed signals to enable with 9S1 to 9S8, bits 0 to 7 of parameter No. 6208).
6. Skip positions are calculated from feedback pulses from the machine. Thus, errors due to delay in acceleration/deceleration and the servo system are small. In skip function for EGB axis, when bit 5 (ESE) of parameter No.6216 is set to 1, positional deviation when the skip signal and the high-speed skip signal are input is considered and compensated.

Signal

For details of skip signals, see the sections on "skip function" and "high-speed signal".

Parameter

	#7	#6	#5	#4	#3	#2	#1	#0
6200		SRE	SLS	HSS			SK0	GSK

[Input type] Parameter input
[Data type] Bit path

#0 GSK As a skip signal, the skip signal SKIPP is:
0: Invalid.
1: Valid.

#1 SK0 This parameter specifies whether the skip signal is made valid under the state of the skip signal SKIP and the multistage skip signals SKIP2 to SKIP8.
0: Skip signal is valid when these signals are “1”.
1: Skip signal is valid when these signals are “0”.

#4 HSS
0: The skip function does not use high-speed skip signals while skip signals are input. (The conventional skip signal is used.)
1: The step skip function uses high-speed skip signals while skip signals are input.

#5 SLS
0: The multi-step skip function does not use high-speed skip signals while skip signals are input. (The conventional skip signal is used.)
1: The multi-step skip function uses high-speed skip signals while skip signals are input.

> **NOTE**
> The skip signals (SKIP and SKIP2 to SKIP8) are valid regardless of the setting of this parameter. They can also be disabled using bit 4 (IGX) of parameter No. 6201.

#6 SRE When a high-speed skip signal or high-speed measurement position arrival signal is used:
0: The signal is assumed to be input on the rising edge (contact open → close).
1: The signal is assumed to be input on the falling edge (contact close → open).

	#7	#6	#5	#4	#3	#2	#1	#0
6201	**SKPXE**		**CSE**	**IGX**				

[Input type] Parameter input
[Data type] Bit path

#4 IGX When the high-speed skip function is used, SKIP, SKIPP, and SKIP2 to SKIP8 are:
0: Enabled as skip signals.
1: Disabled as skip signals.

#5 CSE For the continuous high-speed skip command, high-speed skip signals are:
0: Effective at either a rising or falling edge (depending on the setting of bit 6 (SRE) of parameter No. 6200).
1: Effective at both the rising and falling edges.

#7 SKPXE For the skip function (G31), the skip signal SKIP is:
0: Enabled.
1: Disabled.

Whether the skip signals are enabled or disabled

Parameter	Bit 4 (IGX) of parameter No. 6201	Bit 0 (GSK) of parameter No. 6200	Bit 7 (SKPXE) of parameter No. 6201	Skip signal SKIPP	Skip signal SKIP	Multistage skip signals SKIP2-SKIP8
Setting	0	0	0	Disabled	Enabled	Enabled
	0	1	0	Enabled	Enabled	Enabled
	0	0	1	Disabled	Disabled	Enabled
	0	1	1	Enabled	Disabled	Enabled
	1	0	0	Disabled	Disabled	Disabled
	1	1	0	Disabled	Disabled	Disabled
	1	0	1	Disabled	Disabled	Disabled
	1	1	1	Disabled	Disabled	Disabled

Bit 4 (IGX) of parameter No. 6201 is valid for the skip function using high-speed skip signals (when bit 4 (HSS) of parameter No. 6200 is set to 1) or for the multistage skip function using high-speed skip signals (when bit 5 (SLS) of parameter No. 6200 is set to 1).

	#7	#6	#5	#4	#3	#2	#1	#0
6208	**9S8**	**9S7**	**9S6**	**9S5**	**9S4**	**9S3**	**9S2**	**9S1**

[Input type] Parameter input
[Data type] Bit path

9S1 to 9S8 Specify which high-speed skip signal is enabled for the continuous high-speed skip command G31P90 or the EGB skip command G31.8.

The settings of each bit have the following meaning:
0: The high-speed skip signal corresponding to the bit is disabled.
1: The high-speed skip signal corresponding to the bit is enabled.
The bits correspond to signals as follows:

Parameter	High-speed skip signal	Parameter	High-speed skip signal
9S1	HDI0	9S5	HDI4
9S2	HDI1	9S6	HDI5
9S3	HDI2	9S7	HDI6
9S4	HDI3	9S8	HDI7

	#7	#6	#5	#4	#3	#2	#1	#0
6216			ESE					

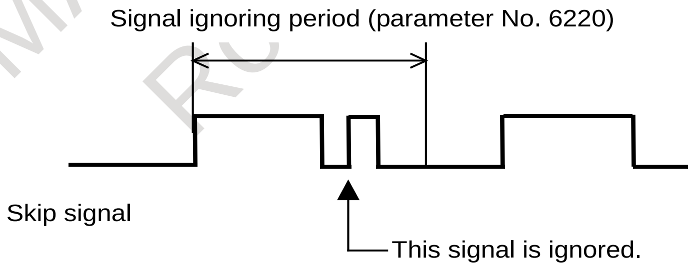
[Input type] Parameter input
[Data type] Bit path

#5 ESE positional deviation when the skip signal and the high-speed skip signal are input:
0: is not considered.
1: is considered.

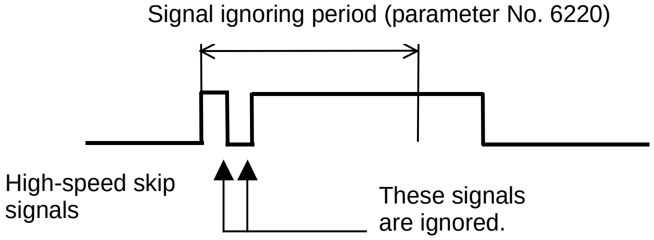
6220	**Period during which skip signal input is ignored for the continuous high-speed skip function and EGB axis skip function**

[Input type] Parameter input
[Data type] Byte path
[Unit of data] 8msec
[Valid data range] 3 to 127(× 8msec)

This parameter specifies the period from when a skip signal is input to when the next skip signal can be input for the continuous high-speed skip function and EGB axis skip function. This parameter is used to ignore chattering in skip signals.
If a value that falls outside the valid range is specified, the setting is assumed to be 24 msec.



When high-speed skip signals are used and bit 5 (CSE) of parameter No. 6201 is set to 1, signals are handled as follows:



Alarm and message

Number	Message	Description
PS0115	VARIABLE NO. OUT OF RANGE	A number that cannot be used for a local variable, common variable, or system variable in a custom macro is specified. In the EGB axis skip function (G31.8), a non-existent custom macro variable number is specified. Or, the number of custom macro variables used to store skip positions is not sufficient.
PS1152	G31.9/G31.8 FORMAT ERROR	There is a format error in the G31.9 or G31.8 block as described below. - No axis address is specified in the G31.9 or G31.8 block. - More than axis address is specified in the G31.9 or G31.8 block. - P is not specified in the G31.9 or G31.8 block

1.9.5 Electronic Gear Box 2 Pair

Overview

The Electronic Gear Box is a function for rotating a workpiece in sync with a rotating tool, or to move a tool in sync with a rotating workpiece. With this function, the high-precision machining of gears, threads, and the like can be implemented. A desired synchronization ratio can be programmed.
Up to two sets of axes can be synchronized. A gear grinding machine can be controlled, for instance, by using one axis for rotating the workpiece in sync with the tool and another axis for performing dressing in sync with the tool.
The electronic gear box is hereinafter called an EGB function.

1.9.5.1 Specification method (G80.5, G81.5)

Format

G81.5 $\left\{\begin{array}{l}\mathbf{T\,t}\\ \mathbf{P\,p}\end{array}\right\}$ $\left\{\begin{array}{l}\beta\,\mathbf{j}\\ \beta\,\mathbf{0}\ \ \mathbf{L}\,l\end{array}\right\}$ **;** Synchronization start

↑ Amount of travel along the master axis

↑ Amount of travel along the slave axis

G80.5 β0 ; Synchronization cancellation

Explanation

- Master axis, slave axis, and dummy axis

The synchronization reference axis is called the master axis, while the axis along which movement is performed in synchronization with the master axis is called the slave axis. For example, if the workpiece moves in synchronization with the rotating tool as in a hobbing machine, the tool axis is the master axis and the workpiece axis is the slave axis.
Which axes to become the master and slave axes depends on the configuration of the machine. For details, refer to the manual issued by the machine tool builder.
A single servo axis is used exclusively so that digital servo can directly read the rotation position of the master axis. (This axis is called the EGB dummy axis.)

- Synchronization start

When the ratio of the master-axis travel to the slave-axis travel is specified, synchronization starts.

<u>Specify the master-axis travel in either of the following ways.</u>

1 Master-axis speed

T t: Master-axis speed (1≤ t ≤5000)

2 Master-axis pulse count

P p : Master-axis pulse count ($1 \leq p \leq 999999999$)

Specify a pulse count on the condition that four pulses correspond to one period in the A and B phases.

Specify the slave-axis travel in either of the following ways.

1 Slave-axis travel

βj : Slave-axis address

j : Slave-axis travel indicated in units of the minimum travel increments(the range of valid settings for usual axis movement applies)

When j = 0, the specified command is regarded as being a command for the slave-axis speed, described below. In this case, if L is not specified, an alarm is output.

2 Slave-axis speed

β0 L±*l*

β : Slave-axis address

l : Slave axis speed($-250 \leq l \leq 250$, $l = 0$ is excluded, however.)

- Synchronization cancellation

1 Canceling synchronization for each axis by issuing a command

With a G80.5 β0 command, synchronization is canceled.

β is the address of the slave axis. Synchronization of the slave axis specified by β is canceled.

A cancellation command can be issued only for one axis in one block.

When β0 is not specified, the synchronization of all currently synchronized axes is canceled.

When a synchronization cancellation command is issued, the absolute coordinates for the slave axis are updated according to the amount of travel during synchronization. For a rotation axis, the value obtained by rounding off the amount of travel during synchronization to the nearest 360 degrees is added to the absolute coordinates.

2 Canceling synchronization by a reset

By setting HBR, bit 0 of parameter No. 7700, to 0, synchronization is canceled with a reset.

3 Others

Synchronization is automatically canceled under the following conditions.

<1> Emergency stop

<2> Servo alarm

<3> Alarm PW0000 (indicating that the power should be turned off)

<4> An IO alarm is generated

- How to reduce the synchronous error

When you use the Electronic gear box function, to reduce the synchronous error, please apply feed-forward to the slave axis and set 100% to the parameter of feed-forward coefficient.

And please confirm the effectiveness of feed-forward by the following procedure.

[Procedure]

1. When the slave axis synchronizes only with the command from master axis (ie. When the slave axis doesn’t use helical gear compensation), the position error of slave axis is regarded as the synchronous error. Please check that the position error (DGN data No.300) of the slave axis becomes 0 or so.
2. And also check the position error is near 0 even when the speed of the master axis is changed.

Set the following parameters to use Feed-forward function with 100% coefficient.

[Setting parameters]

Bit 3 (PIENx) of parameter No. 2003 = 1 (Slave axis)	Use PI control in velocity control
Bit 1 (FEEDx) of parameter No. 2005 = 1 (Slave axis)	Use Feed-forward function

Bit 1 (FFALx) of parameter No. 2011 = 1 (Slave axis) Use Feed-forward function irrespective of feed mode
Parameter No.2068 (FF coefficient) = 10000 (Slave axis) Feed-forward coefficient is 100%.

Please refer to the chapter of “Feed-forward Function” in FANUC AC SERVO MOTOR α*i* series FANUC AC SERVO MOTOR β*i* series FANUC LINEAR MOTOR L*i*S series FANUC SYNCHRONOUS BUILT-IN SERVO MOTOR D*i*S series Parameter manual (B-65270EN) about the detail of Feed-forward function.

- How to reduce shock at the start of acc./dec.

If the shock of slave axis is large when the master axis accelerates or decelerates in velocity control mode, please apply “Soft start/stop” function to the master axis (spindle axis).
Please set the following parameters to use Soft start/stop function.

[Setting parameters]

Bit 2 (SOSALWs) of parameter No. 4399 = 1 Use Soft start/stop function even at emergency stop
Note) If the spindle axis is a sub axis of spindle switching control, please set bit 2 of parameter No. 4472 instead of bit 2 of parameter No. 4399.
Parameter No. 4030 Soft start/stop setting time
Parameter No. 4508 Rate of change in acceleration at soft start/stop
Note) Parameters Nos. 4030 and 4508 should be tuned according to the spindle characteristic to reduce the shock well.

[Signals]

Soft start/stop signal SOCNA <Gn071.4> : First spindle
Soft start/stop signal SOCNB <Gn075.4> : Second spindle
Soft start/stop signal SOCNC <Gn205.4> : Third spindle
Soft start/stop signal SOCND <Gn267.4> : Fourth spindle

Please refer to FANUC AC SPINDLE MOTOR α*i*/β*i* series BUILT-IN SPINDLE MOTOR B*i* series parameter manual (B-65280EN) about the detail of Soft start/stop function.

⚠ CAUTION

1. Feed hold, interlock, and machine lock are invalid to a slave axis in EGB synchronization.
2. Even if an OT alarm is issued for a slave axis in EGB synchronization, synchronization will not be canceled.
3. During synchronization, it is possible to execute a move command for a slave axis and other axes, using a program. The move command for a slave axis must be an incremental one.

NOTE

1. If bit 0 (HBR) of parameter No. 7700 is set to 1, EGB synchronization will not be canceled due to a reset. Usually, set this parameter bit to 1.
2. In synchronization mode, it is not possible to specify G27, G28, G29, G30, and G53 for a slave axis.
3. It is not possible to use controlled axis detach for a slave axis.
4. During synchronization, manual handle interruption can be performed on the slave and other axes.
5. In synchronization mode, no inch/metric conversion commands (G20 and G21) cannot be issued.
6. In synchronization mode, only the machine coordinates on a slave axis are updated.
7. If, during synchronization, G81.5 is issued again, alarm PS1594, “EGB FORMAT ERROR” is issued if bit 3 (ECN) of parameter No. 7731 is 0. If bit 3 (ECN) of parameter No. 7731 is 1, the synchronization coefficient can be changed to a newly specified one.
8. Actual cutting feedrate display does not take synchronization pulses into consideration.
9. For an EGB slave axis, synchronous and composite control cannot be executed.
10. In EGB synchronization mode, AI contour control mode is temporarily canceled.
11. Not advanced preview feed-forward but conventional feed-forward is enabled in the path where EGB synchronization mode is effective.

1.9.5.2 Description of commands compatible with those for a hobbing machine (G80, G81)

A command compatible with that for a hobbing machine can be used as a synchronization command.
Usually, a hobbing machine performs machining by synchronizing the workpiece axis (usually, the C-axis) to the hobbing axis (spindle).
If there are two synchronization sets with the EGB, which synchronization set to start with this specification method can be specified with parameter No. 7710.

Format

	Bit 0 (EFX) of parameter No.7731=0	Bit 0 (EFX) of parameter No.7731=1	
		Bit 5 (HBR) of parameter No.7731=1	Bit 5 (HBR) of parameter No.7731=0
Start of synchronization	**G81 T__ (L__) (Q__ P__) ;**	**G81.4 R__ (L__) (Q__ P__) ;**	**G81.4 T__ (L__) (Q__ P__) ;**
Cancellation of synchronization	**G80 ;**	**G80.4 ;**	**G80.4 ;**
	(*1) (*4)	**(*2) (*4)**	**(*3) (*4)**

T(or R) : Number of teeth (Specifiable range: 1 to 5000)

L : Number of hob threads (Specifiable range: -250 to 250)
The sign of L determines the direction of rotation for the workpiece axis.
When L is positive, the direction of rotation for the workpiece axis is positive (+ direction).
When L is negative, the direction of rotation for the workpiece axis is negative (- direction).
When L is 0, it follows the setting of bit 3 (LZR) of parameter No.7701.
If L is not specified, the number of hob threads is assumed 1.

Q : Module or diametral pitch
Specify a module in the case of metric input.
(Unit: 0.00001mm, Specifiable range: 0.01 to 25.0mm)
Specify a diametral pitch in the case of inch input.
(Unit: 0.00001inch^{-1}, Specifiable range: 0.01 to 254.0 inch^{-1})

P : Gear helix angle
(Unit: 0.0001deg, Specifiable range: -90.0 to 90.0deg)

*1 Use it for machining centers.
*2 Use it for lathes.
*3 Use it for machining centers.
This format enables specification of the same G codes as those for lathes.
*4 When specifying Q and P, the user can use a decimal point.

NOTE
Specify G81, G80, G81.4, and G80.4 in a single block.

Explanation

- Synchronization start

Specify P and Q to use helical gear compensation. In this case, if only one of P and Q is specified, alarm PS1594 "EGB FORMAT ERROR" is generated.

When G81 is issued so that the machine enters synchronization mode, the synchronization of the workpiece axis to the spindle is started.

During synchronization, control is performed such that the ratio of the spindle speed to the workpiece-axis speed is the same as that of T (number of teeth) to L (number of hob threads).

If, during synchronization, G81 is issued again without synchronization cancellation, alarm PS1595 "ILL-COMMAND IN EGB MODE" is generated if ECN, bit 3 of parameter No. 7731, is 0. If ECN, bit 3 of parameter No. 7731, is 1, helical gear compensation is conducted with the synchronization coefficient being changed to the one newly specified with T and L commands if T and L commands are issued, and if T and L commands are not issued and only P and Q commands are issued, helical gear compensation is conducted with the synchronization coefficient kept intact. This allows consecutive fabrication of helical gears and spur gears.

- Synchronization cancellation

Synchronization of all synchronized axes is canceled.
When a synchronization cancellation command is issued, the absolute coordinates for the slave axis are updated according to the amount of travel during synchronization.
For a rotation axis, the value obtained by rounding off the amount of travel during synchronization to the nearest 360 degrees is added to the absolute coordinates.
In a G80 block, do not specify addresses other than O or N.

⚠ CAUTION

1 Feed hold, interlock, and machine lock are invalid to a slave axis in EGB synchronization.
2 Even if an OT alarm is issued for a slave axis in EGB synchronization, synchronization will not be canceled.
3 During synchronization, it is possible to execute a move command for a slave axis and other axes, using a program. The move command for a slave axis must be an incremental one.

NOTE

1 If bit 0 (HBR) of parameter No. 7700 is set to 1, EGB synchronization will not be canceled due to a reset. Usually, set this parameter bit to 1.
2 In synchronization mode, it is not possible to specify G27, G28, G29, G30, and G53 for a slave axis.
3 It is not possible to use controlled axis detach for a slave axis
4 During synchronization, manual handle interruption can be performed on the slave and other axes.
5 In synchronization mode, no inch/metric conversion commands (G20 and G21) cannot be issued.
6 In synchronization mode, only the machine coordinates on a slave axis are updated.
7 If bit 0 (EFX) of parameter No. 7731 is 0, no canned cycle for drilling can be used. To use a canned cycle for drilling, set bit 0 (EFX) of parameter No. 7731 to 1 and use G81.4 instead of G81 and G80.4 instead of G80.
8 If bit 0 (TDP) of parameter No. 7702 is 1, the permissible range of T is 0.1 to 500 (1/10 of the specified value).
9 If, at the start of EGB synchronization (G81), L is specified as 0, synchronization starts with L assumed to be 1 if bit 3 (LZR) of parameter No.7701 is 0; if bit 3 (LZR) of parameter No.7701 is 1, synchronization is not started with L assumed to be 0. At this time, helical gear compensation is performed.
10 Feed per revolution is performed on the feedback pulses on the spindle. By setting bit 0 (ERV) of parameter No. 7703 to 1, feed per revolution can be performed based on the speed on the synchronous slave axis.
11 Actual cutting feedrate display does not take synchronization pulses into consideration.
12 For an EGB slave axis, synchronous and composite control cannot be executed.
13 In EGB synchronization mode, AI contour control mode is temporarily canceled.
14 Not advanced preview feed-forward but conventional feed-forward is enabled in the path where EGB synchronization mode is effective.

- Helical gear compensation

For a helical gear, the workpiece axis is subjected to compensation for movement along the Z axis (axial feed axis) according to the twisted angle of the gear.
Helical gear compensation is performed with the following data.

$$\text{Compensation angle} = \frac{Z \times \sin(P)}{\pi \times T \times Q} \times 360 \text{ (for metric input)}$$

$$\text{Compensation angle} = \frac{Z \times Q \times \sin(P)}{\pi \times T} \times 360 \text{ (for inch input)}$$

where

Compensation angle : Absolute value with sign (degrees)
Z : Amount of travel along the Z axis after a G81 command is issued (mm or inch)
P : Twisted angle of the gear with sign (degrees)
π : Circular constant
T : Number of teeth
Q : Module (mm) or diametral pitch (inch^{-1})

Use P, T, and Q specified in the G81 block.
In helical gear compensation, the machine coordinates on the workpiece axis and the absolute coordinates are updated with helical gear compensation.
The updated timing is as follows.

<table>
<tr><th>Machine coordinates</th><th colspan="2">Absolute coordinates</th></tr>
<tr><td rowspan="3">During helical gear compensation</td><td colspan="2">Bit 7(HAD) of parameter No.7731</td></tr>
<tr><td>= 0</td><td>= 1</td></tr>
<tr><td>Synchronization cancel</td><td>During helical gear compensation</td></tr>
</table>

- Direction of helical gear compensation

The direction depends on bit 2 (HDR) of parameter No. 7700.

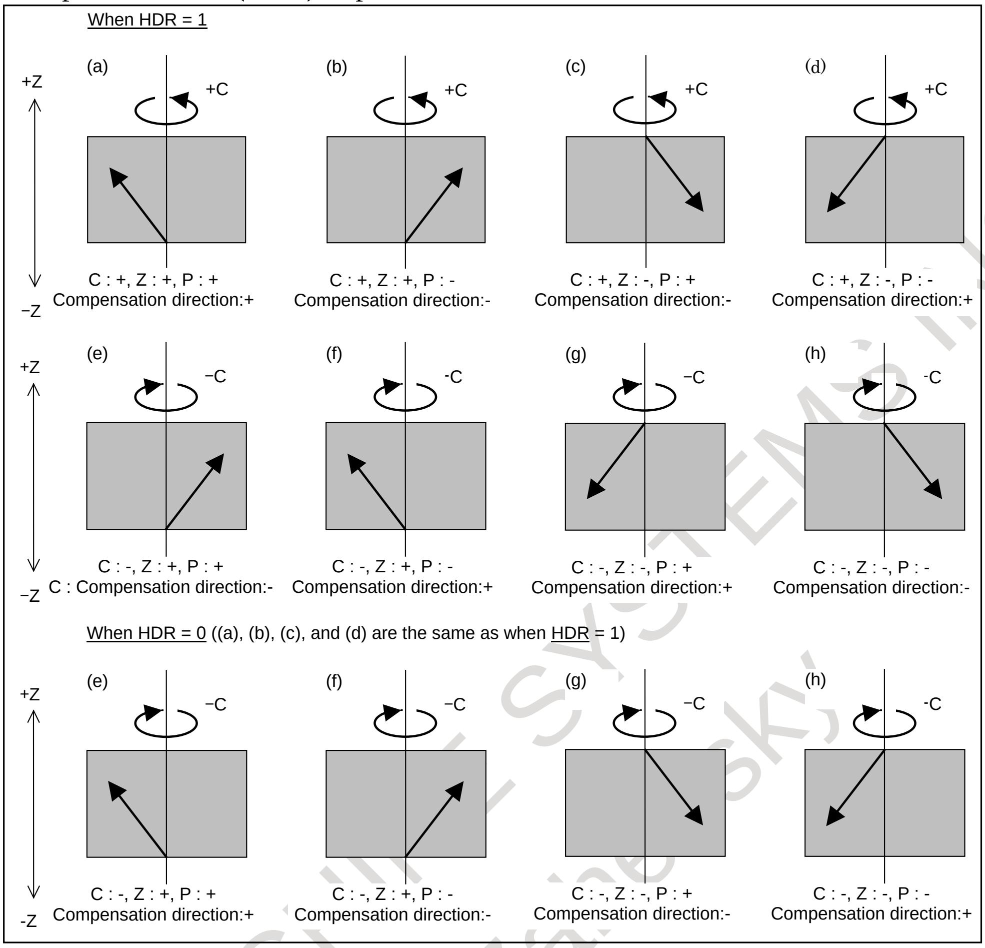


Fig. 1.9.5.2 (a) Direction of helical gear compensation

1.9.5.3 Controlled axis configuration example

- For gear grinders

Spindle : EGB master axis : Tool axis
1st axis : X axis
2nd axis : Y axis
3rd axis : C axis (EGB slave axis : Workpiece axis)
4th axis : C axis (EGB dummy axis : Cannot be used as a normal controlled axis)
5th axis : V axis (EGB slave axis : Dressing axis)
6th axis : V axis (EGB dummy axis : Cannot be used as a normal controlled axis)

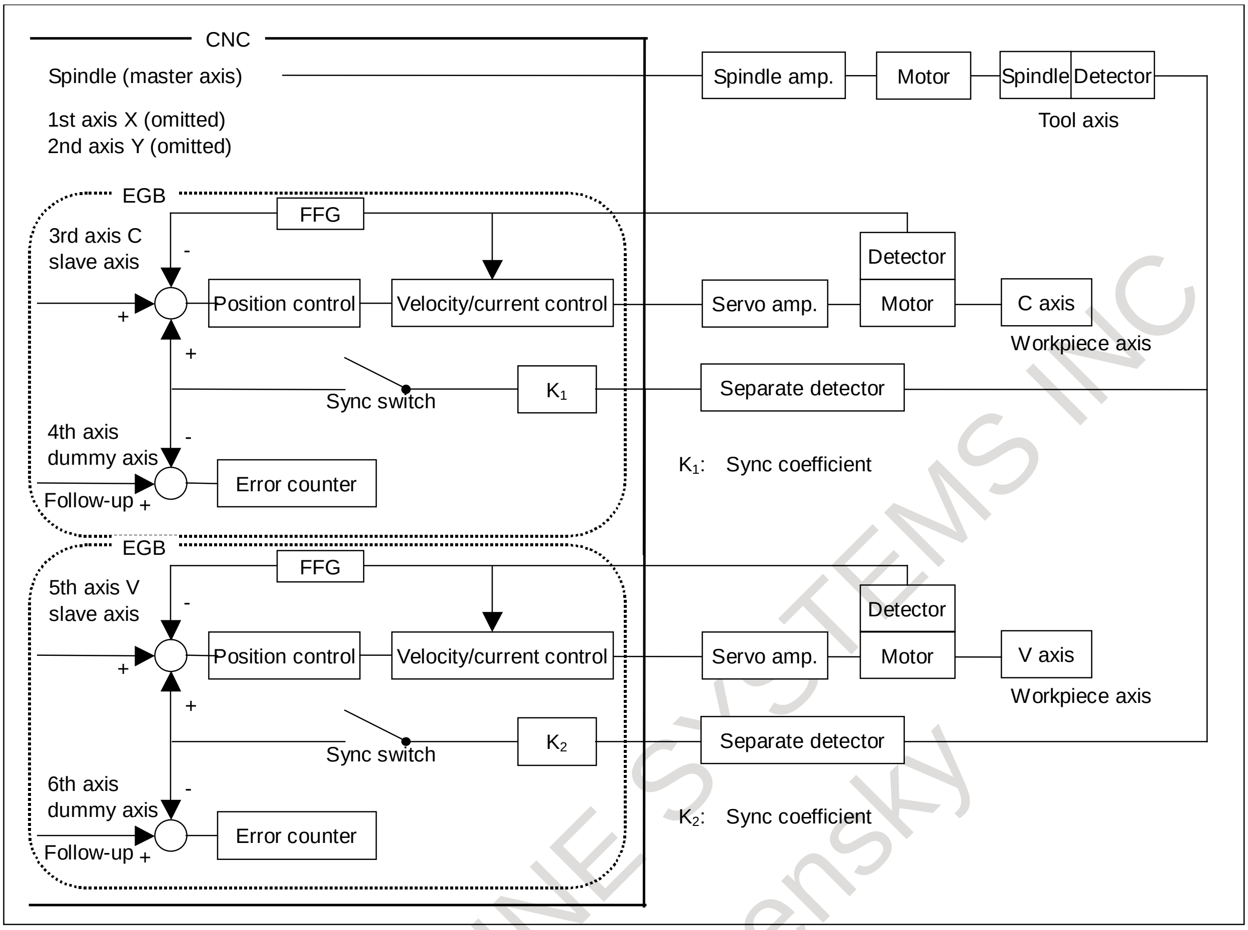

Fig. 1.9.5.3 (a)

For EGB axis configuration parameter setting examples, see the section on "FSSB setting".

- Example of use of dressing

Gear grinder in the following machine configuration

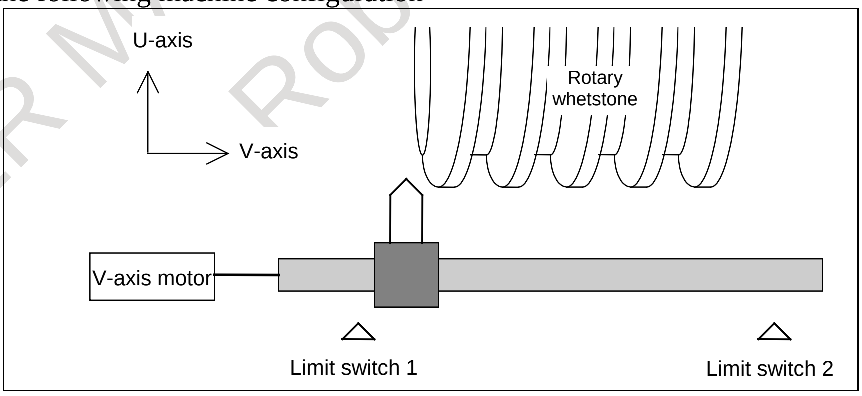

Fig. 1.9.5.3 (b)

O9500 ;

N01 G01 G91 U_ F100 ;	Dressing axis approach
N02 M03 S100 ;	The M03 command causes the PMC to rotate the whetstone in the positive direction. In accordance with this, the tool moves along the V-axis in the + direction. When the tool reaches the position of limit switch 2 on the V-axis, the PMC stops the whetstone and returns FIN.
N02 U_ V_ ;	Movement to the next dressing position

N03 M04 S100 ; The M04 command causes the PMC to rotate the whetstone in the negative direction.
In accordance with this, the tool moves along the V-axis in the - direction. When the tool reaches the position of limit switch 1 on the V-axis, the PMC stops the whetstone and returns FIN.

N04 U_ V_ ; Movement to the next dressing position
If required, N02 to N04 are repeated to conduct dressing.

....
....
M99 ;

> **NOTE**
> If the V-axis (linear axis) is synchronized with the spindle as in dressing, the V-axis travel range is determined by the rotation of the spindle. To perform dressing with the tool moving back and forth along the V-axis in a certain range, therefore, the PMC must perform an operation in which the tool is stopped temporarily and is reversed when it reaches a certain position on the V-axis.
> In the above example, limit switches are provided to determine the range of travel along the V-axis and the PMC performs control so that the whetstone rotates until the tool reaches the position of each limit switch on the V-axis.
> By using the position switch function instead of limit switches, dressing can be performed as in the following example, without the need to mount limit switches to the machine. By rewriting the operating ranges of the position switches (parameters Nos. 6930 to 6945 and 6950 to 6965) using the G10 programmable parameter input, the range of travel along the V-axis can be specified using a program.

1.9.5.4 Retract function

See Item, "Retract function" in the Subsection "Electronic Gear Box".

Signal

Retract signal RTRCT<Gn066.4>

[Classification] Input signal
[Function] Retracts along the axis specified in the parameter.
[Operation] When this signal is set to “1”, the CNC operates in the following way.
At the rising edge of this signal, retraction can be performed for the axis for which a retract value is set in parameter No. 7741. The retract value and retract feedrate set in parameters Nos. 7741 and 7740 are used. Upon the completion of retraction, retract completion signal RTRCTF <Fn065.4> is output. The retract signal is valid in either automatic operation mode (MEM, MDI, etc.) or manual operation mode (HND, JOG, etc.). When the retract signal is set to “1” during automatic operation, retraction is performed and automatic operation is stopped.

Retraction completion signal RTRCTF<Fn065.4>

[Classification] Output signal
[Function] Reports that retraction is finished.
[Operation] This signal is set to “1” in the following case.
- When retraction is finished (movement is finished)

This signal is set to “0” in the following case.
- When a move command is issued for any retract axis after the end of a retract operation.

> **NOTE**
> When the retraction completion signal is "1," the retract signal is not accepted.

EGB mode signal SYNMOD< Fn065.6>

[Classification] Output signal

[Function] Reports that synchronization with the EGB is in progress.

[Operation] This signal becomes “1” if:

- Synchronization with the EGB is in progress.

It becomes “0” if:

- Synchronization with the EGB is canceled.

EGB mode confirmation signal EGBM1<Fn208.0>, EGBM2<Fn208.1>, …

[Classification] Output signal

[Function] Reports that synchronization is being executed by EGB. This signal is output to a slave axis.

EGBMx

x : 1 ..... First axis synchronized by EGB
2 ..... Second axis synchronized by EGB
3 ..... Third axis synchronized by EGB
: :
: :

[Operation] This signal is set to “1” in the following case.

- During synchronization caused by EGB

This signal is set to “0” in the following case.

- When synchronization caused by EGB is released

Signal address

	#7	#6	#5	#4	#3	#2	#1	#0
Gn066				RTRCT				
Fn065		SYNMOD		RTRCTF				
Fn208	EGBM8	EGBM7	EGBM6	EGBM5	EGBM4	EGBM3	EGBM2	EGBM1

Parameter

The following table lists the parameters related to EGB.

Parameter number	Description
1006#0 1006#1	To specify the speed for the slave axis by L in synchronization command, an EGB slave axis and an EGB dummy axis require that the setting of a rotary axis (type A) (bit 0 (ROT) of parameter No. 1006 be 1 and bit 1 (ROS) of parameter No. 1006 be 0).
1023	Set from the FSSB setting screen. For FSSB manual setting, be sure to set the EGB axis as described below: The slave axis must be set with an odd number, and the dummy axis with an even number. They must be consecutive. Example: If the servo axis number of the slave axis is 1, the servo axis number of the dummy axis must be set to 2. If the servo axis number of the slave axis is 3, the servo axis number of the dummy axis must be set to 4.
2011 #0	Specify an axis to be synchronized. Specify 1 for both an EGB slave axis and EGB dummy axis.
3115#0	The current position is not indicated for an axis for which this parameter is set to 1.Since the current position for an EGB dummy axis has no meaning, set this parameter to 1 to delete the current position indication for the axis from the screen.
7700#0	The synchronization mode is canceled (0)/not canceled by a reset (1).

Parameter number	Description
7700#2	Compensation direction for helical gear compensation
7701#3	At the start of synchronization (G81), synchronization is started (0)/not started (1) if the number of hob threads L is specified as 0.
7702#0	The specifiable number of teeth, T, at the start of synchronization (G81) is not reduced to a 1/10 of a specified value (0)/reduced (1).
7702#3	The retract function with an alarm is disabled (0)/enabled (1).
7703#0	During synchronization (G81), feed per revolution is performed for feedback pulses (0)/pulses converted to the speed for the workpiece axis(1).
7703#1,#2	Specify when to perform a retract operation with the retract function with an alarm; during synchronization; during synchronization and automatic operation; or during synchronization or automatic operation.
7709	Number of the axial feed axis in helical gear compensation
7710	Axis number of an axis to be synchronized using the method of command specification for a hobbing machine
7731#0	The EGB command is G80 and G81(0)/G80.4 and G81.4(1).
7731#3	When the automatic phase synchronization function for the electronic gear box is disabled, the G81 command cannot be issued again (an alarm is issued) (0)/can be issued again (1)during EGB synchronization.
7731#5	In EGB synchronization start command G81.4, the number of teeth is specified in T (0)/specified in R (1).
7740	Feedrate during retraction
7741	Retract amount
7772	Number of position detector pulses per rotation about tool axis
7773	Number of position detector pulses per rotation about workpiece axis
7782	Pulse count of position detector per rotation about EGB master axis
7783	Pulse count of position detector per rotation about EGB slave axis

For FSSB settings, see the section on “FSSB settings”.
If FSSB setting mode is automatic setting mode, setting is made automatically by inputting data to the FSSB setting screen. For the slave/dummy axes of EGB, set the value in the “M/S” item in the FSSB axis setting screen same way of the tandem setting.
Note the following points when specifying parameters for the electronic gear box.

1 Specify an axis that is not used or the same name as that for a slave axis for the name of a dummy axis. Do not use a name which is usually not allowed to be used as an axis address, such as D.
2 Specify the same values for an EGB slave axis and an EGB dummy axis in the following parameters.
   1013#0 to 3 Increment system
   1004#7 Ten times minimum input increment
   1006#0,1 Rotary axis setting
   1006#3 Diameter/radius specification
   1420 Rapid traverse rate
   1421 Rapid-traverse override F0 speed
   1820 Command multiplication
   2000 and over Parameters related to digital servo
3 To specify the speed for the slave axis by L in the synchronization command, set parameter No. 1260 (amount of travel per rotation about a rotation axis) for the slave and dummy axes.
4 Make the specification for a dummy axis in the following way.
   1815#1 Whether to use separate detectors. Although an EGB dummy axis uses the interface of a separate detector, set these parameters to 0.
5 Reducing synchronous errors requires enabling the feed-forward function for the slave axis.
   For details, see “How to reduce the synchronous error” in “Explanation” of this chapter.
6 Reducing shocks that may occur at the beginning of acceleration/deceleration requires enabling the soft start/stop function for the spindle axis. For details, see “How to reduce shock at the start of acc./dec.” in “Explanation” of this chapter.

1023	Number of the servo axis for each axis

> **NOTE**
> When this parameter is set, the power must be turned off before operation is continued.

[Input type] Parameter input
[Data type] Byte axis
[Valid data range] 0 to 80

This parameter associates each control axis with a specific servo axis. Specify values 1+8n, 2+8n, 3+8n, 4+8n, 5+8n, and 6+8n (n = 0, 1, 2, …, 9) like 1, 2, 3, 4, 5, …, 77, and 78.
The control axis number is the order number that is used for setting the axis-type parameters or axis-type machine signals
For electronic gear box (EGB) controlled axes, two axes need to be specified as one pair. So, make a setting as described below.
For a slave axis, set an odd (1, 3, 5, 7, 9, ...) servo axis number. For a dummy axis to be paired, set a value obtained by adding 1 to the value set for the slave axis.

	#7	#6	#5	#4	#3	#2	#1	#0
2011								SYNx

[Input type] Parameter input
[Data type] Bit axis

#0 SYNx When the electronic gear box function (EGB) is used, this bit sets the axis to be synchronized.
0: Axis not synchronized by EGB
1: Axis synchronized by EGB
Set 1 for both of the slave and dummy axes of EGB.

> **NOTE**
> The setting of this parameter becomes valid after the power is turned off then back on.

	#7	#6	#5	#4	#3	#2	#1	#0
3115								NDPx

[Input type] Parameter input
[Data type] Bit axis

#0 NDPx The current position is:
0: Displayed.
1: Not displayed.

> **NOTE**
> When using the electronic gear box (EGB) function, set 1 for the EGB dummy axis to disable current position display.

	#7	#6	#5	#4	#3	#2	#1	#0
7700						**HDR**		**HBR**

[Input type] Parameter input
[Data type] Bit path

#0 HBR When the electronic gear box (EGB) function is used, performing a reset:
0: Cancels the synchronization mode (G81 or G81.5).
1: Does not cancel the synchronization mode. The mode is canceled only by the G80 or G80.5 command.

#2 HDR Direction of helical gear compensation (usually, set 1.)
(Example) To cut a left-twisted helical gear when the direction of rotation about the C-axis is the negative (-) direction:
0: Set a negative (-) value in P.
1: Set a positive (+) value in P.

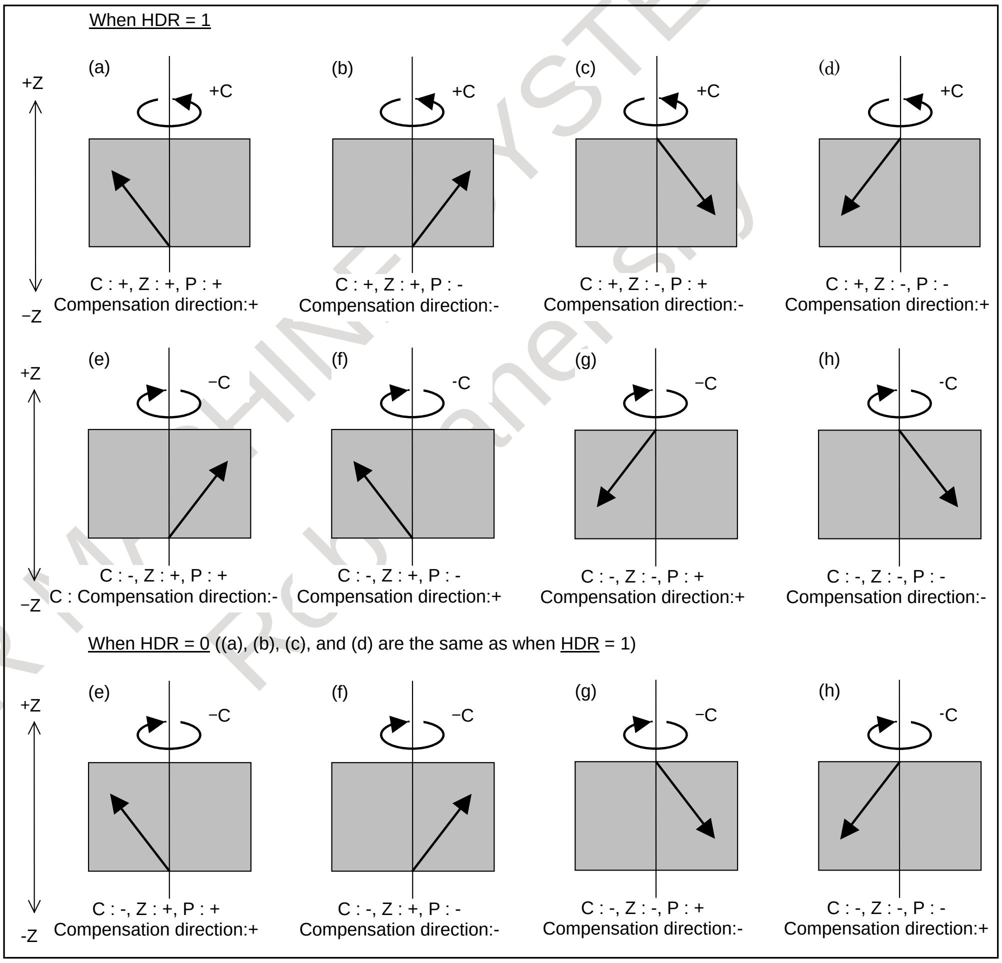

Fig. 1.9.5.4 (a) Direction of helical gear compensation

	#7	#6	#5	#4	#3	#2	#1	#0
7701					**LZR**			

[Input type] Parameter input
[Data type] Bit path

#3 LZR When L (number of hob threads) = 0 is specified at the start of EGB synchronization (G81):

0: Synchronization is started, assuming that L = 1 is specified.
1: Synchronization is not started, assuming that L = 0 is specified. However, helical gear compensation is performed.

	#7	#6	#5	#4	#3	#2	#1	#0
7702					ART			TDP

[Input type] Parameter input
[Data type] Bit path

#0 TDP The specifiable number of teeth, T, of the electronic gear box (G81) is:
0: 1 to 5000
1: 0.1 to 500 (1/10 of a specified value)

> **NOTE**
> In either case, a value from 1 to 5000 can be specified.

#3 ART The retract function executed when an alarm is issued is:
0: Disabled.
1: Enabled.
When an alarm is issued, a retract operation is performed with a set feedrate and travel distance (parameters Nos. 7740 and 7741).

> **NOTE**
> If a servo alarm is issued for other than the axis along which a retract operation is performed, the servo activating current is maintained until the retract operation is completed.

	#7	#6	#5	#4	#3	#2	#1	#0
7703						ARO	ARE	ERV

[Input type] Parameter input
[Data type] Bit path

#0 ERV During EGB synchronization (G81), feed per revolution is performed for:
0: Feedback pulses.
1: Pulses converted to the speed for the workpiece axis.

#1 ARE The retract function executed when an alarm is issued retracts the tool during:
0: EGB synchronization or automatic operation (automatic operation signal OP <Fn000.7> = “1”).
1: EGB synchronization.

#2 ARO The retract function executed when an alarm is issued retracts the tool during:
0: EGB synchronization.
1: EGB synchronization and automatic operation (automatic operation signal OP <Fn000.7> = “1”).

> **NOTE**
> This parameter is valid when bit 1 (ARE) of parameter No. 7703 is set to 1.

The following table lists the parameter settings and corresponding operation.

ARE	ARO	Operation
1	0	During EGB synchronization
1	1	During EGB synchronization and automatic operation
0	0	During EGB synchronization or automatic operation
0	1	

> **NOTE**
> Parameters ARE and ARO are valid when bit 3 (ART) of parameter No. 7702 is set to 1 (when the retract function executed when an alarm is issued).

7709	Number of the axial feed axis for helical gear compensation

[Input type] Parameter input
[Data type] 2-word path
[Valid data range] 0 to Number of controlled axes

This parameter sets the number of the axial feed axis for a helical gear.

> **NOTE**
> When this parameter is set to 0 or a value outside the valid setting range, the Z-axis becomes the axial feed axis.

7710	Axis number of an axis to be synchronized using the method of command specification for a hobbing machine

[Input type] Parameter input
[Data type] 2-word path
[Valid data range] 0 to Number of controlled axes

When there are several groups of axes to be synchronized (the axes for which bit 0 (SYNMOD) of parameter No. 2011 is set to 1), an axis for which to start synchronization is specified using the following command (for a hobbing machine):

G81 T t L ± *l* ;

t: Spindle speed ($1 \le t \le 5000$)

l: Number of synchronized axis rotations ($-250 \le l \le 250$)

Synchronization between the spindle and a specified axis is established with the ratio of $\pm l$ rotations about the synchronized axis to t spindle rotations.

t and *l* correspond to the number of teeth and the number of threads on the hobbing machine, respectively.

Above command is issued without setting this parameter when there are several groups of axes to be synchronized, the alarm PS1593, “EGB PARAMETER SETTING ERROR” is issued.

> **NOTE**
> 1 Set this parameter when there are two or more groups of servo and spindle EGBs in the same path. Set 0 when there is one group of EGBs in the same path.
> 2 When there are two or more groups of servo and spindle EGBs in the same path, setting a value outside the valid data range in this parameter causes alarm PS1593 to be issued.
> 3 For Series 16*i*, when a value outside the valid data range is set in this parameter, the fourth axis is assumed according to the specifications.

NOTE
4 The setting of this parameter becomes valid after the power is turned off then back on.

	#7	#6	#5	#4	#3	#2	#1	#0
7731	HAD		HBR		ECN			EFX

[Input type] Parameter input
[Data type] Bit path

#0 EFX As the EGB command:
0: G80 and G81 are used.
1: G80.4 and G81.4 are used.

NOTE
When this parameter is set to 0, no canned cycle for drilling can be used.

#3 ECN When the automatic phase synchronization function for the electronic gear box is disabled, during EGB synchronization, the G81 or G81.5 command:
0: Cannot be issued again. (The alarm PS1595, "ILL-COMMAND IN EGB MODE" is issued.)
1: Can be issued again.

#5 HBR In EGB synchronization start command G81.4, the number of teeth is:
0: Specified in T.
1: Specified in R.

NOTE
This parameter is valid when bit 0 (EFX) of parameter No. 7731 is set to 1.

#7 HAD In electronic gear box, the timing for reflecting helical gear compensation and travel distance of automatic phase synchronization to absolute coordinates is:
0: When synchronization is canceled.
1: During helical gear compensation and automatic phase synchronization.

7740	Feedrate during retraction

[Input type] Parameter input
[Data type] Real axis
[Unit of data] mm/min, inch/min, deg/min (machine unit)
[Min. unit of data] Depend on the increment system of the applied axis
[Valid data range] Refer to the standard parameter setting table (C)
(When the increment system is IS-B, 0.0 to +999000.0)
This parameter sets the feedrate during retraction for each axis.

7741	Retract amount

[Input type] Parameter input
[Data type] Real axis
[Unit of data] mm, inch, deg (machine unit)
[Min. unit of data] Depend on the increment system of the applied axis
[Valid data range] 9 digit of minimum unit of data (refer to standard parameter setting table (A))
(When the increment system is IS-B, -999999.999 to +999999.999)

This parameter sets the retract amount for each axis.

7772	Number of position detector pulses per rotation about the tool axis

[Input type] Parameter input
[Data type] 2-word path
[Unit of data] Detection unit
[Valid data range] 1 to 999999999

This parameter sets the number of pulses per rotation about the tool axis (on the spindle side), for the position detector.

For an A/B phase detector, set this parameter with four pulses equaling one A/B phase cycle.

7773	Number of position detector pulses per rotation about the workpiece axis

[Input type] Parameter input
[Data type] 2-word path
[Unit of data] Detection unit
[Valid data range] 1 to 999999999

This parameter sets the number of pulses per rotation about the workpiece axis (on the slave side), for the position detector.

Set the number of pulses output by the detection unit.

Set parameters Nos. 7772 and 7773 when using the G81 EGB synchronization command.

[Example 1] When the EGB master axis is the spindle and the EGB slave axis is the C-axis

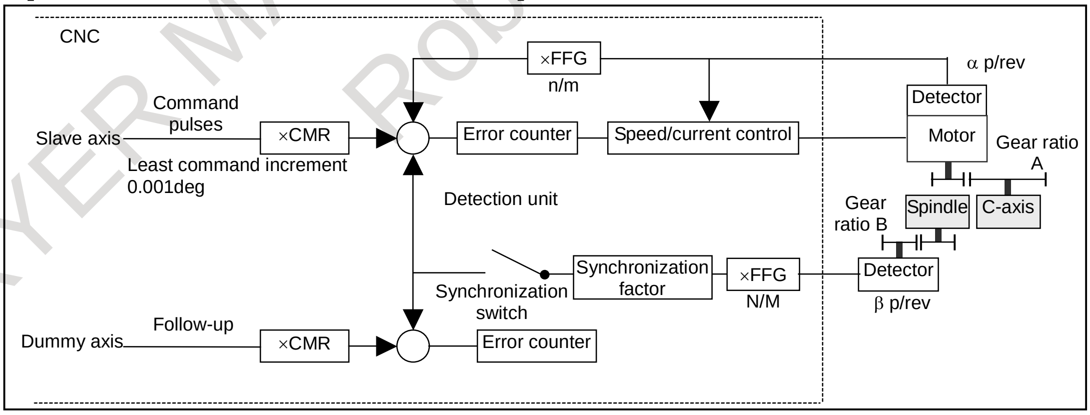

Fig. 1.9.5.4 (b)

Gear ratio of the spindle to the detector B:
    1/1 (The spindle and detector are directly connected to each other.)
Number of detector pulses per spindle rotation β: 80,000 pulses/rev
(Calculated for four pulses for one A/B phase cycle)
FFG N/M of the EGB dummy axis: 1/1
Gear ratio of the C-axis A: 1/36 (One rotation about the C-axis to 36 motor rotations)
Number of detector pulses per C-axis rotation α: 1,000,000 pulses/rev

C-axis CMR: 1
C-axis FFG n/m: 1/100

In this case, the number of pulses per spindle rotation is:
$80000 \times 1/1 = 80000$
Therefore, set 80000 for parameter No. 7772.
The number of pulses per C-axis rotation in the detection unit is:

$$1000000 \div \frac{1}{36} \times \frac{1}{100} = 360000$$

Therefore, set 360000 for parameter No. 7773.

[Example 2] When the gear ratio of the spindle to the detector B is 2/3 for the above example (When the detector rotates twice for three spindle rotations)
In this case, the number of pulses per spindle rotation is:

$$80000 \times \frac{2}{3} = \frac{160000}{3}$$

160000 cannot be divided by 3 without a remainder. In this case, change the setting of parameter No. 7773 so that the ratio of the settings of parameters Nos. 7772 and 7773 indicates the value you want to set.

$$\frac{\text{No.7772}}{\text{No.7773}} = \frac{160000/3}{360000} = \frac{160000}{360000 \times 3} = \frac{160000}{1080000}$$

Therefore, set 160000 for parameter No. 7772 and 1080000 for parameter No. 7773.
As described above, all the settings of parameters Nos. 7772 and 7773 have to do is to indicate the ratio correctly. So, you can reduce the fraction indicated by the settings. For example, you may set 16 for parameter No. 7772 and 108 for parameter No. 7773 for this case.

7782	Number of pulses from the position detector per EGB master axis rotation

[Input type] Parameter input
[Data type] 2-word axis
[Unit of data] Detection unit
[Valid data range] 1 to 999999999

For a slave axis, set the number of pulses generated from the position detector per EGB master axis rotation.
For an A/B phase detector, set this parameter with four pulses equaling one A/B phase cycle.

7783	Number of pulses from the position detector per EGB slave axis rotation

[Input type] Parameter input
[Data type] 2-word axis
[Unit of data] Detection unit
[Valid data range] 1 to 999999999

For a slave axis, set the number of pulses generated from the position detector per EGB slave axis rotation.
Set the number of pulses output by the detection unit.
Set this parameter when using the G81.5 EGB synchronization command.
The method for setting parameters Nos. 7782 and 7783 is the same as for parameters Nos. 7772 and 7773. For the method, see the description of parameters Nos. 7772 and 7773.

The ratio of the number of pulses for the master slave to that of pulses for the slave axis may be valid, but the settings of the parameters may not indicate the actual number of pulses. For example, the number of pulses may not be able to be divided without a remainder for the reason of the master and slave axis gear ratios as described in example 2. In this case, the following methods cannot be used for the G81.5 command:

G81.5 T_ C_ ; When the speed is specified for the master axis and the travel distance is specified for the slave axis
G81.5 P_ C0 L_ ; When the number of pulses is specified for the master axis and the speed is specified for the slave axis

	#7	#6	#5	#4	#3	#2	#1	#0
2005							FEEDx	

[Input type] Parameter input
[Data type] Bit axis

#1 FEEDx Feed-forward function is:
0: Invalid.
1: Valid.

Set 1 for the EGB slave axis.

> **NOTE**
> This parameter is Initial setting parameter. For details, refer to the appendix "Automatic setting / Initial setting parameter" in this manual.

2068	Feed-forward function coefficient

[Input type] Parameter input
[Data type] Word axis
[Valid data range] 0 to 100
Setting value = $\alpha \times 100$

Set 10000 for the EGB slave axis.

	#7	#6	#5	#4	#3	#2	#1	#0
2273		EGFx						

[Input type] Parameter input
[Data type] Bit axis

#6 EGFx FFG is:
0: Not considered in the synchronization coefficient.
1: Considered.

The synchronization coefficient is subject to the following restriction:

Synchronization coefficient $= \frac{L}{T} \times \frac{\beta}{\alpha}$

where $\frac{\mathrm{L}}{\mathrm{T}} \times \frac{\beta}{\alpha} \leq \frac{\mathrm{2word}}{\mathrm{1word}}$: Condition <1>

where
L : Number of hob threads
T : Number of teeth

α : Number of pulses of the position detector per rotation about the master axis (parameter No. 7772 or 7782)
β : Number of pulses of the position detector per rotation about the slave axis (parameter No. 7773 or 7783)

If this condition, <1>, cannot be satisfied, set this parameter bit to 1. With this setting, FFG is considered in the synchronization coefficient, and by selecting FFG appropriately, it is possible to set α and β in such a way that condition <1> can be satisfied with the synchronization coefficient kept intact.

Synchronization coefficient $= \frac{L}{T} \times \frac{\beta}{\alpha} \times \frac{N}{M}$

where $\frac{L}{T} \times \frac{\beta}{\alpha} \leq \frac{2word}{1word}$: Condition <1>

N: Numerator of FFG
M: Denominator of FFG

The new value of α is the old one multiplied by FFG.

$$\alpha[\text{New}] = \alpha[\text{Old}] \times \frac{N}{M}$$

Setting example

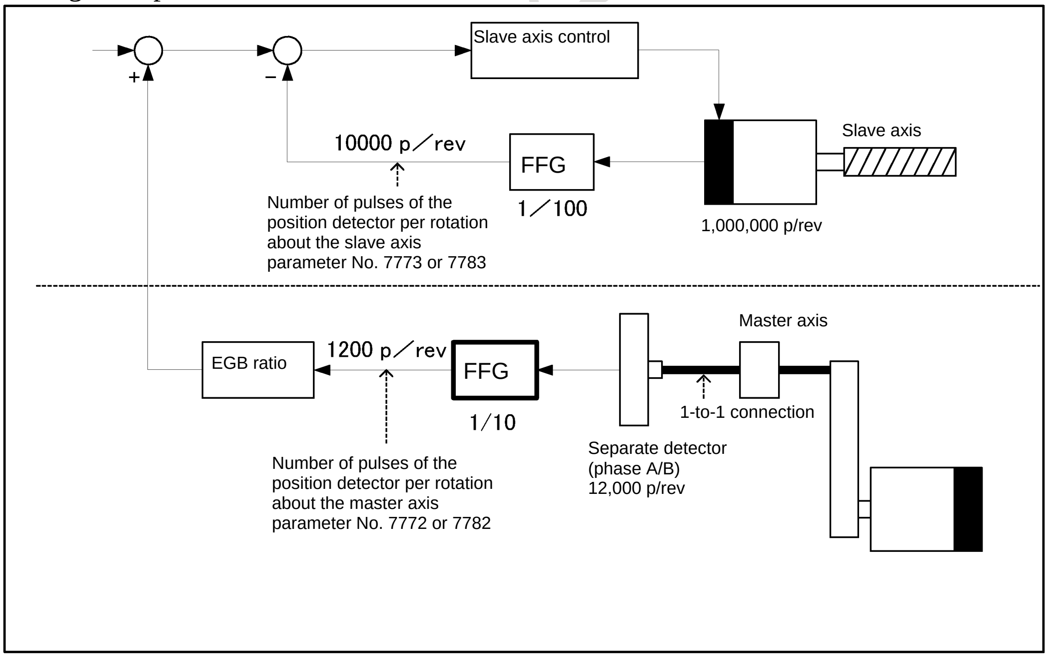

Fig. 1.9.5.4 (c)

Master axis conditions:
The separate detector must be 12000 p/rev.
The master axis and the separate detector must have a 1-to-1 connection.

Slave axis conditions:
The motor Pulsecoder must be 1 million p/rev.
FFG must be 1/100.

Determine FFG so that condition <1> is satisfied.

$\frac{L}{T} \times \frac{\beta}{\alpha} \leq \frac{2\text{word}}{1\text{word}}$: Condition <1>

In this example, FFG is set to 1/10. Set bit 6 (EGF) of parameter No. 2273, which is a function bit to consider FFG in EGB, to 1, and set the number of pulses of the position detector per rotation about the master and slave axes.

As the number of pulses of the position detector per rotation about the master axis, set 12000 x FFG (1/10) = 1200.
As the number of pulses of the position detector per rotation about the slave axis, set 10000.

	#7	#6	#5	#4	#3	#2	#1	#0
4399						**SOSALWs**		

[Input type] Parameter input
[Data type] Bit spindle

#2 SOSALWs The Soft start/stop function is:
0: Disabled at an emergency stop (*ESP is ”0”) or MRDY is ”0”.
1: Enabled even at an emergency stop (*ESP is ”0”) or MRDY is ”0”.

4030	**Soft start/stop setting time**

[Input type] Parameter input
[Data type] Word spindle
[Unit of data] $1min^{-1}/sec$
[Valid data range] 0 to 32767

This parameter sets an acceleration (rate at which the speed changes) applied when the Soft start/stop function is enabled (the Soft start/stop signal SOCNA <Gn071> is ”1”).

4508	**Acceleration rate change applied at Soft start/stop**

[Input type] Parameter input
[Data type] Word spindle
[Unit of data] $10min^{-1}/sec^2$
[Valid data range] 0 to 32767

This parameter sets an acceleration rate (rate at which the acceleration changes) applied when the Soft start/stop function is enabled (the Soft start/stop signal SOCNA <Gn071> is ”1”).

> **NOTE**
> If the setting of this parameter is 0, it means that the speed to be applied when the Soft start/stop function is enabled is linear.

Alarm and message

Number	Message	Description
PS1593	EGB PARAMETER SETTING ERROR	Error in setting a parameter related to the EGB (1) The setting of bit 0 (SYNx) of parameter No. 2011, is not correct. (2) The slave axis specified with G81 is not set as a rotation axis. (bit 0 (ROTx) of parameter No. 1006) (3) Number of pulses per rotation (Parameter (No. 7772 or 7773) or (No. 7782 or 7783)) is not set. (4) Parameter No. 7710 is not set for a command compatible with that for a hobbing machine.

Number	Message	Description
PS1594	EGB FORMAT ERROR	Error in the format of the block of an EGB command (1) T (number of teeth) is not specified in the G81 block. (2) In the G81 block, the data specified for one of T, L, P, and Q is out of its valid range. (3) In the G81 block, only one of P and Q is specified. (4) In the G81.5 block, no command is specified for the master or slave axis. (5) In the G81.5 block, data outside the valid data range is specified for the master or slave axis.
PS1595	ILL-COMMAND IN EGB MODE	During synchronization with the EGB, a command that must not be issued is issued. (1) Slave axis command using G27, G28, G29, G30, G33, G53, etc. (2) Inch/metric conversion command using G20, G21, etc. (3) Synchronization start command using G81 or G81.5 when bit 3 (ECN) of parameter No. 7731 is 0
PS1596	EGB OVERFLOW	An overflow occurred in the calculation of the synchronization coefficient.

1.9.6 U-axis Control

Overview

To control an axis on a spindle such as the U-axis of a vertical lathe from a motor mounted on other than the spindle, a mechanism was conventionally required which used a planetary gear box, differential gears, and others to prevent the movement along the U-axis as the spindle rotated.
The U-axis control function enables the tool to remain in a fixed position on the U-axis or to move at a programmed feedrate without using a mechanism such as a planetary gear box. This is done by causing the U-axis motor to rotate in such a way that the movement along the U-axis, which should be caused by rotation of the spindle, is canceled out.

An electronic gear box (EGB) is used to cause the U-axis motor to rotate in synchronization with the spindle.
With the EGB, the servo CPU processes signals received from the position coder mounted on the spindle at high speed to control the movement along the U-axis. It is capable of high-precision synchronous control. The EGB requires axis control circuits for two axes (U-axis and U’-axis). It acquires the pulses necessary for synchronization from the separate feedback connector on the U’-axis side. With the EGB, the spindle, which is used as the reference for synchronization, is called the master axis. The U-axis, along which the tool moves in synchronization with the master axis, is called the slave axis. The U’-axis, which acquires the pulses necessary for synchronization, is called the dummy axis.

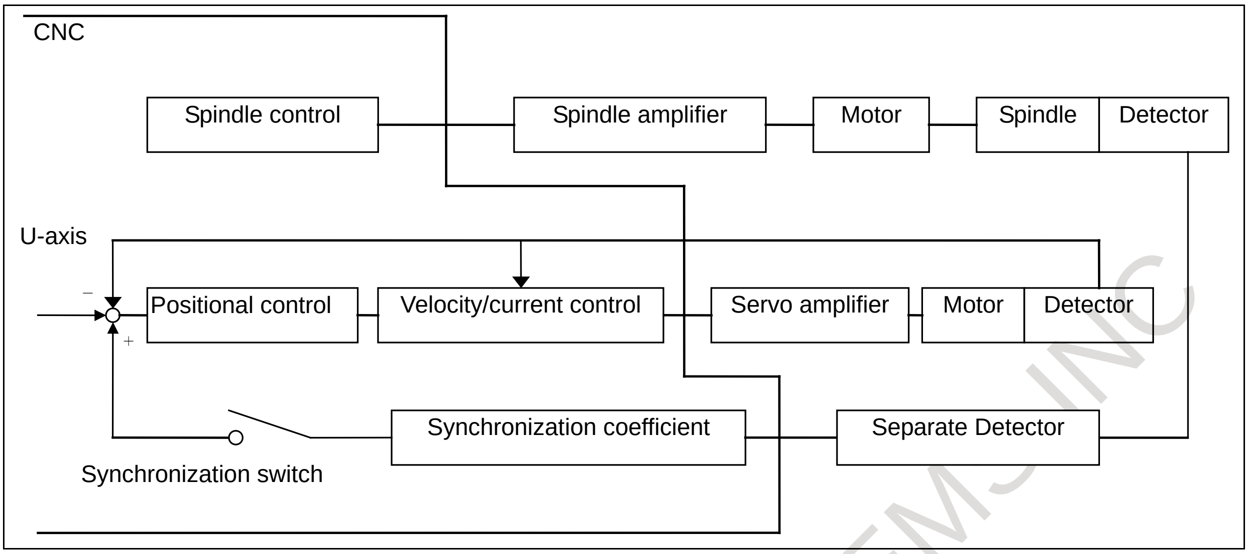

Fig. 1.9.6 (a) Block diagram of U-axis control

Example

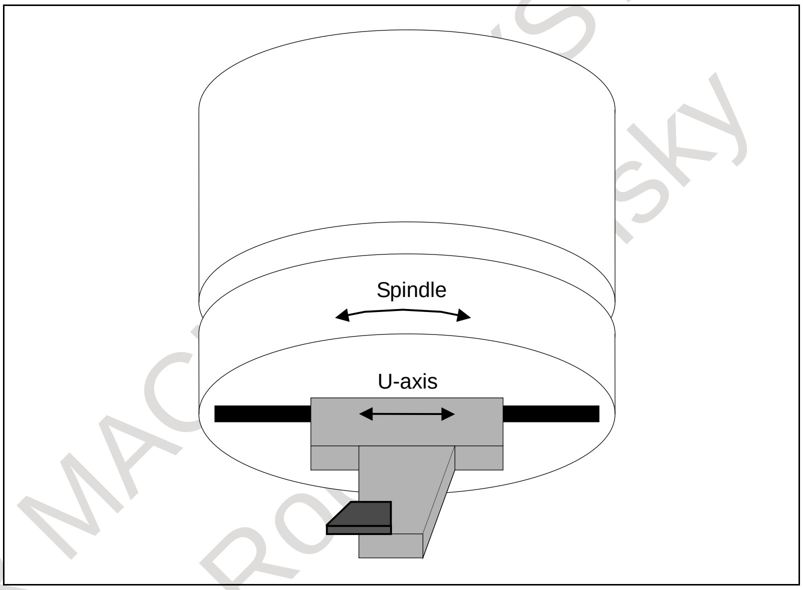

Fig. 1.9.6 (b) Example of a machine having the U-axis

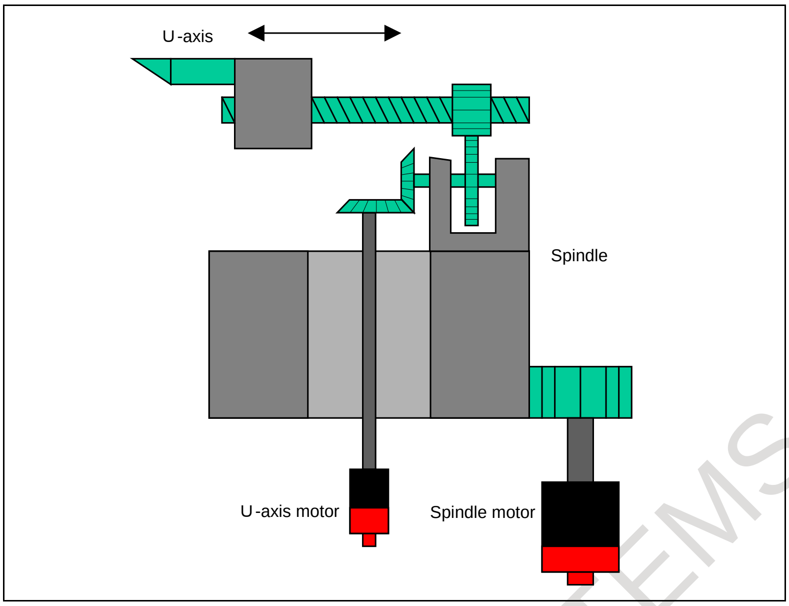

Fig. 1.9.6 (c) Example of the structure of a machine having the U-axis

In the example of the above structure, the tool moves along the U-axis when the spindle rotates. This movement is canceled out by rotating the U-axis motor.

Explanation

- Synchronization start

Synchronization is started when the EGB synchronization mode selection signal EGBS<Gn067.4> is set to "1". In the synchronization mode, the EGB synchronization mode confirmation signal EGBSM<Fn082.6> becomes "1".

If the U-axis motor rotates in synchronization with the spindle in the synchronization mode, the machine coordinates are not updated, that is, the machine coordinates indicate the position on the U-axis based on the spindle.

- Synchronization cancellation

Synchronization is canceled when the EGB synchronization mode selection signal EGBS<Gn067.4> is set to "0". When synchronization is canceled, the EGB synchronization mode confirmation signal EGBSM<Fn082.6> also becomes "0".

- Parameter Setting

(1) Set the following parameters:
- U-axis control enable: Bit 1 (UAX) of parameter No. 7702
- Number of pulses per rotation about the spindle: Parameter No. 7772
- Amount of travel by the U-axis motor per rotation about the spindle: Parameter No. 7773
- EGB function enable: Bit 0 (SYNx) of parameter No. 2011
- Parameters for feed forward control

(2) Be sure to set bit 0 (SYNx) of parameter No. 2011 to 1 for both the U-axis and dummy axis.

(3) Set the servo parameters for the dummy axis (parameters Nos. 2000 to 2999) such that they are consistent with the settings made for the U-axis.

(4) Be sure to set the command multiplier (CMR) for the dummy axis to the same value as for the U-axis.

(5) The following parameters need not be set for the dummy axis:
- Reference counter size: Parameter No. 1821
- In-position width: Parameter No. 1826
- Positioning deviation limit in movement/in the stopped state: Parameters Nos. 1828 and 1829
- Stored stroke limits: Parameter No. 1320 and others

(6) Set the values related to the flexible feed gear ratio for the dummy axis (parameters Nos. 2084 and 2085) to 1.
(7) The dummy axis occupies one servo axis interface. Set servo axis numbers consecutively for the dummy axis and U-axis so that an odd number and an even number are assigned.

Example 1)
When the dummy axis is the 4th out of total four axes:
1st axis Parameter No. 1023: 1
2nd axis Parameter No. 1023: 2
3rd axis Parameter No. 1023: 3 (U-axis)
4th axis Parameter No. 1023: 4 (dummy axis)

Example 2)
When the dummy axis is the 5th out of total five axes:
1st axis Parameter No. 1023: 1
2nd axis Parameter No. 1023: 2
3rd axis Parameter No. 1023: 5
4th axis Parameter No. 1023: 3 (U-axis)
5th axis Parameter No. 1023: 4 (dummy axis)

(8) Set bit 0 (HBR) of parameter No. 7700 to 1 so as not to cancel synchronization by the reset operation.
(9) Set bit 1 (UFF) of parameter No. 7786 to 1, when a interpolation command to between the U-axis and the other axes is specified while U-axis synchronization.
(10) Parameter setting related to feed forward control

Step 1.
Modify the motor type for the U-axis and dummy axis and set them automatically.
- Parameter No. 2020 = Motor number
- Bit 1 (DGPx) of parameter No. 2000 = 0

Set the above parameters, then turn the power off, then on again.

Step 2.
Set the parameters related to the EGB again.
- Bit 0 (SYNx) of parameter No. 2011 = 1 (for both the U-axis and dummy axis)
  Bit 1 (FFAL) of parameter No. 2011 = 1, when feed forward control is also enabled in rapid traverse.

Step 3.
Other parameters (set them for the U-axis only.)
- Bit 3 of parameter No. 2003 = 1 (P-I control)
- Bit 1 of parameter No. 2005 = 1 (feed forward enable)
- Parameter No. 2068 = 10000 (feed forward coefficient)
- Parameter No. 2092 = 10000 (look-ahead feed forward coefficient)

Step 4.
Suppressing load variation
Increase the value of parameter No. 2021 (within the range in which the motor does not oscillate).
Set this parameter to the value obtained from the following:
256 × (machine load inertia) / (motor rotor inertia)

For details of parameter setting, refer to the subsection titled “Feed-forward Function” in “CONTOUR ERROR SUPPRESSION FUNCTION” in “FANUC AC SERVO MOTOR α*i*/β*i* series, FANUC LINEAR MOTOR L*i*S series, FANUC SYNCHRONOUS BUILT-IN SERVO MOTOR D*i*S series PARAMETER MANUAL (B-65270EN)”.

(11) Set bit 0 (NDPx) of parameter No.3115 to 1 for the U axis control dummy axis to disable current position display.
(12) When the U-axis control mode is released, when the tool is moved along the U-axis to the position where the reference counter is 0, set bit 3 (UOC) is parameter No.7704 to 1.

- Notes related to alarms

(1) Servo alarm, spindle alarm, and emergency stop
All axis motors are de-energized, U-axis synchronization is canceled, and the EGB synchronization mode confirmation signal EGBSM<Fn082.6> becomes “0”. If the spindle is rotating, the cancellation of synchronization may cause the tool to abruptly move along the U-axis.

(2) U-axis servo off
The U-axis motor is de-energized, but U-axis synchronization is not canceled. If the spindle is rotating, the tool may abruptly move along the U-axis since the U-axis motor is de-energized. If the tool moves long the U-axis when the U-axis is in the servo off state, the pulses corresponding to the amount of travel is stored in the servo error counter regardless of the follow-up setting by bit 0 (FUP) of parameter No. 1819 and the signal *FLWU <Gn007.5>. Therefore, when the servo off signal becomes “0”, the tool moves the along the U-axis so that the stored pulses become 0. When the EGB synchronization mode selection signal EGBS<Gn067.4> is set to “0”, the error amount also becomes 0.

(3) Other alarms
The tool stops moving along each axis with the synchronization maintained.

- Notes for safety measures

(1) Synchronization is not maintained when the U-axis is in any of the following states:
- Emergency stop (both the CNC and serial spindle)
- Servo alarm
- Spindle alarm
- Servo-off
- Control axis detach
- Power failure

If the spindle is rotating due to inertia in any of these states, the tool may abruptly move along the U-axis. In such cases, therefore, it is necessary to install some safety measures on the machine, such as applying a brake to the spindle or disengaging the clutch of the U-axis drive mechanism.

(2) Design the machine such that, when the U-axis motor comes to a halt, the tool always moves along the U-axis away from the workpiece, that is, to the safer side.

(3) When synchronization is off, it is dangerous, because the tool moves along the U-axis when the spindle rotates. The PMC must be equipped with some safety measures, such as monitoring the EGB synchronization mode confirmation signal EGBSM<Fn082.6> and preventing the spindle from rotating if the confirmation signal is “0”.

(4) When you use U-axis control by Electronic Gear Box(FSSB type), set “1” to EGB synchronization mode selection signal EGBS<Gn067.4> according to following procedure (a) to (c).
(a) Turn on CNC and confirm the ready of all spindle (All-spindle operation ready signal SRSRDY<Fn034.7>=”1”).
(b) Wait about 40msec after (a).
(c) Set the signal EGBS<Gn067.4> to “1”.
If EGBS<Gn067.4> has been “1” since turning on CNC, a shock might occur at the point where the spindle passes the first one rotation signal.

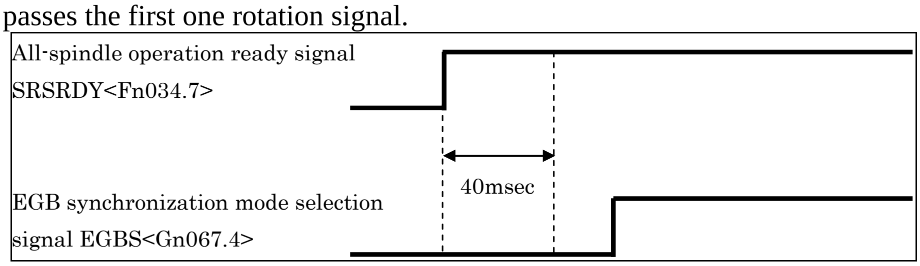

Fig. 1.9.6 (d) EGBS ON

▪ Notes

(1) A synchronization coefficient is internally represented using a fraction (K2/K1) to eliminate an error. The formula below is used for calculation.

$$\text{Synchronization coefficient} = \frac{K2}{K1} = \frac{\beta}{\alpha}$$

where
α: Number of position detector pulses per rotation about the spindle (parameter No. 7772)
β: Amount of travel by the U-axis motor per rotation about the spindle (parameter No. 7773)
In the formula above, K2/K1 is obtained by reducing β/α to lowest terms, but K1 and K2 must satisfy the following restriction:
$-2147483648 \le K2 \le 2147483647$
$1 \le K1 \le 2147483647$
When this restriction is not satisfied, alarm PS1596,“EGB OVERFLOW” is issued when synchronization starts.

(2) During synchronization, G00, G53, and canned cycles for drilling can be specified.

(3) Synchronization is maintained even if the U-axis or CNC unit is in any of the following states:
- Interlock
- Feed hold
- OT alarm
- PS alarm

(4) Synchronization pulses do not cause the machine, absolute, or relative coordinate of the U-axis to be updated. And the absolute coordinate of the U-axis is not updated when synchronization is canceled.

(5) EGB synchronization requires axis control circuits for two axes (U-axis and dummy axis). It acquires the pulses necessary for synchronization from the separate feedback connector on the dummy axis side.

(6) Any absolute position detector cannot be used for the U-axis.

(7) Controlled axes detach cannot be applied to the U-axis. If controlled axes detach is used for the U-axis, the synchronization mode is canceled.

(8) To turn synchronization on or off during automatic operation, use an M code preventing buffering to control the EGB synchronization mode selection signal EGBS<Gn067.4>.

(9) Dual check safety cannot be applied to the U-axis.
Set bit 6 (DCNx) of parameter No. 1904 to 1 to disable dual check safety of the U-axis.

(10) Perform reference position return with synchronization off, when reference position return is not performed after power on.

Signal

EGB synchronization mode selection signal
EGBS<Gn067.4>

[Classification] Input signal
[Function] Selects the EGB synchronization mode for U-axis control.
[Operation] When this signal becomes “1”, the control unit operates as follows:
Starts EGB synchronization.

All-spindle operation ready signal
SRSRDY <Fn034.7>

[Classification] Output signal
[Function] This signal posts that all spindles used are ready for operation.
[Operation] This signal becomes “1” when:
All used spindles become ready for operation.
It becomes “0” when:
Some of the used spindles are not ready for operation.

EGB synchronization mode confirmation signal
EGBSM<Fn082.6>

[Classification] Output signal
[Function] Notifies the EGB synchronization for the U-axis control in active.
[Operation] This signal becomes “1” when:
EGB synchronization in U-axis control is active.
It becomes “0” when:
EGB synchronization in U-axis control is canceled.

Signal address

	#7	#6	#5	#4	#3	#2	#1	#0
Gn067				EGBS				
Fn034	SRSRDY							
Fn082		EGBSM						

Parameter

1023	Number of the servo axis for each axis

NOTE
When this parameter is set, the power must be turned off before operation is continued.

[Input type] Parameter input
[Data type] Byte axis
[Valid data range] 0 to 80

This parameter associates each control axis with a specific servo axis.
Usually set to same number as the control axis number.
Specify values 1+8n, 2+8n, 3+8n, 4+8n, 5+8n, and 6+8n (n = 0, 1, 2, …, 9) like 1, 2, 3, 4, 5, …, 77, and 78.
For electronic gear box (EGB) controlled axes, two axes need to be specified as one pair. So, make a setting as described below.
For a slave axis, set an odd (1, 3, 5, 7, 9, ...) servo axis number. For a dummy axis to be paired, set a value obtained by adding 1 to the value set for the slave axis.

1320	Coordinate value I of stored stroke check 1 in the positive direction on each axis
1321	Coordinate value I of stored stroke check 1 in the negative direction on each axis

[Input type] Parameter input
[Data type] Real axis
[Unit of data] mm, inch, deg (machine unit)
[Min. unit of data] Depend on the increment system of the applied axis
[Valid data range] 9 digit of minimum unit of data (refer to standard parameter setting table (A))
(When the increment system is IS-B, -999999.999 to +999999.999)

Set the coordinate value of stored stroke check 1 on each axis in the + or - direction in the machine coordinate system.

NOTE
1. Specify diameter values for any axes for which diameter programming is specified.
2. The area outside the area set by parameters Nos. 1320 and 1321 is a prohibited area.

	#7	#6	#5	#4	#3	#2	#1	#0
1819								**FUPx**

[Input type] Parameter input
[Data type] Bit axis

#0 FUPx To perform follow-up when the servo is off is set for each axis.
0: The follow-up signal, *FLWU<Gn007.5>, determines whether follow-up is performed or not.
When *FLWU<Gn007.5> is “0”, follow-up is performed.
When *FLWU<Gn007.5> is “1”, follow-up is not performed.
1: Follow-up is not performed.

NOTE
When using the index table indexing function, set FUPx to 1 for a control axis subject to index table indexing.

1821	**Reference counter size for each axis**

NOTE
When this parameter is set, the power must be turned off before operation is continued.

[Input type] Parameter input
[Data type] 2-word axis
[Unit of data] Detection unit
[Valid data range] 0 to 999999999
Set a reference counter size.
As a reference counter size, specify a grid interval for reference position return based on the grid method.
When a value less than 0 is set, the specification of 10000 is assumed.
When a linear scale with absolute address reference marks is used, set the interval of mark 1.

1826	**In-position width for each axis**

[Input type] Parameter input
[Data type] 2-word axis
[Unit of data] Detection unit
[Valid data range] 0 to 99999999
The in-position width is set for each axis.
When the deviation of the machine position from the specified position (the absolute value of the positioning deviation) is smaller than the in-position width, the machine is assumed to have reached the specified position. (The machine is in the in-position state.)

1828	Positioning deviation limit for each axis in movement

[Input type] Parameter input
[Data type] 2-word axis
[Unit of data] Detection unit
[Valid data range] 0 to 99999999

Set the positioning deviation limit in movement for each axis.
If the positioning deviation exceeds the positioning deviation limit during movement, a servo alarm SV0411, "EXCESS ERROR (MOVING)" is generated, and operation is stopped immediately (as in emergency stop).
Generally, set the positioning deviation for rapid traverse plus some margin in this parameter.

1829	Positioning deviation limit for each axis in the stopped state

[Input type] Parameter input
[Data type] 2-word axis
[Unit of data] Detection unit
[Valid data range] 0 to 99999999

Set the positioning deviation limit in the stopped state for each axis.
If, in the stopped state, the positioning deviation exceeds the positioning deviation limit set for stopped state, a servo alarm SV0410, "EXCESS ERROR (STOP)" is generated, and operation is stopped immediately (as in emergency stop).

	#7	#6	#5	#4	#3	#2	#1	#0
2011								SYNx

[Input type] Parameter input
[Data type] Bit axis

#0 SYNx When the electronic gear box function (EGB) is used, this bit sets the axis to be synchronized.
0: Axis not synchronized by EGB
1: Axis synchronized by EGB
Set 1 for both of the slave and dummy axes of EGB.

> **NOTE**
> The setting of this parameter becomes valid after the power is turned off then back on.

	#7	#6	#5	#4	#3	#2	#1	#0
3115								NDPx

[Input type] Parameter input
[Data type] Bit axis

#0 NDPx The current position is:
0: Displayed.
1: Not displayed.

> **NOTE**
> When using the electronic gear box (EGB) function, set 1 for the EGB dummy axis to disable current position display.

	#7	#6	#5	#4	#3	#2	#1	#0
7700								HBR

[Input type] Parameter input
[Data type] Bit path

#0 HBR Performing a reset:
0: Cancels the EGB synchronization mode.
1: Does not cancel the EGB synchronization mode.

> **NOTE**
> To perform U-axis control, set this parameter to 1 so that performing a reset does not cancel the EGB synchronization mode.

	#7	#6	#5	#4	#3	#2	#1	#0
7702							UAX	

[Input type] Parameter input
[Data type] Bit path

#1 UAX U-axis control is:
0: Not performed.
1: Performed.

	#7	#6	#5	#4	#3	#2	#1	#0
7704					UOC			

[Input type] Parameter input
[Data type] Bit path

#3 UOC When the U-axis control mode is released, the tool is:
0: Not moved along the U-axis to the position where the reference counter is 0.
1: Moved along the U-axis to the position where the reference counter is 0.

Use this parameter to change the U-axis mode.

> **NOTE**
> Before changing the mode, be sure to perform reference position return along the U-axis and spindle orientation to change the mode at the same position (origin along the U-axis).

7772	Number of position detector pulses per rotation about the spindle

[Input type] Parameter input
[Data type] 2-word path
[Unit of data] Detection unit
[Valid data range] 1 to 999999999

This parameter sets the number of pulses per rotation about the spindle (master axis), for the position detector.
For an A/B phase detector, set this parameter with four pulses equaling one A/B phase cycle.

7773	Amount of travel by the U-axis motor per rotation about the spindle

[Input type] Parameter input
[Data type] 2-word path
[Unit of data] Detection unit
[Valid data range] 1 to 999999999

This parameter sets the amount of travel by the U-axis motor per rotation about the spindle in detection units.
When the EGB synchronization mode selection signal becomes 1, synchronization between the spindle and U-axis starts with the synchronization coefficient specified by parameters Nos. 7772 and 7773.

	#7	#6	#5	#4	#3	#2	#1	#0
7786							UFF	

[Input type] Parameter input
[Data type] Bit

> **NOTE**
> When this parameter is set, the power must be turned off before operation is continued.

#1 UFF During U-axis synchronization, a interpolation command to between the U-axis and the other axes is
0: not available.
1: available.

> **NOTE**
> Set this parameter to 1, when a command like this is specified.
> Example) Axis Configuration: U(U-axis) Z(not U-axis)
> G01 U_ Z_ F_;

Alarm and message

Number	Message	Description
PS1593	EGB PARAMETER SETTING ERROR	Error in setting a parameter related to the EGB (1) The setting of bit 0 (SYNx) of parameter No. 2011 is not correct. (2) Number of pulses per rotation (parameter No. 7772 or 7773) is not set.
PS1596	EGB OVERFLOW	An overflow occurred in the calculation of the synchronization coefficient.

1.9.7 Signal-based Servo EGB Synchronous Control

Overview

This function can use input signals to make the spindle (master axis) synchronize with the servo motor (slave axis). It is possible to make the servo motor synchronize with the spindle without using programmed commands. An example of using this function might be rotary guide bushing control between the servo motor and spindle.

> **NOTE**
> 1 Using this function does not requires the electronic gear box option. When the option of the electronic gear box is effective, this function cannot be used.

Because the electronic gear box (hereafter called the EGB function), which uses digital servo for direct control, is used as a method for synchronization between the master and slave axes, the slave axis can follow the speed change of the master axis, thus realizing high-precision machining.
Using bit 0 (SVE) of parameter No. 7786 can select whether to enable/disable this function.
The PMC input signal is used to turn on/off the EGB synchronous mode.

- Example of controlled axis configuration

Spindle : EGB master axis
1st axis : X axis
2nd axis : Z axis
3rd axis : A axis (EGB slave axis)
4th aFxis : A axis (EGB dummy axis[*1] : Cannot be used as a normal controlled axis.)

(*1) One servo axis is exclusively used for the servo to directly read information about the rotation position of the master axis connected to the spindle motor.

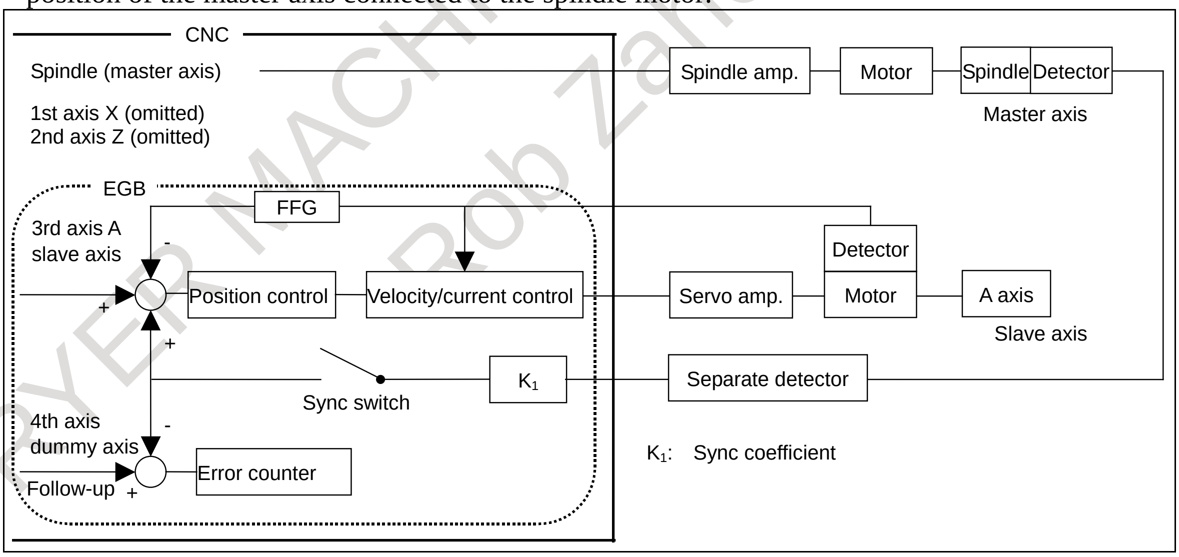

Fig. 1.9.7 (a)

For EGB axis configuration parameter setting examples, see the section on "FSSB setting".

Explanation

- Start of synchronization

Setting the EGB synchronization start signal EGBS1 to EGBS8<Gn530> to “1” starts synchronization.

- Cancellation of synchronization

Setting the EGB synchronization start signal EGBS1 to EGBS8<Gn530> to “0” cancels synchronization.

> **NOTE**
> Each of the following states cancels synchronization. When the state is cleared, synchronization restarts.
> (1) Emergency stop
> (2) Servo alarm

- Synchronization coefficient

The ratio of the slave axis travel distance to the master axis travel distance (synchronization coefficient) is converted to a detection unit ratio within the NC. If the resulting detection unit ratio exceeds the data range held in the NC, no synchronization can be attained normally, leading to alarm PS1596,"EGB OVERFLOW".
Let the synchronization coefficient be K. K in internal data form can be represented as Kn/Kd with a fraction reduced to its lowest term where Kn is the slave axis travel distance in detection unit and Kd is the master axis travel distance in detection unit.

$$K = \frac{Kn}{Kd} = \frac{\text{Slave axis travel distance in detection unit}}{\text{Master axis travel distance in detection unit}} = \frac{L}{T} \times \frac{\beta}{\alpha}$$

Where,

L : Synchronication ratio numerator (parameter No. 7784)
T : Synchronication ratio denominator (parameter No. 7785)
α : Number of position detector pulses per master rotation (parameter No. 7782)
β : Number of position detector pulses per slave rotation (parameter No. 7783)

Kn and Kd must be in the following respective ranges.

$-2147483648 \le Kn \le 2147483647$
$1 \le Kd \le 2147483647$

If Kn and Kd get out of the respective ranges, alarm PS1596 is issued.

- How to reduce the synchronous error

When you use the Electronic gear box function, to reduce the synchronous error, please apply feed-forward to the slave axis and set 100% to the parameter of feed-forward coefficient.
And please confirm the effectiveness of feed-forward by the following procedure.

[Procedure]
1. When the slave axis synchronizes only with the command from master axis, the position error of slave axis is regarded as the synchronous error. Please check that the position error (diagnosis data No.300) of the slave axis becomes 0 or so.
2. And also please check the position error is near 0 even when the speed of the master axis is changed.

Please set the following parameters to use Feed-forward function with 100% coefficient.

[Setting parameters]

Bit 3 (PIEN) of parameter No. 2003 = 1 (Slave axis)	Use PI control in velocity control
Bit 1 (FEED) of parameter No. 2005 = 1 (Slave axis)	Use Feed-forward function
Bit 1 (FFAL) of parameter No. 2011 = 1 (Slave axis)	Use Feed-forward function irrespective of feed mode
Parameter No.2068 (FF coefficient) = 10000 (Slave axis)	Feed-forward coefficient is 100%.

Please refer to the chapter of “Feed-forward Function” in FANUC AC SERVO MOTOR α*i* series FANUC AC SERVO MOTOR β*i* series FANUC LINEAR MOTOR L*i*S series FANUC SYNCHRONOUS BUILT-IN SERVO MOTOR D*i*S series Parameter manual (B-65270EN) about the detail of Feed-forward function.

⚠ CAUTION

1. Reset, feed hold, interlock, and machine lock are invalid to a slave axis in EGB synchronization.
2. It is not possible to use controlled axis detach for a master or slave axis.

NOTE

1. When starting/canceling EGB synchronization, keep the master and slave axes at halt with the axes energized. To put it another way, make the master axis start rotating when the EGB mode confirmation signal EGBM1 to EGBM8<Fn208> is “1”. No synchronization can be attained normally if the master axis starts rotating before the EGB mode confirmation signal EGBM1 to EGBM8 becomes “1”.
2. When you use Servo EGB synchronization by Electronic Gear Box(FSSB type), set “1” to EGB synchronization start signals EGBS1-EGBS8<Gn530> according to following procedure (a) to (c).
   (a) Turn on CNC and confirm the ready of all spindle (All-spindle operation ready signal SRSRDY<Fn034.7>=”1”).
   (b) Wait about 40msec after (a).
   (c) Set the signal EGBS1-EGBS8 to “1”.
   If EGBS1-EGBS8 have been “1” since turning on CNC, a shock might occur at the point where the spindle passes the first one rotation signal.

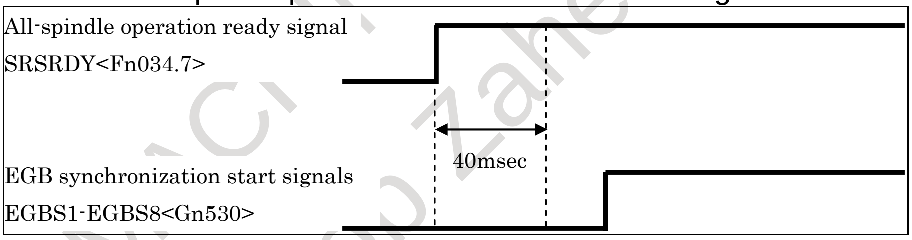

Fig.1.9.7 (b) EGBS1-EGBS8 ON

3. The rotation direction of the slave axis depends on that of the master axis. When the rotation direction of the master axis is positive, that of the slave axis is also positive. When the rotation direction of the master axis is negative, that of the slave axis is also negative. However, using the sign of the setting of parameter No. 7784 can reverse the rotation relation between the axes.
4. No synchronization can be maintained if the slave axis is in the servo-off state.
5. Actual cutting feedrate display does not take synchronization pulses into consideration.
6. In synchronization mode, it is not possible to specify G27, G28, G29, G30, and G53 for a slave axis.
7. The position of the slave axis is updated according to synchronization pulses as described below.
   - During synchronization, only the machine coordinates are updated. No absolute or relative coordinate is updated.
   - When synchronization is canceled, the distance traveled before cancellation is rounded up to 360 degrees before being added to the absolute coordinates

> **NOTE**
> 8 During EGB synchronization, no synchronization coefficient can be changed. Before changing the synchronization coefficient, cancel synchronization.
> 9 For an EGB slave axis, synchronous and composite control cannot be executed.
> 10 Using this function requires the separate detector interface unit and dedicated cables. For explanations about the cables, refer to "αi SP Series Connection Diagram" and "Details of cable K36" in "FANUC SERVO AMPLIFIER αi–B series Descriptions" (B-65412EN).

Signal

EGB synchronization start signals
EGBS1<Gn530.0>, EGBS2<Gn530.1>, …

[Classification] Input signal

[Function] Performs servo EGB synchronous control with the axis of interest used as a salve axis.

[Operation] When this signal becomes "1", the control unit operates as follows:

- Starts servo EGB synchronous control with the axis of interest used as a salve axis.

When this signal becomes "0", the control unit operates as follows:

- Cancels servo EGB synchronous control for the axis of interest used as a salve axis.

> **NOTE**
> If the master axis (spindle) or slave axis (servo axis) is not at halt, turning the EGB mode on/off causes the salve axis to accelerate/decelerate abruptly. Before turning the EGB mode on/off, be sure to keep both the master and slave axes at halt.

All-spindle operation ready signal
SRSRDY <Fn034.7>

[Classification] Output signal

[Function] This signal posts that all spindles used are ready for operation.

[Operation] This signal becomes "1" when:

All used spindles become ready for operation.

It becomes "0" when:

Some of the used spindles are not ready for operation.

EGB mode confirmation signals
EGBM1<Fn208.0>, EGBM2<Fn208.1>, …

[Classification] Output signal

[Function] Informs that EGB-based synchronization is in progress. Output is directed to the slave axis.

EGBMx

x : 1 ..... The first axis is in synchronization based on EGB.
2 ..... The second axis is in synchronization based on EGB.
3 ..... The third axis is in synchronization based on EGB.
: :
: :

[Operation] This signal becomes "1" if:

- EGB-based synchronization is in progress.

This signal becomes "0" if:

- EGB-based synchronization is canceled.

Signal Address

	#7	#6	#5	#4	#3	#2	#1	#0
Gn530	EGBS8	EGBS7	EGBS6	EGBS5	EGBS4	EGBS3	EGBS2	EGBS1

Parameter

The table below gives parameters related to this function.

Parameter number	Description
1006#0,#1	An EGB slave axis and an EGB dummy axis require that the setting of a rotary axis (type A) (bit 0 (ROT) of parameter No. 1006 be 1 and bit 1 (ROS) of parameter No. 1006 be 0.
1023	Set from the FSSB setting screen. For FSSB manual setting, be sure to set the EGB axis as described below: The slave axis must be set with an odd number, and the dummy axis with an even number. They must be consecutive. Example: If the servo axis number of the slave axis is 1, the servo axis number of the dummy axis must be set to 2. If the servo axis number of the slave axis is 3, the servo axis number of the dummy axis must be set to 4.
2011#0	Specify an axis to be synchronized. Specify 1 for both an EGB slave axis and EGB dummy axis.
3115#0	The current position is not indicated for an axis for which this parameter is set to 1.Since the current position for an EGB dummy axis has no meaning, set this parameter to 1 to delete the current position indication for the axis from the screen.
7782	Pulse count of position detector per rotation about EGB master axis
7783	Pulse count of position detector per rotation about EGB slave axis
7784	Numerator of a signal-based servo EGB synchronization ratio
7785	Denominator of a signal-based servo EGB synchronization ratio
7786#0	The signal-based servo EGB synchronization function is disabled(0) / enabled(1).

For FSSB settings, see the section on “FSSB settings”.
If FSSB setting mode is automatic setting mode, setting is made automatically by inputting data to the FSSB setting screen. For the slave/dummy axes of EGB, set the value in the “M/S” item in the FSSB axis setting screen same way of the tandem setting.

Note the following points when specifying parameters for this function.

1 Specify an axis that is not used or the same name as that for a slave axis for the name of a dummy axis. Do not use a name which is usually not allowed to be used as an axis address, such as D.
2 Specify the same values for an EGB slave axis and an EGB dummy axis in the following parameters.
   1013#0 to 3 Increment system
   1004#7 Ten times minimum input increment
   1006#0,1 Rotary axis setting
   1006#3 Diameter/radius specification
   1420 Rapid traverse rate
   1421 Rapid-traverse override F0 speed
   1820 Command multiplication
   2000 and over Parameters related to digital servo
3 Specify the amount of travel per rotation about a rotation axis for a slave axis and dummy axis in a parameter No. 1260.
4 Make the specification for a dummy axis in the following way.
   1815#1 Whether to use separate detectors. Although an EGB dummy axis uses the interface of a separate detector, set these parameters to 0.
5 Reducing synchronous errors requires enabling the feed-forward function for the slave axis.
   For details, see “How to reduce the synchronous error” in “Explanation” of this chapter.

[Example 1] When the EGB master axis is the spindle and the EGB slave axis is the A-axis

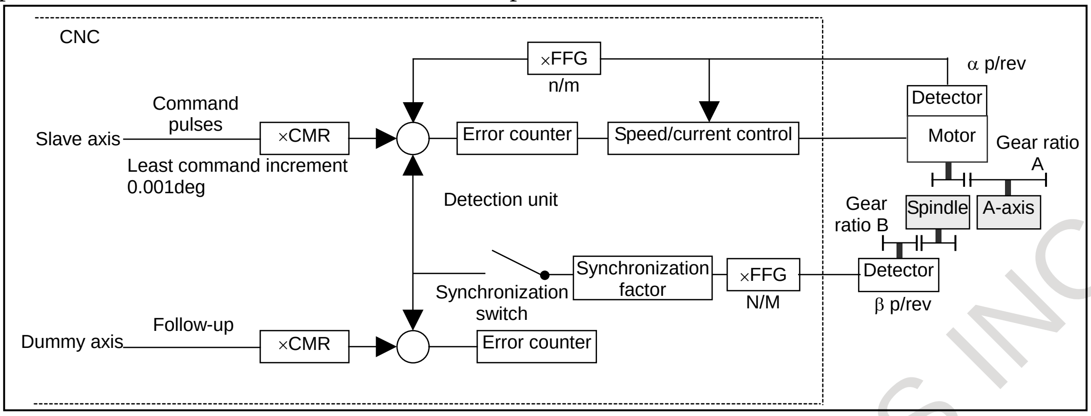

Fig.1.9.7 (c)

Gear ratio of the spindle to the detector B	: 1/1 (The spindle and detector are directly connected to each other.)
Number of detector pulses per spindle rotation β	: 4096 pulse/rev (Calculated for four pulses for one A/B phase cycle)
FFG N/M of the EGB dummy axis	: 1/1
Gear ratio of the A-axis A	: 1/36 (One rotation about the A-axis to 36 motor rotations)
Number of detector pulses per A-axis rotation α	: 1,000,000 pulses/rev
A-axis CMR	: 1
A-axis FFG n/m	: 1/100

In this case, the number of pulses per spindle rotation is:
4096 × 1/1 = 4096
Therefore, set 4096 for parameter No. 7782.
The number of pulses per C-axis rotation in the detection unit is:
1000000÷1/36×1/100 = 360000
Therefore, set 360000 for parameter No. 7783.

1023	Number of the servo axis for each axis

NOTE
When this parameter is set, the power must be turned off before operation is continued.

[Input type] Parameter input
[Data type] Byte axis
[Valid data range] 0 to 80

This parameter associates each control axis with a specific servo axis. Specify values 1+8n, 2+8n, 3+8n, 4+8n, 5+8n, and 6+8n (n = 0, 1, 2, …, 9) like 1, 2, 3, 4, 5, …, 77, and 78.

The control axis number is the order number that is used for setting the axis-type parameters or axis-type machine signals.

* For electronic gear box (EGB) controlled axes, two axes need to be specified as one pair. So, make a setting as described below.
EGB axis:
For a slave axis, set an odd (1, 3, 5, 7, 9, ...) servo axis number. For a dummy axis to be paired, set a value obtained by adding 1 to the value set for the slave axis.

	#7	#6	#5	#4	#3	#2	#1	#0
1006							ROSx	ROTx

[Input type] Parameter input
[Data type] Bit axis

> **NOTE**
> When at least one of these parameters is set, the power must be turned off before operation is continued.

#0 ROTx Setting linear or rotary axis.
#1 ROSx

ROSx	ROTx	Meaning
0	1	Rotary axis (A type)

	#7	#6	#5	#4	#3	#2	#1	#0
2005							FEEDx	

[Input type] Parameter input
[Data type] Bit axis

#1 FEEDx Feed-forward function is:
0: Invalid.
1: Valid.

Set 1 for the EGB slave axis.

> **NOTE**
> This parameter is Initial setting parameter. For details, refer to the appendix "Automatic setting / Initial setting parameter" in this manual.

	#7	#6	#5	#4	#3	#2	#1	#0
2011								SYN

[Input type] Parameter input
[Data type] Bit axis

#0 SYN When the electronic gear box function (EGB) is used, this bit sets the axis to be synchronized.
0: Axis not synchronized by EGB
1: Axis synchronized by EGB
Set 1 for both of the slave and dummy axes of EGB.

> **NOTE**
> The setting of this parameter becomes valid after the power is turned off then back on.

	#7	#6	#5	#4	#3	#2	#1	#0
3115								NDPx

[Input type] Parameter input
[Data type] Bit axis

#0 NDPx The current position is:
0: Displayed.
1: Not displayed.

> **NOTE**
> When using the electronic gear box (EGB) function, set 1 for the EGB dummy axis to disable current position display.

7782	Number of pulses from the position detector per EGB master axis rotation

[Input type] Parameter input
[Data type] 2-word axis
[Unit of data] Detection unit
[Valid data range] 1 to 999999999

For a slave axis, set the number of pulses generated from the position detector per EGB master axis rotation.
For an A/B phase detector, set this parameter with four pulses equaling one A/B phase cycle.

7783	Number of pulses from the position detector per EGB slave axis rotation

[Input type] Parameter input
[Data type] 2-word axis
[Unit of data] Detection unit
[Valid data range] 1 to 999999999

For a slave axis, set the number of pulses generated from the position detector per EGB slave axis rotation.
Set the number of pulses output by the detection unit.

7784	Numerator of a signal-based servo EGB synchronization ratio

[Input type] Parameter input
[Data type] 2-word axis
[Valid data range] -999999999 to 999999999

Set the numerator of a synchronization ratio for signal-based servo EGB synchronization.

The sign of this parameter specifies the direction in which the slave axis rotates.
When the sign is plus, the slave axis rotates in the positive direction (+ direction).
When the sign is minus, the slave axis rotates in the negative direction (- direction).

7785	Denominator of a signal-based servo EGB synchronization ratio

[Input type] Parameter input
[Data type] 2-word axis
[Valid data range] -999999999 to 999999999

Set the denominator of a synchronization ratio for signal-based servo EGB synchronization.

	#7	#6	#5	#4	#3	#2	#1	#0
7786								SVE

[Input type] Parameter input
[Data type] Bit

> **NOTE**
> When this parameter is set, the power must be turned off before operation is continued.

#0 SVE Signal-based servo EGB synchronization is:
0: Disabled (servo and spindle synchronization is enabled).
1: Enabled (servo and spindle synchronization is disabled).

Alarm and message

Number	Message	Description
PS1593	EGB PARAMETER SETTING ERROR	Error in setting a parameter related to the EGB (1) The setting of bit 0 (SYNx) of parameter No. 2011, is not correct. (2) The salve axis has not been specified as a rotation axis. (Bit 0 (ROT) of parameter No. 1006). (3) Number of pulses per rotation (parameter No. 7782 or 7783) is not set. (4) No signal-based EGB synchronization ratio (parameters Nos. 7784 and 7785) has been set.
PS1595	ILL-COMMAND IN EGB MODE	During synchronization with the EGB, a command that must not be issued is issued. (1) Slave axis command using G27, G28, G29, G30, G33, G53, etc.
PS1596	EGB OVERFLOW	An overflow occurred in the calculation of the synchronization coefficient.

1.9.8 Electronic Gear Box (FSSB type)

Overview

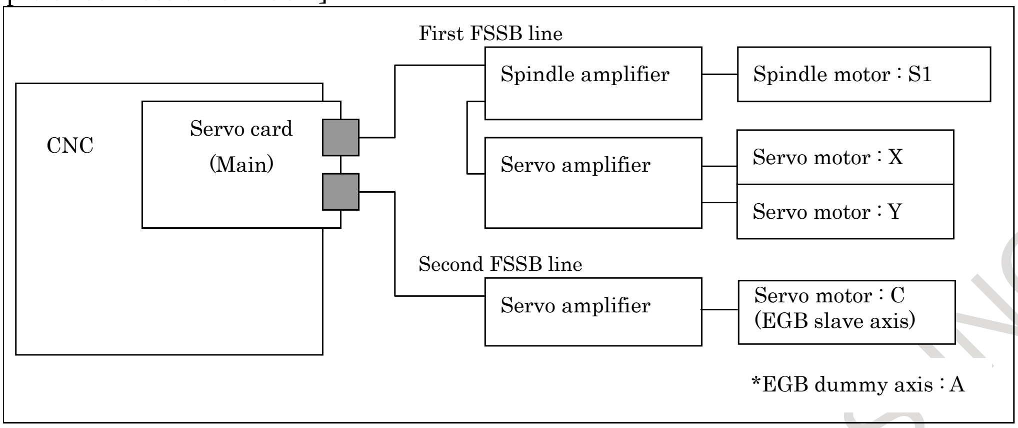
By the FSSB communication between a CNC and a spindle amplifier, rotational position information of a spindle can be transmitted from a spindle amplifier to a servo control on CNC. Electronic Gear Box (FSSB type) is a new function that a servo axis follows a spindle axis by utilizing this FSSB communication (the electronic gear box is hereinafter called the EGB). And it is a feature of this function that the separate detector interface unit becomes unnecessary compared with the ordinary function.

Explanation

The spindle amplifier and the servo amplifier used for EGB (FSSB type) need to be connected to the main servo card. The spindle amplifier and the servo amplifier used for this function can be connected to both the first FSSB line and the second FSSB line. This function can be done between two motors connected to another line.

Ex.1) EGB (FSSB type) with C axis (EGB dummy axis is A axis) and S1 spindle axis in the one path system

[Example of connection of FSSB]



[Example of parameter setting]

The following settings are necessary in addition to setting of existing parameters related to the EGB.

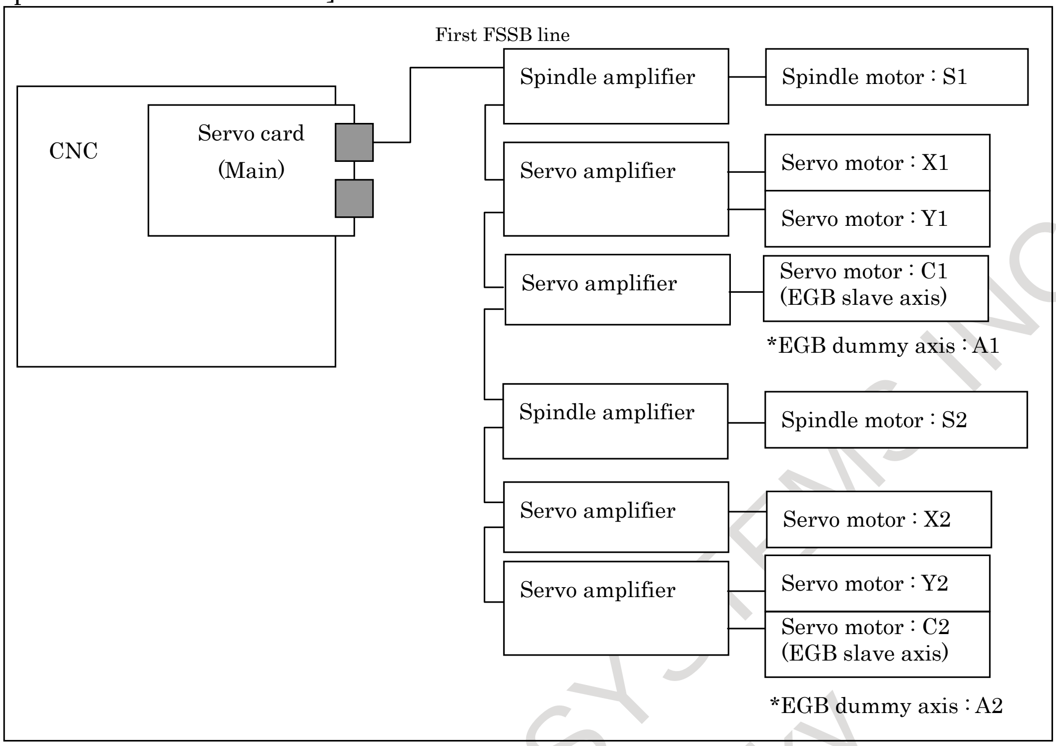
When bit 0 (FHR) of parameter No. 24203 is set to 1, position data transmission by FSSB is enabled.
And, the index number of the spindle axis that synchronizes with the EGB dummy axis used by EGB (FSSB type) is set to the parameter No. 24204 as follows.

24204	SP INDEX OF SV FSSB SYNC
X	0
Y	0
C	0
A	1

In addition, set 1 to bit 2 (FSBSYNx) of parameter No. 2429 of EGB dummy axis and bit 2 (FHESPs) of parameter No. 4549 of S1 spindle axis.

Ex.2) Two groups of EGB (FSSB type) with C1 – S1 (EGB dummy axis is A1 axis) and C2 – S2 (EGB dummy axis is A2 axis) in two paths system

[Example of connection of FSSB]



[Example of parameter setting]

The following settings are necessary in addition to setting of an existing parameters related to the EGB.

When bit 0 (FHR) of parameter No. 24203 is set to 1, position data transmission by FSSB is enabled.
And, the index number of the spindle axis that synchronizes with the EGB dummy axis used by EGB (FSSB type) is set to the parameter No. 24204 as follows.

Path 1

24204	SP INDEX OF SV FSSB SYNC
X1	0
Y1	0
C1	0
A1	1

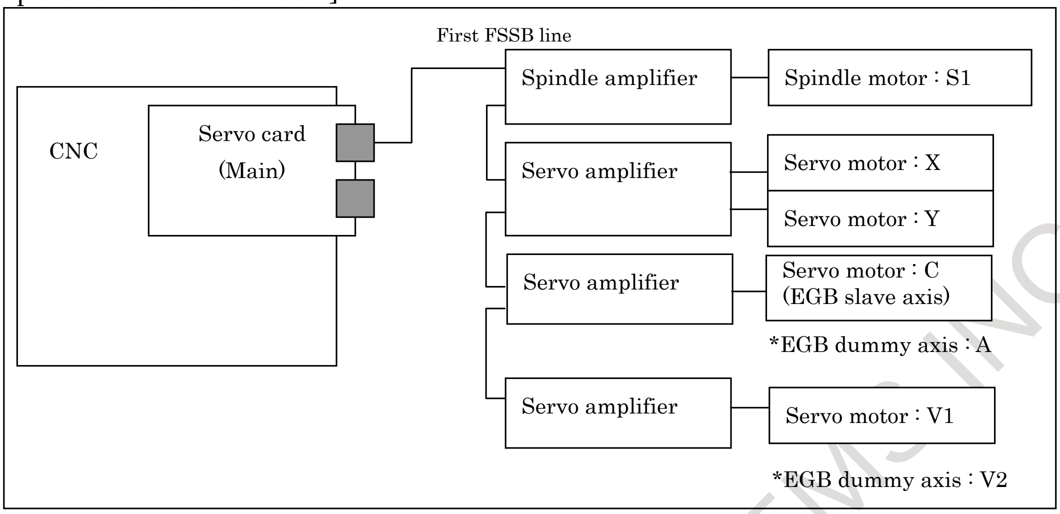
Path 2

24204	SP INDEX OF SV FSSB SYNC
X2	0
Y2	0
C2	0
A2	2

In addition, set 1 to bit 2 (FSBSYNx) of parameter No. 2429 of A1 and A2 axes and bit 2 (FHESPs) of parameter No. 4549 of S1 and S2 spindle axes.

Ex.3) EGB (FSSB type) by EGB 2 pair with using common master axis to C1 – S1 (EGB dummy axis is A axis) and V1 – S1 (EGB dummy axis is V2 axis) in the one path system

[Example of connection of FSSB]



[Example of parameter setting]

The following settings are necessary in addition to setting of an existing parameters related to the EGB.

When bit 0 (FHR) of parameter No. 24203 is set to 1, position data transmission by FSSB is enabled.
And, the index number of the spindle axis that synchronizes with the EGB dummy axis used by EGB (FSSB type) is set to the parameter No.24204 as follows.

24204	SP INDEX OF SV FSSB SYNC
X	0
Y	0
C	0
A	1
V1	0
V2	1

In addition, set 1 to bit 2 (FSBSYNx) of parameter No. 2429 of A and V2 axes and , bit 2 (FHESPs) of parameter No. 4549 of S1 spindle axis.

The servo axes that can receive the feedback data from the spindle axis through FSSB are eight axes or less in all system. If nine axes or more of the servo axis or illegal index number of the spindle axis is set, the alarm (PW0037) “SV/SP COMBINATION ERROR” is issued.

NOTE

1 This function can be used by the following EGB functions.
 - Electronic gear box
 - U-axis control
  - Signal-based servo EGB synchronous control

2 As following EGB functions are realized by 2 spindles, it is impossible to apply this FSSB type.
 - Spindle electronic gear box
 - Simple spindle electronic gear box

NOTE

3 When the parameter is changed, the power must be turned off before an operation is continued.

4 EGB (FSSB type) cannot be used with the analog spindle or the spindle control with servo motor. If the above EGB (FSSB type) is set, the alarm (PW0037) “SV/SP COMBINATION ERROR” is issued.

5 When you don’t use spindle sensor and drive the axis only by motor a sensor, arbitrary gear ratio between motor and spindle (parameter No.4171-No.4174) is used. In the case, please set 1 in bit 1 (EGBAGR) of parameter No.4004.

6 When you use automatic phase synchronization of EGB (FSSB type) from the stop state or slow moving, you have to rotate the spindle axis at least one rotation with higher speed than 10min^{-1} before the phase synchronization operation.

7 With EGB dummy axis used by EGB (FSSB type), the following functions cannot be used.
- FSSB high-speed rigid tapping
- Servo/spindle synchronous control
- Fully closed control

If EGB (FSSB type) is used with either of the above functions, the alarm (SV0417) “ILL DGTL SERVO PARAMETER” is issued.

8 When you use U-axis Control or Signal-based Servo EGB Synchronous Control by Electronic Gear Box(FSSB type), set “1” to EGB synchronization mode selection signal EGBS<Gn067.4> or EGB synchronization start signals EGBS1-EGBS8<Gn530> according to following procedure (a) to (c).

(a) Turn on CNC and confirm the ready of all spindle (All-spindle operation ready signal SRSRDY<Fn034.7>=”1”).

(b) Wait about 40msec after (a).

(c) Set the signal EGBS or EGBS1-EGBS8 to “1”.

If EGBS<Gn067.4> or EGBS1-EGBS8<Gn530> has been “1” since turning on CNC, a shock might occur at the point where the spindle passes the first one rotation signal.

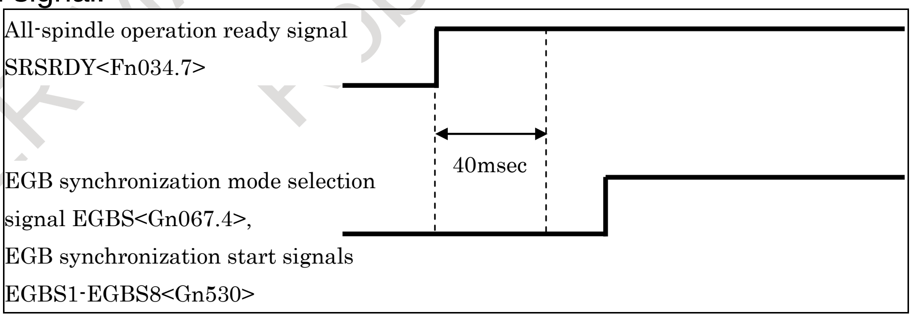


Fig.1.9.8 (a) EGBS or EGBS1-EGBS8 ON

Signal

EGB synchronization mode selection signal
EGBS<Gn067.4>

[Classification] Input signal

[Function] Selects the EGB synchronization mode for U-axis control.

[Operation] When this signal becomes “1”, the control unit operates as follows:
Starts EGB synchronization.

EGB synchronization start signals
EGBS1<Gn530.0>, EGBS2<Gn530.1>, …

[Classification] Input signal

[Function] Performs servo EGB synchronous control with the axis of interest used as a slave axis.

[Operation] When this signal becomes “1”, the control unit operates as follows:
- Starts servo EGB synchronous control with the axis of interest used as a slave axis.

When this signal becomes “0”, the control unit operates as follows:
- Cancels servo EGB synchronous control for the axis of interest used as a slave axis.

> **NOTE**
> If the master axis (spindle) or slave axis (servo axis) is not at halt, turning the EGB mode on/off causes the slave axis to accelerate/decelerate abruptly. Before turning the EGB mode on/off, be sure to keep both the master and slave axes at halt.

All-spindle operation ready signal
SRSRDY <Fn034.7>

[Classification] Output signal

[Function] This signal posts that all spindles used are ready for operation.

[Operation] This signal becomes “1” when:
All used spindles become ready for operation.

It becomes “0” when:
Some of the used spindles are not ready for operation.

Signal Address

	#7	#6	#5	#4	#3	#2	#1	#0
Gn067				EGBS				
Gn530	EGBS8	EGBS7	EGBS6	EGBS5	EGBS4	EGBS3	EGBS2	EGBS1
Fn034	SRSRDY							

Parameter

	#7	#6	#5	#4	#3	#2	#1	#0
2429						FSBSYNx		

[Input type] Parameter input

[Data type] Bit axis

#2 FSBSYNx Servo control by EGB (FSSB type) is:
0: Disabled.
1: Enabled.

> **NOTE**
> 1 When using EGB (FSSB type), set this parameter to 1.
> 2 In the EGB dummy axis, in which bit 2 (FSBSYNx) of parameter No.2429 is 1, the following functions cannot be used. If EGB (FSSB type) is used with either of the following functions, the alarm (SV0417) “ILL DGTL SERVO PARAMETER” is issued. (Detail number of diagnosis data No.0352 :4292 or 4291)
>   - FSSB high-speed rigid tapping (Bit 1 (FHRSVx) of parameter No.2429)
>   - Servo/spindle synchronous control (Bit 4 (SPSx) of parameter No.2016)
>
> 3 When this parameter is set, the power must be turned off before operation is continued.

	#7	#6	#5	#4	#3	#2	#1	#0
4004							EGBAGR	

[Input type] Parameter input
[Data type] Bit spindle

#1 EGBAGR Arbitrary gear ratio between the motor and spindle (parameter No.4171-No.4174) by EGB (FSSB type) is:
0: Disabled.
1: Enabled.

> **NOTE**
> 1 To use arbitrary gear ratio between the motor and spindle in case of using a motor sensor only without a spindle sensor, set the parameter EGBAGR to 1.
>   For details of parameter of arbitrary gear ratio (No.4171-No.4174), refer to spindle parameter manual (B-65280).
> 2 To use this function bit, it’s necessary to prepare the applicable CNC software and spindle software.
> 3 When bit 1 (EGBAGR) of parameter No.4004 is 0, the feedback pulsed from EGB master axis doesn’t take the arbitrary gear ratio into account.
> 4 Do not change parameter of arbitrary gear ratio and clutch/gear signals (CTH) during EGB mode. If parameters or signals are changed, the alarm (SP9167) "Spindle control sequence fault" and the alarm (SV0385) "Serial data error (EXT)" will occur.

	#7	#6	#5	#4	#3	#2	#1	#0
4549						FHESPs		

[Input type] Parameter input
[Data type] Bit spindle

#2 FHESPs Spindle control by EGB (FSSB type) is:
0: Disabled.
1: Enabled.

NOTE
1 When using EGB (FSSB type), set this parameter to 1.
2 In the spindle axis, in which bit 2 (FHESPs) of parameter No.4549 is 1, FSSB high-speed rigid tapping (bit 1 (FHRSPs) of parameter No.4549) cannot be used. If EGB (FSSB type) is used with the FSSB high-speed rigid tapping, the alarm (SP9068) “ILLEGAL SPINDLE PARAMETER” is issued.

	#7	#6	#5	#4	#3	#2	#1	#0
24203								FHR

NOTE
When the parameter is set, the power must be turned off before operation is continued.

[Input type] Parameter input
[Data type] Bit

#0 FHR Position data transmission by FSSB is:
0: Disabled.
1: Enabled.

NOTE
1 In addition, it is necessary to set parameter No.24204.
2 When the following function is used, set 1 to this parameter.
- FSSB high-speed rigid tapping
- Electronic gear box (FSSB type)
- Servo/Spindle synchronous control (FSSB type)

24204	The index number of the spindle axis that synchronizes to each servo axis

NOTE
When the parameter is set, the power must be turned off before operation is continued.

[Input type] Parameter input
[Data type] Byte axis
[Valid data range] 0 to the maximum number of spindles

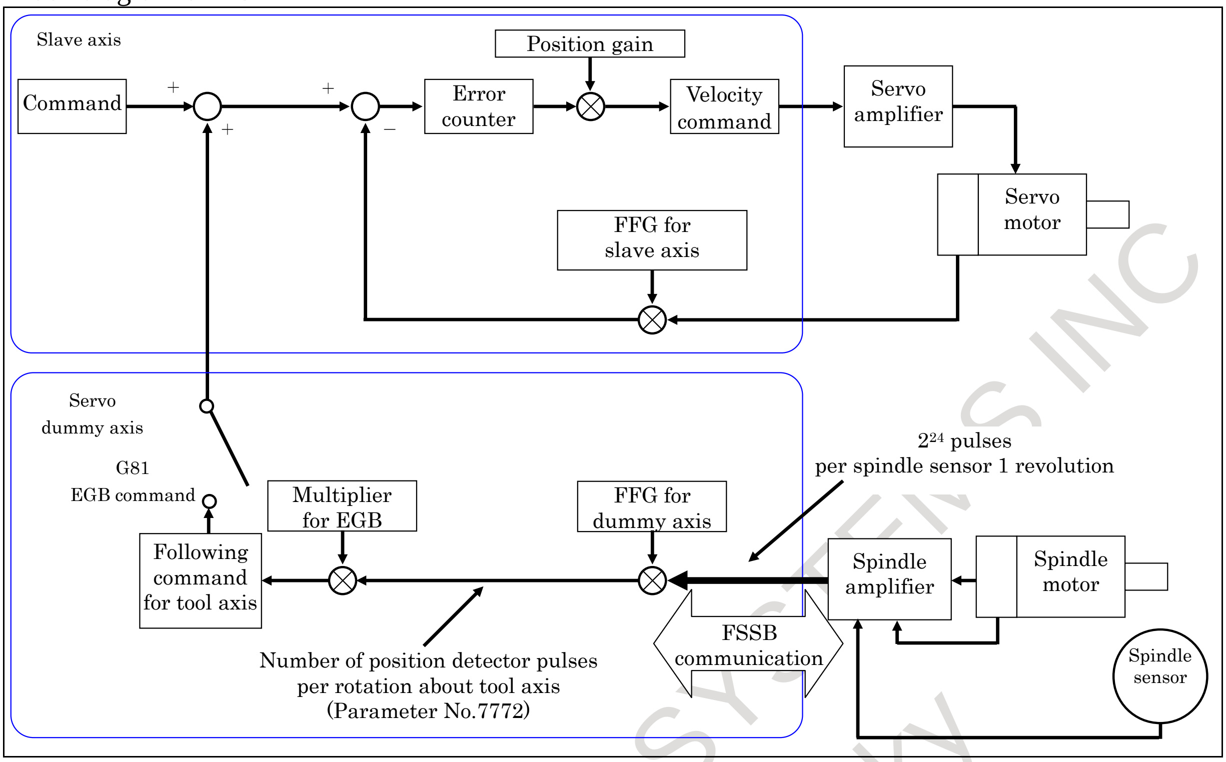
Set the index number of the spindle axis that synchronizes with EGB dummy axis used by EGB (FSSB type).

NOTE
1 When bit 0 (FHR) of parameter No.24203 is 1, this parameter is enabled.
2 Eight or less index numbers of the spindle axis can be set in the system. If nine or more index numbers of the spindle axis are set, the alarm (PW0037) "SV/SP COMBINATION ERROR" is issued.

Reference) Existing parameters related to the EGB.

Parameter number	Description
1006#0 1006#1	To specify the distance for the slave axis by L in the synchronization command, an EGB slave axis and an EGB dummy axis require that the setting of a rotary axis (type A) (bit 0 (ROT) of parameter No. 1006 be 1 and bit 1 (ROS) of parameter No. 1006 be 0.
1023	Set from the FSSB setting screen. For FSSB manual setting, be sure to set the EGB axis as described below: The slave axis must be set with an odd number, and the dummy axis with an even number. They must be consecutive. Example: If the servo axis number of the slave axis is 1, the servo axis number of the dummy axis must be set to 2. If the servo axis number of the slave axis is 3, the servo axis number of the dummy axis must be set to 4.
2011#0	Specify an axis to be synchronized. Specify 1 for both an EGB slave axis and EGB dummy axis.
2084/2085	Flexible feed gear. The feed back data from spindle position sensor is regarded as 2^{24} pulses/rev for input to dummy axis. If you want to thin it out, please use Flexible feed gear in dummy axis. (See following figure)
3115#0	The current position is not indicated for an axis for which this parameter is set to 1.Since the current position for an EGB dummy axis has no meaning, set this parameter to 1 to delete the current position indication for the axis from the screen.
7700#0	The synchronization mode is canceled (0)/not canceled (1) by a reset.
7700#2	Compensation direction for helical gear compensation
7701#3	At the start of synchronization (G81), synchronization is started (0)/not started (1) if the number of hob threads L is specified as 0.
7702#0	The specifiable number of teeth, T, at the start of synchronization (G81) is not reduced to a 1/10 of a specified value (0)/reduced (1).
7702#3	The retract function with an alarm is disabled (0)/enabled (1).
7703#0	During synchronization (G81), feed per revolution is performed for feedback pulses (0)/pulses converted to the speed for the workpiece axis(1).
7703#1,#2	Specify when to perform a retract operation with the retract function with an alarm; during synchronization; during synchronization and automatic operation; or during synchronization or automatic operation.
7709	Number of the axial feed axis in helical gear compensation
7731#0	The EGB command is G80 and G81(0)/G80.4 and G81.4(1).
7731#3	When the automatic phase synchronization function for the electronic gear box is disabled, the G81 command cannot be issued again (an alarm is issued) (0)/can be issued again (1) during EGB synchronization.
7731#5	In EGB synchronization start command G81.4, the number of teeth is specified in T (0)/specified in R (1).
7740	Feedrate during retraction
7741	Retract amount
7772	Number of position detector pulses per rotation about tool axis. Please set the value which takes the Flexible feed gear and EGB exponent setting into consideration. (See following figure.)
7773	Number of position detector pulses per rotation about workpiece axis
7782	Pulse count of position detector per rotation about EGB master axis
7783	Pulse count of position detector per rotation about EGB slave axis
7784	Numerator of a signal-based servo EGB synchronization ratio
7785	Denominator of a signal-based servo EGB synchronization ratio
7786#0	The signal-based servo EGB synchronization function is invalid (0) / valid (1).

Block diagram of EGB



Example 1)

Gear ratio of the spindle to the spindle sensor: 1/1 (The spindle and detector are directly connected to each other.)
FFG N/M of the EGB dummy axis: 1/1
Gear ratio of the C-axis (Slave axis): 1/36 (One rotation about the C-axis to 36 motor rotations)
Number of detector (αi Pulsecoder) pulses per C-axis rotation: 1,000,000 pulses/rev
C-axis CMR: 1
C-axis detection unit: 0.001 deg

In this case, the number of position detector pulses per one rotation in tool axis (spindle) is:
$2^{24} * 1/1 = 16777216$
Therefore, set 16777216 for parameter No. 7772.
The number of pulses per C-axis rotation in the detection unit is:
360(deg) / 0.001(deg) = 360000
Therefore, set 360000 for parameter No. 7773.

Regarding FFG for C-axis is
360000 / (36*1000000) = 1/100

Example 2)

Gear ratio between spindle and spindle motor: 1/3 (The spindle sensor is none. Arbitrary gear ratio : 1/3)
FFG N/M of the EGB dummy axis: 1/1
The configuration of C axis is same as example 1.

In this case, by setting 1 in bit 1 (EGBAGR) of parameter No.4004, the feedback data from spindle to servo takes arbitrary gear ratio into account. In spindle one rotation, the motor sensor rotates 3 revolutions. But as the feedback pulses from the motor sensor is multiplied by arbitrary gear ratio, the number of position detector pulses per one rotation in tool axis (spindle) is calculated by following formula,
$2^{24}*3*(1/3)*(1/1) = 16777216$

Motor 3 revolutions any gear ratio FFG. It means No.7772 should be 16777216.

Alarm and message

Number	Message	Description
PW0037	SV/SP COMBINATION ERROR	- The servo axis has dummy axis setting. Please check parameters (No.1023, bit 0 of No.2009, bit 4 of No.11802). - The setting for spindle axis number to synchronize with servo is wrong. Please check parameters (bit 0 of No.3716, No.3717, No.24204).
SV0417	ILL DGTL SERVO PARAMETER	- The setting for the function, which is not available with EGB (FSSB type) together, is done. Please turn it off.
SP9068	ILLEGAL SPINDLE PARAMETER	- EGB (FSSB type) and FSSB high-speed rigid tapping cannot be used together. Please check the parameters (bit 1 of No.4549, bit 2 of No.4549) - In the case of EGB (FSSB type) using, please turn off FSSB high-speed rigid tapping,
SP9167	SPINDLE CONTROL SEQUENCE FAULT	- Arbitrary gear ratio should not be changed during EGB mode. When you need to change arbitrary gear ratio, you have to change the parameters and clutch/gear signals before starting EGB operation.

Diagnosis data

1612	The index number of the spindle axis that synchronizes with each servo axis

[Data Type] Byte axis

The index number of the spindle axis that can use direct communication between a spindle amplifier and a servo amplifier on FSSB connection is displayed.

1.10 DUAL POSITION FEEDBACK TURNING MODE / COMPENSATION CLAMP

Overview

To the axis to be controlled with the dual position feedback function, add the turning mode and a compensation clamp. For details of the dual position feedback function, refer to the FANUC AC SERVO MOTOR α*i*/β*i* series, FANUC LINEAR MOTOR L*i*S series, FANUC SYNCHRONOUS BUILT-IN SERVO MOTOR D*i*S series PARAMETER MANUAL (B-65270EN).

- Turning mode

Select the turning mode by inputting the dual position feedback turning mode selection signal. In the turning mode, the full closed side feedback for the axis set in bit 0 (STHx) of parameter No. 11803 is ignored. If a move command is issued in the turning mode, it is operated only with control with a semi-closed loop.

This function is used to switch the control method depending on the case; for example, to perform position control on a given axis, using the servo motor or to control a given axis as a spindle, using a spindle motor.

In the turning mode, full closed side feedback is ignored, so that all coordinates (machine, workpiece, and local coordinates) will be shifted by the amount of operation in the turning mode. Thus, after the end of the turning mode, a reference position return is required to correct the coordinates. If an attempt is made to perform automatic operation without performing a reference position return, alarm PS0224 "ZERO RETURN NOT FINISHED" is issued.

> **NOTE**
> An absolute position detector cannot be used for the axis that uses the turning mode.

- Compensation clamp

The compensation operation of dual position feedback is canceled by inputting the dual position feedback compensation clamp signal. When the compensation operation is canceled, full closed side feedback is interrupted and an operation with a semi-closed loop is assumed. If a mechanical clamp is to be performed on the axis on which to perform dual position feedback, a compensation clamp must be performed. This function is enabled for an axis for which bit 1 (CDPx) of parameter No. 11803 is 1.

Signal

Dual position feedback turning mode selection signal HBTRN <Gn531.3>

[Classification] Input signal
[Function] Selects the turning mode.
[Operation] When set to “1”, this signal selects the dual position feedback turning mode, ignoring the full closed side feedback for the axis set in bit 0 (STH) of parameter No. 11803.

Dual position feedback compensation clamp signal *CL1 to *CL8<Gn548>

[Classification] Input signal
[Function] Cancels the compensation operation of dual position feedback.
[Operation] When set to “0”, this signal cancels the compensation operation of dual position feedback. This signal is valid only if bit 1 (CDPx) of parameter No. 11803 is 1.

Signal address

11803							CDPx	STHx

[Input type] Parameter input
[Data type] Bit axis

#0 STHx The dual position feedback turning mode is:
0: Disabled.
1: Enabled.

> **NOTE**
> Before the dual position feedback turning mode function can be used, a setting to enable dual position feedback is required in addition to the setting of this bit.

#1 CDPx Dual position feedback compensation clamping is:
0: Not performed.
1: Performed.

> **NOTE**
> Before the dual position feedback compensation clamp function can be used, a setting to enable dual position feedback is required in addition to the setting of this bit.

Alarm and message

Number	Message	Description
PS0224	ZERO RETURN NOT FINISHED	A reference return has not been performed before the start of automatic operation. (Only when bit 0 (ZRNx) of parameter No. 1005 is 0) Perform a reference position return.

1.11 FUNCTION OF DECELERATION STOP IN CASE OF POWER FAILURE

Overview

If a power failure occurs during an axial movement, this function stops the movement by decreasing the speed on each axis at a rate specified in parameter No. 1791. This function prevents the machine from being damaged by an overrun.

Explanation

- Deceleration pattern

Both cutting feed and rapid traverse are decelerated linearly, at a constant rate.

- Example of deceleration

If the rates on the X-axis and Y-axis are different

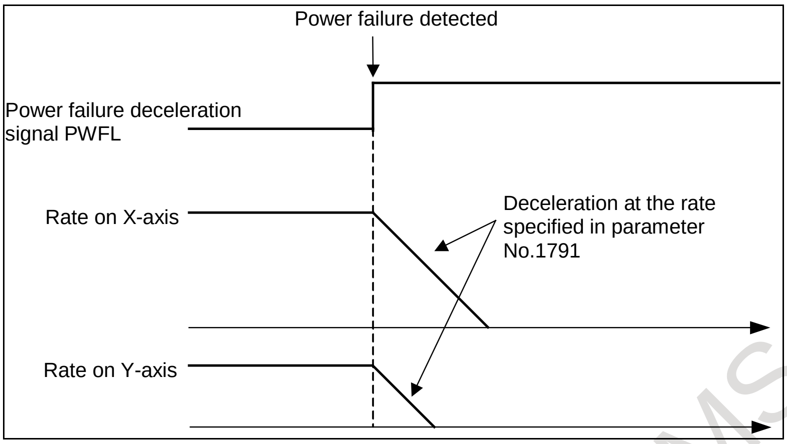

Fig. 1.11

> **NOTE**
> 1 After the completion of deceleration started by bringing the power failure deceleration signal PWFL to "1", no axial movement can be made.
> 2 To make another axial movement, turn the power off and on again.
> 3 This function does not perform deceleration on a torque control axis or a velocity control axis under PMC axis control or on an EGB axis.
> 4 Prevent an emergency stop from occurring until the deceleration is completed.
> 5 The stored stroke check function is disabled while deceleration by this function is in progress.

- Application

This function is used to decelerate and stop a linear motor in a system connected to a power-failure backup module and sub-module C (capacitor module), in case of a power failure.

- Effect of application

If a power failure occurs, energy required to decelerate and stop the linear motor is supplied from sub-module C (capacitor module). The amount of energy required for deceleration increases as the time constant decreases, or as the acceleration increases.
Generally, linear-motor machines perform high-acceleration operation, so that the time constant is set to the lowest possible level. A number of C sub-modules (capacitor modules) are required to decelerate and stop the linear motor when a power failure occurs.
The number of necessary C sub-modules (capacitor modules) can be reduced by using this function to lower the acceleration in deceleration performed in case of a power failure.

Caution

If an acceleration lower than the normal acceleration is set by this function, the braking distance at a power failure becomes longer than usual. Accordingly, a collision with a stroke end can occur, depending on the acceleration start position at a power failure.
Because the rate of the collision with a stroke end is decreased by this function, the impact of the collision is reduced than that occurring without this function (when a DB stop occurs).

Signal

Power failure deceleration signal PWFL <G203.7>

[Classification] Input signal

[Function] Indicates that a power failure has been detected.

[Operation] When this signal is set to "1", the control unit performs the following operation.

- Immediately starts deceleration at the constant rate specified in parameter No.1791, and stops the movement.

> **NOTE**
> 1 This signal is effective on all the paths.
> 2 Avoid changing any state after the signal is brought to “1”.

Signal address

	#7	#6	#5	#4	#3	#2	#1	#0
G203	PWFL							

Parameter

1791	Acceleration rate on each axis for the outage-time deceleration stop function

[Input type] Parameter input

[Data type] Real axis

[Unit of data] mm/sec^2, inch/sec^2, deg/sec^2 (machine unit)

[Min. unit of data] Depend on the increment system of the applied axis

[Valid data range] Refer to the standard parameter setting table (D)
(0.0 to +100000.0 for the metric system, 0.0 to +10000.0 for the inch system)

Set an acceleration rate for deceleration on an axis on which the tool is decelerated to a stop at the time of power outage.
On an axis for which this parameter is set to 0, deceleration based on the outage-time deceleration signal is not performed.

In synchronization control or tandem control, set the same parameter for the master axis and slave axis.

1.12 FLEXIBLE SYNCHRONIZATION CONTROL

1.12.1 Flexible Synchronization Control

Overview

This function is provided for those machines like hobbing machines that require the synchronization of various multiple gear ratios.
Synchronization with this function enables up to four pairs to be operated independently and simultaneously. This achieves special functions for hobbing machines such as the synchronization of the hobbing axis and a single workpiece axis, Z-C synchronization in helical gear cutting, and Y-C synchronization in a hobbing axis shift.
Specifications for flexible synchronization control are as follows:

1) A master axis number, a slave axis number, and a gear ratio are set in parameters.
2) There can be up to four groups to these parameters. Synchronization of the four groups can be executed at the same time.
3) A single slave axis can be specified for multiple master axes.
4) Synchronization is started and canceled with DI signals from the PMC.
   If DI signals are to be switched during automatic operation, this needs to be performed with an M code set in a parameter.

5) Two Cs axes can be used as master and slave axes.
6) A retract operation can be performed during the flexible synchronization control mode and inter-path flexible synchronization control mode. The retract operation complies with the specifications of the general-purpose retract function. (Refer to section, “GENERAL PURPOSE RETRACT”, in this manual for descriptions of the specifications of the general-retract function.)

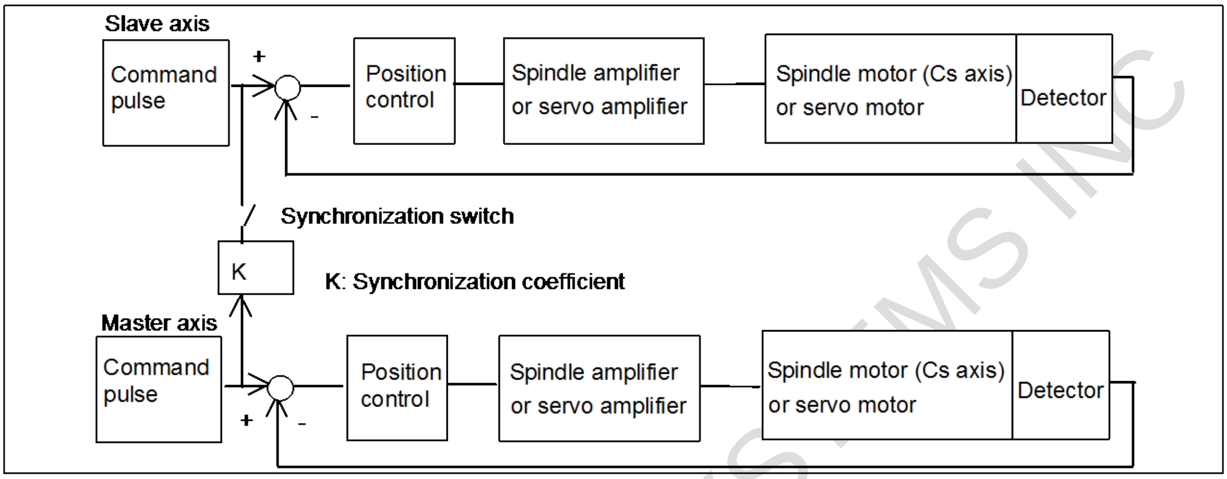

Fig. 1.12.1 Block diagram

Parameter setting

Parameters for flexible synchronization control include the following:
(1) Denominator for determining a gear ratio (parameters Nos. 5681, 5683, 5685, and 5687)
(2) Numerator for determining a gear ratio (parameters Nos. 5680, 5682, 5684, and 5686)
(3) Exponent for the denominator of a gear ratio (parameters Nos. 5690, 5691, 5692, and 5693)
(4) Master axis number (parameters Nos. 5660, 5662, 5664, and 5666)
(5) Slave axis number (parameters Nos. 5661, 5663, 5665, and 5667)
(6) M code number for turning on the synchronization mode (parameters Nos. 5670, 5672, 5674, and 5676)
(7) M code number for turning off the synchronization mode (parameters Nos. 5671, 5673, 5675, and 5677)
(8) Parameters related to the update of machine coordinates (bits 0 (ACA) to 3 (ACD) of parameter No.5668)

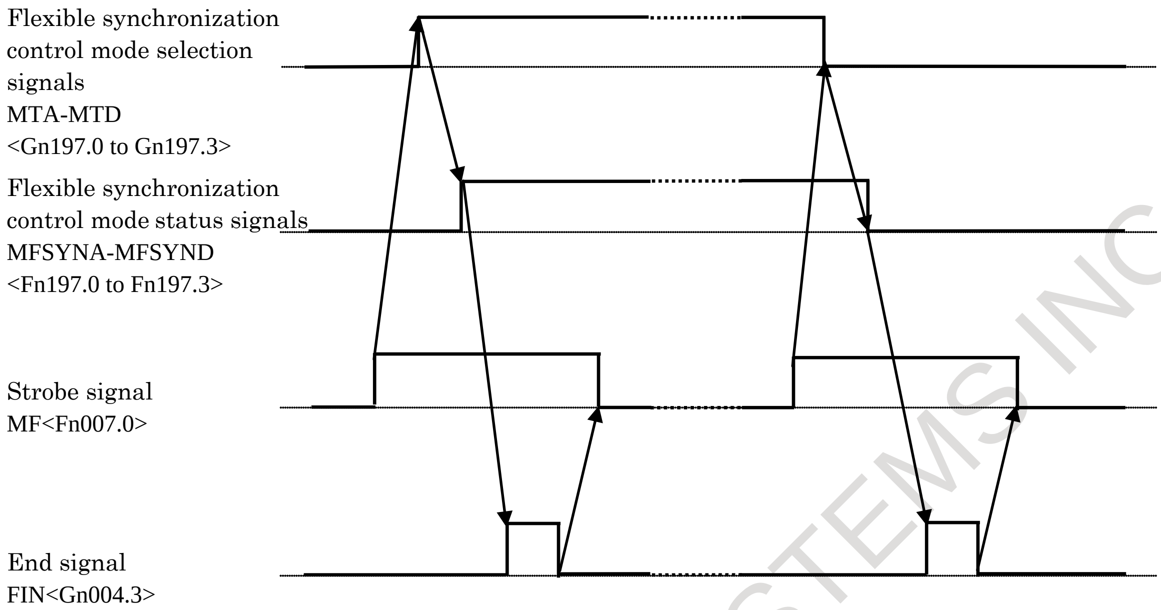
Start of synchronization

Synchronization is started by setting one of the flexible synchronization control mode selection signals MTA, MTB, MTC, and MTD<Gn197.0, Gn197.1, Gn197.2, Gn197.3> to "1". Note that to set one of MTA, MTB, MTC, and MTD to "1" during automatic operation, this needs to be performed with an M code set in parameter No. 5670, 5672, 5674, or 5676. Up to three of these M codes can be specified in a single block by enabling the multiple-Ms-per-block command (setting bit 7 (M3B) of parameter No. 3404 to 1).
When one of MTA, MTB, MTC, and MTD is accepted, one of the flexible synchronization control mode status signals MFSYNA, MFSYNB, MFSYNC, and MFSYND<Fn197.0, Fn197.1, Fn197.2, Fn197.3> is set to "1".

Cancellation of synchronization

Synchronization is canceled by setting one of the flexible synchronization control mode selection signals MTA, MTB, MTC, and MTD<Gn197.0, Gn197.1,Gn197.2,Gn197.3> to "0".
When one of MTA, MTB, MTC, and MTD is accepted, one of the flexible synchronization control mode status signals MFSYNA, MFSYNB, MFSYNC, and MFSYND<Fn197.0, Fn197.1, Fn197.2, Fn197.3> is set to "0".

Example of time chart for start and cancellation of synchronization



G27/G28/G29/G30/G53 commands

If an attempt is made to issue one of these commands for a master axis or a slave axis during flexible synchronization control, alarm PS0010 "IMPROPER G-CODE" is issued, but by setting bit 2 (FRF) of parameter No. 13421 to 1, they can be issued for a master axis.
In this case, the slave axis is linked to the operation of the master axis, so that its movement is the same as in normal flexible synchronization control.
Note, however, that even if parameter FRF is set to 1, if an attempt is made to issue G28 when a reference position has not been established for a master axis or to issue it for a slave axis, alarm PS5381 "INVALID COMMAND IN FSC MODE" is issued.

Program example

Axis configuration X, Y, Z, B (Cs axis), C, U, V
Group A: Master axis B, slave axis C, gear ratio 1:50, on M50, off M51
Group B: Master axis Z, slave axis C, gear ratio 1:5, on M52, off M53
Group C: Master axis Y, slave axis C, gear ratio 23:20, on M54, off M55
Group D: Master axis B, slave axis U, gear ratio 1:100, on M56, off M57

```

Flexible synchronization control in case a master axis is controlled by “Spindle Control with Servo Motor”

Flexible synchronization control can be applied to the case where an axis that is controlled by “Spindle Control with Servo Motor” is assigned as a master axis, when flexible synchronization control selection signal MTA, MTB, MTC, or MTD<Gn197.0 to Gn197.3 > is set to "1" in the SV speed control mode. In this case, a master axis should be in the SV speed control mode of “Spindle Control with Servo Motor” to enter flexible synchronization mode. Please do not change the SV speed mode during flexible synchronization control. Flexible synchronization control should be turned on/off during the SV speed mode according to the following example of programming.

Example of the machining program)

```
G00 X10.Z50.;
S0P11;
G96.4P11;       : SV speed control mode ON
M16;            : Flexible synchronization control ON
S100P11;
:
:
S0P11;
M17;            : Flexible synchronization control OFF
N9G96.1P11;     : SV speed control mode OFF
```

Retract by alarm

In case that bit 3 (ART) of parameter No. 7702=1, when a CNC alarm occurs during flexible synchronization control or automatic operation, the axis retracts according to the amount of retract (parameter No. 7741) and the speed (parameter No. 7740). As a result, a tool and a workpiece can be prevented from being damaged when the sudden alarm occurs. The axis whose amount of retract is set to “0” does not move. This improvement becomes effective to “General purpose retract” and “Retract of flexible synchronization control”. Moreover, the excitation of a servomotor is kept until the retract operation of the axis related to synchronization is completed, even when a servo alarm occurs in an axis not related to the synchronization in flexible synchronization control.

Conditions under the retract function with an alarm

The conditions under which the retract function with an alarm can be changed using the settings of bit 1 (ARE) of parameter No. 7703 and bit 2 (ARO) of parameter No. 7703.

The table below lists parameter settings and corresponding conditions.

ARE	ARO	Condition
1	0	During function mode
1	1	During function mode and automatic operation
0	0	During function mode or automatic operation
0	1	

Servo off

When the axis related to synchronization is servo off state while flexible synchronization control, an automatic operation is stopped. By setting bit 3 (FSV) of parameter No. 13421 to 1, an automatic operation can be stopped only when the axis related to synchronization moves.

Notes

1) Synchronization is not canceled with a reset.
2) Synchronization is executed even if the slave axis is in either of the following states:
   - Interlock
   - Feed hold
3) Synchronization is not maintained if the slave axis is in either of the following states:
   - Machine lock
   - Servo off
4) The master axis must not be a oscillation axis, an axis related to arbitrary angular axis control, an axis related to composite control, or an axis related to superimposed control.
   The slave axis must not be a oscillation axis, a PMC axis, an axis related to arbitrary angular axis control, an axis related to synchronization control, an axis related to composite control, or an axis related to superimposed control.
5) If an attempt is made to issue one of G28/G30/G53 during synchronization, alarm PS0010 is issued. To issue one of G28/G30/G53, cancel synchronization first. By setting parameter FRF to 1, they can be issued for a master axis.
6) Parameters for use with synchronization (Nos. 5660 to 5667, 5670 to 5677, 5680 to 5687, and 5690 to 5693) can be set in a part program that uses programmable parameter input (G10).
   Note that changes made to the parameters for a group that is already in synchronization mode do not take effect immediately. For the changes made to the parameters to take effect, it is necessary to turn off synchronization mode and turn it back on.
7) With a synchronization pulse, the position display for a slave axis is updated as follows:
   - Machine position display is updated.
     (It is updated with the amount of travel after acceleration/deceleration and, therefore, the display may appear not to be in synchronization.)
   - Absolute position display and relative position display are not updated.
     At the cancellation of synchronization, absolute position display and relative position display for a slave axis are updated by adding the amount of travel due to synchronization.
     If, however, bits 0 (ACA) to 3 (ACD) of parameter No. 5668 are set to 1 so that the machine coordinates for that group are not updated, the above-mentioned machine coordinate display, absolute coordinate display, and relative coordinate display are not updated.
8) If, during automatic operation, the synchronization mode is turned from off to on, alarm PS5242 "ILLEGAL AXIS NUMBER" is issued if a master axis number or a slave axis number is not set correctly.
9) If, during automatic operation, the synchronization mode is turned from off to on, alarm PS5243, "DATA OUTRANGE" is issued if a gear ratio is not set correctly.
10) If, during automatic operation, the synchronization mode is turned from off to on or from on to off, alarm PS5244, "TOO MANY DI ON" is issued if the mode signal is turned on or off after an M code is executed.
11) For a synchronization group for which a PMC axis is a master axis, be sure to set the controlled axis selection signal EAXn<Gn136> for PMC axis control to "1" before turning on the synchronization mode.
12) For a synchronization group for which spindle control with servo motor or spindle control with Cs contour control is a master axis, be sure to turn on the SV speed mode of spindle control with servo motor before turning on the synchronization mode.
13) For a synchronization group for which a PMC axis or spindle control with servo motor is a master axis, be sure to turn on the synchronization mode with an M code during automatic operation.
    If an attempt is made to turn on the synchronization mode not during automatic operation, alarm PS5245, "OTHERAXIS ARE COMMANDED" is issued.

14) For a synchronization group for which a PMC axis or spindle control with servo motor is a master axis, AI contour control I and AI contour control II are automatically turned off from the time the synchronization mode is turned on until it is turned off. However, when inter-path flexible synchronization mode select signal OVLN<Gn531.4> is assumed to be "1", advanced preview feed forward of a slave axis can be made effective. Advanced preview feed forward of a slave axis is controlled by a mode or modal of a slave axis.
15) For a synchronization group for which a PMC axis or spindle control with servo motor is a master axis, be sure to turn on the synchronization mode first. Also, for a synchronization group for which a PMC axis or spindle control with servo motor is a master axis, be sure to turn off the synchronization mode last.
16) If an attempt is made to turn on a synchronization group for which an PMC axis or spindle control with servo motor is a master axis when there exists a synchronization group for which a non-PMC or non-spindle control with servo motor, normal axis is a master axis, alarm PS5245 is issued.
17) In the synchronization mode or when the mode is turned on, alarm PS5245 is issued in the following cases:
    - The master and slave axes as synchronization axes overlap the EGB dummy axis.
    - The master and slave axes as synchronization axes overlap the oscillation axis.
    - The master and slave axes as synchronization axes overlap the axis related to arbitrary angular axis control.
    - The master and slave axes as synchronization axes overlap the axis related to composite control.
    - The master and slave axes as synchronization axes overlap the axis related to superimposed control.
    - The slave axis as a synchronization axis overlaps the axis related to synchronization control.
    - The reference position return mode is turned on (was turned on).
18) If an SV alarm is issued, the synchronization mode is automatically turned off after a deceleration stop.
19) The output pulses for the master axis in detection units are multiplied by the gear ratio, and the result is regarded the output pulses for the slave axis.
20) To synchronize with a spindle, using a servo motor, it is necessary to adjust the loop gain of the servo motor to the spindle and make sure that the position deviations are equal.
21) Actual cutting feedrate display does not take synchronization pulses into consideration.
22) Before the synchronization mode can be turned on or off, the master and slave axes must be stopped. If an attempt is made to turn on or off the synchronization mode when the axes are not stopped, alarm PS5244 is issued.
23) Specify retract only for the master axis. Specifying retract for the slave axis prevents normal retract operations. Set the retract operation parameter to 0 for the slave axis.
24) A retract operation for the master axis comes to halt if any of the following conditions occurs when retract is under flexible synchronization control. As for emergency stop, servo alarm, and alarm PS5245, the retraction operation comes to halt only when they occur within the path to which the synchronization axis belongs.
    - Emergency stop
    - Servo alarm
    - Overtravel alarm（referenced for individual axes）
    - Servo off（referenced for individual axes; The path to which the synchronization axis belongs is caused to stop.）
    - Alarm PS5245（OTHERAXIS ARE COMMANDED）

> ⚠ **WARNING**
>
> If two or more flexible synchronization control pairs are linked as stated below, the highest-order master axis (X1 axis) can be caused to stop by referencing the stop condition of the second slave axis (X3 axis) as viewed from the highest-order master axis (X1 axis). However, the stop condition of the third slave axis (X4) cannot be referenced.
>
> | | Master axis | | Slave axis |
> |---|---|---|---|
> | First pair | X1（Path 1） | → | X2（Path 2） |
> | Second pair | X2（Path 2） | → | X3（Path 3） |
> | Third pair | X3（Path 3） | → | X4（Path 4） |

25) In case parameter ART (No.7702#3)=1, the retract operation of “General purpose retract” / “Flexible synchronization control” has been changed from conventional one to new one in order to realize the retract operation at alarm generating. When an alarm occurs, a new retract operation is shown as follows.

Alarm	Conventional retract Bit 3 (ART) of parameter No. 7702=0	Retract with an alarm is enable. Bit 3 (ART) of parameter No. 7702=1
PW alarm	All retract operation stops.	Retract operation does not stop.
DS alarm / IE alarm (Malfunction prevent functions is enable.)	All retract operation stops because PW alarm occurs after this alarm.	Only the axis where alarm occurs stops. All retract operation stops for non-axis type alarm.
SV alarm	All retract operation stops.	Only the axis where alarm occurs stops. All retract operation stops for non-axis type alarm.

26) The retract function with an alarm does not perform a retract operation on the retract axis if an overtravel alarm or a servo alarm occurs on the retract axis. The retract function with an alarm does not perform a retract operation on the retract axis if an overtravel alarm or a servo alarm occurs on the slave axis in case of flexible synchronization control.
27) If a new alarm is issued during retraction with the retract function with an alarm, a retract operation is not performed.
28) After the end of retraction with a servo alarm, servo position control stops in 400 ms.
29) Please set increment system of the master axis and the slave axis to the same setting. It becomes operation different from the set ratio of the gear when assuming a different setting.
30) Flexible synchronization control cannot be used together with speed command in PMC axis control (Speed control).

Parameter

5660	**Master axis number (group A)**
5661	**Slave axis number (group A)**
5662	**Master axis number (group B)**
5663	**Slave axis number (group B)**
5664	**Master axis number (group C)**
5665	**Slave axis number (group C)**
5666	**Master axis number (group D)**
5667	**Slave axis number (group D)**

[Input type] Parameter input
[Data Input type] Word path
[Valid data range] 0 to Number of controlled axes or m × 100+n
(m: 1 to Number of paths, n: 1 to Number of controlled axes)
Specify both master and slave axis numbers.
[Example of setting]
1 to 24: Controlled axes on own path (for single-path systems only)
101 to 124: Controlled axes on path 1
201 to 224: Controlled axes on path 2

In inter-path flexible synchronization control, an axis of a path can be specified as the master axis of another path.

NOTE
In inter-path flexible synchronization control, an axis of any path cannot be specified as the slave axis of another path.

	#7	#6	#5	#4	#3	#2	#1	#0
5668					ACD	ACC	ACB	ACA

[Input type] Parameter input
[Data Input type] Bit axis

#0 ACA Update of the machine coordinates of flexible synchronization control group A is:
0 : Executed.
1 : Not executed.

#1 ACB Update of the machine coordinates of flexible synchronization control group B is:
0 : Executed.
1 : Not executed.

#2 ACC Update of the machine coordinates of flexible synchronization control group C is:
0 : Executed.
1 : Not executed.

#3 ACD Update of the machine coordinates of flexible synchronization control group D is:
0 : Executed.
1 : Not executed.

NOTE
The machine coordinates update is not done though the slave axis operates on the motor.
In this case, if an automatic reference position return to origin is done after the synchronization mode is canceled, the alarm of DS0405, "ZERO RETURN END NOT ON REF" is issued.
Please use a manual reference position return to origin to do the return to origin.

5670	M code number for turning on the flexible synchronization control mode(group A)
5671	M code number for turning off the flexible synchronization control mode(group A)
5672	M code number for turning on the flexible synchronization control mode(group B)

5684	Numerator determining gear ratio for flexible synchronization(group C)
5685	Denominator determining gear ratio for flexible synchronization(group C)
5686	Numerator determining gear ratio for flexible synchronization(group D)
5687	Denominator determining gear ratio for flexible synchronization(group D)

[Input type] Parameter input
[Data Input type] 2 word path
[Valid data range] -99999999 to 99999999

Specify a gear ratio between the master and slave axes.

5690	Index to gear ratio denominator for flexible synchronization(group A)
5691	Index to gear ratio denominator for flexible synchronization(group B)
5692	Index to gear ratio denominator for flexible synchronization(group C)
5693	Index to gear ratio denominator for flexible synchronization(group D)

[Input type] Parameter input
[Data Input type] Byte path
[Valid data range] 0 to 8

Specify an index to the denominator of a gear ratio between the master and slave axes.
Let p, q, and k be, respectively, a denominator determining gear ratio for flexible synchronization, numerator determining gear ratio for flexible synchronization, and index to the gear ratio denominator for flexible synchronization:

The gear ratio is $\dfrac{q}{p \times 10^k}$

	#7	#6	#5	#4	#3	#2	#1	#0
7702					ART			

[Input type] Parameter input

[Data type] Bit path

#3 ART The retract function executed when an alarm is issued is:
0: Disabled.
1: Enabled.
When an alarm is issued, a retract operation is performed with a set feedrate and travel distance (parameters Nos. 7740 and 7741).

> **NOTE**
> If a servo alarm is issued for other than the axis along which a retract operation is performed, the servo activating current is maintained until the retract operation is completed.

	#7	#6	#5	#4	#3	#2	#1	#0
7703						ARO	ARE	

[Input type] Parameter input
[Data type] Bit path

#1 ARE In the retract function by an alarm, the tool retracts:
0: During the function mode (refer to NOTE.2) or automatic operation (automatic operation signal OP <Fn000.7> = “1”).
1: During the function mode (refer to NOTE.2).

#2 ARO In the retract function by an alarm, the tool retracts :
0: During the function mode (refer to NOTE.2).
1: During the function mode (refer to NOTE.2) and automatic operation (automatic operation signal OP = “1”).

> **NOTE**
> This parameter is effective when bit 1 (ARE) of parameter No. 7703 is set to 1.

The following table lists the parameter settings and corresponding operation.

ARE	ARO	Operation
1	0	During function mode
1	1	During function mode and automatic operation
0	0	During function mode or automatic operation
0	1	

> **NOTE**
> 1 Parameters ARE and ARO are valid when bit 3 (ART) of parameter No. 7702 is set to 1 (when the retract function executed when an alarm is issued).
> 2 The function mode described in the parameter ARE and ARO shows that the following functions are activated.
> - Electronic gear box(EGB)
> - Flexible synchronization control

	#7	#6	#5	#4	#3	#2	#1	#0
13421				FPA	FSV	FRF		

[Input type] Parameter input
[Data type] Bit path

> **NOTE**
> Set these parameters for the first path only. It will be effective to all paths.

#2 FRF If G27/G28/G29/G30/G53 is specified during flexible synchronization control, alarm PS0010 is:
0: Issued.
1: Is not issued. Commands to the master axis are possible.
Even if, however, parameter bit FRF is set to 1, and G28 is specified for the master axis in the state in which the reference position of the master axis subject to flexible synchronization control is not established, or if G27/G28/G29/G30/G53 is specified for the slave axis, alarm PS5381 is issued.

#3 FSV When the axis related to synchronization is servo off state while flexible synchronization control or inter-path flexible synchronization control, an automatic operation is:
0: Stopped.
1: Stopped if the axis related to synchronization moves.

> **NOTE**
> In inter-path flexible synchronization control, this parameter becomes effective when parameter FCN (No.13421#1) is set to 1.

#4 FPA For a synchronization group for which a PMC axis is a master axis, when the controlled axis selection signal EAXn<Gn136> for PMC axis control is set to "1" after starting flexible synchronization control mode, and the master axis is specified by PMC axis control, or for a synchronization group for which spindle control with servo motor is a master axis, when SV speed control mode of the master axis is turned on after starting flexible synchronization control mode:
0: Alarm is not generated.
1: Alarm PS5381 ”INVALID COMMAND IN FSC MODE” is generated.

This function generates the alarm when flexible synchronization control is operated by in the incorrect procedure.

> ⚠**CAUTION**
> When this parameter is set to 0, it operates without generating the alarm even if flexible synchronization control mode is started according to a procedure not correct. However, the position shift of a slave axis may occur.

Signal

Flexible synchronization control mode selection signals MTA,MTB,MTC,MTD <Gn197.0 to Gn197.3>

[Classification] Input signal
[Function] These signals select flexible synchronization control.
[Operation] 1) Synchronization is started by setting one of these signals to "1".
2) Synchronization is canceled by setting one of these signals to "0".
MTA: Synchronization of group A is selected.
MTB: Synchronization of group B is selected.

MTC: Synchronization of group C is selected.
MTD: Synchronization of group D is selected.

Flexible synchronization control mode status signals
MFSYNA, MFSYNB, MFSYNC, MFSYND <Fn197.0 to Fn197.3>

[Classification] Output signal

[Function] These signals are used to check that the groups selected with the flexible synchronization control mode selection signals are actually switched to that mode.

[Operation]
1) When the synchronization mode actually becomes effective to a group, the corresponding one of these signals is set to "1".
2) When the synchronization mode is actually canceled for a group, the corresponding one of these signals is set to "0".

MFSYNA: Group A is in the synchronization mode.
MFSYNB: Group B is in the synchronization mode.
MFSYNC: Group C is in the synchronization mode.
MFSYND: Group D is in the synchronization mode.

Signal address

Alarm and message

Number	Message	Description
PS0010	IMPROPER G-CODE	In case parameter FRF (No.13421#2)=1, One of G27/G28/G29/G30/G30/G53 is commanded to a master axis or a slave axis in flexible synchronization control mode.
PS5242	ILLEGAL AXIS NUMBER	A master axis number or a slave axis number was not set correctly when the flexible synchronization control mode was turned from off to on during automatic operation.
PS5243	DATA OUTRANGE	A gear ratio was not set correctly when the flexible synchronization control mode was turned from off to on during automatic operation.
PS5244	TOO MANY DI ON	- During automatic operation, the mode signal was not turned on or off if the flexible synchronization control mode was turned from off to on or from on to off, after an M code was executed. - An attempt was made to turn on or off the flexible synchronization control mode when the axis was not stopped.

Number	Message	Description
PS5245	OTHERAXIS ARE COMMANDED	- For a flexible synchronization control group for which a PMC axis or spindle control with servo motor was a master axis, an attempt was made to turn on the synchronization mode during time other than automatic operation. - An attempt was made to turn on a synchronization group for which an PMC axis or spindle control with servo motor was a master axis when there existed a flexible synchronization control group for which a non-PMC or non-spindle control with servo motor, normal axis was a master axis. - The master and slave axes as synchronization axes overlap the EGB dummy axis. - The master and slave axes as synchronization axes overlap the oscillation axis. - The master and slave axes as synchronization axes overlap the axis related to arbitrary angular axis control. - The master and slave axes as synchronization axes overlap the axis related to composite control. - The master and slave axes as synchronization axes overlap the axis related to superimposed control. - The slave axis as a synchronization axis overlaps the axis related to synchronization control. - The reference position return mode is turned on (was turned on).
PS5381	INVALID COMMAND IN FSC MODE	An attempt was made to issue the following commands: - When the reference position for the master axis under flexible synchronization control has not been established, G28 command for the master axis. - G27/G28/G29/G30/G53 command for a slave axis.
DS405	ZERO RETURN END NOT ON REF	In case parameter ACA to ACD (No.5668#0 to #3)=1, a slave axis is executed an automatic reference position return after canceling synchronization mode. Please use a manual reference position return to origin to do the return to origin.

1.12.2 Automatic Phase Synchronization for flexible synchronization Control

Overview

This function applies acceleration/deceleration when the start or cancellation of synchronization is specified in flexible synchronization control.

This acceleration/deceleration allows synchronization to be started or canceled while the tool is moving along the master axis.

This function can also execute automatic phase synchronization so that the slave axis machine coordinate position at the start of synchronization matches the machine coordinate system zero point of the master axis (the machine coordinate is 0).

Acceleration/deceleration

When bit 0 (PHA) to 3 (PHD) of parameter No. 5669 is set to 1, acceleration/deceleration is applied when the start or cancellation of synchronization is specified.

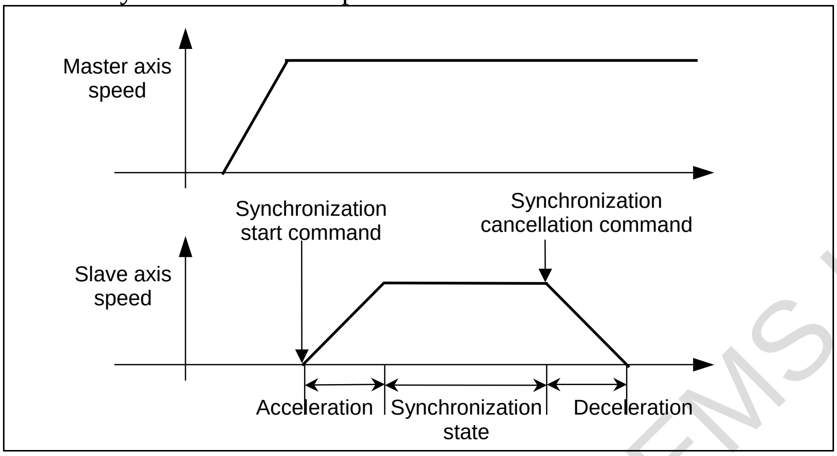

Fig. 1.12.2 (a)

Synchronization start
Command sequence

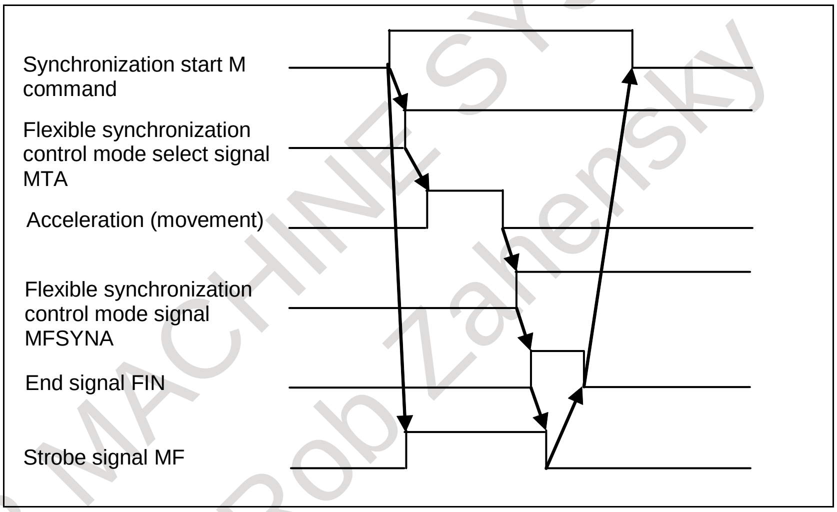

Fig. 1.12.2 (b)

1. When the M code for turning the synchronization control mode on is specified, and the flexible synchronization control mode selection signal MTA, MTB, MTC, or MTD which corresponds to the M code is set to "1", synchronization starts.
2. The tool moves along the slave axis at the acceleration rate set in parameters Nos. 1420 and 13425 to 13428. Once the synchronization feedrate is reached, the flexible synchronization control mode status signal MFSYNA, MFSYNB, MFSYNC, or MFSYND becomes "1".
3. When the flexible synchronization control mode status signal becomes "1", the completion of the M code for starting synchronization is returned.

Synchronization cancellation
Command sequence

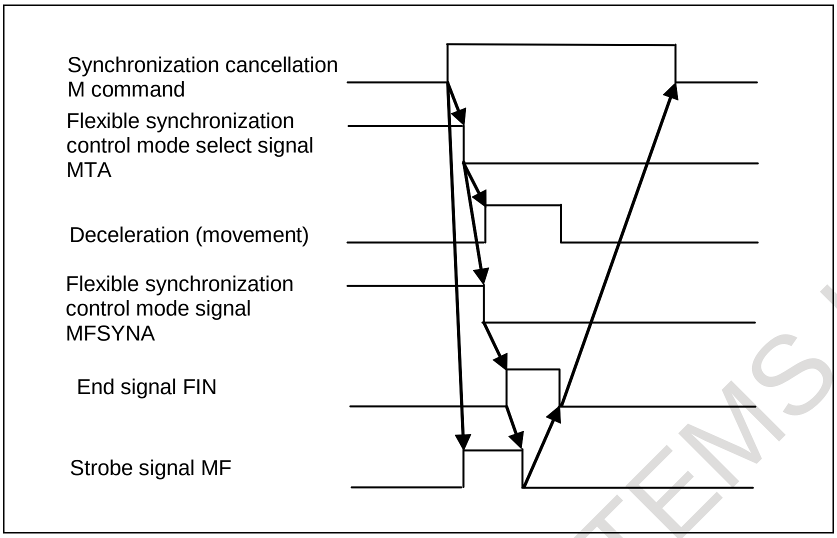

Fig. 1.12.2 (c)

1. Move the tool away from the workpiece before cancellation.
2. When the M code for turning the flexible synchronization control mode off (canceling synchronization) is specified, and the flexible synchronization control mode selection signal which corresponds to the M code is set to "0", synchronization cancellation starts. The tool decelerates along the slave axis at the acceleration rate set in parameters Nos. 1420 and 13425 to 13428.
3. When deceleration starts, the flexible synchronization control mode status signal becomes "0".
4. The completion of the M code for canceling synchronization is returned.

NOTE
1 Linear acceleration/deceleration is applied to synchronization start/cancellation.
2 When time constant parameters No. 13425 to 13428 are 0, acceleration/deceleration is not applied.
3 The next block is not executed until deceleration is completed during automatic operation.

Automatic phase synchronization

When bit 0 (PHA) to 3 (PHD) of parameter No. 5669 is set to 1, and the flexible synchronization control automatic phase synchronization signal AUTPHA, AUTPHB, AUTPHC, or AUTPHD is set to "1", automatic phase synchronization is executed after acceleration/deceleration applied at the start of synchronization is completed. Phase synchronization is automatically executed so that the slave axis machine coordinate position at the start of synchronization (when the flexible synchronization control mode selection signal is set to "1") matches the machine coordinate system zero point of the master axis (the machine coordinate is 0).
When automatic phase synchronization for flexible synchronization control is enabled, acceleration/ deceleration is applied when the start or cancellation of synchronization is specified.

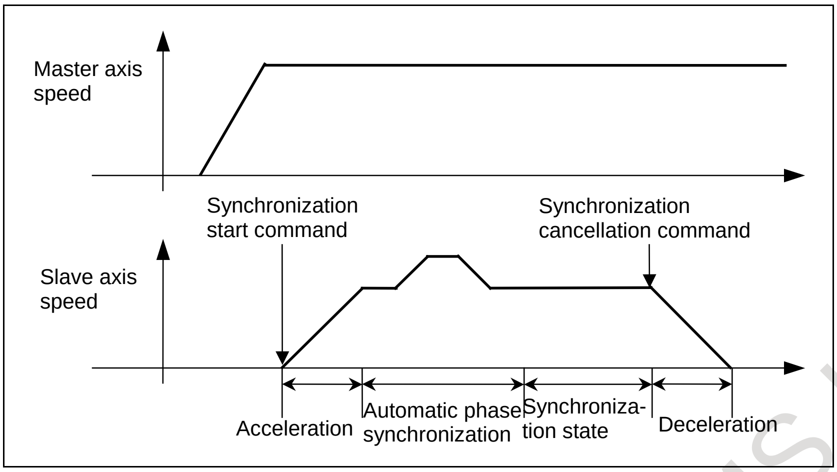

Fig. 1.12.2 (d)

Command sequence

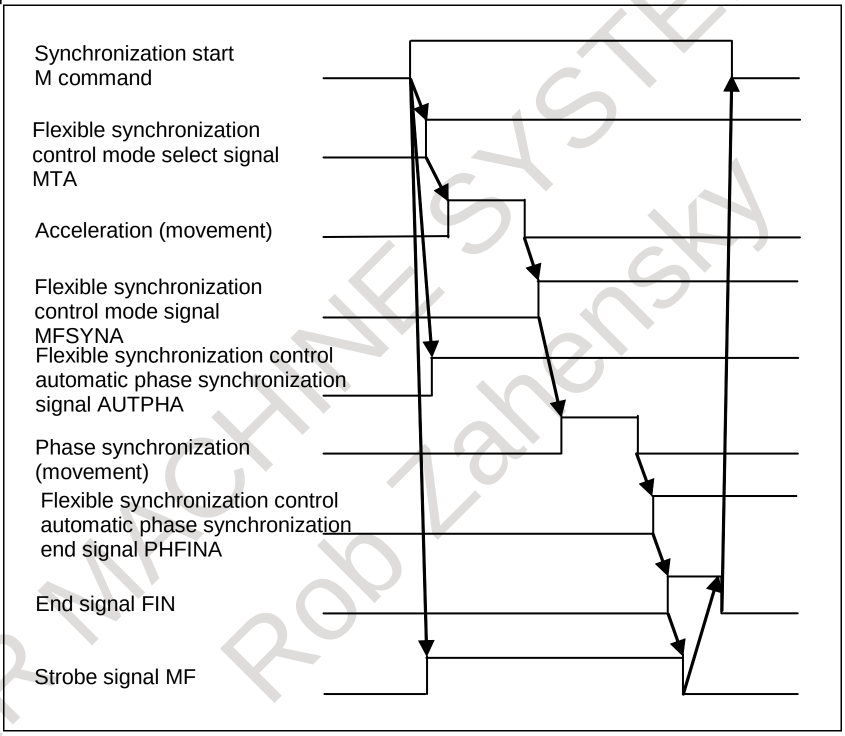

Fig. 1.12.2 (e)

1. When the M code for turning the flexible synchronization control mode on is specified, and the flexible synchronization control mode selection signal which corresponds to the M code is set to "1", synchronization starts.
   The flexible synchronization control automatic phase synchronization signal is also set to "1".
2. The tool moves along the slave axis at the acceleration rate set in parameters Nos. 1420 and 13425 to 13428.
3. Once the synchronization feedrate is reached, the flexible synchronization control mode status signal becomes "1".
4. When the flexible synchronization control mode status signal becomes "1", phase synchronization is executed automatically.
5. When phase synchronization is completed, the flexible synchronization control phase synchronization end signal PHFINA, PHFINB, PHFINC, or PHFIND becomes "1".
6. When the flexible synchronization control phase synchronization end signal becomes "1", the completion of the M code for starting synchronization is returned.

> **NOTE**
> 1 Set the feedrate in automatic phase synchronization in parameters Nos. 13429 to 13432.
> 2 Specify the movement direction for automatic phase synchronization in bit 0 (DIA) to 3 (DID) of parameter No. 13420. (Rotation axis only)
> 3 Linear acceleration/deceleration is applied to automatic phase synchronization. (The acceleration rate is the same as that at the synchronization start or cancellation.)
> 4 The feedrate along the slave axis is obtained by superposing the feedrate in automatic phase synchronization onto the feedrate in synchronization with the movement along the master axis. In consideration of this superposition, set a position deviation limit in parameter No. 1828.
> 5 By setting parameters Nos. 13433 to 13436, the position at which the phase of the slave axis is matched can be shifted from the machine coordinate system zero point of the master axis.
> 6 If the automatic phase synchronization signal is set to "0", then "1" again during synchronization, automatic phase synchronization is executed again.
> 7 When the flexible synchronization control automatic phase synchronization signal is set to "1" during synchronization (when the flexible synchronization control mode status signal is "1"), automatic phase synchronization is also executed if the tool does not move along the master axis. The tool moves only along the slave axis.

Change of a gear ratio

A gear ratio can be changed during automatic operation by changing values of parameters for the gear ratio (parameters Nos.5680 to 5687 and 5690 to 5693) using programmable parameter input (G10).

> **NOTE**
> 1 When the values of the parameters for a gear ratio are changed, the flexible synchronization control mode status signal becomes "0", and acceleration /deceleration is applied. When the synchronization feedrate is reached, the signal becomes "1" again.
> 2 If automatic phase synchronization is executed after a gear ratio is changed, the position for automatic phase synchronization is as follows:
> Master axis: Machine coordinate system zero point
> (value set in parameters Nos. 13433 to 13436)
> Slave axis: Position when synchronization starts
> (when the flexible synchronization mode selection signal is set to "1")
> 3 If you want to change the values of the parameters for two or more gear ratios, stop the machine before changing them.

Speed-up of automatic phase synchronization

During accelerating of a slave axis that begins synchronization, automatic phase synchronization or decelerating of the slave axis that cancels synchronization, it is possible to command other program. This function is enabled to set the bit 1 (PHS) of parameter No.5694 to 1.

(1) During accelerating of a slave axis that begins synchronization

In command of M code for beginning synchronization, when flexible synchronization control mode selecting signals FSYSA, FSYSB, FSYSC, FSYSD <Fn553.4, Fn553.5, Fn553.6, Fn553.7> is ‘1’, it is possible to return end signal FIN <Gn004.3>. It is possible to command programs though a slave axis is accelerating until flexible synchronization control mode status signals MFSYNA, MFSYNB, MFSYNC, MFSYND <Fn197.0, Fn197.1, Fn197.2, Fn197.3> are "1" after being set flexible synchronization control mode selecting signal to "1".

(2) During automatic phase synchronization

When flexible synchronization control automatic phase synchronization signals AUTPHA, AUTPHB, AUTPHC, AUTPHD <Gn381.0 to Gn381.3> are set to "1" by M code In automatic operation, it is possible to return end signal FIN <Gn004.3> at once. When flexible synchronization control automatic phase synchronization signals are set to "1" by M code for turning on synchronization, return end signal after being set flexible synchronization control mode selecting signal to "1". It is possible to command programs though a slave axis is accelerating or decelerating until flexible synchronization control phase synchronization end signals PHFINA, PHFINB, PHFINC, PHFIND <Fn381.0 to Fn381.3> is "1" after being set flexible synchronization control automatic phase synchronization signal to "1". In previous in the block that would like to be executed with a master axis suitable for the phase of a slave axis, confirm flexible synchronization control phase synchronization end signal.

(3) During decelerating of a slave axis that cancels synchronization

Meanwhile, other program instructions can be executed by decelerating a slave axis for canceling synchronization before instruction M code of canceling synchronization (Parameters No.5671, No.5673, No.5675 and No.5677). Parameter No.5696 is set decelerating start M code for turning off synchronization. When M code for beginning deceleration for turning off synchronization is specified, the deceleration of the slave axis is begun. The block of M code for beginning deceleration for turning off synchronization finishes at once, and advances to next block. It is possible to command programs though a slave axis is decelerating until executing M code for turning off synchronization after executing deceleration start M code for turning off synchronization. M code for beginning deceleration for turning off synchronization can be executed in two or more M codes in one block.

Hob command by flexible synchronization control

When G81 or G81.4 for turning on synchronization is specified, the block of instruction is finished at once, and advances to next block. It is possible to command programs though a slave axis is accelerating to synchronous speed until flexible synchronization control mode status signal is "1". During decelerating of a slave axis that cancels synchronization and automatic phase synchronization are similar to usual flexible synchronization control.

NOTE

1. When a master axis or slave axis would like to specify in finished synchronization, confirm flexible synchronization control mode status signal.
2. When a master axis or slave axis would like to specify in finished phase synchronization, confirm flexible synchronization control phase synchronization end signal.
3. Decelerating start M code for turning off synchronization (Parameter No.5696) does not output code signal and strobe signal.
4. When decelerating start M code for turning off synchronization is specified, synchronization cannot begin again if synchronization can begin again only after it is cancelled first. When a gear ratio is changed after specifying decelerating start M code for turning off synchronization, alarm PS5381 "INVALID COMMAND IN FSC MODE" is issued.

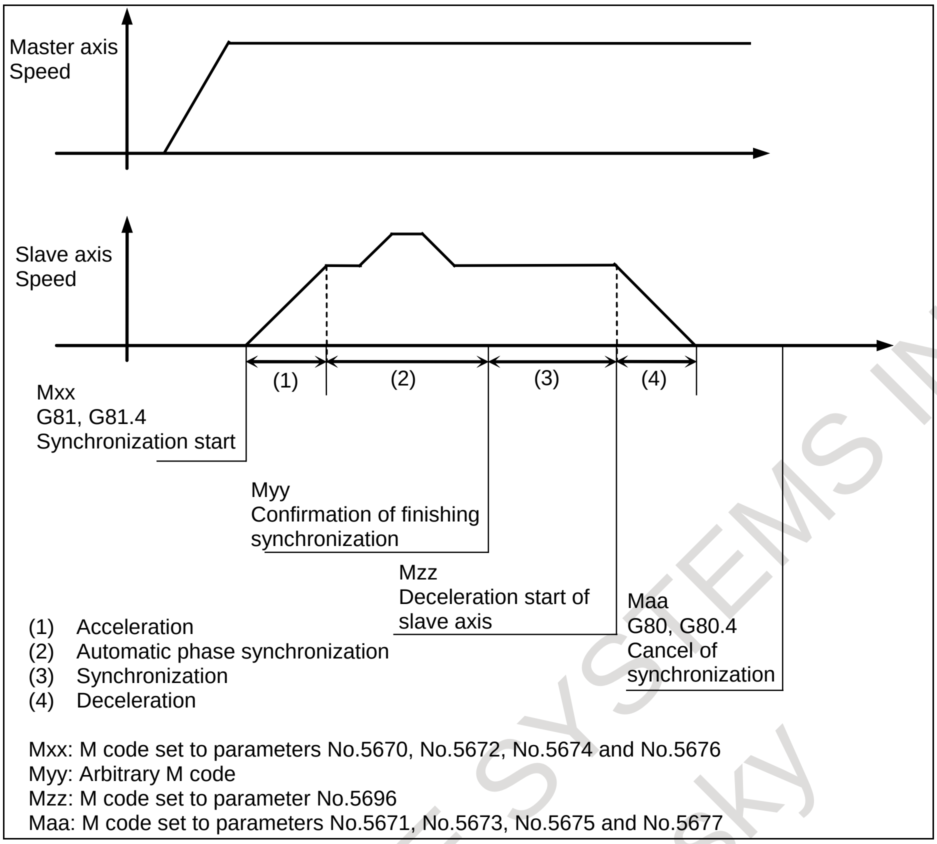

Fig. 1.12.2 (f) Type of acceleration / deceleration and automatic phase synchronization

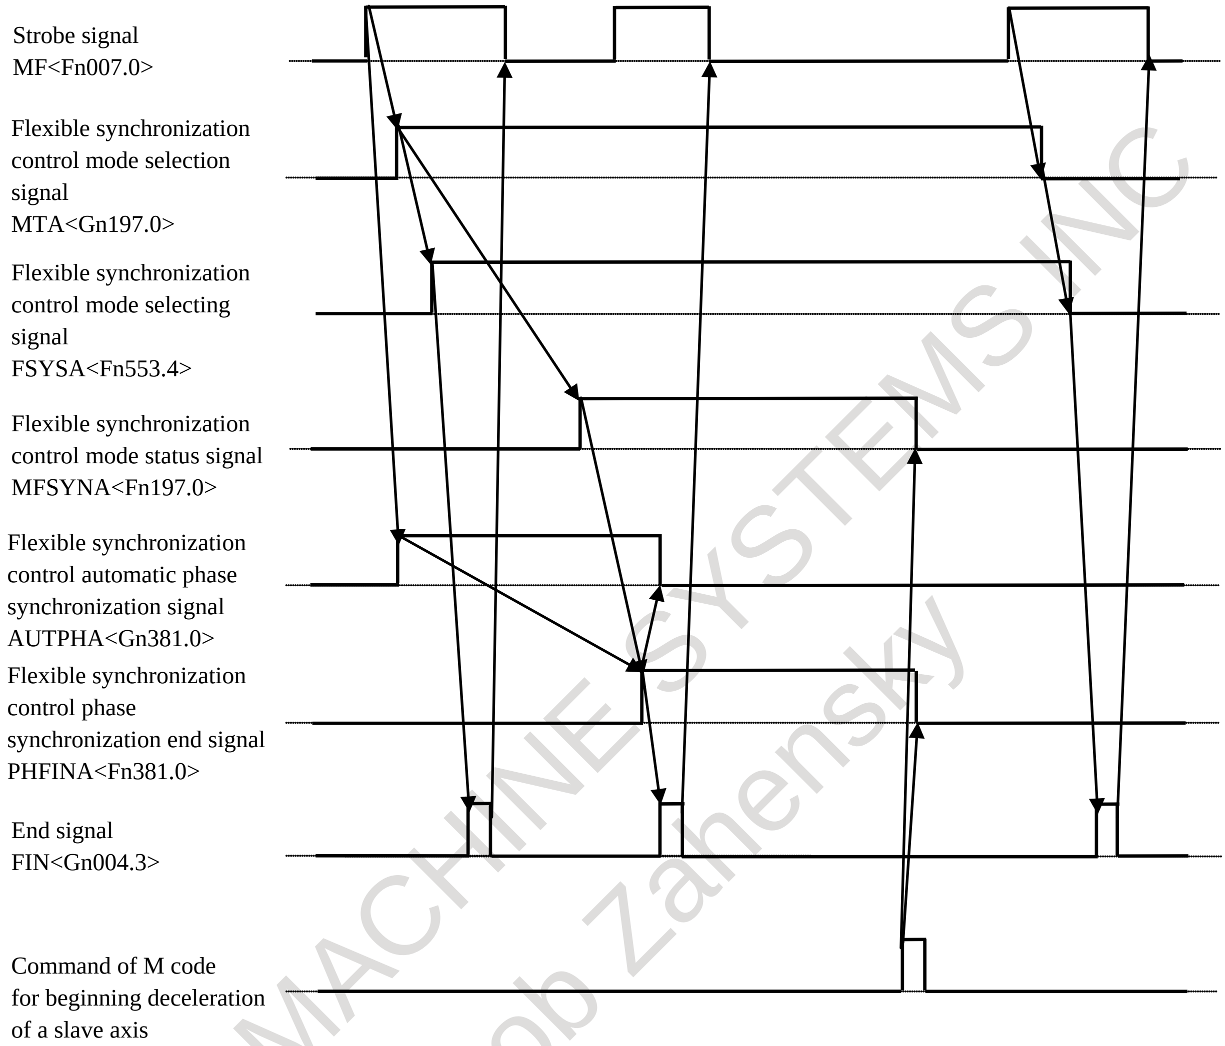
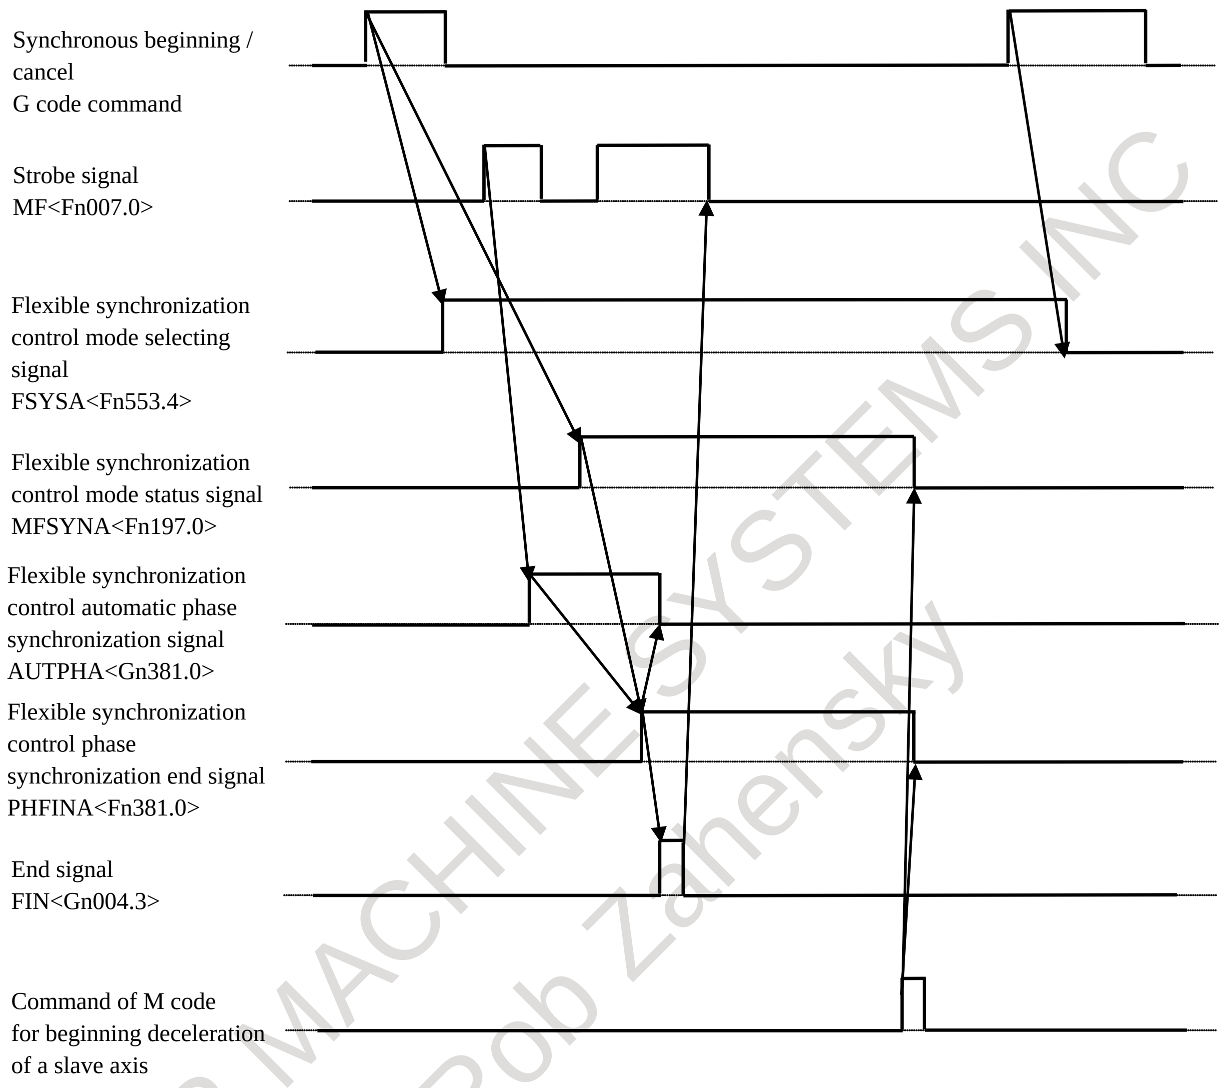
Example of time chart high speed type for acceleration / deceleration and automatic phase synchronization



Example of time chart high speed type for acceleration / deceleration and automatic phase synchronization (Hob command)



Signal

Flexible synchronization control mode selection signals MTA, MTB, MTC, MTD <Gn197.0 to Gn197.3>

[Classification] Input signal

[Function] These signals select flexible synchronization control.

[Operation]
1) Synchronization starts when these signals become "1".
2) Synchronization is canceled when these signals become "0".

MTA: Selects synchronization for group A.
MTB: Selects synchronization for group B.
MTC: Selects synchronization for group C.
MTD: Selects synchronization for group D.

Flexible synchronization control mode status signals MFSYNA, MFSYNB, MFSYNC, MFSYND <Fn197.0 to Fn197.3>

[Classification] Output signal

[Function] These signals check whether the group selected by a flexible synchronization control mode selection signal has actually entered the mode.

[Operation] These signals become "1" when:

- Acceleration/deceleration is applied at the start of synchronization and the synchronization feedrate is reached.

These signals become "0" when:

- Deceleration starts at synchronization cancellation.
- The gear ratio is changed during automatic operation.

MFSYNA: Synchronization select switching for group A has been accepted.
MFSYNB: Synchronization select switching for group B has been accepted.
MFSYNC: Synchronization select switching for group C has been accepted.
MFSYND: Synchronization select switching for group D has been accepted.

Flexible synchronization control automatic phase synchronization signals
AUTPHA, AUTPHB, AUTPHC, AUTPHD <Gn381.0 to Gn381.3>

[Classification] Input signal

[Function] These signals select automatic phase synchronization for flexible synchronization control.

[Operation] When these signals are "0", automatic phase synchronization is not executed.
When these signals are "1", automatic phase synchronization is executed after acceleration/deceleration applied at the start of synchronization start is completed.
(When the flexible synchronization control mode status signal is "1", automatic phase synchronization is executed.)
When these signals are set to 0, then "1" again during synchronization, automatic phase synchronization is executed again.

AUTPHA: Selects automatic phase synchronization for group A.
AUTPHB: Selects automatic phase synchronization for group B.
AUTPHC: Selects automatic phase synchronization for group C.
AUTPHD: Selects automatic phase synchronization for group D.

Flexible synchronization control phase synchronization end signals
PHFINA, PHFINB, PHFINC, PHFIND <Fn381.0 to Fn381.3>

[Classification] Output signal

[Function] These signals notify that automatic phase synchronization for flexible synchronization control is completed.

[Operation] These signals become "1" when:

- Automatic phase synchronization is completed.

These signals become "0" when:

- The flexible synchronization control mode status signal becomes "0".

PHFINA: Notifies that automatic phase synchronization for group A is completed.
PHFINB: Notifies that automatic phase synchronization for group B is completed.
PHFINC: Notifies that automatic phase synchronization for group C is completed.
PHFIND: Notifies that automatic phase synchronization for group D is completed.

Flexible synchronization control mode selecting signals
FSYSA, FSYSB, FSYSC, FSYSD <Fn553.4 to Fn553.7>

[Classification] Output signal

[Function] These signals notify that the change to flexible synchronization control mode is begun.

[Operation] These signals become "1" when:

- The change to flexible synchronization control mode is begun.

These signals become "0" when:

- Flexible synchronization control mode is canceled

> **NOTE**
> If the bit 1 (PHS) of parameter No.5694 is set to 1, this signal is enabled.

1: Enabled.

5696	M code for beginning deceleration for canceling synchronization

[Input type] Parameter input
[Data type] 2 Word path
[Valid data range] 0 to 99999999

This parameter set M code for beginning deceleration for canceling synchronization.
The M code of group A : Number set to this parameter
The M code of group B : Number set to this parameter + 1
The M code of group C : Number set to this parameter + 2
The M code of group D : Number set to this parameter + 3
When this parameter is set to 0, the M code is disabled.

> **NOTE**
> 1 If the bit 1 (PHS) of parameter No.5694 is set to 1, this parameter is enabled.
> 2 Do not set an M code used with other functions (such as M00-05, 30, 98, and 99, and M codes for calling subprograms).

	#7	#6	#5	#4	#3	#2	#1	#0
13420					DID	DIC	DIB	DIA

[Input type] Parameter input
[Data type] Bit path

#0 DIA The movement direction of the automatic phase synchronization of group A is:
0: + direction.
1: - direction.

#1 DIB The movement direction of the automatic phase synchronization of group B is:
0: + direction.
1: - direction.

#2 DIC The movement direction of the automatic phase synchronization of group C is:
0: + direction.
1: - direction.

#3 DID The movement direction of the automatic phase synchronization of group D is:
0: + direction.
1: - direction.

13425	Acceleration/deceleration time constant of the slave axis when synchronization is started/canceled (group A)

13426	Acceleration/deceleration time constant of the slave axis when synchronization is started/canceled (group B)

13427	Acceleration/deceleration time constant of the slave axis when synchronization is started/canceled (group C)

13428	Acceleration/deceleration time constant of the slave axis when synchronization is started/canceled (group D)

[Input type] Parameter input
[Data type] Word path
[Unit of data] msec
[Valid data range] 0 to 4000

These parameters set the acceleration/deceleration time constants of the slave axis subject to automatic phase synchronization for flexible synchronization control.
The acceleration when synchronization is started/canceled will be as follows:
Acceleration = parameter No.1420 / parameters Nos.13425 to 13428

13429	Automatic phase synchronization feedrate for the slave axis (group A)

13430	Automatic phase synchronization feedrate for the slave axis (group B)

13431	Automatic phase synchronization feedrate for the slave axis (group C)

13432	Automatic phase synchronization feedrate for the slave axis (group D)

[Input type] Parameter input
[Data type] Real path
[Unit of data] mm/min, inch/min, deg/min (machine unit)
[Min. unit of data] Depend on the increment system of the applied axis
[Valid data range] Refer to the standard parameter setting table (C)
(When the increment system is IS-B, 0.0 to +999000.0)

These parameters set the automatic phase synchronization feedrates for the slave axis subject to automatic phase synchronization.
These feedrates are superimposed on the feedrate synchronized to the master axis.
If the setting of one of the parameters is 0, the automatic phase synchronization feedrate for the corresponding group will be 6 (mm/min).

13433	Machine coordinates of the master axis used as the reference for phase synchronization (group A)

13434	Machine coordinates of the master axis used as the reference for phase synchronization (group B)

13435	Machine coordinates of the master axis used as the reference for phase synchronization (group C)

13436	Machine coordinates of the master axis used as the reference for phase synchronization (group D)

[Input type] Parameter input
[Data type] Real path
[Unit of data] mm, inch, deg (machine unit)
[Min. unit of data] Depend on the increment system of the applied axis
[Valid data range] 9 digit of minimum unit of data (refer to standard parameter setting table (A))
(When the increment system is IS-B, -999999.999 to +999999.999)

These parameters set the machine coordinates of the master axis used as the reference for phase synchronization. If the setting of this parameter is 0, the origin position (coordinates: 0) of the machine coordinate system of the master axis will be the reference position for automatic phase synchronization.

Alarm and message

Number	Message	Description
PS5242	ILLEGAL AXIS NUMBER	- A master axis number or a slave axis number was not set correctly when the flexible synchronization control mode was turned from off to on during automatic operation. - Automatic phase synchronization is effective, and a set increment system of the master axis and the slave axis is different. - Automatic phase synchronization is effective, and the setting of the rotation axis of the master axis or the slave axis is illegal.
PS5381	INVALID COMMAND IN FSC MODE	- The gear ratio is changed without canceling synchronization after specifying M code of beginning deceleration for canceling synchronization.

Notes

NOTE

1 The next block is not executed until acceleration/deceleration at the start or cancellation of synchronization is completed during automatic operation.
2 Due to an error produced when the output pulses for the slave axis are calculated, the phase of the slave axis may not be matched by least input increment. This error is not accumulated.
3 If a retract operation is performed during automatic phase synchronization, the automatic phase synchronization is stopped and the retract operation is performed. After the completion of the retract operation, restarting the program resumes the automatic phase synchronization. However, no request for automatic phase synchronization is accepted during a retract operation.
4 It is necessary to set increment system of the master axis and the slave axis to the same setting. If flexible synchronization is started when it is different setting, alarm PS5242 "OTHER AXIS ARE COMMANDED" is issued.
5 When the master axis and the slave axis are the following settings, automatic phase match cannot be used. If flexible synchronization is started, alarm PS5242 "OTHER AXIS ARE COMMANDED" is issued.
   - Either the master axis or the slave axis is rotation axis, and the type of rotation axis is A type.
   - Both the master axes and the slave axes are the rotation axes, and the type of the rotation axis is different.
   - Both the master axes and the slave axes are the rotation axes of type A, and the value of parameter No.1260 is different.

1.12.3 Variable Acceleration Function in Automatic Phase Synchronization for Flexible Synchronization Control

Outline

In automatic phase synchronization for flexible synchronization control, acceleration of slave axis can be changed depending on the speed in during synchronization start/cancellation.

Explanation

Over the base speed, output characteristic of a spindle motor is constant and its torque characteristic decreases in inverse proportion to the speed. Therefore if the target speed is over the base speed in the linear acceleration pattern, low acceleration must be set depending on torque characteristic at the target speed, and motor torque can not be used efficiently in the low speed area. If this variable acceleration function is used, the acceleration is constant (specified by parameter No.7778) in lower speed area than parameter No.5697 and the acceleration decreases in inverse proportion to the speed in higher speed area than parameter No.5697. To use this function, set the parameter PAV(No.5694#2) to 1.

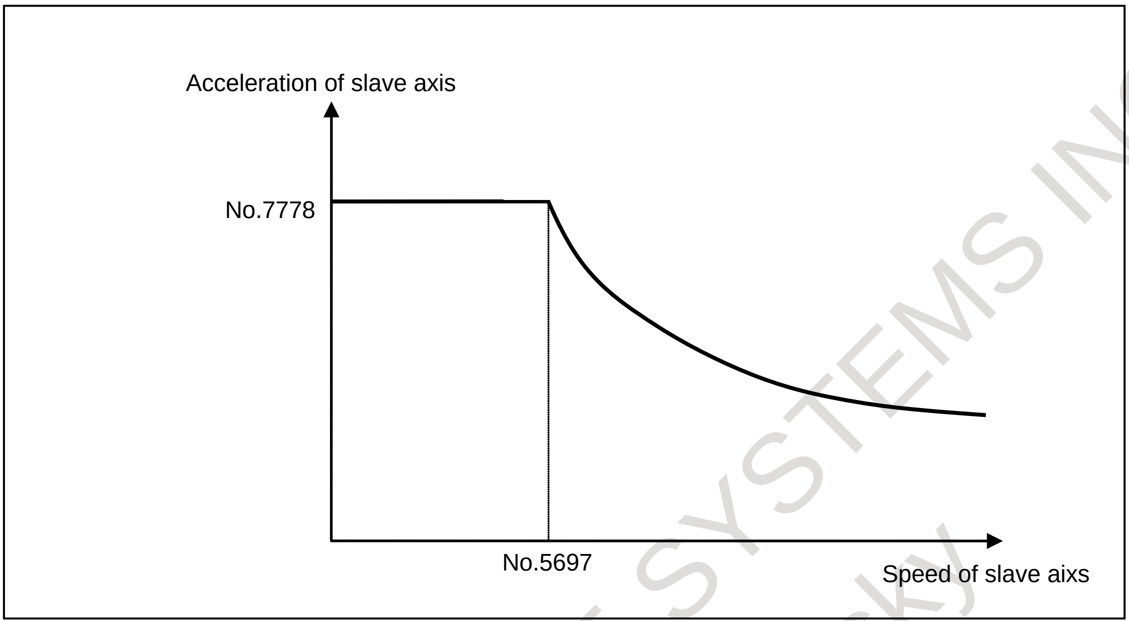

Fig. 1.12.3 (a) Acceleration of slave in synchronization start/cancellation

Speed of slave axis

Speed of slave axis used for acceleration calculation of this function is the number of rotation calculated by the shift amount per one rotation of a rotary axis specified by the parameter No.1260. Set the value to parameter No.5697 considering this calculation.

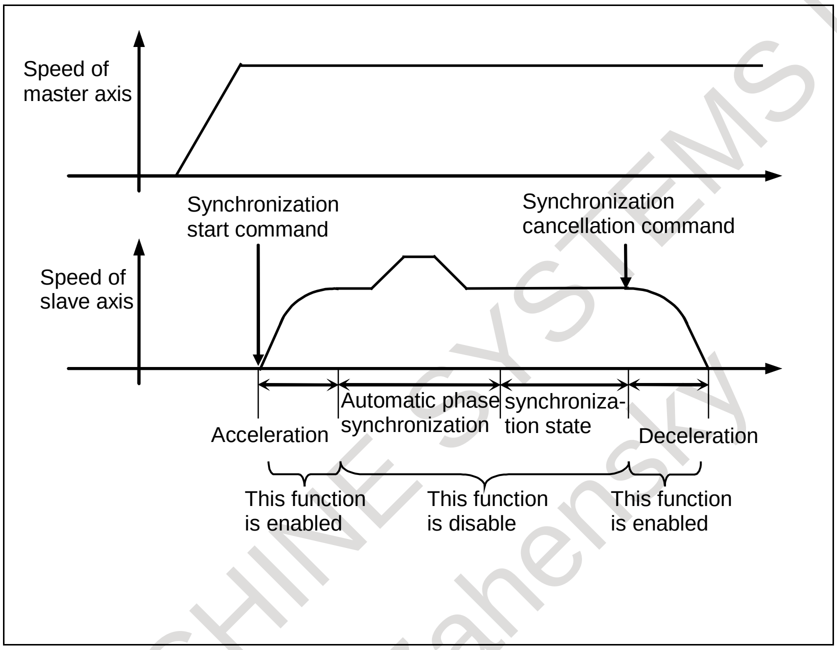
Acceleration in higher speed area than parameter No.5697

The acceleration decreases in inverse proportion to the speed. The acceleration is as follows:

$$\text{Acceleration} = \text{Parameter No.7778} \times \frac{\text{Parameter No.5697}}{\text{Current speed}}$$

NOTE

1 To use this function, the axes related to the synchronization must be rotary axes A type.
2 If 0 or less is set to parameter No.7778, this function is disabled.
3 If 0 or less is set to parameter No.5697, constant acceleration (specified by parameter No.7778) is applied in all speed area.
4 This function is valid in acceleration/deceleration of synchronization start/cancellation. This function is invalid in acceleration/deceleration of automatic phase synchronization.



Parameter

	#7	#6	#5	#4	#3	#2	#1	#0
5694						PAV		

[Input type] Parameter input
[Data type] Bit path

NOTE
When this parameter is set, the power must be turned off before operation is continued.

#2 PAV Variable acceleration function in automatic phase synchronization for flexible synchronization control is:
0: Disabled.
1: Enabled.

5697	Acceleration switch speed of slave axis in synchronization start/cancellation

[Input type] Parameter input
[Data type] 2-word axis
[Unit of data] min^{-1}

[Valid data range] 0 to 99999999

This parameter set the acceleration switch speed of slave axis in synchronization start/cancellation. If 0 or less is set to this parameter, constant acceleration (specified by parameter No.7778) is applied in all speed area.

> **NOTE**
> This parameter is valid If 1 is set to the parameter PAV(No.5694#2).

7778	Acceleration of slave axis in synchronization start/cancellation

[Input type] Parameter input
[Data type] Real axis
[Unit of data] mm/sec^2, inch/ sec^2, deg/sec^2
[Minimum unit of data] Depend on the increment system of the applied axis
[Valid data range] Refer to the standard parameter setting table (D)
(For a millimeter machine, 0.0 to +100000.0, for an inch machine, 0.0 to +10000.0)

When variable acceleration function in automatic phase synchronization for flexible synchronization control is valid (PAV(No.5694#2)=1), this parameter sets acceleration of slave axis in synchronization start/cancellation. If 0 or less is set to this parameter, variable acceleration function in automatic phase synchronization for flexible synchronization control is disabled.

1.12.4 Synchronization Positional Difference Detection Diagnosis Display and Signal Output in Flexible Synchronization Control

Overview

This function displays the diagnosis data and outputs DO signal <Fn533> for confirming error of between master axis and slave axis after executing automatic phase synchronization for flexible synchronization control.

Diagnosis data

Error (parameters Nos. 5600 to 5603) and maximum error (parameters Nos. 5604 to 5607) between master axis and slave axis after executing automatic phase synchronization are displayed.

Output signal

If a positional error detected after automatic phase synchronization exceeds any of the settings of parameters Nos. 13437 to 13440 (threshold values for phase synchronization positional error detection signal output), the DO signal <Fn553> is output.

Signal

Automatic phase synchronization error detection signals PHERA, PHERB, PHERC, PHERD <Fn553.0-Fn553.3>

[Classification] Output signal

[Function] This signal can be used to check whether an automatic phase synchronization positional difference has exceeded the setting of parameters Nos. 13437 to 13440 (threshold values for automatic phase synchronization positional error detection signal output).

This signal becomes "1" when:

- Error of automatic phase synchronization excess threshold values.

This signal becomes "0" when:

- Error of automatic phase synchronization does not excess threshold values.

- Flexible synchronization control phase synchronization end signal PHFINA, PHFINB, PHFINC, PHFIND <Fn381.0-Fn381.3> is "0".

Signal address

	#7	#6	#5	#4	#3	#2	#1	#0
Fn553					PHERD	PHERC	PHERB	PHERA

Parameter

13437	Threshold value for automatic phase synchronization error detection signal output (group A)
13438	Threshold value for automatic phase synchronization error detection signal output (group B)
13439	Threshold value for automatic phase synchronization error detection signal output (group C)
13440	Threshold value for automatic phase synchronization error detection signal output (group D)

[Input type] Parameter input
[Data type] Real path
[Unit of data] mm, inch, deg (machine unit)
[Min. unit of data] Depend on the increment system of the reference axis
[Valid data range] 0 or positive 9 digit of minimum unit of data (refer to the standard parameter setting table (B))
(When the increment system is IS-B, 0.000 to +999999.999)

If error between master axis and slave axis after executing automatic phase synchronization for flexible synchronization control, automatic phase synchronization error detection signal PHERA, PHERB, PHERC, PHERD is turned "1".

Please set this parameter in the path of slave axis in inter-path flexible synchronization control.

Diagnosis data

5600	Error of automatic phase synchronization (group A)
5601	Error of automatic phase synchronization (group B)
5602	Error of automatic phase synchronization (group C)
5603	Error of automatic phase synchronization (group D)

[Data type] Real path
[Unit of data] mm, inch, deg (machine unit)
[Min. unit of data] Depend on the increment system of the reference axis
[Valid data range] 9 digit of minimum unit of data
(When the increment system is IS-B, -999999.999 to +999999.999)

Error between master axis and slave axis after executing automatic phase Synchronization for flexible synchronization control is displayed.

This data is displayed in the path of slave axis in inter-path flexible synchronization control.

5604	Maximum error of Automatic Phase Synchronization (group A)
5605	Maximum error of Automatic Phase Synchronization (group B)
5606	Maximum error of Automatic Phase Synchronization (group C)
5607	Maximum error of Automatic Phase Synchronization (group D)

[Data type] Real path
[Unit of data] mm, inch, deg (machine unit)
[Min. unit of data] Depend on the increment system of the reference axis
[Valid data range] 9 digit of minimum unit of data
(When the increment system is IS-B, -999999.999 to +999999.999)
Maximum error between master axis and slave axis after executing automatic phase synchronization for flexible synchronization control is displayed.
This data is displayed in the path of slave axis in inter-path flexible synchronization control.
This data is cleared when automatic operation is started in auto mode.
This data is cleared when flexible synchronization control is started in manual mode.

Notes

NOTE

Diagnosis data is displayed after the following time passes since flexible synchronization control phase synchronization end signal is turned "1".
1/ (Parameter No.1825 ∗ 0.01) ∗ 3 [sec]
Example)
If No. 1825 = 3000, diagnosis data is displayed 100 msec later.
This function is usable only when the gear ratio between the master and slave axes is 1 vs. 1.

1.12.5 Inter-path Flexible Synchronization Control

Overview

Inter-path flexible synchronization control enables flexible synchronization control between axes in different paths in a multi-path system.
Up to four slave axes can be specified in one path.
An axis in another path can be specified as the master axis of each slave axis.
Synchronization for all synchronization pairs in all paths can be executed simultaneously.

Example)
In a multi-path system with the following axis configuration (Fig. 1.12.5 (a)), not only synchronization between the C1 axis in path 1 (master axis) and the A1 axis in path 1 (slave axis), but also synchronization between the C1 axis in path 1 (master axis) and the A2 axis in path 2 (slave axis) can be performed.

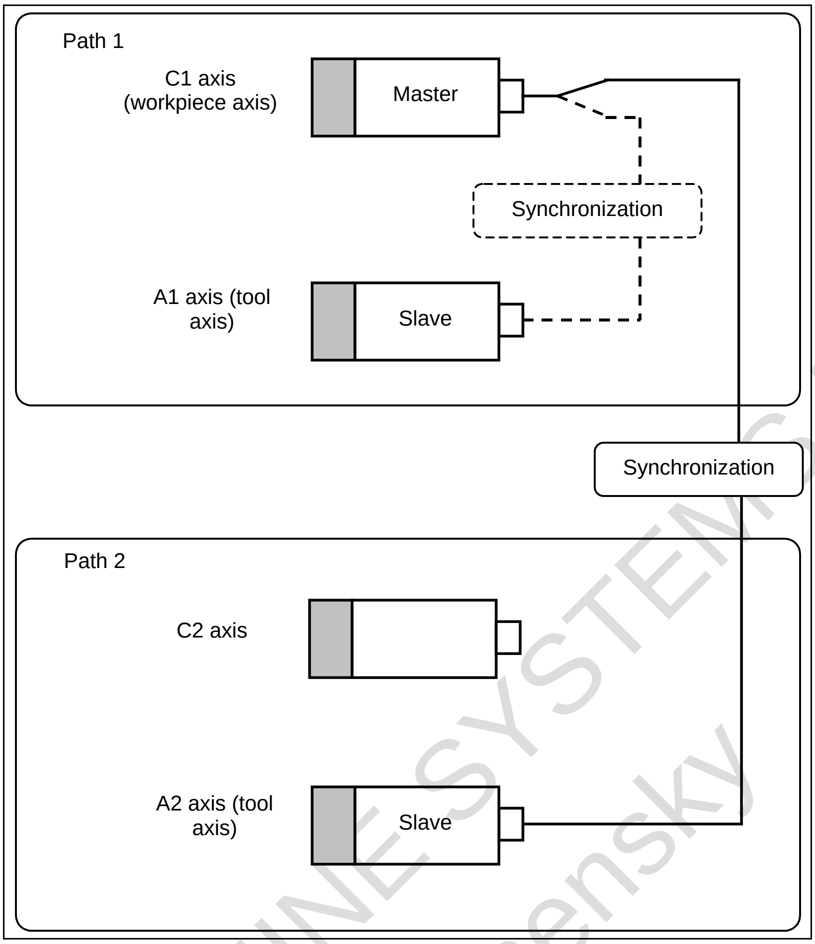


Fig. 1.12.5 (a)

Details

Setting of synchronization axes

Set master axis numbers in parameters Nos. 5660, 5662, 5664, and 5666.
Set slave axis numbers in parameters Nos. 5661, 5663, 5665, and 5667.
Set the number obtained by adding the controlled axis number to path number × 100 in these parameters for the slave axis path.

Example)
Master axis: 1st axis in path 1, slave axis: 1st axis in path 2
Parameter No. 5660 (path 2) = 101
Parameter No. 5661 (path 2) = 201

A slave axis in a synchronization group can be set as the master axis in another group.
Example)
The following synchronization is be applied:

$$\begin{tikzcd} X1 \arrow[r] & X2 \arrow[d] \\ Y1 & Y2 \arrow[l] \end{tikzcd}$$

X1 (master) → X2 (slave)
X2 (master) → Y2 (slave)
Y (master) → Y1 (slave)

If the relation among the master and slave axes makes a loop, however, alarm PS5242 "ILLEGAL AXIS NUMBER" is issued when synchronization starts.

Example)

The following synchronization cannot be applied:

$$\begin{tikzcd} X1 \arrow[r] & X2 \arrow[d] \\ Y1 & Y2 \arrow[ul] \end{tikzcd}$$

X1 (master) → X2 (slave)
X2 (master) → Y2 (slave)
Y2 (master) → X1 (slave)

X1 is defined as its own master axis.

Specification method

To execute inter-path flexible synchronization control during automatic operation, it is necessary to put the CNC in the inter-path flexible synchronization mode by setting the inter-path flexible synchronization mode select signal OVLN <Gn531.4> to "1" with a ladder program by specifying an M code in the paths to which the master and slave axes belong.

If flexible synchronization is started when the inter-path flexible synchronization mode is off, alarm PS5245 "OTHER AXIS ARE COMMANDED" is issued.
The inter-path flexible synchronization mode is disabled by setting OVLN to "0".

For the program sequence of the inter-path flexible synchronization mode status and M code commands for flexible synchronization control, see the following example.

Example)

Path of master axis	Path of slave axis
M210; ------ Turns the inter-path flexible synchronization mode on. M100P12; ------ Waiting (Note 1) ~	M310; ------ Turns the inter-path flexible synchronization mode on. M100P12; ------ Waiting (Note 1) ~
: ------ Master axis move commands	M60; ------ Starts inter-path flexible synchronization. ~ M61; ------ Cancels inter-path flexible synchronization.
~ M110P12; ------ Waiting (Note 1) M211; ------ Turns the inter-path flexible synchronization mode off.	~ M110P12; ----- Waiting (Note 1) M311; ------ Turns the inter-path flexible synchronization mode off.

AI contour control I/II can be turned on or off when both the master and slave paths are in the inter-path flexible synchronization mode.
AI contour control I/II can also be turned on or off even if PMC axis control is used for the master axis during flexible synchronization.

NOTE

1. Specify the waiting M code after the M code for turning the inter-path flexible synchronization mode on and before the M code for turning the inter-path flexible synchronization mode off during automatic operation.
2. The M code for turning the inter-path flexible synchronization mode on controls signals as follows:
   Sets the inter-path flexible synchronization mode select signal OVLN to "1" and confirms that the inter-path flexible synchronization mode signal OVLNS <Fn545.1> is changed to "1".
3. The M code for turning the inter-path flexible synchronization mode off controls signals as follows:
   Sets the inter-path flexible synchronization mode select signal OVLN to "0" and confirms that the inter-path flexible synchronization mode signal OVLNS is changed to "0".

Restrictions

The following functions cannot be specified in the inter-path flexible synchronization mode.
If any of these functions is specified in the inter-path flexible synchronization mode, alarm PS0502 "ILLEGAL G-CODE" is issued.

- Reference return in Cs contouring control (G00, G28)
- Skip function (G31)
- Automatic tool length measurement/Automatic tool offset function
- Automatic reference return operation of low-speed type (G28)
- High-speed program check function

These functions can be specified when flexible synchronization control and the inter-path flexible synchronization mode are turned off.

Inter-path flexible synchronization mode turned on immediately after power-on

When the inter-path flexible synchronization mode select signal is set to "1" immediately after power-on, the waiting M code does need to be specified.
For the program sequence of the inter-path flexible synchronization mode status and M code commands for flexible synchronization control, see the following example. (This example also explains the sequence when G31 is specified.)

Example)

Path of master axis	Path of slave axis
Set OVLN to 1. (The inter-path flexible synchronization mode is turned on.)	Set OVLN to 1. (The inter-path flexible synchronization mode is turned on.)
~	~
: ------ Master axis move commands	M60; ------ Starts inter-path flexible synchronization. ~ M61; ------ Cancels inter-path flexible synchronization.
M110P12; ------ Waiting M211; ------ Turns the inter-path flexible synchronization mode off. (NOTE 1)	M110P12; ----- Waiting M311; ------ Turns the inter-path flexible synchronization mode off. (NOTE 1)
G31_ ;	~
M210; ------ Turns the inter-path flexible synchronization mode on. (NOTE 1) M100P12; ------ Waiting	M310; ------ Turns the inter-path flexible synchronization mode on. (NOTE 1) M100P12; ------ Waiting
: ------ Master axis move commands	M60; ------ Starts inter-path flexible synchronization. ~ M61; ------ Cancels inter-path flexible synchronization.

NOTE

1. Turn the inter-path flexible synchronization mode on or off after flexible synchronization is canceled in the slave path.
2. Start or cancel flexible synchronization control with the signal (MTA, MTB, MTC, or MTD) in the slave path. Specify the M code for starting or canceling flexible synchronization in a block without specifying other commands.

NOTE

3 Flexible synchronization control cannot be started or canceled in the slave axis path while the path is in any of the following modes. In any of these modes, alarm PS5244, "TOO MANY DI ON" is issued.
   - Tilted working plane indexing

   Flexible synchronization control can be started or canceled in the master axis path, however.

4 Use an M code preventing buffering as the M code for turning the inter-path flexible synchronization mode on or off. (Parameter No. 3411 to 3420 or 11290 to 11299)
   Specify the M code for turning the inter-path flexible synchronization mode on or off in a block without specifying other commands.

5 Do not specify any move or PMC axis control command between the M code for turning the inter-path flexible synchronization mode on or off and a waiting M code.

6 An axis in spindle control with servo motor cannot be used as the master axis of flexible synchronization control.

Synchronization start
Command sequence

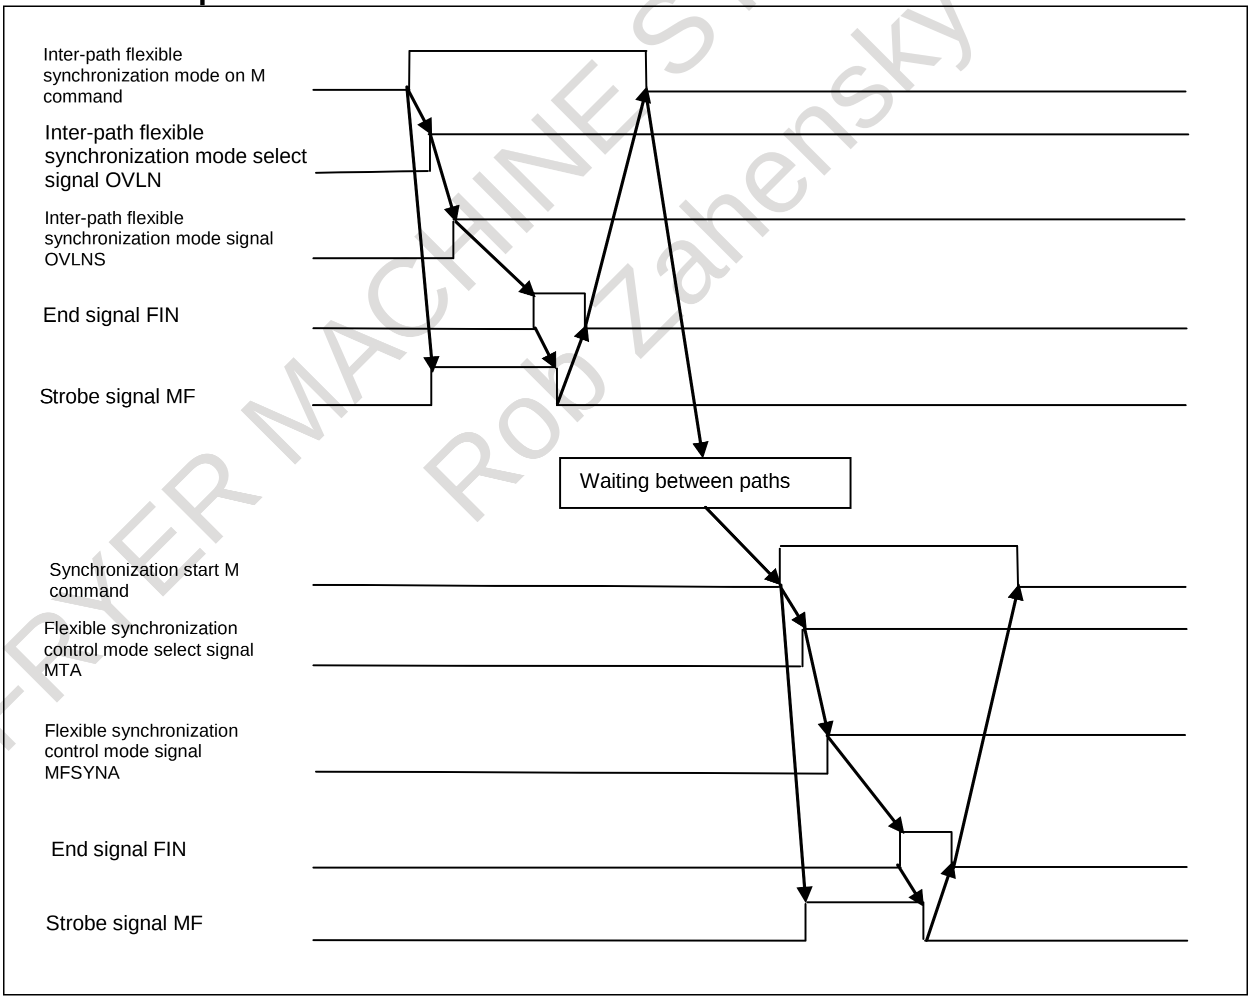

Fig. 1.12.5 (b)

1. When the M code for enabling the inter-path flexible synchronization mode is specified and the inter-path flexible synchronization mode select signal OVLN is set to "1", the inter-path flexible synchronization mode signal becomes "1".
2. The end signal FIN is operated for completion.
3. The waiting M code is specified in both the master and slave axis paths.
4. When the M code for enabling flexible synchronization control is specified, and the flexible synchronization control mode selection signal MTA, MTB, MTC, or MTD is set to "1", synchronization starts.
   And the flexible synchronization control mode status signal MFSYNA, MFSYNB, MFSYNC, or MFSYND becomes "1".
5. When the flexible synchronization control mode signal becomes "1", the end signal FIN is operated for completion.

Synchronization cancellation
Command sequence

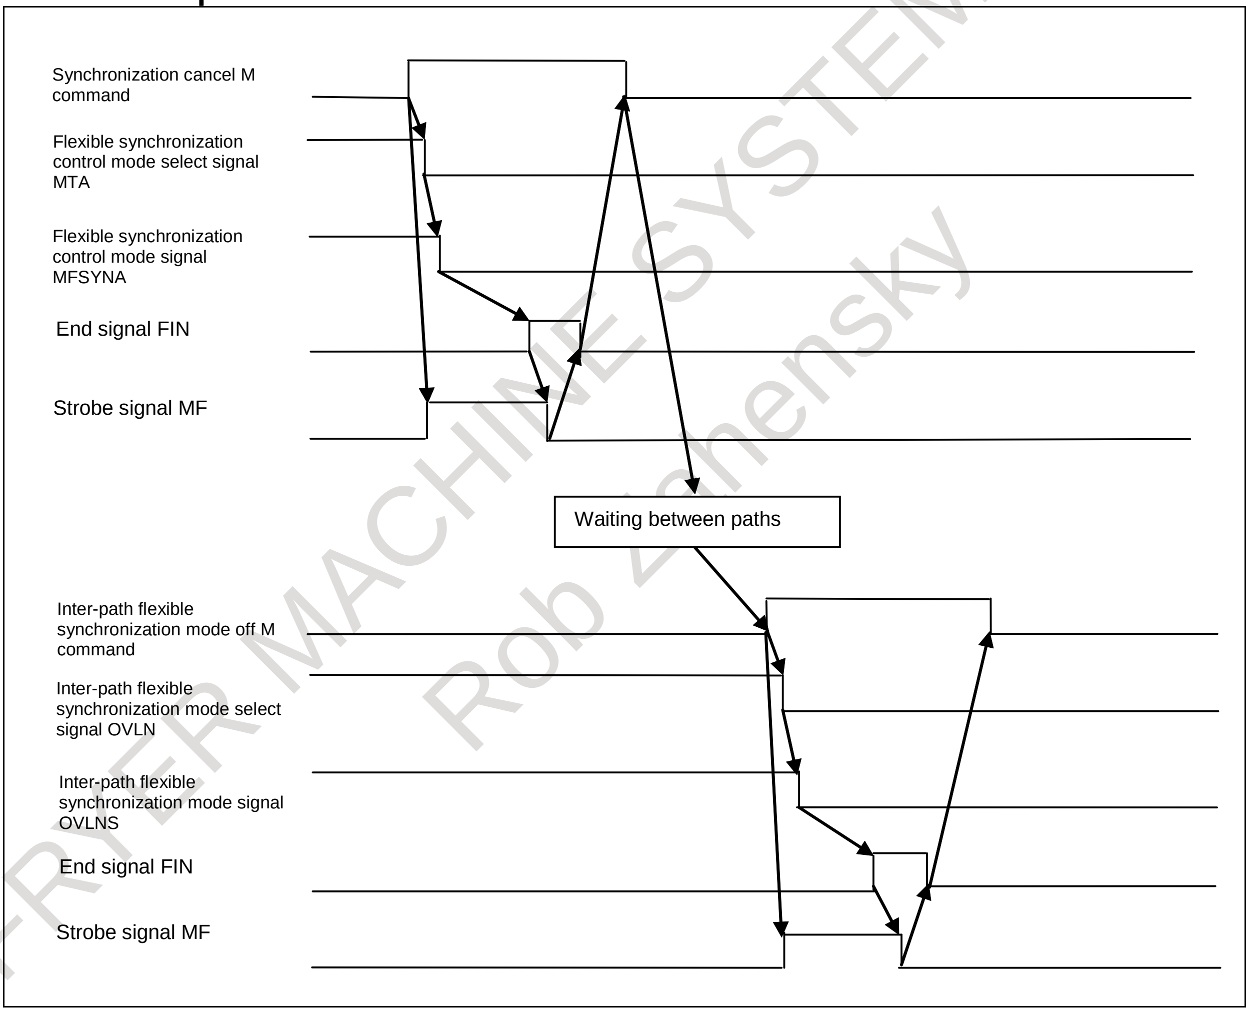

Fig. 1.12.5 (c)

1. When the M code for canceling flexible synchronization control is specified, and the flexible synchronization control mode selection signal is set to "0", synchronization is canceled.
2. When the flexible synchronization control mode status signal becomes "0", the end signal FIN is operated for completion.
3. The waiting M code is specified in both the master and slave axis paths.
4. When the M code for disabling the inter-path flexible synchronization mode is specified, and the inter-path flexible synchronization mode select signal OVLN is set to "0", the inter-path flexible synchronization mode is canceled.

5. When the inter-path flexible synchronization mode signal becomes 0, the end signal FIN is operated for completion.

Notes

NOTE

1 If an overtravel alarm occurs on the slave axis, the tool is stopped along both the master and slave axes, and alarm PS5245, "OTHER AXIS ARE COMMANDED" is issued in the master axis path.
2 If a servo alarm occurs, flexible synchronization control is canceled, and alarm PS5245 is issued in both the master and slave paths.
3 If an emergency stop is applied, flexible synchronization control is canceled and alarm PS5245 is issued in the path in which the emergency stop is not applied. When bit 1 (FCN) of parameter No. 1342 is 1, however, synchronization is not canceled and no alarm is issued.
4 Machine lock, if applied to the slave axis, is disabled while flexible synchronization is enabled.

Parameter

5660	Master axis number for flexible synchronization control (group A)
5661	Slave axis number for flexible synchronization control (group A)
5662	Master axis number for flexible synchronization control (group B)
5663	Slave axis number for flexible synchronization control (group B)
5664	Master axis number for flexible synchronization control (group C)
5665	Slave axis number for flexible synchronization control (group C)
5666	Master axis number for flexible synchronization control (group D)
5667	Slave axis number for flexible synchronization control (group D)

[Input type] Parameter input
[Data Input type] Word path
[Valid data range] 0 to Number of controlled axes
or m × 100+n (m:1 to Number of paths, n:1 to Number of controlled axes)
Specify both master and slave axis numbers.
Setting value)
1 to 24: Controlled axes on own path (one path system only)
101 to 124: Controlled axes in path 1
201 to 224: Controlled axes in path 2

In inter-path flexible synchronization control, an axis of a path can be specified as the master axis of another path.

NOTE

In inter-path flexible synchronization control, an axis of any path cannot be specified as the slave axis of another path.

	#7	#6	#5	#4	#3	#2	#1	#0
13421					FSV	FRF	FCN	

[Input type] Parameter input
[Data type] Bit path

> **NOTE**
> Set these parameters for the first path only. It will be effective to all paths.

#1 FCN In the emergency stop/servo off state, inter-path flexible synchronization control is:
0: Canceled.
1: Not canceled.

#2 FRF If G27/G28/G29/G30/G53 is specified during flexible synchronization control, alarm PS0010 is:
0: Issued.
1: Is not issued. Commands to the master axis are possible.
Even if, however, parameter bit 2 (FRF) is set to 1, and G28 is specified for the master axis in the state in which the reference position of the master axis subject to flexible synchronization control is not established, or if G27/G28/G29/G30/G53 is specified for the slave axis, alarm PS5381 is issued.

> **NOTE**
> When Inter-path flexible synchronization control is valid, even if 0 is set in the parameter bit FRF, the operation will be the same as that if 1 is set.

#3 FSV When the axis related to synchronization is servo off state while flexible synchronization control or inter-path flexible synchronization control, an automatic operation is:
0: Stopped.
1: Stopped if the axis related to synchronization moves.

> **NOTE**
> In inter-path flexible synchronization control, this parameter becomes effective when parameter FCN (No.13421#1) is set to 1.

Signal

Inter-path flexible synchronization mode select signal OVLN<Gn531.4>

[Classification] Input signal
[Function] Inter-path flexible synchronization control is enabled during automatic operation when the inter-path flexible synchronization mode is enabled in the relevant paths.
[Operation] When this signal becomes "1", the control unit operates as follows:
- Enables the inter-path flexible synchronization mode in the relevant paths.

> **NOTE**
> 1 To switch the inter-path flexible synchronization mode select signal between "1" and "0", the tool must be stopped along all axes (other than PMC axes) in the target path. If the tool moves along any axis, alarm DS0071 "START OR RELEASE CANNOT BE DONE" is issued.

> **NOTE**
> 2 Be sure to specify the waiting M code following the M code for enabling the inter-path flexible synchronization mode during automatic operation.
> 3 Be sure to specify the waiting M code preceding the M code for disabling the inter-path flexible synchronization mode during automatic operation.

Inter-path flexible synchronization mode signal OVLNS<Fn545.1>

[Classification] Output signal

[Function] This signal indicates the inter-path flexible synchronization mode status.

[Operation] This signal becomes "1" when:

- The relevant path is in the inter-path flexible synchronization mode.

This signal becomes "0" when:

- The relevant path is not in the inter-path flexible synchronization mode.

Alarm and message

Number	Message	Description
PS0502	ILLEGAL G-CODE	A G code unavailable in the inter-path flexible synchronization mode was specified.
PS5242	ILLEGAL AXIS NUMBER	This alarm is issued when either of the following conditions is satisfied. (It is issued at the start of inter-path flexible synchronization control.) 1. The master or slave axis number is invalid. 2. The relation among master and slave axes makes a loop.
PS5244	TOO MANY DI ON	- When an attempt was made to change the flexible synchronization control status, the select signal was not turned on or off after the execution of the M code. - An attempt was made to turn flexible synchronization control on or off without stopping the tool along all axes. (Except when automatic phase synchronization for flexible synchronization control is used) - Flexible synchronization control was turned off in any of the following function modes: - Tilted working plane indexing
PS5245	OTHER AXIS ARE COMMANDED	This alarm is issued when one of the following conditions is satisfied: 1. An overtravel alarm occurred in the slave axis. 2. A servo alarm occurred in a path in inter-path flexible synchronization control. 3. An emergency stop was applied in another path in inter-path flexible synchronization control. 4. When an attempt was made to execute flexible synchronization between different paths during automatic operation, the inter-path flexible synchronization mode was not enabled.

Number	Message	Description
PS5381	INVALID COMMAND IN FSC MODE	Either of the following commands was specified: - G28 was specified for the master axis when the reference position was not established for the master axis of flexible synchronization control. - G27, G28, G29, G30, or G53 was specified for the slave axis.
DS0071	START OR RELEASE CANNOT BE DONE	To start or cancel the inter-path flexible synchronization mode, the tool must be stopped along all axes.

1.12.6 Skip Function for Flexible Synchronization Control

Outline

This function enables the skip or high-speed skip signal (in the following explanation, these signals are collectively called skip signal) for the slave axis that is moved by command of the master axis in the flexible synchronization control mode.
This function has features such as the following:

- If a skip signal is input while a skip command for flexible synchronization control block is being executed, this block does not terminate until the specified number of skip signals have been input.
- The machine coordinates assumed when skip signals are input and the number of input skip signals are stored in specified custom macro variables.
- The total number of the skip signal inputs is stored in another specified custom macro variable.

Format

Mxx ; **Flexible synchronization control mode on**

G31.8 G91 α0 P_ Q_ R_ ; **Skip command for flexible synchronization control**

α : Specify the slave axis. The instruction value must be 0. It is considered 0 even if numbers except 0 are specified.
P_ : The top number of the consecutive custom macro variables in which the machine coordinate positions of the slave axis at the skip signal inputs are stored.
Q_ : The maximum allowable number of the skip signal inputs. (Range of command value: 1 to 512)
R_ : The number of the custom macro variables in which the total number of the inputs is stored.
This data is usually the same as the value specified by Q.
Therefore this is not necessarily specified. Specify it to check the number of skip signal inputs.

G31.8 is a one-shot G code.
During the execution of the G31.8 block, the machine coordinate positions of the slave axis at the skip signal inputs are stored in the consecutive custom macro variables where the top number of the variables is specified by P and the maximum allowable number of the skip signal inputs is specified by Q.
Also, this total number of the skip signal inputs is stored in the variable specified by R.

Example)

```
Mxx                          Flexible synchronization control mode on
X--
Y--
G31.8 G91 A0 P100 Q30 R1     Skip command for flexible synchronization control
```

After 30 times of skip signal inputs, 30 machine coordinate positions of the A axis are stored respectively in the consecutive custom macro variables #100 to #129.
The total number of skip signal inputs is stored in the custom macro variable #1.

NOTE

1. In the G31.9 or G31.8 block, when the axis was not specified, the alarm (PS1152) "G31.9/G31.8 FORMAT ERROR" occurs.
2. In the G31.8 block, only one slave axis should be commanded. When more than two slave axes are specified, the alarm (PS1152) occurs.
3. If G31.8 is commanded out of the flexible synchronization control mode (Flexible synchronization control mode status signal switching accepted signal (MFSYNA, MFSYNB, MFSYNC or MFSYND) is “0”), the alarm (PS1152) occurs.
4. If P is not specified, the alarm (PS1152) occurs.
5. If the axis besides a slave axis is specified, the alarm (PS1152) occurs.
6. If Q is specified out of range, the alarm (PS1152) occurs.
7. If P is not specified, the alarm (PS1152) occurs.
8. If R is not specified, the number of input skip signals is not written to a custom macro variable.
9. The number of custom macro variables specified in P and R must be the existing ones. If any nonexistent variable is specified, the alarm (PS0115) "VARIABLE NO. OUT OF RANGE" occurs. If a variable shortage occurs, the alarm (PS0115) occurs, too.
10. Whether to use conventional skip signals or high-speed skip signals with this function can be specified with the bit 4(HSS) of parameter No.6200. When high-speed skip is selected, specify which high-speed signals to enable with setting parameter 9S1 to 9S8 (No.6208#0 to #7).
11. The accumulated pulses and positional deviation due to acceleration/deceleration is considered and compensated when storing the machine coordinate positions to the custom macro variables.

Signal

- Please refer about signals of skip and flexible synchronization control to the following specification. ”Skip function” and “Flexible synchronization control” of “FANUC Series 0*i*-F Plus CONNECTION MANUAL (FUNCTION) (B- 64693EN-1)”.

Parameter

	#7	#6	#5	#4	#3	#2	#1	#0
6200		SRE	SLS	HSS			SK0	GSK

[Input type] Parameter input
[Data type] Bit path

#0 GSK As a skip signal, the skip signal SKIPP is
0: Invalid.
1: Valid.

#1 SK0 This parameter specifies whether the skip signal is made valid under the state of the skip signal SKIP and the multistage skip signals SKIP2 to SKIP8.
0: Skip signal is valid when these signals are "1".
1: Skip signal is valid when these signals are "0".

#4 HSS 0: The skip function does not use high-speed skip signals while skip signals are input. (The conventional skip signal is used.)
1: The step skip function uses high-speed skip signals while skip signals are input.

#5 SLS 0: The multi-step skip function does not use high-speed skip signals while skip signals are input.
(The conventional skip signal is used.)
1: The multi-step skip function uses high-speed skip signals while skip signals are input.

> **NOTE**
> The skip signals (SKIP and SKIP2 to SKIP8) are valid regardless of the setting of this parameter. They can also be disabled using bit 4 (IGX) of parameter No. 6201.
> If you want to use high-speed skip signals when the multi-step skip function is used, set this parameter to 1.

#6 SRE When a high-speed skip signal is used:
0: The signal is assumed to be input on the rising edge (contact open → close).
1: The signal is assumed to be input on the falling edge (contact close → open).

	#7	#6	#5	#4	#3	#2	#1	#0
6201	**SKPXE**		**CSE**	**IGX**				

[Input type] Parameter input
[Data type] Bit path

#4 IGX When the high-speed skip function is used, SKIP, SKIPP, and SKIP2 to SKIP8 are:
0: Enabled as skip signals.
1: Disabled as skip signals.

#5 CSE For the continuous high-speed skip command, high-speed skip signals are:
0: Effective at either a rising or falling edge (depending on the setting of bit 6 (SRE) of parameter No.6200)
1: Effective at both the rising and falling edges.

#7 SKPXE For the skip function (G31), the skip signal SKIP is:
0: Enabled.
1: Disabled.

Whether the skip signals are enabled or disabled

Parameter	Bit 4 (IGX) of parameter No. 6201	Bit 0 (GSK) of parameter No. 6200	Bit 7 (SKPXE) of parameter No .6201	Skip signal SKIPP	Skip signal SKIP	Multistage skip signals SKIP2-SKIP8
Setting	0	0	0	Disabled	Enabled	Enabled
	0	1	0	Enabled	Enabled	Enabled
	0	0	1	Disabled	Disabled	Enabled
	0	1	1	Enabled	Disabled	Enabled
	1	0	0	Disabled	Disabled	Disabled
	1	1	0	Disabled	Disabled	Disabled
	1	0	1	Disabled	Disabled	Disabled
	1	1	1	Disabled	Disabled	Disabled

Bit 4 (IGX) of parameter No. 6201 is valid for the skip function using high-speed skip signals (when bit 4 (HSS) of parameter No. 6200 is set to 1) or for the multi-step skip function using high-speed skip signals (when bit 5 (SLS) of parameter No. 6200 is set to 1).

	#7	#6	#5	#4	#3	#2	#1	#0
6208	9S8	9S7	9S6	9S5	9S4	9S3	9S2	9S1

[Input type] Parameter input
[Data type] Bit path

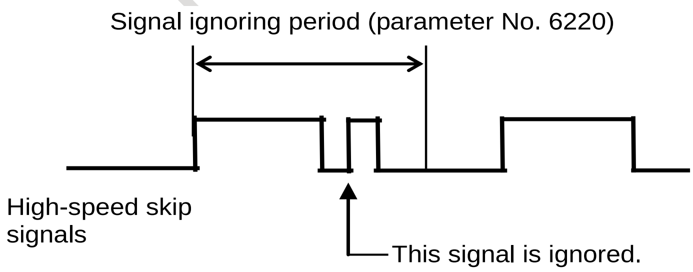
9S1 to 9S8 Specify which high-speed skip signal is enabled for the continuous high-speed skip command G31P90 or the EGB skip and the skip function for flexible synchronization control command G31.8.
The settings of each bit have the following meaning:
0: The high-speed skip signal corresponding to the bit is disabled.
1: The high-speed skip signal corresponding to the bit is enabled.
The bits correspond to signals as follows:

Parameter	High-speed skip signal	Parameter	High-speed skip signal
9S1	HDI0	9S5	HDI4
9S2	HDI1	9S6	HDI5
9S3	HDI2	9S7	HDI6
9S4	HDI3	9S8	HDI7

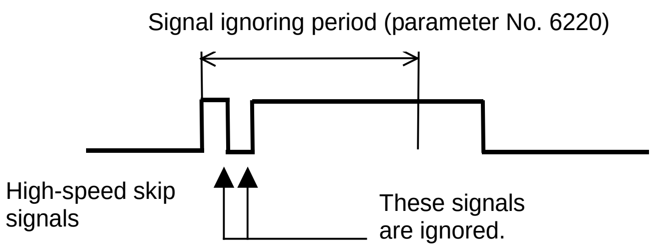
6220	Period during which skip signal input is ignored for the continuous high-speed skip function , EGB axis skip function , and flexible synchronization control skip function

[Input type] Parameter input
[Data type] Byte path
[Unit of data] 8msec
[Valid data range] 3 to 127(× 8msec)
This parameter specifies the period from when a high-speed skip signal is input to when the next high-speed skip signal can be input for the continuous high-speed skip function, EGB axis skip function, and flexible synchronization control skip function.
This parameter is used to ignore chattering in skip signals.
If a value that falls outside the valid range is specified, the setting is assumed to be 24 msec.

Example 1) When bit 5 (CSE) of parameter No. 6201 is 0 and bit 6 (SRE) of parameter No. 6200 is 0:



Example 2) When bit 5 (CSE) of parameter No. 6201 is 1:



Alarm and message

Number	Message	Description
PS0115	VARIABLE NO. OUT OF RANGE	A number that cannot be used for a local variable, common variable, or system variable in a custom macro is specified. In the EGB axis skip function or skip function for flexible synchronization control (G31.8), a non-existent custom macro variable number is specified. Or, the number of custom macro variables used to store skip positions is not sufficient.
PS1152	G31.9/G31.8 FORMAT ERROR	G31.8 is commanded out of the flexible synchronization control mode. The format of the G31.9(continuous high-speed skip function) or G31.8(EGB skip function / skip function for flexible synchronization control) block is erroneous in the following cases: - The axis was not specified in the G31.9 or G31.8 block. - Multiple axes were specified in the G31.9 or G31.8 block. - The P code was not specified in the G31.9 or G31.8 block. - G31.8 was commanded the axis besides a slave axis in the flexible synchronization control mode. - The Q command of G31.8 block is out of range in flexible synchronization control mode.

1.12.7 Hob Command by Flexible Synchronization Control

Overview

The same hob command as the electronic gearbox can be used as a synchronization command of flexible synchronization control.

Format

	Bit 0 (EFX) of parameter No.7731=0	Bit 0 (EFX) of parameter No.7731=1	
		Bit 5 (HBR) of parameter No.7731=1	Bit 5 (HBR) of parameter No.7731=0
Start of synchronization	G81 T_ (L_) (I_) (Q_ P_) ;	G81.4 R_ (L_) (I_) (Q_ P_) ;	G81.4 T_ (L_) (I_) (Q_ P_) ;
Cancellation of synchronization	G80 ;	G80.4 ;	G80.4 ;
	(*1) (*4)	(*2) (*4)	(*3) (*4)

T(or R) : Number of teeth (Specifiable range: 1 to 5000)

L : Number of hob threads (Specifiable range: -250 to 250)
The sign of L determines the direction of rotation for a slave axis.
When L is positive, the direction of rotation for a slave axis is positive (+ direction).
When L is negative, the direction of rotation for a slave axis is negative (- direction).
When L is 0, it follows the setting of bit 3 (LZR) of parameter No.7701.
If L is not specified, the number of hob threads is assumed 1.

Q : Module or diametrical pitch
Specify a module in the case of metric input.
(Unit: 0.00001mm, Specifiable range: 0.01 to 25.0mm)
Specify a diametrical pitch in the case of inch input.
(Unit: 0.00001inch^{-1}, Specifiable range: 0.01 to 254.0 inch^{-1})

P : Gear helix angle
(Unit: 0.0001deg, Specifiable range: -90.0 to 90.0deg)

I : The number of a group starting flexible synchronization control
(Group A = 1, B = 2, C = 3, D = 4)
If I is not specified, the group is assumed A.

*1 Use it for machining center system.
*2 Use it for lathe system.
*3 Use it for machining center system.
*4 When processing a helical gear, it specifies both Q and P. A decimal point can be used when specifying Q and P.

NOTE
Specify G81, G80, G81.4, and G80.4 in separate blocks.

Explanation

In conventional, flexible synchronization control has been started synchronization by setting flexible synchronization control mode selection signals MTA, MTB, MTC and MTD <Gn197.0, Gn197.1, Gn197.2 and Gn197.3> to "1". In this function, a command compatible with that for a hobbing machine can be used as a synchronization command of flexible synchronization control. This function is enabled by setting bit 0 (HOB) of parameter No.5694 to 1.

NOTE
If bit 0 (HOB) of parameter No.5694 is set to 1, the function related to "Electronic gear box" cannot be used.

Example of programming)
Group A : The master axis is B, the slave axis is C, and gear ratio is 1 : 50.
Group B : The master axis is Z, the slave axis is C, and gear ratio is 1 : 5.
Group C : The master axis is Y, the slave axis is C, and gear ratio is 23 : 20.

G81 T1 L50 I1 ; .... B - C synchronization start
G81 T1 L5 I2 ; .... Z - C synchronization start
:
G81 T23 L20 I3 ; .... Y - C synchronization start
:
G80 ; .... All synchronization cancellation
:

- Synchronization start

Specify P and Q to use helical gear compensation.
In this case, if only either of P and Q is specified, alarm PS0544 "FSC FORMAT ERROR" is issued. When G81 is specified so that the machine enters synchronization mode, the synchronization of a master axis and a slave axis is started.
During synchronization, control is performed such that the ratio of the master axis speed to the slave axis speed is the same as that of T (number of teeth) to L (number of hob threads).
During synchronization, if G81 is specified again without synchronization cancellation, it is changed to the one newly specified with T, L, P and Q commands.
It is possible that two or more groups are synchronization mode at same time as the above-mentioned example of programming.

- Synchronization cancellation

The synchronization of all synchronized groups is canceled with G80.
Absolute position display and relative position display for a slave axis are updated by adding the amount of movement due to the synchronization in synchronization cancellation. If the group is not updated machine position display by setting bit 0 to 3 (ACA to ACD) parameter No.5668 to 1, the above-mentioned absolute position display and relative position display are not updated.
In a G80 block, do not specify addresses other than O or N.

NOTE

1 If bit 0 (EFX) of parameter No. 7731 is 0, no canned cycle for drilling can be used. To use a canned cycle for drilling, set bit 0 (EFX) of parameter No. 7731 to 1 and use G81.4 instead of G81 and G80.4 instead of G80.
2 If bit 0 (TDP) of parameter No. 7702 is 1, the permissible range of T is 0.1 to 300 (1/10 of the specified value).
3 If, at the start of flexible synchronization control (G81), L is specified as 0, the synchronization starts with L assumed to be 1 if bit 3 (LZR) of parameter No.7701 is 0; if bit 3 (LZR) of parameter No.7701 is 1, the synchronization is not started with L assumed to be 0. At this time, helical gear compensation is performed.

- Synchronization coefficient

Synchronization coefficient of flexible synchronization control by hob command is calculated from the following equation.

Synchronization coefficient = $L/T \times \beta/\alpha$

T: Number of teeth
L: Number of hob threads

α: Pulse count of position detector per rotation about a master axis (Parameter No.7782)
β: Pulse count of position detector per rotation about a slave axis (Parameter No.7783)

- Inter-path flexible synchronization control

Start and cancellation by hob command is effective for the group of flexible synchronization control to which belongs to a path specified. In inter-path flexible synchronization control, it specifies in the path to which a slave axis belongs.

Example of programming)

The path to which a master axis belongs	The path to which a slave axis belongs
:	:
M210 ; .... Inter-path flexible synchronization control mode on	M310 ; .... Inter-path flexible synchronization control mode on
M100 P12 ; . Waiting	M100 P12 ; .... Waiting
:	G81 T1 L50 I1 ; . Flexible synchronization control start
:	:
:	:
:	G80 ; .... Flexible synchronization control cancellation
:	
M110P 12 ; . Waiting	M110 P12 ; .... Waiting
M211 ; .... Inter-path flexible synchronization control mode off	M311 ; .... Inter-path flexible synchronization control mode off
:	::

NOTE

1 Specify a waiting M code after the M code for turning inter-path flexible synchronization mode on and before the M code for turning inter-path flexible synchronization mode off during automatic operation.
2 In the M code for turning inter-path synchronization mode on, it sets inter-path flexible synchronization mode select signal OVLN to "1" and confirms that inter-path flexible synchronization mode signal OVLNS is changed to "1".
3 In the M code for turning inter-path synchronization mode off, it sets inter-path flexible synchronization mode select signal OVLN to "0" and confirms that inter-path flexible synchronization mode signal OVLNS is changed to "0".
4 Use the M code preventing buffering as the M code for turning inter-path flexible synchronization mode on or off.
(Parameter Nos. 3411 to 3420 or 11290 to 11299)
5 In the others note or limitation, refer to the specification of "Inter-path flexible synchronization control".

- Flexible synchronization control in case a master axis is controlled by "Spindle control with servo motor or PMC axis"

If PMC axis or spindle control with servo motor is a master axis, be sure to set the controlled axis selection signal EAXn<Gn136> for PMC axis control to "1" or turn on the SV speed mode of spindle control with servo motor before turning on the synchronization mode.
By setting bit 4 (FPA) of parameter No.13421 to 1, it is possible to issue the alarm PS5381 “INVALID COMMAND IN FSC MODE” when flexible synchronization control is operated in the incorrect procedure.

Example of programming)
:
S0 P11 ;
G96.4 P11 ; .... : SV speed control mode ON (In case of PMC axis,

```
                                                  EAXn<Gn136> is set to "1".)
G81 T1 L0 I1 ; ............................................. : Flexible synchronization control ON
S100 P11 ;
:
:
S0 P11 ;
G80 ; ............................................................ : Flexible synchronization control OFF
G96.1 P11 ; ................................................... : SV speed control mode OFF (In case of PMC axis,
                                                  EAXn<Gn136> is set to "0".)
:
```

NOTE

1 For a synchronization group for which PMC axis or spindle control with servo motor is a master axis, be sure to turn on the synchronization mode first. Also, for a synchronization group for which PMC axis or spindle control with servo motor is a master axis, be sure to turn off the synchronization mode last.
2 If an attempt is made to turn on a synchronization group for which PMC axis or spindle control with servo motor is a master axis when there exists a synchronization group for which non-PMC or non-spindle control with servo motor, normal axis is a master axis, alarm PS5245 "OTHER AXIS ARE COMMANDED" is issued.
3 In the others note or limitation, refer to the specification of "Flexible synchronization control".

When a master axis of flexible synchronization control is the axis of spindle control with servo motor, feed per revolution can be performed based on the rotation compensated with a gear ratio of a slave axis of flexible synchronization control.
Rotation speed that is used for the slave axis is shown as follows.

$$\text{Rotation compensated with a gear ratio of a slave axis} = \text{Feedback pulse of a position coder selected} \times \frac{L}{T}$$

T : Number of hob threads

L : Number of teeth

⚠ CAUTION

1. In case that all of following conditions are satisfied, feed per revolution is executed by the feedback pulse of position coder.
   - A group of flexible synchronization control set with parameter No.5695 is under synchronization mode.
   - A master axis is the axis of spindle control with servo motor.
   - The rotation of the master axis is selected as the feedback pulse.
2. The rotation compensated with a synchronization coefficient used by feed per revolution is not included the superimposed pulse from other master axes and the pulse instructed oneself.
3. Select the rotation of a master axis as the feedback pulse before turning on flexible synchronization control mode.

- Automatic phase synchronization

It is performed with operating signal as well as conventional. Automatic phase synchronization for flexible synchronization control can be used. Please show the specification of "Automatic phase synchronization for flexible synchronization control".

> ⚠ **CAUTION**
> The group of flexible synchronization control by hob command is changed the position for automatic phase synchronization of the slave axis by bit 6 (EPA) of parameter No.7731.

- Helical gear compensation

For a helical gear, a slave axis is subjected to compensation for movement along the Z axis (axial feed axis) according to the twisted angle of the gear.
Helical gear compensation is performed with the following data.

$$\text{Compensation angle} = \frac{Z \times \sin(P)}{\pi \times T \times Q} \times 360 \text{ (for metric input)}$$

$$\text{Compensation angle} = \frac{Z \times Q \times \sin(P)}{\pi \times T} \times 360 \text{ (for inch input)}$$

Compensation angle: Absolute value with sign (degrees)
Z : Amount of travel along the Z axis after a G81 command is issued (mm or inch)
P : Twisted angle of the gear with sign (degrees)
π : Circular constant
T : Number of teeth
Q : Module (mm) or diametral pitch (inch-1)
Use P, T, and Q specified in the G81 block.

In helical gear compensation, the machine coordinates and the absolute coordinates on a slave axis are updated with helical gear compensation.

- Direction of helical gear compensation

The direction depends on bit 2 (HDR) of parameter No. 7700.

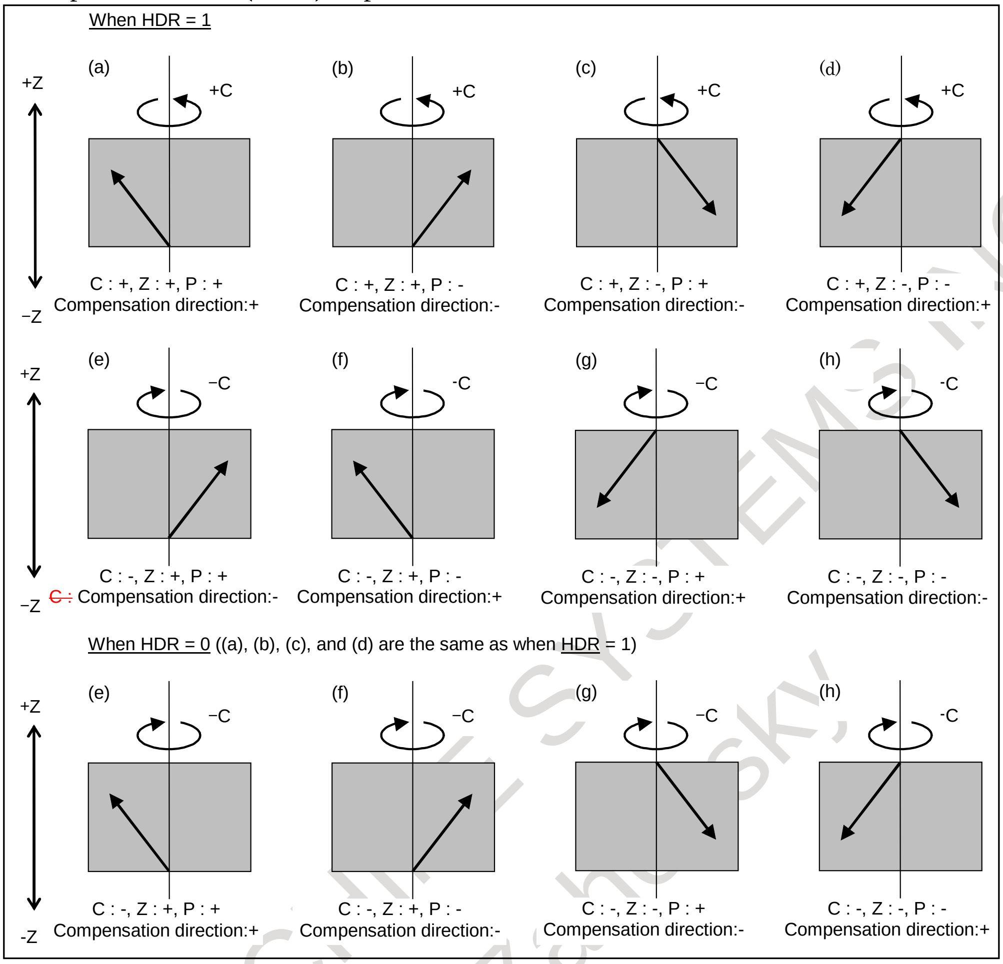


Fig. 1.12.7 Direction of helical gear compensation

- Acceleration/Deceleration of helical gear compensation

The time constant of acceleration/deceleration after interpolation of the slave axis is applied to the movement by helical gear compensation. Furthermore, when acceleration/deceleration before interpolation is valid, maximum allowable acceleration rate of the slave axis is not considered. If the acceleration of the movement by helical gear compensation is too large, reduce maximum allowable acceleration rate of the axial feed axis.

Note

- Set a master axis number and a slave axis number to the number of a master axis for flexible synchronization control (Parameters Nos.5660, 5662, 5664 and 5666) and the number of a slave axis for flexible synchronization control (Parameters Nos.5661, 5663, 5665 and 5667).
- It is necessary that a slave axis of flexible synchronization control that performs the hob command is set the type A of a rotation axis.
- If the M code number for turning on the flexible synchronization control mode is specified to a group of flexible synchronization control by hob command, alarm PS5381 "INVALID COMMAND IN FSC MODE" is issued.
- If hob command is specified to a group of flexible synchronization control by flexible synchronization control mode selection signals MTA, MTB, MTC and MTD, alarm PS5381 is issued.
- G81, G81.4, G80 and G80.4 used with hob command by flexible synchronization control prevent buffering.
- The synchronization mode by hob command is not canceled by reset operation.

- If G81 or G81.4 is re-specified to the group during the synchronization mode, it is necessary that automatic phase synchronization for flexible synchronization control is enabled.
- A synchronization group of turning on the flexible synchronization control mode by hob command is sure to turn on the synchronization mode first. Also, for a synchronization group of turning on the flexible synchronization control mode is sure to turn off the synchronization mode last. However, if the inter-path flexible synchronization mode select signal OVLN is set to "1", there is no restriction about the order. The inter-path flexible synchronization mode select signal OVLN can be used with flexible synchronization control in the path.
- The operation of synchronization mode that is not described in this specification is the same as turning on it by flexible synchronization control mode selection signals MTA, MTB, MTC and MTD. Please refer to the specification of "Flexible synchronization control" and "Inter-path flexible synchronization control".

Limitation

- If bit 0 (HOB) of parameter No.5694 is set to 1, the function related to electronic gear box cannot be used.
- In the group of turning on the flexible synchronization control mode by hob command, flexible synchronization control mode selection signals MTA, MTB, MTC and MTD is disabled.
- Inch/metric conversion commands (G20 and G21) cannot be specified in the synchronization mode by hob command.
- In the synchronization mode by hob command, AI contour control mode is temporarily canceled. However, when the inter-path flexible synchronization mode select signal OVLN is assumed to be "1", AI contour control I, AI contour control II and advanced preview feed forward of a slave axis can be made effective. Advanced preview feed forward of a slave axis is controlled by the mode or modal of a slave axis.
- In the program included hob command, "Program restart" and "Quick program restart" cannot be used.
- In "Retrace" and "Manual handle retrace", the blocks specified with G81, G81.4 are backward movement prohibition.
- This function cannot be used together with the function that cannot be used together with G code command (G81, G81.4, G80 and G80.4) of "Electronic gear box".

Signal

Inter-path flexible synchronization mode select signal OVLN<Gn531.4>

[Classification] Input signal

[Function] Inter-path flexible synchronization control is enabled during automatic operation when the inter-path flexible synchronization mode is enabled in the relevant paths.

[Operation] When this signal becomes "1", the control unit operates as follows:

- Enables the inter-path flexible synchronization mode in the relevant paths.

> **NOTE**
> 1 To switch the inter-path flexible synchronization mode select signal between "1" and "0", the tool must be stopped along all axes (other than PMC axes) in the target path. If the tool moves along any axis, alarm DS0071 "START OR RELEASE CANNOT BE DONE" is issued.
> 2 Be sure to specify the waiting M code following the M code for enabling the inter-path flexible synchronization mode during automatic operation.
> 3 Be sure to specify the waiting M code preceding the M code for disabling the inter-path flexible synchronization mode during automatic operation.

Flexible synchronization control mode status signals
MFSYNA, MFSYNB, MFSYNC, MFSYND <Fn197.0 to Fn197.3>

[Classification] Output signal

[Function] These signals are used to check that the groups selected with the flexible synchronization control mode selection signals are actually switched to that mode.

[Operation]
1) When the synchronization mode actually becomes effective to a group, the corresponding one of these signals is set to "1".
2) When the synchronization mode is actually canceled for a group, the corresponding one of these signals is set to "0".

> **NOTE**
> When the synchronization mode is switched by hob command, it becomes similar to the operation.

Inter-path flexible synchronization mode signal OVLNS<Fn545.1>

[Classification] Output signal

[Function] This signal indicates the inter-path flexible synchronization mode status.

[Operation] This signal becomes "1" when:
- The relevant path is in the inter-path flexible synchronization mode.

This signal becomes "0" when:
- The relevant path is not in the inter-path flexible synchronization mode.

Signal address

	#7	#6	#5	#4	#3	#2	#1	#0
Gn531				OVLN				
Fn197					MFSYND	MFSYNC	MFSYNB	MFSYNA
Fn545							OVLNS	

Parameter

The parameter used by this function is shown as follows.

5660	Master axis number for flexible synchronization control (group A)
5661	Slave axis number for flexible synchronization control (group A)
5662	Master axis number for flexible synchronization control (group B)
5663	Slave axis number for flexible synchronization control (group B)
5664	Master axis number for flexible synchronization control (group C)
5665	Slave axis number for flexible synchronization control (group C)
5666	Master axis number for flexible synchronization control (group D)
5667	Slave axis number for flexible synchronization control (group D)

[Input type] Parameter input

[Data Input type] Word path

[Valid data range] 0 to Number of controlled axes
or m × 100+n (m:1 to Number of paths, n:1 to Number of controlled axes)
Specify both master and slave axis numbers.
Setting value)
1 to 24: Controlled axes on own path (one path system only)

101 to 124: Controlled axes in path 1
201 to 224: Controlled axes in path 2

In inter-path flexible synchronization control, an axis of a path can be specified as the master axis of another path.

> **NOTE**
> In inter-path flexible synchronization control, an axis of any path cannot be specified as the slave axis of another path.

	#7	#6	#5	#4	#3	#2	#1	#0
5694								**HOB**

[Input type] Parameter input
[Data type] Bit path

> **NOTE**
> When this parameter is set, the power must be turned off before operation is continued.

#0 HOB The command of G80 and G81 or G80.4 and G81.4 is:
0: Used with "Electronic gear box".
1: Used with "Hob command by flexible synchronization control".

> **NOTE**
> It is selected whether to use G80 and G81 or G80.4 and G81.4 by bit 0 (EFX) of parameter No.7731.

5695	**Group number to which feed per revolution can be performed based on the rotation compensated with a synchronization coefficient of a slave axis of flexible synchronization control**

[Input type] Parameter input
[Data type] Byte path
[Valid data range] 0 to 4

The group number of flexible synchronization control which slave axis used with feed per revolution belongs is set.
Feed per revolution can be performed based on the rotation compensated with a synchronization coefficient of a slave axis of flexible synchronization control .
Set the group number of flexible synchronization control as follows.
Group A = 1, Group B = 2, Group C = 3, Group D = 4
If this parameter is set to 0, feed per revolution is performed based on the feedback pulse.

	#7	#6	#5	#4	#3	#2	#1	#0
7700						**HDR**		

[Input type] Parameter input
[Data type] Bit path

#2 HDR Direction of helical gear compensation (usually, set 1.)
(Example) To cut a left-twisted helical gear when the direction of rotation about the C-axis is the negative (-) direction:
0: Set a negative (-) value in P.
1: Set a positive (+) value in P.

	#7	#6	#5	#4	#3	#2	#1	#0
7701					LZR			

[Input type] Parameter input
[Data type] Bit path

#3 LZR When L (number of hob threads) = 0 is specified at the start of flexible synchronization control (G81):
0: Synchronization is started, assuming that L = 1 is specified.
1: Synchronization is not started, assuming that L = 0 is specified. However, helical gear compensation is performed.

	#7	#6	#5	#4	#3	#2	#1	#0
7702								TDP

[Input type] Parameter input
[Data type] Bit path

#0 TDP The specifiable number of teeth, T, of flexible synchronization control (G81) is:
0: 1 to 5000
1: 0.1 to 500 (1/10 of a specified value)

> **NOTE**
> In either case, a value from 1 to 5000 can be specified.

7709	Number of the axial feed axis for helical gear compensation

[Input type] Parameter input
[Data type] 2-word path
[Valid data range] 0 to Number of controlled axes

This parameter sets the number of the axial feed axis for a helical gear.

> **NOTE**
> When this parameter is set to 0 or a value outside the valid setting range, the Z-axis becomes the axial feed axis.

	#7	#6	#5	#4	#3	#2	#1	#0
7731	HAD	EPA	HBR					EFX

[Input type] Parameter input
[Data type] Bit path

#0 EFX Hob command by flexible synchronization control:
0: G80 and G81 are used.
1: G80.4 and G81.4 are used.

> **NOTE**
> When this parameter is set to 0, no canned cycle for drilling can be used.

#5 HBR In flexible synchronization control start command G81.4, the number of teeth is:
0: Specified in T.
1: Specified in R.

> **NOTE**
> This parameter is valid when bit 0 (EFX) of parameter No. 7731 is set to 1.

#6 EPA Automatic phase synchronization for flexible synchronization control by hob command is performed in such a way that:
0: The machine coordinate 0 of the slave axis is aligned to the machine coordinate 0 of the master axis.
1: The position of the slave axis at synchronization start is aligned to the machine coordinate 0 of the master axis.

#7 HAD In the absolute coordinate, the amount of helical gear compensation is updated:
0: When the synchronization is canceled.
1: During executing helical gear compensation.

7782	Number of pulses from the position detector per flexible synchronization control master axis rotation

[Input type] Parameter input
[Data type] 2-word axis
[Unit of data] Detection unit
[Valid data range] 1 to 999999999

For a slave axis, set the number of pulses generated from the position detector per flexible synchronization control master axis rotation. For an A/B phase detector, set this parameter with four pulses equaling one A/B phase cycle.

> **NOTE**
> This parameter is enabled when hob command is specified.

7783	Number of pulses from the position detector per flexible synchronization control slave axis rotation

[Input type] Parameter input
[Data type] 2-word axis
[Unit of data] Detection unit
[Valid data range] 1 to 999999999

For a slave axis, set the number of pulses generated from the position detector per flexible synchronization slave axis rotation. Set the number of pulses output by the detection unit.
All the settings of parameters Nos. 7782 and 7783 have to do is to indicate the ratio correctly. So, you can reduce the fraction indicated by the settings.

> **NOTE**
> This parameter is enabled when hob command is specified.

[Data type] Bit path

> **NOTE**
> Set these parameters for the first path only. It will be effective to all paths.

#4 FPA For a synchronization group for which a PMC axis is a master axis, when the controlled axis selection signal EAXn<Gn136> for PMC axis control is set to "1" after starting flexible synchronization control mode, and the master axis is specified by PMC axis control, or for a synchronization group for which spindle control with servo motor is a master axis, when SV speed control mode of the master axis is turned on after starting flexible synchronization control mode:

0: Alarm is not generated.
1: Alarm PS5381 ”INVALID COMMAND IN FSC MODE” is generated.

This function generates the alarm when flexible synchronization control is operated by in the incorrect procedure.

> ⚠**CAUTION**
> When this parameter is set to 0, it operates without generating the alarm even if flexible synchronization control mode is started according to a procedure not correct. However, the position shift of a slave axis may occur.

Alarm and message

Number	Message	Description
PS0543	FSC PARAMETER SETTING ERROR	- The slave axis specified with G81 is not set as a rotation axis. (bit 0 (ROTx) of parameter No. 1006) - Number of pulses per rotation (parameter No. 7782 or 7783) is not set. - The group number of flexible synchronization control which slave axis used with feed per revolution belongs is not correctly set.
PS0544	FSC FORMAT ERROR	Error in the format of the block of hob command flexible synchronization control - T (number of teeth) is not specified in the G81 block. - In the G81 block, the data specified for one of T, L, P, and Q is out of its valid range. - In the G81 block, only one of P and Q is specified.
PS5243	DATA OUTRANGE	An overflow occurred in the calculation of the synchronization coefficient in hob command by flexible synchronization control.
PS5244	TOO MANY DI ON	In the program included hob command by flexible synchronization control (G81, G81.4, G80 and G80.4), the synchronization mode was not correctly switched when "Program restart" or "Quick program restart" was executed.
PS5245	OTHER AXIS ARE COMMANDED	An attempt was made to issue the following commands: An attempt was made to turn on a synchronization group for which an PMC axis or spindle control with servo motor was a master axis or the synchronization by hob command when there existed a flexible synchronization control group by the signal for which a non-PMC or non-spindle control with servo motor, normal axis was a master axis.

Number	Message	Description
PS5381	INVALID COMMAND IN FSC MODE	An attempt was made to issue the following commands: - An attempt was made to specify a M code for turning on or off flexible synchronization control to a synchronization group of turned on flexible synchronization control mode by hob command. - Hob command was specified to a synchronization group for which the synchronization mode was turned on with flexible synchronization mode selection signals MTA, MTB, MTC and MTD. - For a synchronization group for which a PMC axis is a master axis, when the controlled axis selection signal EAXn<Gn136> for PMC axis control was set to "1" after starting flexible synchronization control mode, and the master axis was specified by PMC axis control. - For a synchronization group for which spindle control with servo motor was a master axis, when SV speed control mode of the master axis was turned on after starting flexible synchronization control mode.

1.12.8 Hob Machining Package

Overview

Hob machining package is added.

Hob machining package enables to switch whether Electronic gear box or Flexible synchronization control is used for hob machining without restarting CNCs. With this function, you can evaluate both functions easily, and switch function to be used according to machining parts.

> **NOTE**
> - For details of Electronic gear box, refer to "ELECTRONIC GEAR BOX" in this manual.
> - For details of Flexible synchronous control, refer to "FLEXIBLE SYNCHRONIZATION CONTROL" in this manual.
> - For using a spindle as the master of hob machining with Hob command by flexible synchronization control, the spindle need to be switched to the Cs contour mode.
>   For details of Cs contour control, refer to "Cs CONTOUR CONTROL" in this manual.

Explanation

Hob machining package enables to switch whether Electronic gear box or Flexible synchronization control is used when a hob command is specified without restarting CNCs.

Conventionally, you can select which function is used for hob machining by changing the bit 0 (HOB) of parameter No.5694, and restarting the CNC is needed when it is changed. When Hob machining package is enabled, you can use the different function from the function selected by the bit 0 (HBS) of parameter No.5698, which can be changed without restarting the CNC, for hob machining.

The step to switch which function to be used for hob machining is as follows.

(1) Change CNC status to switch hob command. (refer to NOTE)
(2) Request to switch hob command by changing the bit 0 (HBS) of parameter No.5698.
(3) Confirm completion of switching hob command by checking the bit 0 (HOB) of diagnosis data No.5040.

Table 1.12.8 (a) Function to be used for hob machining when Hob machining package is enabled

parameter HOB(No.5694#0)	parameter HBS(No.5698#0)	Function to be used for hob machining
0	0	Electronic gear box
0	1	Flexible synchronization control
1	0	Flexible synchronization control
1	1	Electronic gear box

NOTE

1 If Hob machining package is enabled, hob commands (G80/G81 or G80.4/G81.4) are the G code for suppressing buffering.
2 When the bit 0 (HBS) of parameter No.5698 is changed, the both of the following conditions need to be met.
   - EGB synchronous control in the path is cancelled.
     (If Electronic gear box 2 pair is used, all pairs need to be cancelled.)
   - Flexible synchronization control in the path is cancelled.
     (All groups need to be cancelled.)
3 If the bit 0 (HBS) of parameter No.5698 is changed when the upper conditions are not met, switching hob command is executed after the conditions are met.
4 Whether switching hob command is finished or not can be confirmed with the bit 0 (HOB) of diagnosis data No.5040.

Restrictions

If the hob command switches without restarting the CNC, there are restrictions on the system configuration.
Examples of system configuration which can switch hob command without restarting CNC are shown as follows. (Assume that 1 path system is used)

(1) Both of the master spindle and the slave axis are the same after hob command is switched
Both of a Cs contour control axis and an EGB dummy axis are needed. In case of hob command by Flexible synchronization control, the master spindle needs to be switched to Cs contour mode. In case of hob command by Electronic gear box, Cs contour mode of the master spindle needs to be cancelled.

- Number of control axis is 6 (includes 2 virtual axes), Number of control spindle is 1

Linear axis	: X, Y, Z
Rotary axis	: A (Slave axis of EGB and FSC)
EGB dummy axis	: B
Cs contour axis	: C (Master axis of FSC)
Spindle	: S (Master axis of EGB and FSC)

(2) The master axis of Flexible synchronization control is a servo axis (Cs contour control isn't needed)
EGB dummy axis is needed. In this case, the master axis changes after a hob command is switched.

- Number of control axis is 6 (includes a virtual axis), Number of control spindle is 1

Linear axis	: X, Y, Z
Rotary axis	: A (The slave axis of EGB and FSC) C (The master axis of FSC)
EGB dummy axis	: B
Spindle	: S (The master axis of EGB)

To use the same master and slave axis between Electronic gear box and Flexible synchronization control, 2 virtual axes (EGB dummy axis and Cs contour axis) are needed to switch hob command without restarting the CNC.
If restarting the CNC is allowed when hob command switches, only a virtual axis (EGB dummy axis and Cs contour axis) is needed.

(3) Only a virtual axis is used (Restarting the CNC is needed to switch hob command)
The same master and slave axis between Electronic gear box and Flexible synchronization control can be used.

- Number of control axis is 5 (includes a virtual axis), Number of control spindle is 1

Linear axis	: X, Y, Z
Rotary axis	: A (The slave axis of EGB and FSC)
EGB dummy axis and Cs contour axis	: C (The master axis of FSC in case of Cs contour axis)
Spindle	: S (The slave axis of EGB and FSC)

> **NOTE**
> To switch the role of C axis (EGB dummy axis or Cs contour axis) with the upper system configuration of (3), parameter settings (parameter No.1023 and parameters related to FSSB) need to be changed.

Parameter

	#7	#6	#5	#4	#3	#2	#1	#0
5694								HOB

[Input type] Parameter input
[Data type] Bit path

> **NOTE**
> When this parameter is set, the power must be turned off before operation is continued.

#0 HOB The command of G80 and G81 or G80.4 and G81.4 is:
0: Used with “Electronic gear box”.
1: Used with “Hob command by flexible synchronization control”.

> **NOTE**
> 1 It is selected whether to use G80 and G81 or G80.4 and G81.4 by bit 0 (EFX) of parameter No.7731.
> 2 If Hob machining package is enabled and the bit 0 (HBS) of parameter No.5698 is 1, the different function from the function selected by this parameter is used.

	#7	#6	#5	#4	#3	#2	#1	#0
5698								HBS

[Input type] Parameter input
[Data type] Bit path

#0 HBS The command of G80 and G81 or G80.4 and G81.4 is:
0: Used with the function selected by the bit 0 (HOB) of parameter No.5694.
1: Used with the different function from the function selected by the bit 0 (HOB) of parameter No.5694.

NOTE
1 This parameter is enabled only when Hob machining package is enabled.
2 When this parameter is changed, the both of the following conditions need to be met.
  - EGB synchronous control in the path is cancelled.
    (If Electronic gear box 2 pair is used, all pairs need to be cancelled.)
  - Flexible synchronization control in the path is cancelled.
    (All groups need to be cancelled.)
3 If this parameter is changed when the upper conditions are not met, switching hob command is executed after the conditions are met.
4 Whether switching hob command is finished or not can be confirmed with the bit 0 (HOB) of diagnosis data No.5040.

	#7	#6	#5	#4	#3	#2	#1	#0
7731								EFX

[Input type] Parameter input
[Data type] Bit path

#0 EFX Hob command by flexible synchronization control:
0: G80 and G81 are used.
1: G80.4 and G81.4 are used.

NOTE
When this parameter is set to 0, no canned cycle for drilling can be used.

Alarm and message

Number	Message	Description
PW0000	POWER MUST BE OFF	A parameter was set for which the power must be turned OFF then ON again.

Diagnosis Data

	#7	#6	#5	#4	#3	#2	#1	#0
5040								HOB

#0 HOB G80/G81 or G80.4/G81.4 are :
0: used with Electronic gear box.
1: used with Flexible synchronization control.

NOTE
1 This is enabled when Hob machining package is enabled.
2 Confirm this to know which function is used for hob command, Electronic gear box or Flexible synchronization control. The different function from the function selected by parameter might be enabled.

1.13 AXIS IMMEDIATE STOP FUNCTION

Overview

When the movement long an axis must be immediately stopped, the axis immediate stop function stops the movement using the axis immediate stop start signal and outputs an alarm. In the AI contour control mode, this function changes the acceleration rate in look-ahead acceleration/deceleration before interpolation and stops the movement immediately.

Explanation

When the movement along an axis must be immediately stopped, this function stops the movement and outputs alarm DS5550 "AXIS IMMEDIATE STOP" by setting the axis immediate stop start signal ESTPR to "1". This function is enabled by setting bit 2 (EST) of parameter No. 1605 to 1.

Acceleration rate at the axis immediate stop

When the movement along an axis must be immediately stopped in the AI contour control mode, this function changes the acceleration rate in look-ahead acceleration/deceleration before interpolation to the value set in parameter No. 1673 or No.1700 (Maximum allowable acceleration rate in the axis immediate stop for each axis), and stops the movement immediately. When the axis immediate stop is executed by the set value of parameter No.1700, the deceleration stop of axis movement is executed by the lowest allowable acceleration rate among the movement axes. When the value set in parameter No. 1673 or selected maximum allowable acceleration rate of parameter No.1700 is smaller than the acceleration rate in look-ahead acceleration/deceleration before interpolation, this function immediately stops the movement at the acceleration rate in look-ahead acceleration/deceleration before interpolation. When the type of acceleration/deceleration is look-ahead bell-shaped acceleration/deceleration before interpolation, this function changes the type to look-ahead linear acceleration/deceleration before interpolation.

When look-ahead acceleration/deceleration before interpolation is used for cutting feed or rapid traverse, this function changes both the acceleration rate and type of acceleration/deceleration.

If 0 or a value lower than the acceleration of look-ahead acceleration/deceleration before interpolation is set to the maximum allowable acceleration rate of parameter No.1673 or No.1700, the acceleration rate and the acceleration/deceleration type of look-ahead acceleration/deceleration before interpolation is not changed, and the tool stops by using the current setting of look-ahead acceleration/deceleration before interpolation.

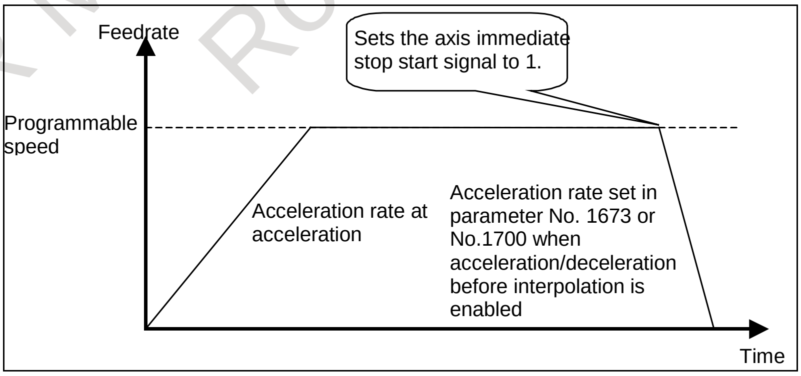

Fig. 1.13 (a)

Acceleration/deceleration after interpolation

Acceleration/deceleration after interpolation is also enabled at the axis immediate stop.

When look-ahead acceleration/deceleration before interpolation is not used, the movement is stopped using the time constant used for acceleration/deceleration after interpolation.

Manual operation

This function is also available during manual operation.

Time chart

The timing chart of the axis immediate stop start signal and deceleration state is shown below (Fig. 1.13 (b)).

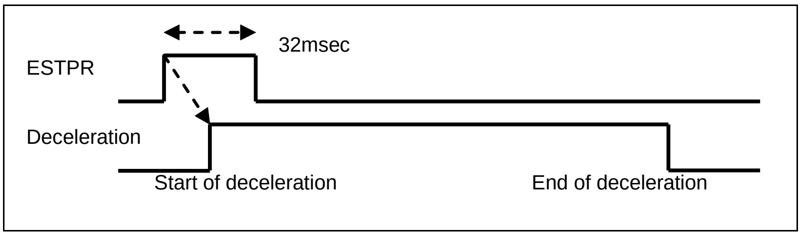

Fig. 1.13 (b)

Arbitrary angular axis control

When the axis immediate stop function is executed for an axis under the arbitrary angular axis control, alarm (PW0000) is issued after the immediate stop.
In this case, the power must be turned off before operation is continued.

Signal

Axis immediate stop start signal ESTPR<Gn203.3>

[Classification] Input signal
[Function] The axis immediate stop function is used to start stopping the movement along an axis.
[Operation] When this signal becomes "1", an axis immediate stop starts.
The width of this signal requires at least 32 msec.

Signal address

	#7	#6	#5	#4	#3	#2	#1	#0
Gn203					ESTPR			

Parameter

	#7	#6	#5	#4	#3	#2	#1	#0
1605						EST		

[Input type] Parameter input
[Data type] Bit path

> **NOTE**
> When this parameter is set, the power must be turned off before operation is continued.

#2 EST Axis immediate stop function is:
0: Disabled.
1: Enabled.

1673	Maximum allowable acceleration rate in tangent direction at axis immediate stop

[Input type] Parameter input
[Data type] Real path
[Unit of data] mm/ sec^2, inch/ sec^2, degree/ sec^2 (machine unit)
[Min. unit of data] Depend on the increment system of the reference axis
[Valid data range] Refer to the standard parameter setting table (D)
(When the machine system is metric system, 0.0 to +100000.0. When the machine system is inch system, machine, 0.0 to +10000.0.)

This parameter sets the maximum allowable acceleration rate in the tangent direction for look-ahead acceleration/deceleration before interpolation at a feed axis immediate stop.
If the parameter is set to a value equal to or greater than 100000.0, the value is clamped to 100000.0.
If 0 or a value lower than the acceleration of look-ahead acceleration/deceleration before interpolation is set, the tool stops by using the current setting without making the following changes:

- Change to the acceleration of look-ahead acceleration/deceleration before interpolation.
- Change to the acceleration/deceleration type from look-ahead bell-shaped acceleration/ deceleration before interpolation to look-ahead linear acceleration/deceleration before interpolation.

1700	Maximum allowable acceleration rate in the axis immediate stop for each axis

[Input type] Parameter input
[Data type] Real axis
[Unit of data] mm/sec^2, inch/sec^2, deg/sec^2 (machine unit)
[Min. unit of data] Depend on the increment system of the applied axis
[Valid data range] Refer to the standard parameter setting table (D)
(When the machine system is metric system, 0.0 to +100000.0. When the machine system is inch system, machine, 0.0 to +10000.0.)

Set a maximum allowable acceleration rate of each axis in look-ahead acceleration/ deceleration before interpolation on the axis immediate stop. The movement axis stops immediately by the lowest allowable acceleration rate in the movement axis. The following changes are executed by axis immediate stop.

- Change the acceleration rate in look-ahead acceleration/deceleration before interpolation.
- Change the look-ahead acceleration/deceleration type from bell-shaped acceleration/deceleration before interpolation to look-ahead linear acceleration/ deceleration before interpolation.

If a value greater than 100000.0 is set, the value is clamped to 100000.0.
If a value lower than the acceleration of look-ahead acceleration/deceleration before interpolation is set, the tool stops by using the current setting of look-ahead acceleration/deceleration before interpolation.

NOTE

If set the value to one or more axis in the parameter No.1700, maximum allowable acceleration rate in the axis immediate stop for each axis becomes effective. And the setting of parameter No.1673 becomes invalid.
In condition the setting of parameter No.1700 is valid, it is considered that the acceleration of look-ahead acceleration/ deceleration before interpolation is set for the axis to which the value is not set.

Alarm and message

Number	Message	Description
DS5550	AXIS IMMEDIATE STOP	The movement along an axis was stopped immediately by the axis immediate stop function.

Notes

NOTE

1 The movement along axes according to the following functions are not stopped with this function:
- PMC axis control
- High precision oscillation function
- Polygon turning
- EGB function
- Live tool control with servo motor

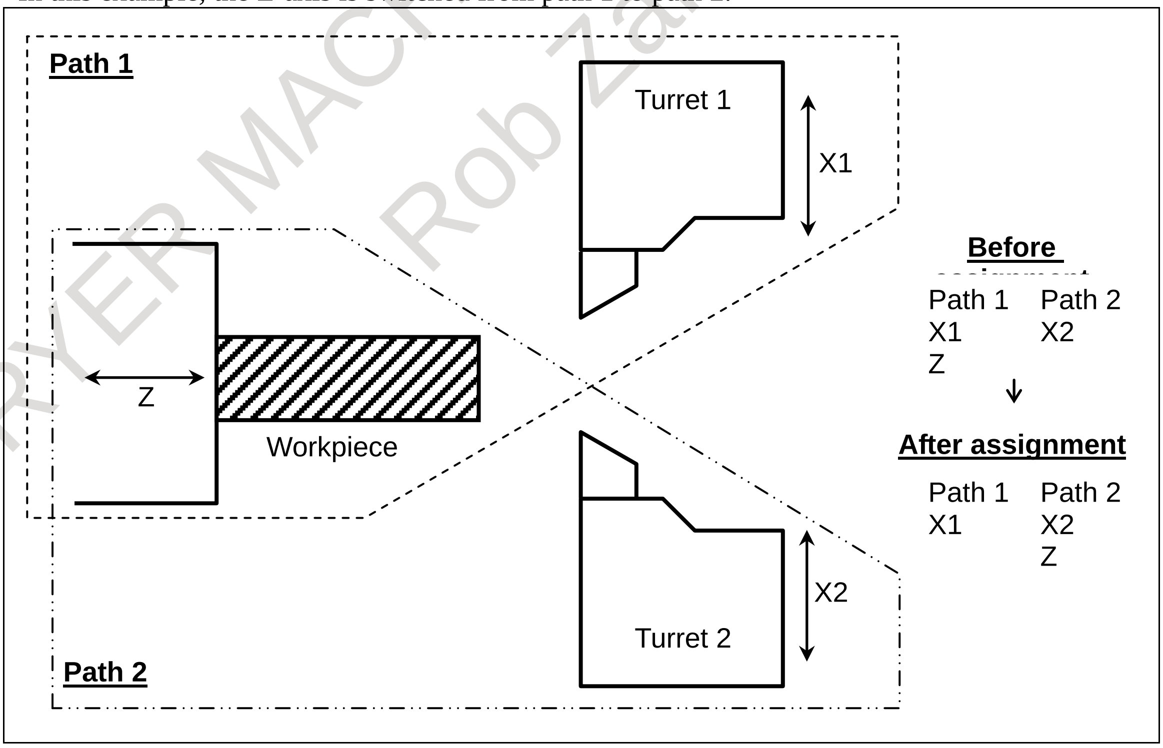
1.14 FLEXIBLE PATH AXIS ASSIGNMENT

Overview

Conventionally, each controlled axis has been controlled within each path. This function can remove each controlled axis from the control of each path and assign them as the controlled axis in the other path.
Using this function makes it possible to control one motor in multiple paths. For example, in the machine having the axis configuration shown in Example 1 (X1 and Z in path 1 and X2 in path 2), the Z-axis can be removed from path 1 and assigned to path 2 to form a different axis configuration (X1 in path 1 and X2 and Z in path 2), therefore requiring no dummy axis unlike composite control.
In the rotary index machine shown in Example 2, axes can be switched among paths.
If an assignment command is issued for an axis yet to be removed, the command waits for the axis to be removed. In this case, no waiting M code is needed.
The new axis configuration (after flexible path axis assignment) is preserved even after the CNC power is turned off.

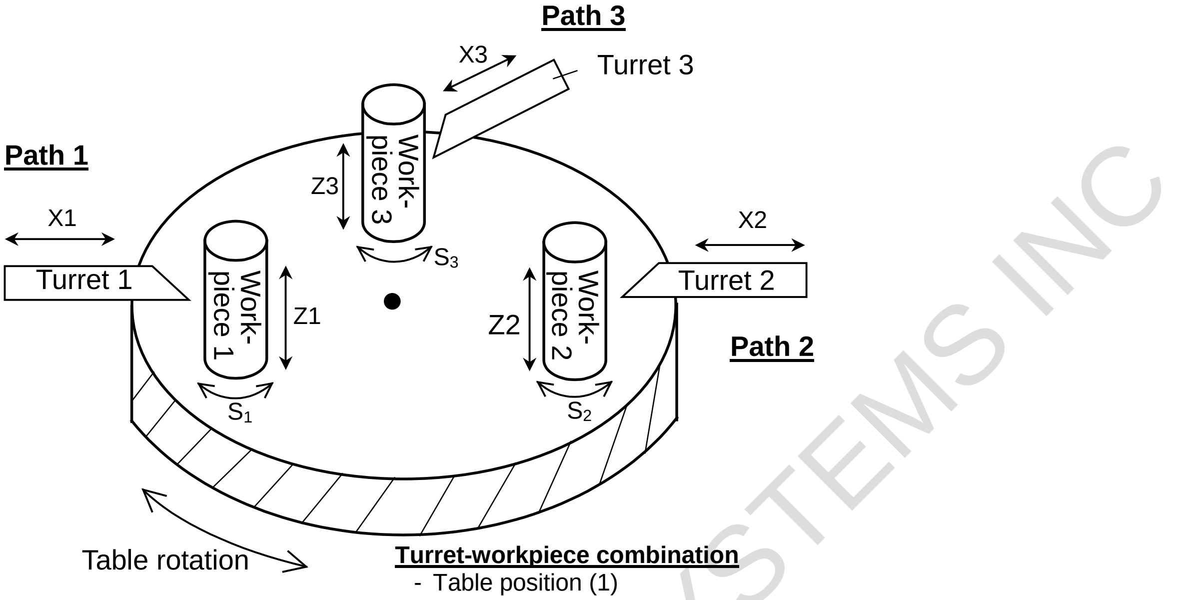
(Example 1)

In this example, the Z-axis is switched from path 1 to path 2.



(Example 2)

In this example, the Z1 axis is switched from path 1 to path 2 or 3.
(Rotary index machine)



Turret-workpiece combination

- Table position (1)
  Axis configuration: Path 1(X1－Z1), Path 2(X2－Z2), Path 3(X3－Z3)
  ↓
- Table position (2)
  Z1, Z2, and Z3 are removed.
  Z2, Z3, and Z1 are assigned, respectively, to paths 1, 2, and 3.
  Axis configuration: Path 1(X1－Z2), Path 2(X2－Z3), Path 3(X3－Z1)
  ↓
- Table position (3)
  Z1, Z2, and Z3 are removed.
  Z3, Z1, and Z2 are assigned, respectively, to paths 1, 2, and 3.
  Axis configuration: Path 1(X1－Z3), Path 2(X2－Z1), Path 3(X3－Z2)

The flexible path axis assignment function provides the following three commands.

1. Controlled-axis removal command
   A specified axis is removed from under control of a specified path.
   No CNC program can direct the removed axis any more.
2. Controlled-axis assignment command
   A specified axis is placed under control of a specified path.
3. Controlled-axis exchange command
   Two specified axes can be exchanged directly.

Explanation

- ID number- and name-based axis assignment methods

- ID number type (bit 3 (FAM) of parameter No.11561 is set to 0)
  The term ID number refers to a unique identification number (parameter No. 11560) for distinguishing a specific axis.
  The ID number-based method can use the ID numbers for axes after address P, Q, or R in the G code stated below to reassign the axes.
  This type of axis assignment can be used even on a machine having two or more axes having the same name.
- Axis name type (bit 3 (FAM) of parameter No.11561 is set to 1)
  Unlike the ID number-based method, this method can use the names of axes in the G to reassign them.
  The method can be used on a machine whose axes have fixed, unique names.

- Format

1) ID number type (bit 3 (FAM) of parameter No.11561 is set to 0)

G52.1 P_ Q_ R_ ; **Command to remove axes**
(Issued to a path having axes to be removed)

P,Q,R : ID numbers for axes to be removed (up to 3 axes can be removed at a time)

G52.2 P_ Q_ R_ I_ J_ K_ ; **Command to assign axes**
(Issued to a path to which axes are to be assigned)

P,Q,R : ID numbers for axes to be assigned (up to 3 axes can be assigned at a time)
I,J,K : Axis order numbers where axes are to be inserted
(An axis position in a path is specified. "I and P","J and Q", and "K and R" are paired. If an axis order number for an axis is omitted, the axis is assigned as the last axis in the path.)

G52.3 P_ Q_ (L_) ; **Command to exchange axes between paths**
(Issued to paths between which axes are to be exchanged)

P : ID number of an axis to be exchanged (in a source path)
Q : ID number of an axis to be exchanged (in a destination path)
L : Destination path number (omissible in a 2-path system)

ID numbers specified in this parameter (No. 11560) must be unique values that can distinguish each axis from one another.

2) Axis name type (bit 3 (FAM) of parameter No.11561 is set to 1)

G52.1 IP0 ; **Command to remove axes**
(Issued to a path having axes to be removed)

IP : ID numbers for axes to be removed (up to 3 axes can be removed at a time)

G52.2 IP_ ; **Command to assign axes**
(Issued to a path to which axes are to be assigned)

IP_ : Names of axes to be assigned (up to 3 axes can be assigned at a time) and axis order numbers (specifying where to assign each axis in a path)

G52.3 IP0 (L_) ; **Command to exchange axes having the same name between paths**

G52.3 IP$_1$0 IP$_2$0 (L_) ; **Command to exchange axes having different names between paths**
(Issued to paths between which axes are to be exchanged)

IP$_1$: Axis name of an axis to be exchanged (in a source path)
IP$_2$: Axis name of an axis to be exchanged (in a destination path)
L : Destination path number (omissible in a 2-path system)

NOTE

1 Be sure to specify ID numbers (parameter No. 11560) even when using the axis name-based assignment method.
2 G52.1, G52.2, and G52.3 are a one-shot G code in group 00.
3 Do not use G52.1, G52.2, and G52.3 together in a single block; they must be used in separate blocks.
4 When axis exchange command G52.3 is issued (in a certain path) for the first time, the axes of interest are put in a wait state. Actual axis exchange takes place next time the command is issued (to the other path).
5 Alarm PS0514 "ILLEGAL COMMAND IN FLEXIBLE PATH AXIS ASSIGNMENT" is issued if a conflict occurs between exchange command G52.3 axis specifications.
6 Alarm PS0514 is issued if an attempt is made to exchange (G52.3) axes within a path.
7 When axis removal, assignment, or exchange is performed actually, be sure to keep the axes of interest at halt.
8 Do not use a decimal point in ID numbers, axis order numbers, or path numbers specified in G52.1, G52.2, or G52.3.

(Example)	Enabled G52.2 P1 I1	Disabled G52.2 P1.0 I1.0
	Enabled G52.2 C1	Disabled G52.2 C1.0

- Specification of the order of axes to be assigned

If a program contains an invalid axis order number specification, the CNC behaves as follows:
Example)

Axis configuration: X,Z
Setting value of Parameter No. 11560: (X,Y,Z,C) = (1, 2, 3, 4)

1) If no axis order is specified:
   Command: G52.2 P2 Q4 ;
   The Y- and C-axes are assigned, respectively, as the third and fourth (last) axes. (X,Z,Y,C)
2) If there is a duplicate axis order specification:
   Command: G52.2 P2 I2 Q4 J2 ;
   Because "I2" and "J2" are doubly specified as the second axis, alarm PS0514 is issued.
3) If a command does not match the axis configuration:
   Command: G52.2 P2 I2 Q4 J5 ;
   Because there is a conflict with "J5" specified as the fifth axis, alarm PS0514 is issued.

- Controlled-axis removal and assignment

- Removal

If an axis is specified in axis removal command G52.1, it is removed from its path. No command can be executed to the removed command any more. Alarm PS0009 "IMPROPER NC-ADDRESS" is issued for any command directed to the removed axis.

On the position screen, the following axis status 'R' is displayed for the removed axis.

- Assignment

An arbitrary axis can be assigned using assignment axis command G52.2. Its arguments (with the ID number-based method, I, J, and K and, with the axis name-based method, numbers that follow axis names) can be used to place axes in arbitrary positions in the path of interest.

If a specified axis is yet to be removed, bit 1 (FAW) of parameter No. 11561 can be used to specify whether to defer the command execution until after the axis is removed or to issue alarm PS0514.

When the removed axis is assigned again, its status display 'R' disappears from the position screen.

Controlled-axis exchange

Axis exchange command G52.3 can be used to exchange arbitrary axes with each other.
Axis names used after exchange are determined according to the setting of bit 1 (FAN) of parameter No. 11562 as follows:

- If parameter FAN = 0, the name previously given to each axis is inherited.
- If parameter FAN = 1, the axis names are also exchanged.

If the setting of the parameter FAN conflicts between paths, FAN = 0 is assumed.

> **NOTE**
> When the setting of bit 1 (FAN) of parameter No. 11562 is valid, an attempt to exchange an axis using an extended axis name with one using no extended axis name resulting in no axis name being displayed normally. Never attempt axis exchange between an axis using an extended axis name and one using no extended axis name.

- Program example
  1) ID number type (bit 3 (FAM) of parameter No.11561 is set to 0)
     Axis configuration and setting of parameter No.11560

Path 1		Path 2		Path 3	
X	0	X	0	X	0
Z	102	Y	202	Z	302

- Fixed axis name of each path

The name of the axis, which assigned by flexible path axis assignment, can be changed to the name which specified in each path.
Set the axis name of assigned axis to parameter No.11555, and axis suffix to parameter No.11556 and No.11557. Select the axis which changes the name in the each path by the bit 0 of parameter No. 1l564(PAN). If the selected axis is assigned to another path by flexible path axis assignment, the axis name is changed to the name specified in the each path.
This setting is available on only one axis in a path.

Example) Identification number (parameter No.11560)(Z11,Z21,Z31)=(102,202,302),
Specified axis name (No.11555) = 49(path1), 49(path2), 49(path3),
Subscript (No.11556)=49(path1), 50(path2), 51(path3),
No.11557 = 49(path1), 49(path2) 49(path3),
Bit 0(PAN) of parameter No.11564=1(path1), 1(path2), 1(path3),
Bit 3(FAM) of parameter No.11561 (FAM)=1

Example of the program for each path

Block number	Path 1	Path 2	Path 3	
	O1001	O2001	O3001	
N0010	G52.1 Z11=0 ;	G52.1 Z21=0 ;	G52.1 Z31=0 ;	O1001: Release Z11(ID 102) O2001: Release Z21(ID 202) O3001: Release Z31(ID 302)
N0100	G52.2 Z21=2 ;	G52.2 Z31=2 ;	G52.2 Z11=2 ;	O1001: Assign Z21(ID 202) O2001: Assign Z31(ID 302) O3001: Assign Z11(ID 102)
:	:	:	:	:

Block number	Path 1 O1001	Path 2 O2001	Path 3 O3001	
:	:	:	:	:
N0030	G52.1 Z11=0 ;	G52.1 Z21=0 ;	G52.1 Z31=0 ;	O1001: Release Z11(ID 302) O2001: Release Z21(ID 102) O3001: Release Z31(ID 202
N0300	G52.2 Z21=2 ;	G52.2 Z31=2 ;	G52.2 Z11=2 ;	O1001: Assign Z21(ID 102) O2001: Assign Z31(ID 202) O3001: Z11(ID 302)

- The combination of the axis name of each path after axis assignment and identification number of flexible path axis assignment.

Block No.		Path 1			Path 2			Path 3		
N0100	Axis name	X11	Z11	Z12	X21	Z21	Z22	X31	Z31	Z32
	ID number		202			302			102	
N0200	Axis name	X11	Z11	Z12	X21	Z21	Z22	X31	Z31	Z32
	ID number		302			102			202	
N0300	Axis name	X11	Z11	Z12	X21	Z21	Z22	X31	Z31	Z32
	ID number		102			202			302	

- Parameter setting for axis exchange used together with other functions

Some NC functions require specifying relative axis numbers within a path (intra-path relative axis number) using parameters (Tables 1.14(a) to (e)). When axes are exchanged between paths, it is likely that an axis number used with a function in the tables may fail to match a parameter value set as an intra-path relative axis number (Example 1).

Example 1)

In this example, a relative axis number is changed after axis exchange.
(Before axis exchange, C in path 1 and Z in path 2 are, respectively, the fourth and second axes (relative axis number). After axis exchange, C in path 1 and Z in path 2 are the third axes in the respective paths.)

Before assignment			After replacement	
Path 1	Path 2		Path 1	Path 2
X	X	→	X	X
Z	Z		Z	'Y'
'Y'			C	Z
C				

(1) Case in which parameter setting requires using G10

When using functions and parameters listed in Table 1.14 (a) to (c) in such a way that the axis order is changed during axis exchange, re-set the related parameters, using programmable parameter input (G10).

Table 1.14 (a) Functions requiring setting intra-path relative numbers using parameters

Function	Related parameter number
Cs contouring control	3900, 3910, 3920, 3930, 3940
Constant surface speed control	3770
Y-axis offset	5043 to 5045
Canned cycle for grinding	5176 to 5183
Polar coordinate interpolation	5460, 5461
Normal direction control	5480
Flexible synchronization control	5660 to 5667
Position switch	6910 to 6925, 8570 to 8579
High precision oscillation function	8370
5-axis machining function	19657, 19681, 19686

Table 1.14 (b) Functions requiring setting intra-path relative axis numbers for individual axes

Function	Related parameter number
Synchronous control	8180
Composite control	8183
Superimposed Control	8186

Table 1.14 (c) Others

Related parameter number	Description
1020, 1025, 1026	Set axis names.
1022	Set 3 basic parallel axes. (Example: Cylindrical interpolation)

(2) Case in which G10 is unusable for parameter setting

Using functions listed in Tables 1.14 (d) and 1.14 (e) in such a way that the axis order is changed in axis exchange does not allow G10 to be used because the parameters used require turning the power off and on again. Follow the examples given in (3), "Case in which it is unnecessary to use G10 for parameter setting", below.

Table 1.14 (d) Functions requiring setting intra-path relative numbers using parameters (with power to be turned off and on again)

Function	Related parameter number
Y-axis offset	5044, 5045
Index table indexing	5510
Straightness compensation	5711 to 5716 5721 to 5726
Electronic gear box	7710
Arbitrary angular axis control	8211, 8212

Table 1.14 (e) Others (with power to be turned off and on again)

Function	Related parameter number	Note
Tandem control	1817#6	Must be specified for both the master and slave axes.

(3) Case in which it is unnecessary to use G10 for parameter setting

Axis configurations shown in Examples 2 to 4 do not cause intra-path relative numbers to be changed in flexible path axis assignment. So, it is unnecessary to use programmable parameter input (G10) for parameter re-setting.

Example 2)

In this example, axes having the same intra-path relative number are exchanged with each other.

Path 1		Path 2
'X'	↔	'X'
Y		Y
Z		Z
C		C

Example 3)

In this example, an axis is removed or assigned as the last one in the respective paths.
(Polygon turning is performed using the rotary axis “C” as the fifth axis in path 1 and the fourth axis in path 2.)

Before assignment		→	After assignment	
Path 1	Path 2		Path 1	Path 2
X	X		X	X
Y	Y	→	Y	Y
Z	Z		Z	Z
A			A	**'C'**
'C'				

Example 4)

When the display order of axes is set by parameter No.3130 and releasing and getting axis excluding the last display order in the path.
In this case, set the axis as the last order in the path, and set the display order in position screen by No.3130.
(Example of Constant surface speed control : "X" of first display axis in path 1, "X" of first display axis in path 2)

Setting				Axis name on position screen	
Path 1		Path 2			
Physical order	Parameter No.3130	Physical order	Parameter No.3130	Path 1	Path 2
Y	2	Y	2	**'X'**	
Z	3	Z	3	Y	Y
A	4			Z	Z
C	5			A	
'X'	1			C	

↓ After assignment

Physical order	Parameter No.3130	Physical order	Parameter No.3130	Path 1	Path 2
Y	2	Y	2		**'X'**
Z	3	Z	3	Y	Y
A	4	**'X'**	1	Z	Z
C	5			A	
				C	

- Signal specifications

Even after the arrangement of axes has been changed in flexible path axis assignment, the signals involved remain enabled if they are of axis type.

- Reset / Emergency stop
If a reset or emergency stop occurs during flexible path axis assignment, the latest axis configuration is preserved.

- Power-off/-on
If the power is turned off and on again during flexible path axis assignment, the axis configuration is changed or preserved depending on the setting of bit 2 (FA0) of parameter No. 11561 as follows:
- If parameter FA0 = 0, the initial axis configuration (parameter No. 0981) is resumed.
- If parameter FA0 = 1, the latest axis configuration is preserved.

- Number of controlled paths in a path
Axis assignment cannot exceed the maximum allowable number of controlled axes in each path. The number includes any removed axes. No removal command can make the number of controllable axes in each path become zero. Such an attempt leads to alarm PS0514.

- Offset
The various offsets such as the cutter compensation and tool length compensation must be kept canceled during execution of flexible path axis assignment. Otherwise, alarm PS0514 is issued.

- Workpiece Coordinate System
Once flexible path axis assignment is executed, it is necessary to select the workpiece coordinate system again.

- Diameter / Radius setting
When arbitrary flexible path axis assignment is executed, diameter or radius setting is in accordance with the parameter DIA (No. 1006 # 3).

- Plane selection
When Flexible Path Axis Assignment is executed to the axis which consist the current plane selection, select the plane again after the Flexible Path Axis Assignment is finished.

- Cs contour controlled axis
To perform Cs contour control, use the Cs contour control change signals CONS1 to CONS4 <Gn274.0 to 3> for each spindle.
No Cs contour control mode changeover can be made for any removed axis.
Gain switching is carried out as follows:
Removing the Cs contour control axis: The gain specified with parameter No. 1825 is resumed.
Assigning the Cs contour control axis: Switching occurs to the gain specified using parameters Nos. 3900 to 3944 for the path to which the Cs contour control axis belongs.
Exchanging Cs contour control axes: Switching occurs to the gain specified using Nos. 3900 to 3944 for the path to which the respective Cs contour control axes belong.

- Reference axis
The reference axis is decided according to the arrangement of axes valid after flexible path axis assignment.

- State of waiting for removal
Alarm PS0514 is issued if either of the following commands is issued from the other path when the CNC is waiting for an axis to be removed.
- Axis exchange command issued from the other path.
- Axis assignment command issued from the other path to an axis yet to be removed

- Dwell

When issuing a dwell command, use address P. If flexible path axis assignment results in no X-axis existing in the path of interest or causes the reference axis to be renamed, it is impossible for the dwell command to use address X or the name of the reference axis.
Alarm PS0009 may be issued if the dwell command attempts to use address X or the reference axis name.

- Axis synchronous control

Alarm PS0514 is issued if an attempt is made to perform flexible path axis assignment for an axis under axis synchronous control. Before performing flexible path axis assignment for an axis, cancel axis synchronous control for that axis.
When flexible path axis assignment changes the arrangement of axes not under axis synchronous control:

- Even if flexible path axis assignment changes the arrangement of the master axis, the master axis is preserved.
- Even if flexible path axis assignment changes the arrangement of axes during axis synchronous control, the relationship between the master and slave axes is preserved.

- Constant surface speed control

If flexible path axis assignment changed the arrangement of axes, which axis to use as a reference in constant-surface speed control calculation is determined according to the axis arrangement used when a constant-surface speed control command (G96) is issued.
Even if the arrangement of axes is changed during constant-surface speed control, the calculation reference axis is preserved until the constant-surface speed control is canceled.

- PMC axis control

No flexible path axis assignment can be performed for any axis under PMC axis control.
Before performing flexible path axis assignment, cancel PMC axis control.
No PMC axis control can be performed for any removed axis. Before performing PMC axis control for an axis, assign that axis.

- Synchronous/Composite control

Alarm PS0514 is issued if an attempt is made to perform flexible path axis assignment for axes under synchronous control or composite control. Before performing flexible path axis assignment, cancel synchronous control and composite control.
If synchronous control or composite control is performed with the arrangement of axes changed in flexible path axis assignment, synchronous control or composite control takes effect on the new axis arrangement.

- Superimposed control

Alarm PS0514 is issued if an attempt is made to perform flexible path axis arrangement for axes under superimposed control. Before performing flexible path axis arrangement, cancel superimposed control.
If superimposed control is performed with the arrangement of axes changed in flexible path axis assignment, superimposed control takes effect on the new axis arrangement.

- Spindle control with servo motor

If flexible path axis assignment is performed for axes under Spindle control with servo motor:

- Alarm PS0514 is issued if flexible path axis assignment is performed during the SV speed control mode. Before performing flexible path axis assignment, switch to the positional control mode.
- If it is necessary to switch to the SV speed control mode for Spindle control with servo motor, do so on the path to which the axis under Spindle control with servo motor belongs.
- Issuing a command for servo motor-based rigid tapping by changing the arrangement of axes under Spindle control with servo motor requires setting rigid tapping based on the spindle of the other spindle.
- No SV speed control mode switching command can be issued for any removed axis. Issuing such a command results in alarm PS0514.

- Parameter No. 3130 (axis display order on the current position display screen)

When using parameter No. 3130, take the following into consideration.

- The parameter settings for an axis newly assigned by flexible path axis assignment are valid for the path to which the new axis is assigned. When specifying parameter No. 3130 or rewriting it using G10, take the conditions of the axis to be assigned into consideration.
- If parameter No. 3130 is already specified, the current position is displayed according to the setting of the parameter No. 3130 even when flexible path axis assignment is performed to change the arrangement of axes.
- When the axis to which parameter No. 3130 is set is removed, the current position display of the removed axis is displayed according to the setting of the parameter No. 3130. When the axis to which parameter No. 3130 is set is assigned, the current position display may include blanks.

- Polygon turning

Even when the axis configuration or axis arrangement is changed by flexible path axis assignment, an axis can be recognized as a tool rotation axis if the axis belongs to a path where a polygon turning command is issued.

If a path where a polygon turning command is issued has no tool rotation axis specified with a parameter when the power is turned on, the tool rotation axis is determined according to the axis arrangement that is valid when a polygon turning command is issued.

When re-assigning a tool rotation axis for polygon turning by flexible path axis assignment, it is necessary to take the axis arrangement into consideration.

- Inch/metric input

No flexible path axis assignment can be applied between paths using different input unit methods (inch input and metric input).

- Extended external machine zero point shift

When apply the Extended external machine zero point shift to the axis which the index in the path has changed by Flexible Path Axis Assignment, set the parameter FES(bit 4 of parameter No.11565) to 1. When the parameter FES is 1, the R addresses of each axis which specifies the shift value of Extended external machine zero point shift is held to the initial order of axis, and becomes not to change by Flexible path axis assignment.

- Position switch

When apply the Position switch to the axis which the index in the path has changed by Flexible Path Axis Assignment, set the parameter FPS(bit 5 of parameter No.11565) to 1. When the parameter FPS is 1, the target axis of each position switch is held to the initial order of axis, and becomes not to change by Flexible path axis assignment.

- 3-dimensional coordinate conversion

In 3-dimensional coordinate conversion mode, Flexible Path Axis Assignment cannot be performed to the target axis of the conversion.

- Number of blocks read ahead

An alarm (PS0514 or DS0080) will issued if an arbitrary axis switching command that satisfies all of the following conditions is performed.

- Number of blocks read ahead differs between paths.
- The total of the axis belonging to the path with the largest number of blocks read ahead at startup and the axis belonging to the other path and being the object of Flexible Path Axis Assignment (the axis whose parameter No. 11560 is not 0) exceeds the maximum for allowable number of controlled axes in each path.
- At startup, the axes that belonged to a path with a small number of blocks read ahead were moved to a path with a large number of blocks read ahead.

In the above case, if the axis on which flexible path axis assignment is performed to a path with a large number of blocks read ahead is limited to a part of the axes for which parameter No. 11560 is set in the other path, bit 3(FHM) of parameter No.11565 is set to 1, disable the automatic judgment of the axis that extends the number of blocks read ahead, then bit 2(FHE) of parameter No.11562 is set to 1 for those axes.
However, the number of axes that can be set to 1 of FHE is up to the system maximum number of control axes minus the number of control axes of the system with the largest number of blocks read ahead.

Diagnosis data

4000	Reason number of alarm in flexible path axis assignment

The cause of the alarm that may be issued in flexible path axis assignment is displayed.

1 The number of axes in the path is 0.
2 The number of axes in the path is larger than its allowable maximum value.
3 The removal command has no ID specification.
4 The removal command has a duplicate ID specification.
5 An axis specified with removal command P does not exist in the path or has been removed from the path.
6 An axis specified with removal command Q does not exist in the path or has been removed from the path.
7 An axis specified with removal command R does not exist in the path or has been removed from the path.
8 An axis specified with the removal command does not exist in the path or has been removed from the path.
9 The removal command has no axis specification or has an ID specification.
10 In flexible path axis assignment, the ID specification is incorrect.
11 The assignment command has no ID specification.
12 The assignment command has a duplicate ID specification.
13 The assignment command has a duplicate axis arrangement specification.
14 The path specified with the arrangement command has no target axis or the arrangement command has no ID specification.
15 The path specified with the arrangement command has an invalid axis assignment specification.
16 An axis whose removal a command is waiting for belongs to the path where the command was issued.
18 An axis whose removal an exchange command is waiting for belongs to the path paired with the path where the exchange command was issued.
19 An axis for which an assignment command was issued is yet to be removed. (Bit 1 of parameter No. 11561 is set to 1.)
20 An axis for which an assignment command is issued in a path belongs to another path where a removal command for it has been issued.
21 An axis for which an assignment command was issued is yet to be removed.
22 The assignment command has no axis specification or has an ID specification.
23 G-code of axis removal, axis assignment, or axis exchange of Flexible Path Axis Assignment is executed when the signal type of Flexible Path Axis Assignment is selected (bit 0 (CSG) of parameter No.11563 is 1).
24 An axis at which an exchange command is targeted belongs to the path where the exchange command was issued.
25 The exchange command has no ID specification.
26 The exchange command has a duplicate ID specification.
27 In a system having 3 or more paths, an exchange command has no L specification.
28 An axis targeted by an exchange command was not found in the source path (path where this exchange command was issued).

29 An axis specified in the exchange command is being processed by another command or has already been removed.
30 An axis targeted by an exchange command was not found in the destination path (path paired with a path where another exchange command was issued for the axis).
32 The exchange command has no target axis.
33 The exchange command has a conflict.
34 The exchange command has no axis specification or has an ID specification.
35 A cycle other than flexible path axis assignment is under way.
36 An attempt was made to perform flexible path axis assignment during the SV rotation control mode.
37 An attempt was made to perform flexible path axis assignment during the polygon turning mode.
38 An attempt was made to perform flexible path axis assignment during PMC axis control.
40 An attempt was made to perform flexible path axis assignment during mirror imaging.
41 An attempt was made to perform flexible path axis assignment during 3-dimensional coordinate conversion.
42 An attempt was made to perform flexible path axis assignment during coordinate system rotation.
43 An attempt was made to perform flexible path axis assignment during scaling.
44 An attempt was made to perform flexible path axis assignment during axis synchronization.
45 An attempt was made to perform flexible path axis assignment for an axis already removed.
46 An attempt was made to perform flexible path axis assignment for an axis under composite control.
47 An attempt was made to perform flexible path axis assignment for an axis under synchronous control.
48 An attempt was made to perform flexible path axis assignment for an axis under superimposed control.
55 An attempt was made to perform flexible path axis assignment simultaneously with an axis move command.
56 An attempt was made to perform flexible path axis assignment during tool compensation.
60 Axis number of axis removal or axis assignment exceed the limitation.
61 An attempt was made to perform Flexible path Axis Assignment in reset operation, or an attempt was made to perform Flexible path Axis Assignment in backward movement or re-forward movement of Manual Handle Retrace, or Setting of reference axis of the path cannot be changed, or An attempt was made to perform Flexible path Axis Assignment for moving axis, or Command for target axis exists (prepared by automatic operation) or Command for target axis exists (prepared by manual operation).
64 An attempt was made to perform Flexible path Axis Assignment for an axis under angular axis control.
65 An attempt was made to perform Flexible path Axis Assignment for an axis under flexible synchronous control.
66 An attempt was made to perform Flexible path Axis Assignment for an axis under EGB control.
70 The number of look ahead block is larger than original path which axis belongs.
71 The axis which belongs to loader path of Loader control function cannot be the target of Flexible path axis assignment.
72 Target path is in reset operation.
73 An attempt was made to perform Flexible path Axis Assignment in backward movement or re-forward movement of Manual Handle Retrace

74 An attempt was made to perform Flexible path Axis Assignment in backward movement or re-forward movement of Retrace.
75 Command for target axis exists (prepared by manual operation)
76 Command for target axis exists (prepared by manual operation)
77 Target axis is moving
78 Target axis is moving
79 Target axis is moving
80 Target axis is moving
81 Command for target axis exists (prepared by automatic operation)

4001	Belonging path of axis in flexible path axis assignment

A path (specified by parameter No. 981) to which an axis specified for flexible path axis assignment belongs is displayed.

0 : Source path
1 to 10 : Destination path (because of assignment or exchange)
-1 to -10 : Already removed

Parameter

0981	Absolute path number to which each axis belongs

> **NOTE**
> When this parameter is set, the power must be turned off before operation is continued.

[Input type] Parameter input
[Data type] Byte axis
[Valid data range] 1 to 10

Set the path to which each axis belongs.

> **NOTE**
> When 0 is set, each axis is assumed to belong to path 1.

11555	Flexible path axis assignment specified axis name

[Input type] Parameter input
[Data type] Byte path
[Valid data range] 0 to 256

When the axis selected by bit0 (PAN) of parameter No.11564 is assigned, the specified axis name is used.

11556	Flexible path axis assignment specified axis name 2

[Input type] Parameter input
[Data type] Byte path
[Valid data range] 0 to 256

When the axis selected by bit0 (PAN) of parameter No.11564 is assigned, the specified axis name is used. If the extended axis name is effective (bit0 (EEA) of parameter No.1000=1), this value becomes the second character of the axis name. Otherwise, this value becomes the subscript of the axis name.

11557	Flexible path axis assignment specified axis name 3

[Input type] Parameter input
[Data type] Byte path
[Valid data range] 0 to 256

When the axis selected by bit0 (PAN) of parameter No.11564 is assigned, the specified axis name is used. If the extended axis name is effective (bit0 (EEA) of parameter No.1000=1), this value becomes the third character of the axis name. When the second axis name(No.11556) is not set, the third axis name becomes invalid.

11560	Identification number for an axis to be subjected to flexible path axis assignment

> **NOTE**
> When this parameter is set, the power must be turned off before operation is continued.

[Input type] Parameter input
[Data type] Word axis
[Valid data range] 0 to 32767

Set an identification number for an axis to be subjected to flexible path axis assignment. The value specified corresponds to a program-specified address P(Q,R) value.

	#7	#6	#5	#4	#3	#2	#1	#0
11561				FAC	FAM	FAO	FAW	FAR

[Input type] Parameter input
[Data type] Bit

> **NOTE**
> When this parameter is set, the power must be turned off before operation is continued.

#0 FAR The flexible path axis assignment function is:
0: Disabled.
1: Enabled.

> **NOTE**
> Setting the parameter FAR erases all history data (operation history, alarm history, and external operator message history) the next time the power is turned on.

#1 FAW If an axis acquisition command is issued for an axis yet to be freed in flexible path axis assignment:
0: The command waits for the axis to be freed.
1: Alarm PS0514 is issued.

#2 FAO If the power is turned off and on again with flexible path axis assignment in effect, the axis configuration is:
0: Returned to the initial state (specified with parameter No. 0981).
1: Kept in the most recent state.

#3 FAM The method of command specification used by programs in flexible path axis assignment is:
0: Identification number method.
1: Axis name method.

#4 FAC If the axis removement command is issued for an axis which already removed, or assigned to the another path in flexible path axis assignment:
0: Alarm PS0514 is issued..
1: The command is ignored.

	#7	#6	#5	#4	#3	#2	#1	#0
11562						FHE	FAN	

[Input type] Parameter input
[Data type] Bit axis

#1 FAN In flexible path axis assignment, axis names used after exchange are:
0: Those previously set for each axis.
1: Those set for the other axes in exchange pairs.

> **NOTE**
> The parameter FAN is invalid when an axis assignment command for flexible path axis assignment is issued. The name set for each axis is inherited.

#2 FHE In flexible path axis assignment, when parameter FHM(bit 3 of parameter No.11565) is 1, this axis :
0: Does not assign to the path which has large number of read ahead blocks more than initial path which the axis belongs.
1: Assigns to the path which has large number of read ahead blocks more than initial path which the axis belongs.

	#7	#6	#5	#4	#3	#2	#1	#0
11563				FAX				

[Input type] Parameter input
[Data type] Bit

> **NOTE**
> When this parameter is set, the power must be turned off before operation is continued.

#4 FAX In flexible path axis assignment, if the target axis of the assignment command is already exists on the target path,
0: The alarm PS0514 occurs.
1: the command is ignored.

	#7	#6	#5	#4	#3	#2	#1	#0
11564								PAN

[Input type] Parameter input
[Data type] Bit axis

NOTE
When this parameter is set, the power must be turned off before operation is continued.

 # 0 PAN The name of the axis which assigned to each path is
0: Not changed.
1: Changed to the specific name selected in each path.
This setting is available on only one axis in a path.

	#7	#6	#5	#4	#3	#2	#1	#0
11565			FPS	FES	FHM			

[Input type] Parameter input
[Data type] Bit

#3 FHM On Flexible Path Axis Assignment, the axis which assigned to the path which has large number of read ahead blocks compared to the initial path which the axis belongs is:
0: selected automatically.
1: selected by parameter bit 2(FHE) of parameter No.11562.

#4 FES For the axis which the order in the path is changed by Flexible path axis assignment, Extended external machine zero point shift is:
0: not used.
1: used. (R address of Extended external machine zero point shift is not changed by Flexible path axis assignment.)

#5 FPS When the axis order is changed by Flexible path axis assignment, axis selection of position switch and high-speed position switch is:
0: depends on axis order after the execution of Flexible path axis assignment.
1: always considered as initial axis order.

Alarm and message

Number	Message	Description
PS0514	ILLEGAL COMMAND IN FLEXIBLE PATH AXIS ASSIGNMENT	1) An assignment command in flexible path axis assignment was issued for an axis not yet to be removed. 2) The P, Q, R, I, J, K, or L value specified by G52.1, G52.2, or G52.3 is invalid. 3) The value of the parameter No. 11560 is duplicated. 4) An attempt was made to execute a removal command (G52.1) for an axis already removed. 5) An attempt was made to exchange axes having different settings of bit 1 (FAN) of parameter No. 11562. 6) An attempt was made to perform flexible path axis assignment without canceling the offset. Refer to the diagnosis data No.4000 for more detailed cause of this alarm.

Caution

> ⚠ **CAUTION**
> Using this function changes the arrangement of axes, thus possibly resulting in an unintended axis (axis not intended by a parameter involving axis specification) being specified. When using this function, take the arrangement of axes into consideration.

> **NOTE**
> When the option is available, synchronous control and composite control are usable.

Limitation

1. This function cannot be used with Manual Guide *i*.
2. This function cannot be used with Program Restart.
3. This function cannot be used between an inch machine and a metric machine.
4. Flexible path axis assignment cannot be performed during the following modes.
   - Canned cycle
   - Coordinate system rotation
   - Mirror image
   - Scaling
   - Spindle control with servo motor
   - Polygon turning
   - High precision oscillation function
5. Do not specify any axis as a target in flexible path axis assignment if it is being used by any of the following:
   - Tandem control
   - Electronic gear box
   - Angular axis control
6. In retrace and manual handle retrace, it is impossible to reverse blocks in which flexible path axis assignment is specified.
7. When the setting of bit 1 (FAN) of parameter No. 11562 is valid, do not attempt axis exchange between an axis using an extended axis name and one using no extended axis name.

Notes concerning the FOCAS2 functions

Explained below are the notes concerning FOCAS2 functions. Observing the notes will make applications use flexible path axis assignment.

- Number of controlled axes in a path

The number of controlled axes in a path can be acquired using a FOCAS2 function (cnc_axisnum). The flexible path axis assignment function may change the number of controlled axes in a path. Therefore, acquire the number of controlled axes in a path as needed

- Information about controlled axes

Information about controlled axes can be acquired using a FOCAS2 function (cnc_rdaxisdata), which reads various data relating to the servo axis or spindle. The flexible path axis assignment function may change the configuration of controlled axes. In such a case, however, it is possible to acquire correct data. The FOCAS2 function can acquire information also about axes removed by flexible path axis assignment.

- History data

In the alarm history and the workpiece offset data change history, the number of controlled axes was changed as stated below according to whether the flexible path axis assignment function is enabled or disabled:

When the function is disabled: Intra-path relative axis number (1 to the allowable maximum number of controlled axes in a path)

When the function is enabled: Absolute axis number + 1000 (1001 to the allowable maximum number of controlled axes + 1000)

For details, refer to “FOCAS2 Function Reference”.

In addition, when acquiring axis names in the order of absolute axis numbers, use the function cnc_exaxisname2, which acquires extended axis names.

1.14.1 Outputting States of Individual Axes

Information about the path to which each axis belongs, their intra-path axis numbers, and whether they have been removed is output to a specified internal relay user area (R). Output information for each axis uses the 3 bytes in the internal relay user area (R) whose address is specified for them. Information output is carried out only for axes for which an internal relay user area (R) address has been specified. The output data is detailed below.

Path to which each axis belongs AXPT1<RXXXX.0> to AXPT4<RXXXX.3>

[Classification] Output signal

[Function] The path number of a path to which the axis of interest belongs is output. When using multi path PMC, only 1st PMC is used.

> **NOTE**
> XXXX represents a value set in parameter No. 11554.

Intra-path axis number for each path AXNM1<RXXXY.0> to AXNM5<RXXXY.4>

[Classification] Output signal

[Function] An axis number in the path to which the axis of interest belongs is output. When using multi path PMC, only 1st PMC is used.

> **NOTE**
> XXXY represents a value specified in parameter No. 11554 plus 1.

Whether each axis has been removed AXRMV<RXXXZ.0>

[Classification] Output signal

[Function] Information about whether each axis has been removed is output. When using multi path PMC, only 1st PMC is used.
Removed: 1
Assigned: 0

> **NOTE**
> XXXZ represents a value specified in parameter No. 11554 plus 2.

Signal address

XXXX represents a value specified in parameter No.11554.
XXXY represents a value specified in parameter No.11554 + 1.
XXXZ represents a value specified in parameter No.11554 + 2.

	#7	#6	#5	#4	#3	#2	#1	#0
RXXXX					AXPT4	AXPT3	AXPT2	AXPT1
RXXXY				AXNM5	AXNM4	AXNM3	AXNM2	AXNM1
RXXXZ								AXRMV

Parameter

11554	Internal relay user area (R) address for individual-axis information

NOTE
When this parameter is set, the power must be turned off before operation is continued.

[Input type] Parameter input
[Data type] 2-word axis
[Valid data range] 0 to 59999

Set an internal relay user area (R) address for information to be output about an individual axis. The information is output only about the axis specified with this parameter. Three bytes starting at the setting are used for each axis.

NOTE
1 The setting must be a multiple of 4 (4, 8, ...).
2 This function is disabled if the parameter is 0.
3 When performing multipath control, be careful to keep the data addresses of each path from overlapping with those of the other paths.
4 The R address area varies depending on the PMC used and its memory. Be sure to select values within the usable range by checking the specifications of the PMC. (Example: R addresses in the range from R0 to R7999 if memory B of the first PMC is used.)

⚠WARNING
If an internal relay of the set address in this parameter is used by another usage, it may cause an unexpected machine behavior. Be careful enough that you must prevent the conflict of the used internal relay.

Example)
If parameter No. 11554 (C) = 1000, the output data of flexible path axis assignment is listed below.

Axis configuration	Path to which the C-axis belongs R1000	Intra-path axis number for the C-axis R1001	Whether the C-axis has been removed R1002
Path1: X Z C Y Path2: X Z Y	00000001	00000011	00000000
Removing the C-axis			
Path1: X Z Y C Path2: X Z Y	00000001	00000100	00000001

Axis configuration	Path to which the C-axis belongs R1000	Intra-path axis number for the C-axis R1001	Whether the C-axis has been removed R1002
Assigning the C-axis to path 2			
Path1: X Z Y Path2: X Z Y C	00000010	00000100	00000000

1.14.2 Direct Assignment Mode of Flexible Path Axis Assignment by signals

OVERVIEW

When the bit 0(CSG) of the parameter No.11563 is set to 1, direct assignment can be commanded by signal command with direct assignment mode signal DASN<G0536.5>.

Description

Direct assignment mode of Flexible path axis assignment

When the bit 2(NMF) of the Parameter No.11563 is set to 1, the direct assignment mode signal DASN<G0536.5> becomes available. If this signal is set to 1, the axis removal command, axis assignment command of flexible axis assignment can be commanded. Therefore, flexible path axis assignment command can be used even in the following situation (for example, command from machine operator panel).
In Direct assignment mode of Flexible path axis assignment, the axis assignment and axis removal is work as follows.

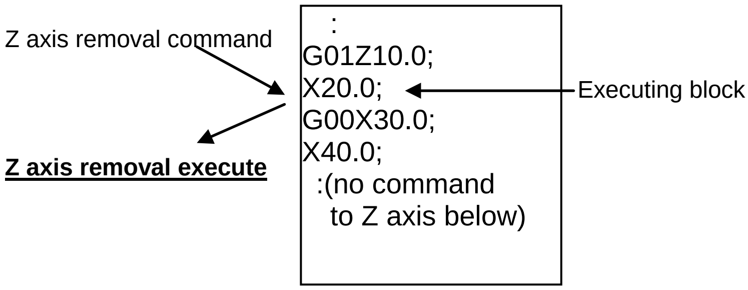
- Removal of control axis

When direct assignment mode signal DASN<G0536.5> and removal command signal RMVST<Gn536.2> are set to “1”, removal command is executed. When removal command is completed, Removal completion signal RMVED<Fn536.2> is set to “1”. When Removal command signal RMVST is set to “0”, Removal completion signal RMVED changes into “0”. The specification of the removal axis is selected by setting bit 0 of the address in user area of internal relay(R) (No.11553) to “1”. The removal command is only effective to the axis that belongs in the same path. It is possible to remove three axes at the same time.

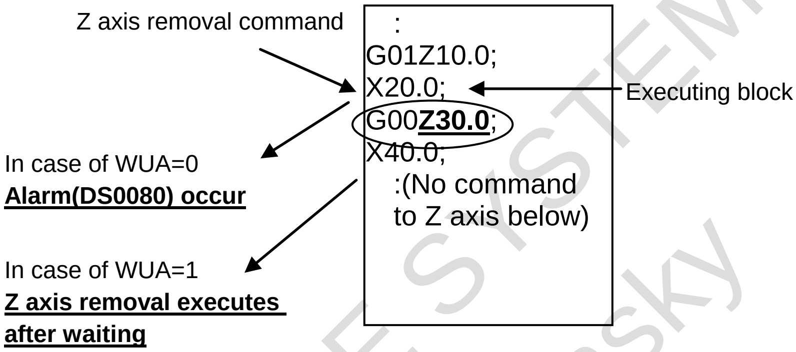
When axis removal is commanded, the CNC is worked as follows.

1. In case of the bit 3(WUA) of the Parameter No.11563 is 0 and any of the following item is applied, the alarm (DS0080) issues immediately and axis removal is not executed.
   1-1. The signal DASN<G0536.5> has changed while executing axis removal command.
   1-2. The axis removal is commanded while reset operation.
   1-3. The axis removal is commanded while emergency stop.
   1-4. The axis removal is commanded to the moving axis.
   1-5. The axis removal is commanded while AI Contour control mode, and any axis in the path is moving.
   1-6. The unit of reference axis (Parameter No. 1031) will change by the axis removal command.
2. In case of WUA(No11563#3) is 1, the CNC waits until item 1-1 to 1-5 becomes irrelevant.
   Keep the removal start signal and specified removal axis signal during waiting.
   The axis is removed when not all of above item 1-1 to 1-6 applies.

Example 1: In case of removal command is executed to Z axis while automatic operation with no Z axis command



Example 2: In case of removal command is executed while the NC is buffering automatic operation with Z axis command



- Assignment of control axis

When direct assignment mode signal DASN<G0536.5> and assignment command signal ASNST<Gn536.3> are set to “1”, assignment command is executed. When assignment command is completed, Assignment completion signal ASNED<Fn536.3> is set to “1”.
When Assignment command signal ASNST is set to “0”, Assignment completion signal ASNED changes into “0”.
The specification of the assignment axis is selected by setting bit 1 of the address in user area of internal relay(R) (No.11553) to “1”, which area is set for each axis. The axis order in the path when the assignment of control axis is commanded is specified by the address from bit 0 to bit 4 in user area of internal relay (R) ((No.11553)+1).
The path from which the control axis is assignment is specified by the address from bit 0 to bit 3 in user area of internal relay(R) ((No.11553)+2).
The assignment command is effective to the axis that belongs in the M code commanded path. Maximum three axes can be assigned at the same time.

When axis assignment is commanded on the path which is not in automatic operation, the axis is assigned immediately. In case of target axis is not removed, the axis assignment is not executed until the axis is removed.
In case of the automatic operation, if no buffered program command exists and every axis which belongs to the assignment path Cs contour controlling axis and servo live tool axis are not moving, the axis assignment is executed. If not, the alarm (DS0080) issues.
Therefore, in case of axis assignment command, start assignment sequence at the assigned path by suppress buffering M code to avoid the alarm above.

When axis assignment is commanded, if any of the following item is applied, the alarm (DS0080) issues immediately and axis assignment is not executed.

- The signal DASN<G0536.5> has changed while executing axis assignment command.

- The axis assignment is commanded while reset operation.
- The axis assignment is commanded while emergency stop.
- The unit of reference axis (Parameter No. 1031) will change by the axis removal command.
- The axis assignment is commanded while program is buffered.

NOTE

1. When the axis assignment command and removal command is executed to the same path, the preceded command is executed first. The next command is executed when the preceded command is finished and the assignment completion signal / removal completion signal becomes 0.
2. When executing macro blocks or executing short length movement blocks, the axis assignment / removal may take time.

-Specification of the order intra-path number of axis on axis assignment command

When no order number or illegal order number of the axis is specified by PMC signals, the CNC operation is as follows.

Ex) Y-axis and C-axis are assigned to the path of the axis configuration X-axis and Z-axis:
Setting value of Parameter No.11560: (X, Y, Z, C) = (1, 2, 3, 4),
No.11553: (X, Y, Z, C) = (100, 104, 108, 112)

1) In case that the axis order is not specified
Command: Assignment command ASNST <Gn536.3>=1 R104.1=1, R112.1=1, R105 = 0, R113 = 0
Y is assigned as the third axis, and C is assigned as the fourth and last axis. (X, Z, Y, C)
2) In case that the axis order is specified doubly.
Command: Assignment command ASNST <Gn536.3>=1 R104.1=1, R112.1=1, R105 = 2, R113 = 2
As "R104=2" and "R113=2" for second axis are specified doubly, the alarm (PS0514) is issued.
3) In case that the command contradicts axis configuration.
Command: Assignment command ASNST <Gn536.3>=1 R104.1=1, R112.1=1, R105 = 2, R113 = 5
As "R113=5" for fifth axis specification is contradicted, the alarm (PS0514) is issued.

Sample program

Example 1:

We show an example of axis assignment in case that M40 is a command for activating axis assignment ladder sequence M code by direct assignment mode signal DASN<G0536.5>.

If execute MDI operation at only one path (The rest of paths which concern to flexible path axis assignment are not executing automatic operation (Reset status)), the M code can be commanded in any path.

```
MDI program in path 1
O0000;
M40;
```

In case of automatic operation, the M code which activates the ladder sequence must be command from the assigned path. The sample program below shows the example that the axis removed from 2nd path and assigned to 1st path. By M40, the direct assignment mode signal is changed to 1, and then the ladder sequence that removes the axis from 2nd path is activated. Then the ladder sequence that assigns the axis to 1st path is activated. At last, the direct assignment mode signal is changed to 0.

(M40 is the M code which suppress buffering)

```
Path 1:
O1001
  :
M40
  :
```

```
Path 2:
O2001
  :
(Waiting M code is not necessary)
  :
```

Example 2:
This sample program shows that in case of the machine has following axis configuration and use the A axis from both 1st path and 2nd path.

1st path axis configuration: X1, Z1, C1, A
2nd path axis configuration: X2, Z2, C2
Parameter No.11553 = 100 for A axis

M104: Change the signal DASN<G0536.5> to 1, then activate the ladder sequence that remove the A axis from 2nd path. Then activate the ladder sequence that assign A axis to 1st path.
At last, change the signal DASN to0 and return FIN signal.

M204: Change the signal DASN<G0536.5> to 1, then activate the ladder sequence that remove the A axis from 1st path. Then activate the ladder sequence that assign A axis to 2nd path.
At last, change the signal DASN to 0 and return FIN signal.

(Both M104 and M204 are the M code which suppress buffering)

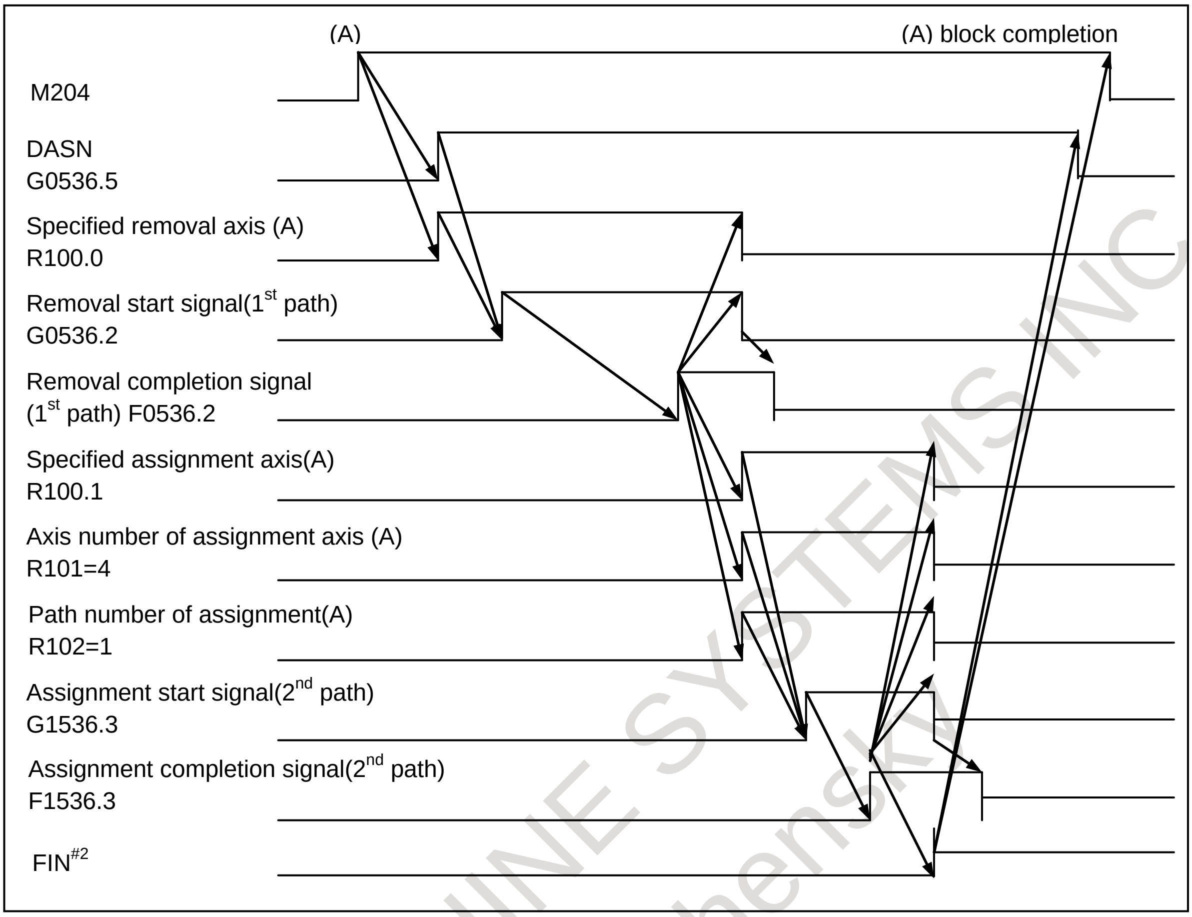
```
1st path
O1001;
  :
G01X1=100.0;                  (A')
G00X1=150.0;
G00Z1=230.0;
  :
M104;                         (B)
A10.0;
  :
```

```
2nd path
O2001;
  :
M204;                         (A)
A10.0;
  :
  :
G01X2=100.0;                  (B')
X2=110.0Z2=110.0;
X2=120.0;
G00X2=200.0Z2=200.0;
  :
```

(A)-(A’) Activate the ladder sequence from 2nd path that remove the A axis from 1st path and assign to 2nd path (M204)

(B)-(B’) Activate the ladder sequence from 1st path that remove the A axis from 2nd path and assign to 1st path (M104)

(Signal sequence on (A))



Signals

Removal start signal RMVST<Gn536.2>

[Classification] Input signal

[Function] Start removal command of flexible path axis assignment.

[Operation] When the signal is set to "1" with M code (Parameter No.11550), the removal command is executed.

Assignment start signal ASNST<Gn536.3>

[Classification] Input signal

[Function] Starts assignment command of flexible path axis assignment.

[Operation] When the signal is set to "1" with M code (Parameter No.11551), the assignment command is executed.

Direct assignment mode signal DASN<G0536.5>

[Classification] Input signal

[Function] Starts direct assignment mode of flexible path axis assignment.

[Operation] When the signal is set to "1", the signal type of flexible path axis assignment can be executed in case that the bit 2(NMF) of parameter No.11563 is 1.

Removal completion signal RMVED<Fn536.2>

[Classification] Output signal

[Function] Notifies the completion of removal command.

[Output condition] 0 : Removal command is not completed or removal command is not commanded.
1 : Removal command is completed.

When Removal command signal RMVST is set to “0”, this signal changes into “0”.

Assignment completion signal ASNED<Fn536.3>

[Classification] Output signal

[Function] Notifies the completion of assignment command.

[Output condition] 0 : Assignment command is not completed or assignment command is not commanded.
1 : Assignment command is completed.
When Assignment command signal ASNST is set to “0”, this signal changes into “0”.

- User area of internal relay (R) for each axis

The address in user area of internal relay (R) of each axis used for flexible path axis assignment is set to the parameter (No.11553). This parameter is used by three bytes an axis. Please set not to overlap with other axes.

The meaning of user area of internal relay (R) of each axis is as follows.

Specified removal axis RMVAX<RXXXX.0>

[Classification] Input signal

[Function] This signal specifies the removal axis. When using multi path PMC, only 1st PMC is used.

> **NOTE**
> XXXX represents a value set in parameterNo.11553.

Specified assignment axis ASNAX<RXXXX.1>

[Classification] Input signal

[Function] This signal specifies the assignment axis. When using multi path PMC, only 1st PMC is used.

> **NOTE**
> XXXX represents a value set in parameterNo.11553.

Axis number of assignment axis ASNM1<RXXXY.0> to ASNM5<RXXXY.4>

[Classification] Input signal

[Function] These signals specify the axis number of assignment axis in the path. When using multi path PMC, only 1st PMC is used.

> **NOTE**
> XXXY represents a value specified in parameter No. 11553 plus 1.

**Path number of assignment or path number of exchange target axis
CMPT1<RXXXZ.0> to CMPT4<RXXXZ.3>**

[Classification] Input signal

[Function] These signals specify the path number of assignment command.
These signals specify the path number of exchange target axis. When using multi path PMC, only 1st PMC is used.

> **NOTE**
> XXXZ represents a value specified in parameter No. 11553 plus 2.

Signal address

Gn536			DASN		ASNST	RMVST

Parameter

11553	The address of command in user area of internal relay(R)

NOTE
When this parameter is set, the power must be turned off before operation is continued.

[Input type] Parameter input
[Data type] 2-word axis
[Valid data range] 0 to 59999

When the signal type of flexible path axis assignment is used, the address of command in user area of internal relay (R) is set in each axis. 3 bytes are used from a set value with each axis.

NOTE
1 Set the value that becomes the multiple of 4. (0, 4, 8, …)
2 The range of the R address differs depending on the PMC used and the memory size. Check the specifications of the PMC, and set a value within the valid range.
(Example: R addresses in the range from R0 to R7999 if memory B of the first PMC is used.)
3 Signal type of flexible path axis assignment is not available for the axis in case of this parameter is set to 0.

⚠WARNING
If an internal relay of the set address in this parameter is used by another usage, it may cause an unexpected machine behavior. Be careful enough that you must prevent the competition of the used internal relay.

11563					WUA	NMF		CSG

[Input type] Parameter input
[Data type] Bit

> **NOTE**
> When this parameter is set, the power must be turned off before operation is continued.

 # 0 CSG Flexible path axis assignment is commanded:
0: By G code command.
1: By PMC signal setting.

> **⚠WARNING**
> Please set an appropriate value to parameter No.11553 beforehand when you set 1 to this parameter.
> If an internal relay of the set address in parameter No.11553 is used by another usage, it may cause an unexpected machine behavior. Be careful enough that you must prevent the competition of the used internal relay.

 # 2 NMF Direct assignment mode signal DASN<G0536.5> is:
0: Not used.
1: Used.

 # 3 WUA In direct assign mode of the flexible path axis assignment, if removal command could not execute,
0: The alarm (DS0080) occurs.
1: Wait execution of the axis removal.

Alarm and message

Number	Message	Description
DS0080	ILLEGAL COMMAND IN FLEXIBLE PATH AXIS ASSIGNMENT	1) The program is buffered. 2) Signal DASN<G0536.5> is changed. 3) Reset operation is executed. 4) The machine is in emergency stop state. 5) Axis exchange command is executed in the direct assignment mode 6) The unit of the reference axis cannot be changed. 7) Target axis is moving Refer to the diagnosis data No.4000 for more detailed cause of this alarm.

Limitation

- Direct assignment of Flexible path axis assignment cannot execute during rigid tapping mode.
- Axis assignment and axis removal cannot execute during backward movement, re-forward movement of Manual handle retrace function.
- Flexible path axis assignment cannot be executed during high precision oscillation.
  If you command as above, the alarm (DS0080) issues.

1.14.3 Axis Assignment Reset

OVERVIEW

When using Flexible path axis assignment, if specified parameter is set, axis assignment can be initialized automatically by reset operation.
When automatic operation is halted by reset operation, it becomes easy to initialize the axis assignment.

Description

When bit 6(RRS) of the parameter No. 11563 is set to 1, and every path which execute the Flexible path axis assignment becomes the reset state simultaneously by MDI reset key operation , external reset signal, or reset and rewind signal, axis assignment is initialized automatically at the completion of reset state.
The axis assignment is initialized or not can be verified by checking Initial axis assignment signal INIST <F0536.7>.

To initialize axis assignment, every axis which belongs to the target path must be the state which the Flexible path axis assignment can execute. If any axis is not, the initialize of axis assignment is not executed.
The state which the flexible axis assignment can execute is based on the specifications of Direct assignment of Flexible path axis assignment.

Following is the examples that axis assignment reset cannot be execute.

- Any axis which enables the Flexible path axis assignment is executing the PMC axis control on target path.
- Tool offset is enabled on target path, and the offset is not cancelled by reset operation.

The axis which is not assigned to another path might be target of axis removal/assignment by Axis assignment reset for restoration to original axis configuration. However, the axis that the Flexible path axis assignment is not enable (the parameter No.11560 = 0) is not becomes target of axis removal / assignment.
Example)
The machine has the original axis configuration that X1,Z1,C1 axes are on 1st path, and X2,Z2,C2 axes are on 2nd path. Flexible path axis assignment is enabled on Z1 and Z2 axis.

1) In case of axis assignment is changed by Flexible path axis assignment that X1, Z1, Z2, C1 on 1st path and X2, C2 on 2nd path.

   When both 1st and 2nd path becomes reset state simultaneously, if Z2 axis is able to execute Flexible path axis assignment, the 1st and 2nd path become initial axis assignment after reset.

2) In case of axis order is changed to X1, C1, Z1 in 1st path and no axis changed in 2nd path by Flexible path axis assignment.
   When reset is executed on 1st path and Z1 axis is able to execute Flexible path axis assignment, the 1st path becomes initial axis order after reset operation.

3) In case of axis order has changed to X1, Z2, C1 on 1st path, and X2, Z1, C2 on 2nd path by Flexible path axis assignment.
   When both 1st and 2nd path becomes reset state simultaneously, and both Z1, Z2 axis is able to execute Flexible path axis assignment, the 1st and 2nd path becomes initial axis assignment after reset.

Signals

Initial axis assignment signal INIST<Fn536.7>

[Classification] Output signal
[Function] Notifies the path has initial axis assignment or not.
[Output condition] 0: The axis assignment of the path is not same as initial state.

1: The axis assignment of the path is same as initial state.

Parameter

	#7	#6	#5	#4	#3	#2	#1	#0
11563		RRS						

[Input type] Parameter input
[Data type] Bit

> **NOTE**
> When this parameter is set, the power must be turned off before operation is continued.

 # 6 RRS When reset is executed, the axis assignment changed by Flexible path axis assignment
0: Is not changed.
1: Is returned to its initial assignment.

Note

High precision oscillation function

When reset is executed during precision oscillation and this function is available, another path which is not in initial assignment keeps reset. The reset is finished when the precision oscillation axis is returned to R position and chopping mode is canceled.

External reset, Reset and Rewind

When this function is enabled, and reset and rewind or external reset is executed to each path individually, the axis assignment reset is executed when all target paths become the reset state.

1.14.4 Improvement of PMC Window Function with Flexible Path Axis Assignment

Outline

In flexible path axis assignment, it has been enabled to read and write the axis information by PMC window function according to the path number and axis number of the initial state specified by parameter (No.981).

Explanation

Behavior of PMC window function with flexible path axis assignment

In the conventional specification, PMC window function with flexible path axis assignment behaves as follows:

- When one axis is specified for read/write, the axis number and the path number changed by flexible path axis assignment should be specified.
- When all axes in a path are specified for read/write, target axes are determined by the path numbers of each axis changed by flexible path assignment. Furthermore, the order of each axis data and the axis number read by function code 433 (CNC alarm detail read) depend on axis number after flexible path assignment.
- The number of axes in a path acquired by function code 0 (reading CNC system information) depends on the path numbers of each axis after flexible path assignment.

If the bit 7(PPW) of parameter No.11563 is set to 1, behavior of PMC window function with flexible path axis assignment is not changed by the execution of flexible path assignment as follows:

- When one axis is specified for read/write, the axis number and the path number of the initial state can be specified.

- When all axes in a path are specified for read/write, target axes are determined by the initial path numbers of each axis. Furthermore, the order of each axis data and the axis number read by function code 433 (CNC alarm detail read) depend on the initial axis number.
- The number of axes in a path acquired by function code 0 (reading CNC system information) depend on the initial path numbers of each axis.

Example)

Flexible path axis assignment is executed as following table.

	Before flexible path axis assignment	
Axis number	**Path 1**	**Path 2**
1	X1	X2
2	Y1	Y2
3	Z1	Z2
4	A1	
5	**'C'**	

→

	After flexible path axis assignment	
Axis number	**Path 1**	**Path 2**
1	X1	X2
2	Y1	Y2
3	Z1	Z2
4	A1	**'C'**
5		

In this example, to read the data of C-axis, specify the axis number and the path number as following table.

		The axis number and path number specified to read the data of C-axis
Parameter PPW (No.11563#7)=0	Before flexible path axis assignment	5th axis in the path 1
	After flexible path axis assignment	4th axis in the path 2
Parameter PPW (No.11563#7)=1	Before flexible path axis assignment	5th axis in the path 1
	After flexible path axis assignment	

When all axes in the path is specified for read/write, target axes are shown in the following table.

		Target axes of read/write with all axes are specified	
		Path 1	**Path 2**
Parameter PPW (No.11563#7)=0	Before flexible path axis assignment	X1,Y1,Z1,A1,C	X2,Y2,Z2,A2
	After flexible path axis assignment	X1,Y1,Z1,A1	X2,Y2,Z2,A2,C
Parameter PPW (No.11563#7)=1	Before flexible path axis assignment	X1,Y1,Z1,A1,C	X2,Y2,Z2,A2
	After flexible path axis assignment		

The numbers of axes in each path are read by function code 0 (reading CNC system information) as shown in the following table.

		The numbers of axes in each path read by function code 0 (reading CNC system information)	
		Number of axes in path 1	**Number of axes in path 2**
Parameter PPW (No.11563#7)=0	Before flexible path axis assignment	5	3
	After flexible path axis assignment	4	4
Parameter PPW (No.11563#7)=1	Before flexible path axis assignment	5	3
	After flexible path axis assignment		

Supported PMC WINDOW functions

Supported PMC WINDOW functions are shown in following table.

Description	Function code	Response	R/W
Reading CNC system information	0	High-speed	R
Reading a work piece origin offset value	15	High-speed	R
Writing a work piece origin offset value	16	Low-speed	W
Reading a parameter	17,154	High-speed	R
Writing a parameter	18	Low-speed	W
Reading a real type parameter	321	High-speed	R
Writing a real type parameter	323	Low-speed	W
Reading setting data	19,155	High-speed	R
Writing setting data	20	Low-speed	W
Reading diagnosis data	33	Low-speed	R
Reading detailed information of CNC	433	Low-speed	R
Reading the absolute position (absolute coordinates) of controlled axes	27	High-speed	R
Reading the machine position (machine coordinates) of controlled axes	28	High-speed	R
Reading a skip position (stop coordinates of skip operation (G31)) of controlled axes	29	High-speed	R
Reading the servo delay for controlled axes	30	High-speed	R
Reading the acceleration/deceleration delay on controlled axes	31	High-speed	R
Reading the feed motor load current value (A/D conversion data)	34	High-speed	R
Reading the relative position on a controlled axis	74	High-speed	R
Reading the remaining travel on a controlled axis	75	High-speed	R
Reading the actual velocity of each controlled axes	91	High-speed	R
Entering torque limit data for the digital servo motor	152	Low-speed	W
Reading the actual speed on a controlled axis	207	High-speed	R
Reading the estimate disturbance torque data	211	High-speed	R
Presetting the relative coordinate	249	Low-speed	W
Reading the actual machine position of controlled axes	428	High-speed	R
Reading the command value of axes	446	High-speed	R

Limitation

Least input increment

When the improvement is valid (No.11563#7=1) and the path number of the axis is changed by flexible path axis assignment, to treat the data of this axis by PMC window function, least input increment of the current path must be same as least input increment of the initial path.

Example)

Flexible path axis assignment is executed as following table.

	Before flexible path axis assignment	
Axis number	**Path 1**	**Path 2**
1	X1	X2
2	Y1	Y2
3	Z1	Z2
4	A1	
5	**'C'**	

→

	After flexible path axis assignment	
Axis number	**Path 1**	**Path 2**
1	X1	X2
2	Y1	Y2
3	Z1	Z2
4	A1	**'C'**
5		

In this example, to execute read/write of the data of C-axis by PMC window function, least input increment of path 1 must be same as least input increment of path 2.

Parameter

	#7	#6	#5	#4	#3	#2	#1	#0
11563	PPW							

[Input type] Parameter input
[Data type] Bit

#7 PPW PMC window function with execution of flexible path axis assignment behaves according to:
0: The path number and the axis number changed by flexible path axis assignment.
1: The path number and the axis number of the initial state (setting of the parameter No.981).

> **NOTE**
> When this parameter is set, the power must be turned off before operation is continued.

1.15 HIGH PRECISION OSCILLATION FUNCTION

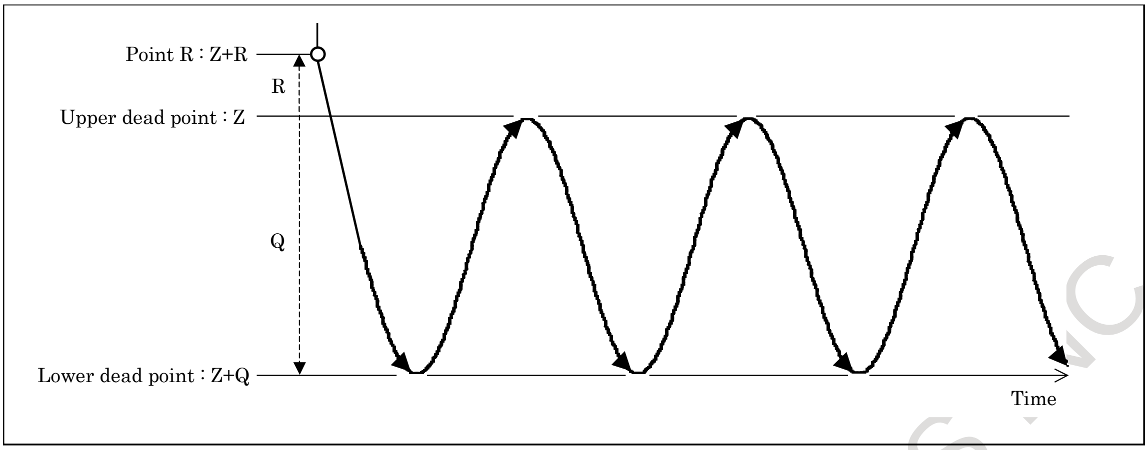
Overview

In this function, the feedrate of oscillation axis (equivalent to a chopping axis that is moved vertically and repeatedly for grinding) changes along sine curve. This function is effective to improve, the accuracy of movement between upper dead point and lower dead point.
Moreover, look-ahead feed forward function can be applied to oscillation motion. Then the servo delay can be almost eliminated and higher accuracy can be achieved even if oscillation feedrate or upper or lower dead point is changed.

This function becomes effective by setting the bit 0 (SSO) of parameter No.25650 is set to 1.

Format

G81.1 Z_ Q_ R_ F_ ;
Z : Upper dead point (In case that an axis is other than the Z-axis, specify the axis address. Specify the distance as an absolute value.)
Q : Distance between the upper dead point and lower dead point
(Specify the distance as an incremental value from the upper dead point.)
R : Distance from the upper dead point to point R
(Specify the distance as an incremental value from the upper dead point.)
F : Oscillation base feedrate
G80 ; Cancels oscillation



If the addresses of Z, Q, R, or F are omitted, the oscillation motion is performed by the value of parameters. On the other hand, the value of parameters is replaced by the value commanded for each address.

Z (Axis address)	Parameter (No.8370)	: Oscillation axis number = Axis number.
	Parameter (No.8372)	: Upper dead point = Value of address Z.
Q	Parameter (No.8373)	: Lower dead point = Value of address Q + value of address Z (If address Z is omitted, the value is parameter (No.8372)).
R	Parameter (No.8371)	: Point R = Value of address R + value of address Z (If address Z is omitted, the value is parameter (No.8372)).
F	Parameter (No.8374)	: Oscillation base feedrate = Value of address F.

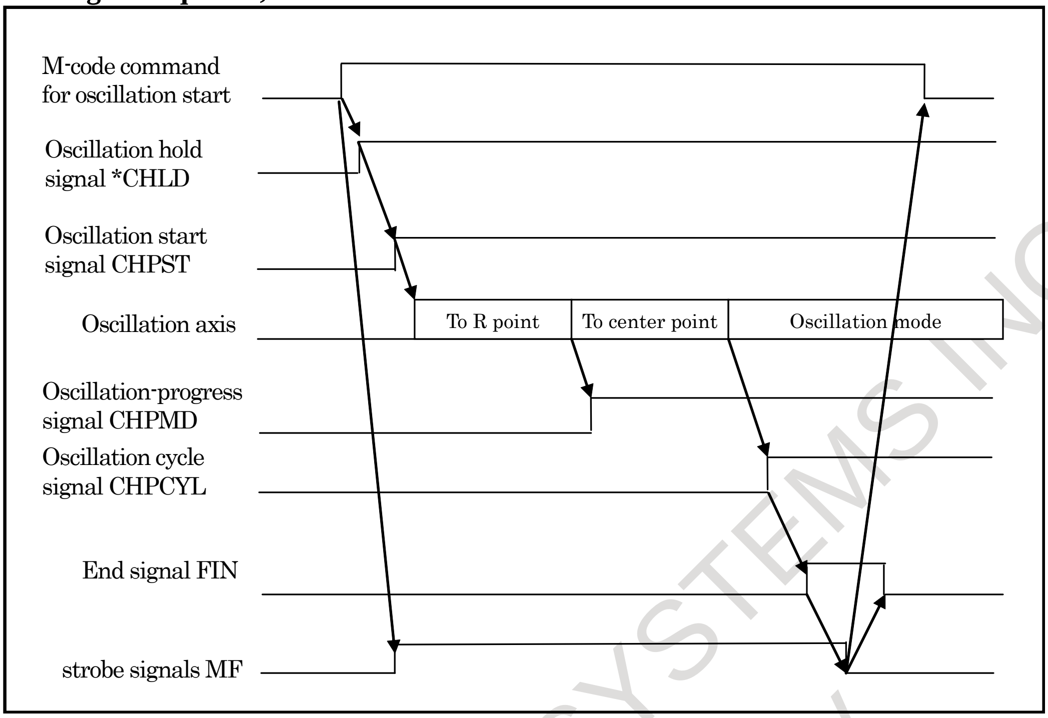
NOTE
1 G81.1/G80 is the G code for suppressing buffering.
2 Specify G81.1/G80 in a single block.

- Oscillation activated by signal input

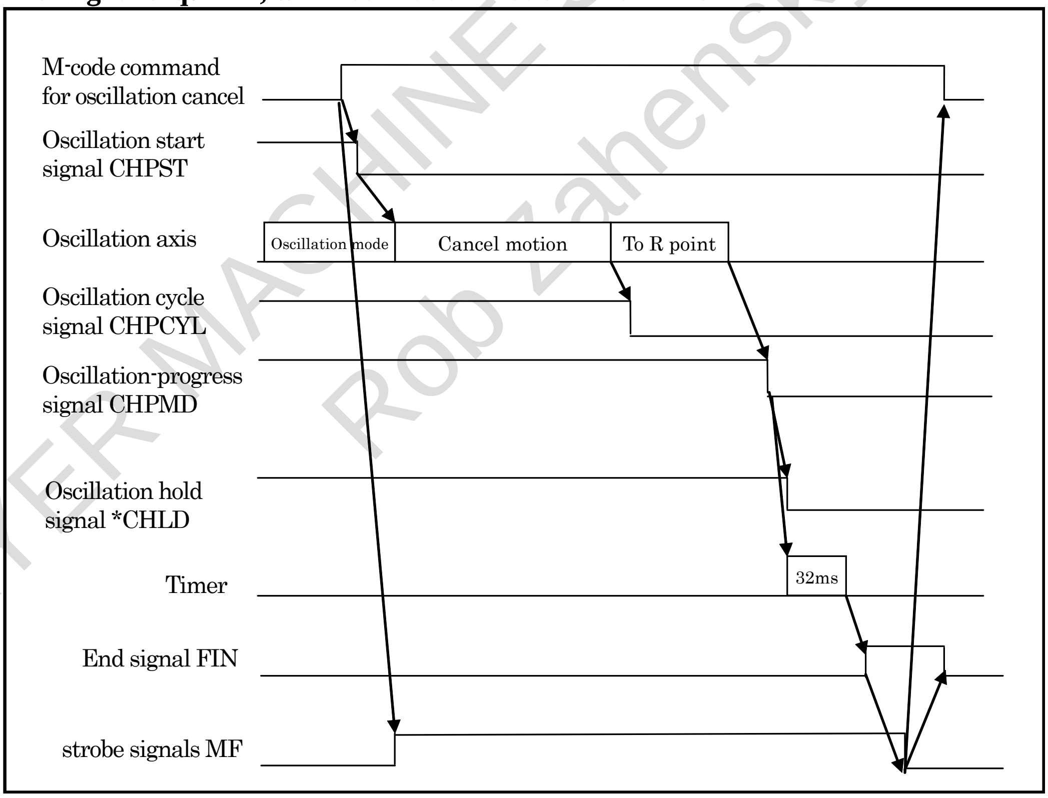
Before oscillation motion is started, oscillation axis, reference position, upper dead point, lower dead point, and oscillation base feedrate must be set on the parameter screen or the oscillation screen. Oscillation motion is started once oscillation start signal CHPST <Gn051.6> has been set to "1". This signal is ignored, however, while oscillation axis is moving during automatic operation.
When oscillation hold signal *CHLD <Gn051.7> is set to "0" during oscillation motion, the tool immediately moves to point R and stops. Setting the oscillation hold signal *CHLD to "1" restarts oscillation motion. Oscillation motion can also be stopped by setting oscillation start signal CHPST to "0", but only when oscillation motion was started by using that signal.

Method of starting oscillation	Method of cancelling oscillation	State
Signal CHPST ="1"	Signal *CHLD = "0"	It stops. (Suspending state)
	Signal CHPST = "0"	It stops. (Cancel state)
	G80 command	It stops. (Cancel state)
G81.1 command	Signal *CHLD = "0"	It stops. (Suspending state)
	Signal CHPST = "0"	It doesn't stop.
	G80 command	It stops. (Cancel state)

- Example of signal sequence, when oscillation motion is started



- Example of signal sequence, when oscillation motion is canceled



NOTE

1. Switching to manual mode or suspending automatic operation, by means of feed hold, does not stop oscillation motion.
2. If a move command is specified for the oscillation axis while oscillation is being performed, an alarm (PS5050) is issued.
3. If a G81.1 command is specified during oscillation started by the signal, oscillation motion is not stopped. If point R, upper dead point, lower dead point, or oscillation feedrate has been modified by using the G81.1 command, oscillation is continued but using the modified data.
4. The use of oscillation start signal CHPST <Gn051.6> to start oscillation motion is not enabled immediately after power-on; it is not enabled until the completion of manual reference position return.
5. The M codes which are used to set the oscillation start signal CHPST <Gn051.6> to "1" or "0" should be specified as M code preventing buffering (parameter Nos. 3411 to 3432).

⚠**CAUTION**

After the cancel of oscillation motion during NC automatic operation, to execute a move command or a coordinate system setting command (in the absolute or incremental mode) for the oscillation axis in an NC block during the same operation, use G-code (G80) for the cancel of oscillation.

If it is necessary to cancel by signal input, execute the following (1) or (2).

(1) M code in which each axis workpiece coordinate system preset signal WPRST<Gn358> is turned ON
(Refer to 1.5.2.7"Each axis workpiece coordinate system preset signals" for details.)

(2) Workpiece coordinate system preset (G92.1)
(Enable workpiece coordinate system preset (G92.1) (bit 1 (NWC) of parameter No.8136 is 0).

For example, in the following program (O0001), to execute the move command (N60) after the cancel (N40) of oscillation motion (Z-axis), “M code in which each axis workpiece coordinate system preset signal WPRST is turned ON” or “Workpiece coordinate system preset (G92.1)” must be specified in N50.

```
O0001
N10 G94 G90 G00 X100.0
N20 M55                  ← Oscillation start signal is turned ON
N30 G01 X30.0 F30.0
N40 M56                  ← Oscillation start signal is turned OFF
                         ← “M code in which each axis workpiece
                            coordinate system preset signal WPRST for
N50 ____                    Z-axis is turned ON” or “Workpiece
                            coordinate system preset (G92.1Z0.0)” is
                            commanded.
N60 G00 Z-50.0           ← Move command of Z-axis
N70 M02
```

- Oscillation feedrate (feedrate of movement to point R)

From the start of oscillation motion to reaching point R, the tool moves at the rapid traverse rate (specified by parameter No.1420).

The override function can be used for either the normal rapid traverse rate or oscillation feedrate, one of which can be selected by setting bit 0 (ROV) of parameter No.8360. When the oscillation feedrate is overridden, settings more than 100% are clamped to 100%.

- Oscillation feedrate (feedrate of movement from point R)

From point R, where reached after the start of oscillation motion, to the center point between upper and lower dead points, the tool moves at the oscillation base feedrate (F). Afterwards, between the center point and the point where the oscillation motion is canceled, the tool moves with sine curve feedrate by Exp. 1.

$$f(t)_{[mm/\min]} = k \times \mathrm{F}_{[mm/\min]} \times \sin\left(\frac{2}{|\mathrm{Q}|_{[1/mm]}} \times \frac{k \times \mathrm{F}}{60}_{[mm/\sec]} \times \frac{180}{\pi}_{[\deg/rad]} \times t_{[\sec]} \right) \qquad \ldots \text{Exp. 1}$$

F(t) : Sine curve feedrate [mm/min]
F : Oscillation base feedrate [mm/min]
Q : Distance between the upper dead point and lower dead point [mm]
k : Oscillation override (0.0 (0%) to 1.5 (150%))
Set by oscillation federate override signals *CHP1 - *CHP8<Gn051.0-3>
t : Time [sec]

The value (*k*F) of the product of oscillation base feedrate and oscillation override is clamped to the maximum oscillation feedrate (parameter No.8375) if the value (*k*F) is greater than the maximum oscillation feedrate. However, even if the value (*k*F) is not greater than maximum oscillation feedrate, it is clamped by the feedrate never exceeds the maximum allowable acceleration rate for acceleration/deceleration (parameter No.25652) during oscillation motion.

- Setting oscillation data

Set the following oscillation data:

Oscillation axis…………………Parameter (No.8370)
Reference point (point R)………Parameter (No.8371)
Upper dead point……………….Parameter (No.8372)
Lower dead point……………….Parameter (No.8373)
Oscillation base feedrate………..Parameter (No.8374)
Maximum oscillation feedrate… Parameter (No.8375)

All data items other than the oscillation axis and maximum oscillation feedrate can be set on the oscillation screen. Moreover, the value of parameters is replaced by the value of G81.1 command.

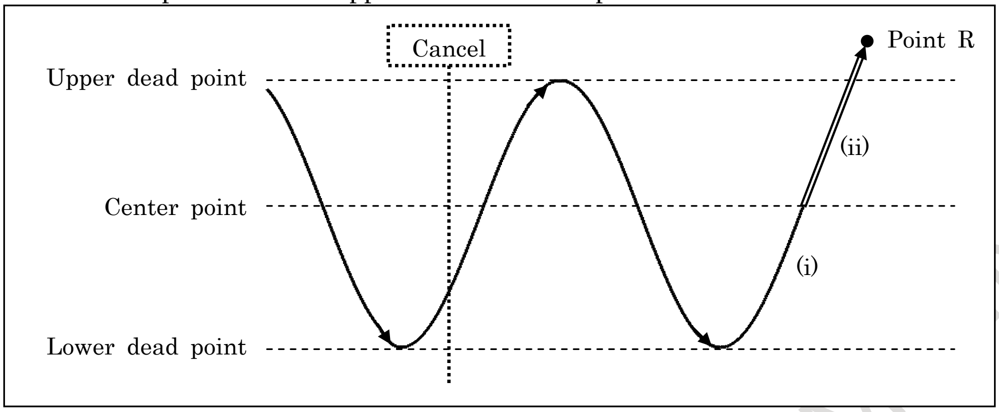
- Stopping oscillation

The following table lists the operations and commands that can be used to stop oscillation motion, the positions at which oscillation stops, and the operation performed after oscillation stops:

Operation/ command	Stop position	Operation after stops
G80 command	It follows parameter OST (No.25651#0). OST=0 : Point R OST=1 : Decelerated and stopped	Canceled
Reset		
PS, OT alarm		
CHPST: "0"	It follows parameters OST, SGS (No.25651#0,#2). OST=0 or SGS=0 : Point R OST=1 and SGS=1 : Decelerated and stopped	Canceled
*CHLD: "0"	It follows parameters OST, SGS, HST (No.25651#0,#2,#3). OST=0, SGS=0, or HST=0 : Point R OST=1, SGS=1, and HST=1 : Decelerated and stopped	Restart after *CHLD goes "1"
Emergency stop	The tool stops immediately.	Canceled
Servo alarm		

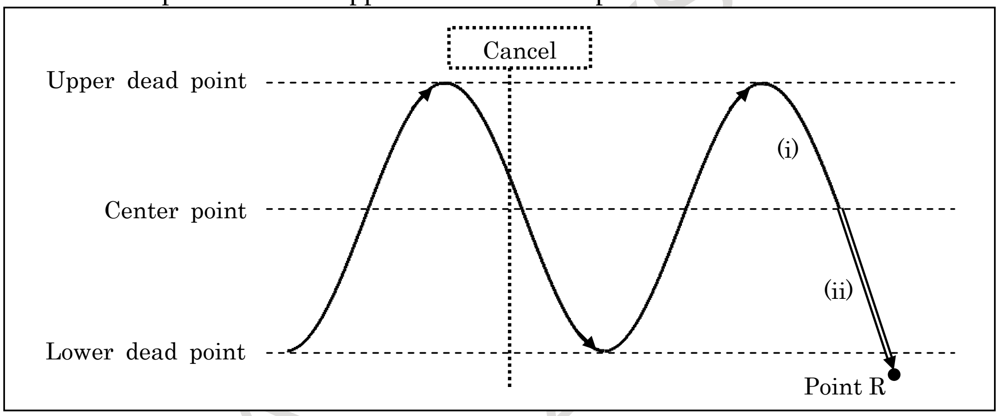
Example of stopping at point R. (Except in the case of suspending by signal *CHLD = 0 or issuing an OT alarm.)

(1) Point R > Center point between upper and lower dead points



After cancel command, oscillation motion is continued until oscillation axis passes center point between upper and lower dead points via next lower dead point (i).
Afterwards, the axis moves to point R by linear interpolation (ii).

(2) Point R < Center point between upper and lower dead points



After cancel command, oscillation motion is continued until oscillation axis passes center point between upper and lower dead points via next upper dead point (i).
Afterwards, the axis moves to point R by linear interpolation (ii).

In the case of suspending by signal *CHLD="0" or cancel by OT alarm, oscillation axis moves to point R at once.

NOTE

The timing of cancellation motion might change according to the position of point R or the setting of acceleration rate of cancellation motion (parameter No.25653).

- Movement from point R to the first dead point

The first dead point is decided by the position of point R.

Point R	The first dead point
Point R is on upper dead point side from center point or is on the center point.	Lower dead point
Point R is on lower dead point side from center point.	Upper dead point

- Omission of movements to point R and to the center point

By setting 1 to bit 0 (OST) and 1 (FFS) of parameters No.25651, if oscillation motion is started by G81.1 command, movements to point R and to the center point can be omitted, and oscillation motion can be immediately started. In this case, the first dead point is as follows.

State before G81.1 command	The first dead point
In case of the first command of oscillation motion after the power is turned on or in the state of reset.	Lower dead point
In the state that command of cancel was specified on the way to lower dead point at last oscillation motion.	
In the state that command of cancel was specified on the way to upper dead point at last oscillation motion.	Upper dead point

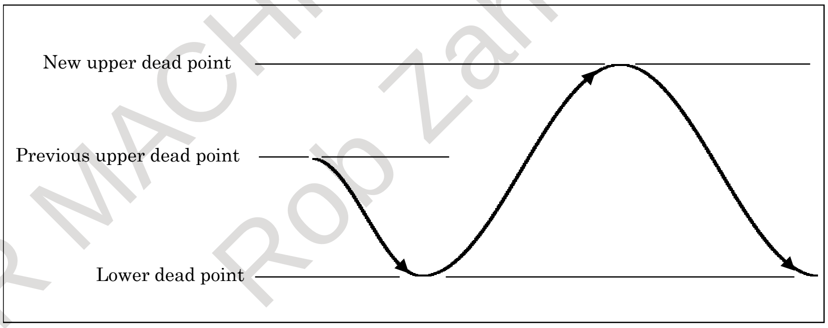
- Acceleration/deceleration

Linear acceleration/deceleration by parameter (No.25653) is applied to the movement from point R to center point or the motion till stop.
Moreover, when override is changed during oscillation motion, the acceleration/deceleration set by parameter (No.25653) is effective.
Acceleration/deceleration of sine curve feedrate control is enabled on oscillation motion.

- Oscillation after the upper dead point or lower dead point has been changed

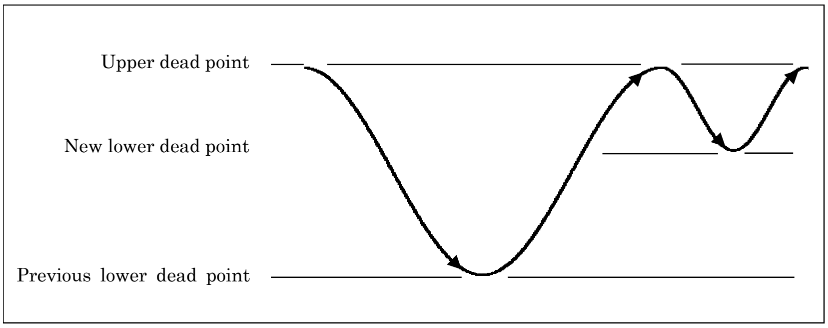
When the upper dead point or lower dead point is changed while oscillation motion is being performed, the tool moves to the dead points specified by the old data. Then, oscillation motion is changed to the new one using the new data.
The following describes the operations performed after the data has been changed.

(1) When the upper dead point is changed during movement from the upper dead point to the lower dead point



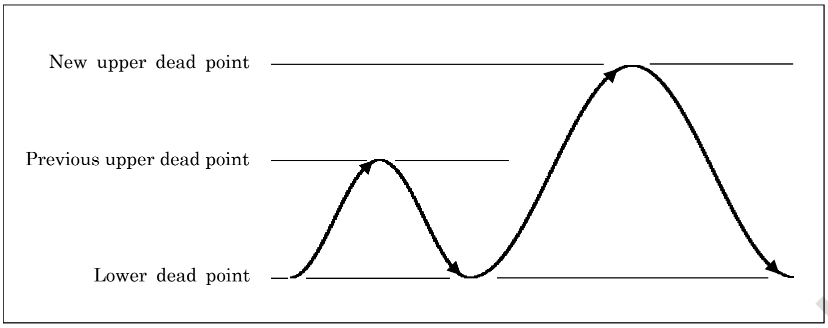
The tool first moves to the lower dead point, then to the new upper dead point.

(2) When the lower dead point is changed during movement from the upper dead point to the lower dead point



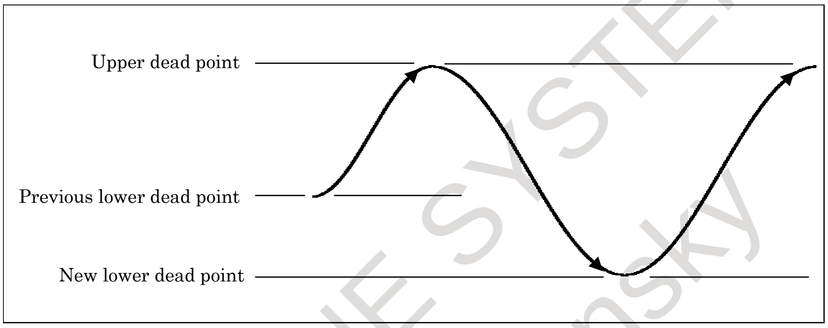
The tool first moves to the previous lower dead point, then to the upper dead point, and finally to the new lower dead point.

(3) When the upper dead point is changed during movement from the lower dead point to the upper dead point



The tool first moves to the previous upper dead point, then to the lower dead point, and finally to the new upper dead point.

(4) When the lower dead point is changed during movement from the lower dead point to the upper dead point



The tool first moves to the upper dead point, then to the new lower dead point.

- Look-ahead feed forward function

Look-ahead feed forward function can be effective for oscillation motion.
Refer to the following manual for details of the setting method and so on.

- FANUC AC SERVO MOTOR *αi* series PARAMETER MANUAL (B-65270EN)
  "Look-ahead feed forward function"

- Mode switching during oscillation motion

If the mode is changed during oscillation motion, oscillation motion does not stop. In manual mode, the oscillation axis cannot be moved manually. It cannot also be moved manually by means of the handle interrupt.

- Single block signal

Even when single block signal SBK<Gn046.1> is input during oscillation motion, oscillation continues.

- Interlock signal

Interlock signal for all axes *IT<Gn008.0> or Interlock signals for each axis *ITx<Gn130> is valid to the oscillation axis in oscillation mode. However, Interlock signal for each axis direction +MITx/-MITx <Gn132/Gn134, X004.2 to X004.5> is invalid to the oscillation axis in oscillation mode.
If interlock is effective to the oscillation axis during oscillation motion, the oscillation axis decelerates and stops immediately.

- Flexible synchronization control

Flexible synchronization control whose master axis is the oscillation axis can be used.
If Look-ahead feed forward function is used, it is necessary to set the parameter also to the slave axis as well as the master axis.
However, Inter-path flexible synchronization control with oscillation axis cannot be used.

- Axis synchronous control

Axis synchronous control whose master axis is the oscillation axis can be used.
If Look-ahead feed forward function is used, it is necessary to set the parameters also to the slave axis as well as the master axis.

- Machine lock during oscillation motion

"If all-axis machine lock signal MLK<Gn044.1> or each-axis machine lock signals MLK1 to MLK8<Gn108> are turned ON or OFF during oscillation movement, an alarm PS5050 "ILL-COMMAND IN G81.1 MODE" is issued.
After an alarm PS5050 is issued, oscillation axes move to the point R, then the axes become the machine lock state. "

- Diameter and Radius Setting

The command and the parameter value (coordinates, feedrate) follow the diameter and radius setting of the oscillation axis. Actual data value (feedrate F) is displayed by the radius.

Limitation

- Workpiece coordinate system

While oscillation is being performed, do not change the workpiece coordinate system for the oscillation axis.

- PMC axis

When the oscillation axis is operating as the PMC axis, oscillation is not started.

- Mirror image

Never attempt to apply the mirror image function about the oscillation axis.

- Move command during oscillation motion

If a move command is specified for the oscillation axis while oscillation motion is being performed, an alarm (PS5050) "ILL-COMMAND IN G81.1 MODE" is issued.

- Canned Cycle

While oscillation is being performed, do not specify canned cycle.

- Program restart / Quick program restart

When a program contains G codes for starting oscillation (G81.1) and stopping oscillation (G80), an attempt to restart that program results in an alarm (PS5050) being output.
When a program that does not include the oscillation axis is restarted during oscillation motion, the coordinates and amount of travel set for the oscillation axis are not affected after the restart of the program.

- Rotation axis

Oscillation operation cannot be used with rotation axis (type-A).

- Inch/Metric conversion commands

While oscillation is being performed, do not specifyinch/metric conversion commands.

- General purpose retract

While oscillation is being performed, do not perform retraction. The oscillation motion does not stop by retraction.

- Stored stroke check

Stored stroke check 1-I (parameter Nos. 1320 and 1321) is effective during oscillation motion.

- Arbitrary angular axis control

Do not set angular axis and perpendicular axis of arbitrary angular axis control to oscillation axis.

- Three-dimensional coordinate conversion / Tilted working plane indexing command

While oscillation is being performed, do not specify three-dimensional coordinate conversion / tilted working plane indexing command.

- Cs contour control axis

Do not set Cs contour control axis to oscillation axis. If oscillation is specified for Cs contour control axis, an alarm (PS5050) "ILL-COMMAND IN G81.1 MODE" is issued.

- Synchronous/Composite control

Do not set synchronous/composite control axis to oscillation axis.

- Polygon turning

Do not set control axis for polygon turning to oscillation axis.

- Manual handle interrupt

Manual handle interrupt is invalid to the axis in the oscillation mode.
(The slave axis of Flexible synchronization control which has oscillation axis as master or Axis synchronous control is contained)

- Constant surface speed control

Do not set reference axis for constant surface speed control to oscillation axis.

- Polar coordinate interpolation

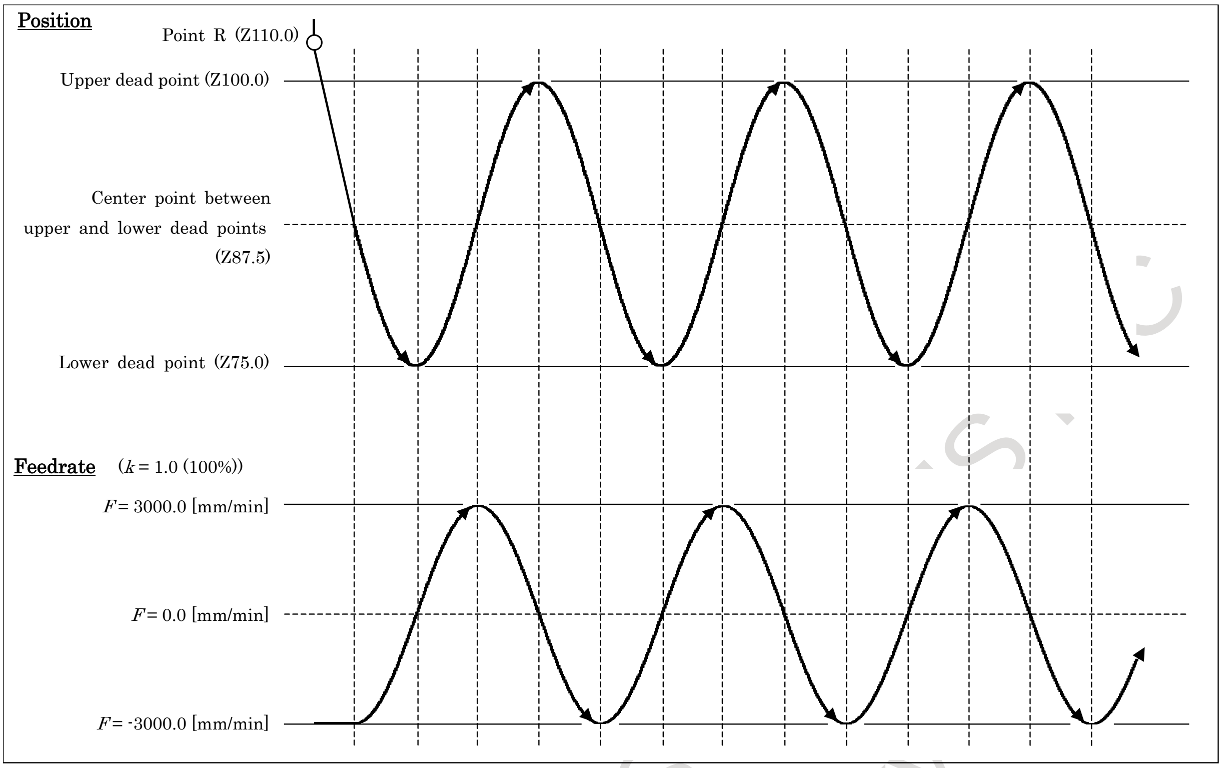
Do not set linear/rotation axis for polar coordinate interpolation to oscillation axis.

Example

To start oscillation, specify the following command:

G90 G81.1 Z100. Q-25. R10. F3000. ;

- The tool moves to point R (Z+R = Z110.0) with rapid traverse feedrate.
- Next, move to center point (Z87.5) between upper dead point (Z100.0) and lower dead point (Z+Q = Z75.0) at oscillation base feedrate (F3000.0 [mm/min]).
- Then, perform repeated movement along the Z-axis between the upper dead point and the lower dead point with sine curve feedrate *F* by Exp. 1. Oscillation override *k* is enabled.



To cancel oscillation motion, specify the following command:

G80 ;

Motion of cancel is as follows.

Bit 0 (OST) of parameter No.25651 is

0: The tool moves to point R and stops.

1: The tool decelerates and stops.

Superimposed control

If oscillation axis is set to master axis and superimposed control is started, it is necessary on the corresponding path to be executing superimposed ahead mode by adjusting superimposed ahead signal OVLN <Gn531.4> to "1". Set superimposed ahead signals OVLN to "1" in each path, if paths of master axis and slave axis are different.

Refer to the following manual for details of the setting method and so on.

"FANUC Series 0*i*-F Plus CONNECTION MANUAL (FUNCTION)" (B-64693EN-1) "Superimposed Control"

Example)

(1) In the case that paths of master axis and slave axis are the same.

```
M210     …Superimposed ahead mode ON
M60      …Starts superimposed control
G81.1    …Starts oscillation motion

G80      …Cancels oscillation motion
M61      …Cancels superimposed control
M211     …Superimposed ahead mode OFF
```

(2) In the case that paths of master axis and slave axis are different.

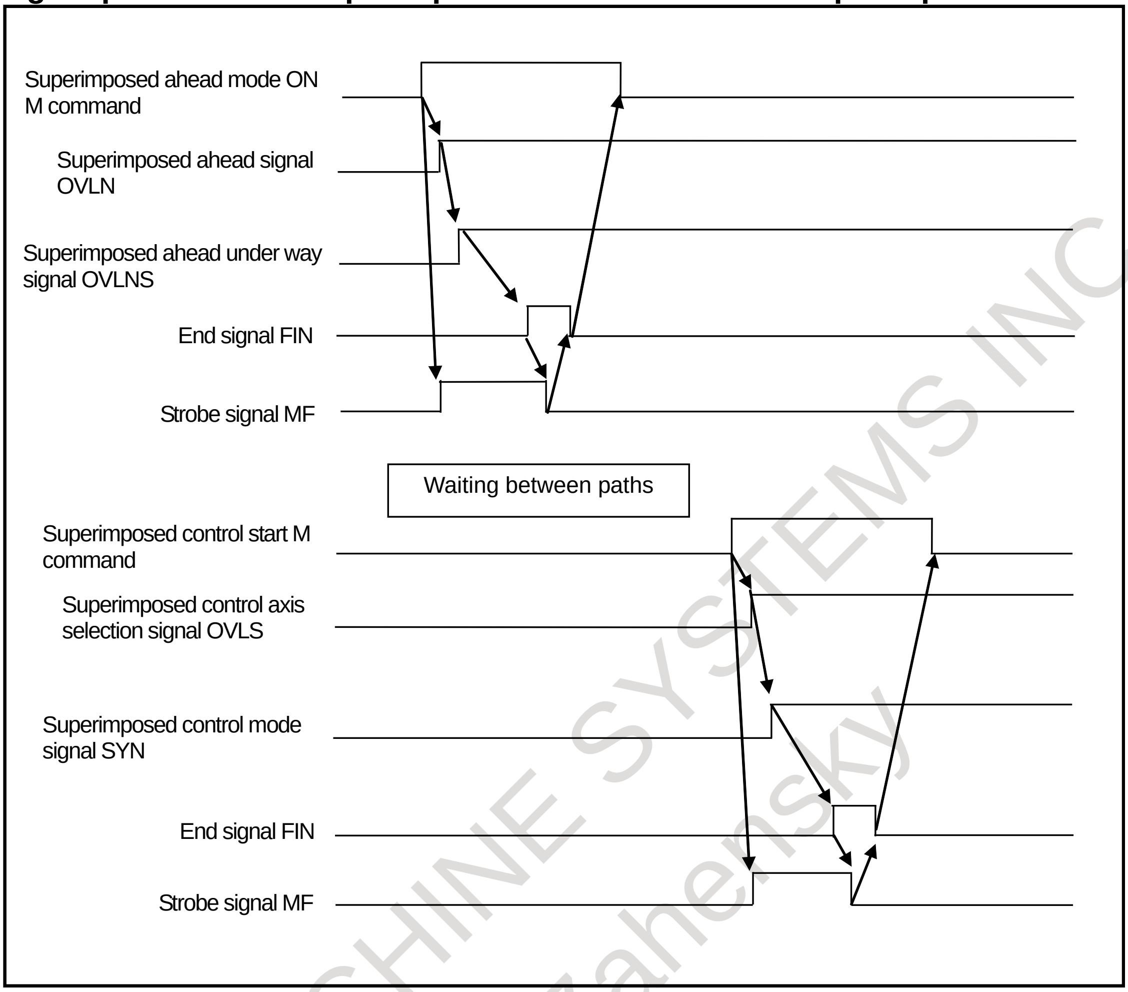
Path of the master axis		Path of the slave axis	
M100P12	…Waiting	M100P12	…Waiting
M210	…Superimposed ahead mode ON	M212	…Superimposed ahead mode ON
		M60	…Starts superimposed control
M101P12	…Waiting	M101P12	…Waiting
G81.1	…Starts oscillation motion		
G80	…Cancels oscillation motion		
M103P12	…Waiting	M103P12	…Waiting
		M61	…Cancels superimposed control
M211	…Superimposed ahead mode OFF	M213	…Superimposed ahead mode OFF
M104P12	…Waiting	M104P12	…Waiting

NOTE

1 To switch superimposed ahead signal ON/OFF, it is necessary to stop all axes (except for PMC axis) of path where this signal is switched.
2 Switch ON/OFF the superimposed ahead mode after the superimposed control has been canceled in slave path.
3 The following functions cannot be commanded in the path to which the superimposed ahead mode is effective.
   - Reference return in Cs contouring control (G00, G28)
   - Skip function (G31)
   - Automatic tool length measurement / Automatic tool offset function
   - Automatic reference return operation of low-speed type (G28)
   - High speed program check function

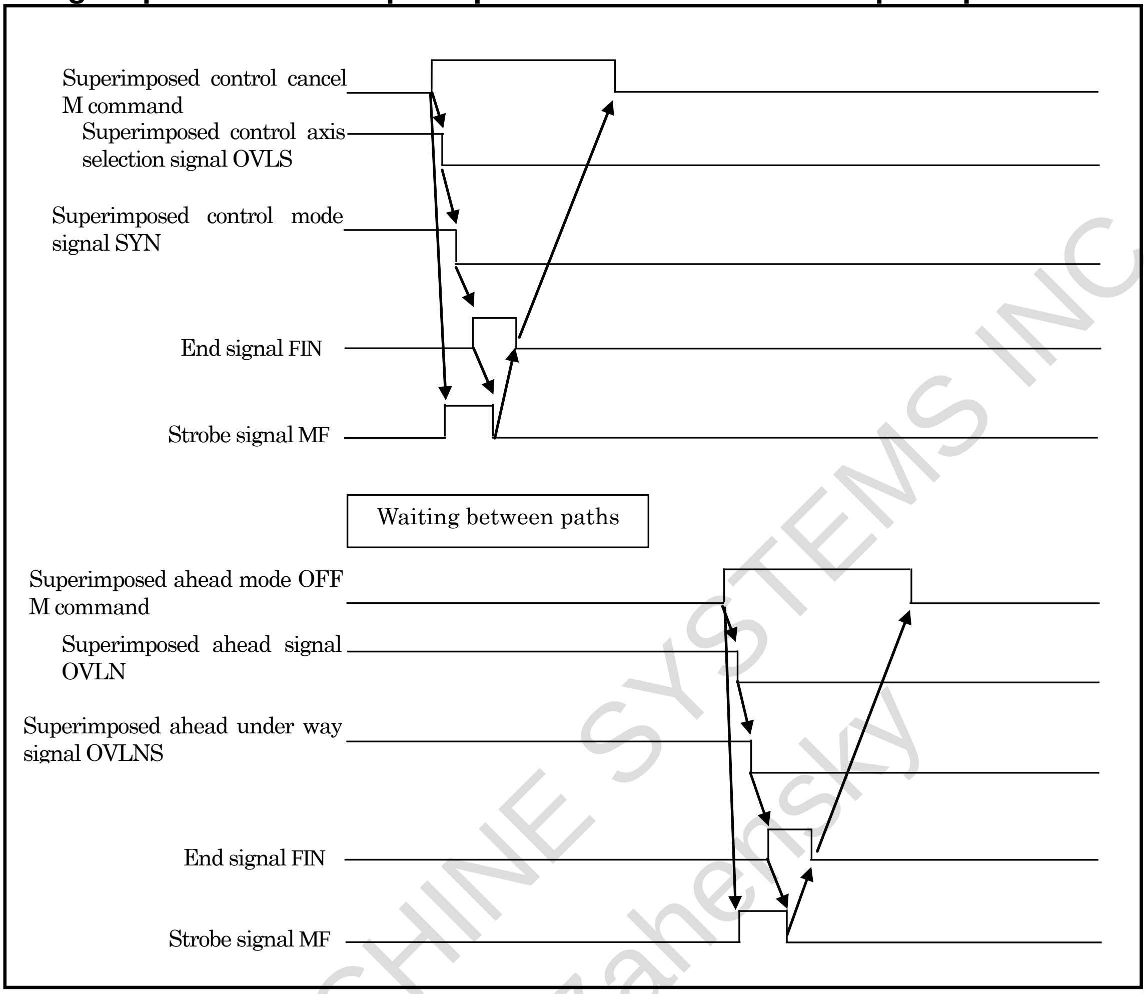
   These functions can be commanded, when superimposed control and superimposed ahead mode are off.
4 The M code for superimposed ahead mode must be assigned to M codes preventing buffering. (Parameter Nos. 3411 to 3432)
5 Oscillation axis cannot be set to slave axis. If oscillation axis is set to slave axis and oscillation motion is started, an alarm PS5050 is issued.

Starting sequence of the superimposed ahead mode and superimposed control.



1. When the M code for enabling superimposed ahead mode is specified and superimposed ahead signal OVLN is set to "1", Superimposed ahead under way signal OVLNS becomes "1".
2. When superimposed ahead under way signal OVLNS becomes "1", operate the end signal FIN in order to complete the procedure.
3. Command the waiting M code in both paths of master axis and slave axis. (If paths of master axis and slave axis belong to the same path, the M code is omitted.)
4. When the M code for enabling superimposed control is specified and superimposed control axis select signal OVLS is set to "1", superimposed control starts. And the superimposed control mode signal SYN becomes "1".
5. When superimposed control mode signal SYN becomes "1", operate the end signal FIN in order to complete the procedure.

Canceling sequence of the superimposed ahead mode and superimposed control.



1. When the M code for canceling the superimposed control is specified, and superimposed control axis select signal OVLS is set to "0", superimposed control will be canceled (superimposed control under way signal SYN turn to “0”).
2. When superimposed control mode signal SYN becomes "0", operate the end signal FIN in order to complete the procedure.
3. Command the waiting M code in both paths of master axis and slave axis. (If paths of master axis and slave axis belong the same path, the M code is omitted.)
4. When the M code for disabling superimposed ahead mode is specified and superimposed ahead signal OVLN is set to "0", superimposed ahead mode is canceled (advanced superimposition mode signal OVLNS turn to “0”).
5. When superimposed ahead under way signal OVLNS becomes to "0", operate the end signal FIN in order to complete procedure.

Signal

Oscillation start signal CHPST <Gn051.6>

[Classification] Input signal
[Function] Starts and stops oscillation.
[Operation] Setting this signal to "1" starts oscillation.
Setting this signal to "0" during oscillation motion causes oscillation to be stopped.

NOTE
1 If an oscillation operation due to the oscillation start signal CHPST has been cancelled by an operation or command that causes it to stop, return the signal CHPST to "0" and then set it "1" again.
2 This signal is not enabled until the completion of manual reference position return.
3 The M codes which are used to set the oscillation start signal CHPST <Gn051.6> to "1" or "0" should be specified as M code preventing buffering (parameter Nos. 3411 to 3432).

Oscillation hold signal *CHLD <Gn051.7>

[Classification] Input signal
[Function] Suspends oscillation.
[Operation] Once this signal has been set to "0", the tool is moved from the current position to point R, thus oscillation is suspended. Setting this signal to "1" while oscillation is suspended causes oscillation to be restarted.

Oscillation feedrate override signals *CHP1 to *CHP8 <Gn051.0 to 3>

[Classification] Input signal
[Function] Overrides the oscillation feedrate.
[Operation] The actual base feedrate during oscillation becomes the specified base feedrate multiplied by the override value specified with this signal. The change amount by the override is affected the parameter No.25653 (Acceleration rate of starting or cancellation oscillation motion). The following table lists the correspondence between the signal states and the override value:

*CHP8	*CHP4	*CHP2	*CHP1	Override value
0	0	0	0	150%
0	0	0	1	140%
0	0	1	0	130%
0	0	1	1	120%
0	1	0	0	110%
0	1	0	1	100%
0	1	1	0	90%
0	1	1	1	80%
1	0	0	0	70%
1	0	0	1	60%
1	0	1	0	50%
1	0	1	1	40%
1	1	0	0	30%
1	1	0	1	20%
1	1	1	0	10%
1	1	1	1	0%

NOTE
According to the range of oscillation motion and the oscillation base federate (Parameter No.8374), shock might occur when override is changed.

Superimposed ahead signal OVLN <Gn531.4>

[Classification] Input signal
[Function] Start superimposed ahead mode.
[Operation] When this signal is "1", the control device operates as follows.

- The corresponding path enters the superimposed ahead state.

To switch superimposed ahead signal to "1" or "0", it is necessary to stop all axes (except for PMC axis) of path where this signal is switched. When axis moves, alarm DS0071 is issued.

Oscillation-in-progress signal CHPMD <Fn039.2>

[Classification] Output signal
[Function] Notify the state of oscillation
[Operation] This signal is set to "1" in the following cases:

- Oscillation start signal CHPST is changed from "0" to "1" to start oscillation.
- Oscillation is started by G81.1 command.

This signal is set to "0" in the following cases:

- Oscillation start signal CHPST is changed from "1" to "0" to stop oscillation.
- Oscillation is terminated by a reset.
- Oscillation is cancelled by G80 command.
- Oscillation is terminated when an alarm is issued.
- Oscillation is terminated by emergency stop.

Oscillation cycle signal CHPCYL <Fn039.3>

[Classification] Output signal
[Function] Notify the state of an oscillation cycle being performed between the upper and lower dead points.
[Operation] This signal is set to "1" in the following case:

- Oscillation cycle is started and sign curve federate control is used between the upper and lower dead points.

This signal is set to "0" in the following cases:

- Once oscillation has been stopped
- When the tool is stopped at the upper or lower dead point
- Oscillation hold signal *CHLD is set to "0"

Superimposed ahead under way signal OVLNS <Fn545.1>

[Classification] Output signal
[Function] Indicates that superimposed ahead mode is executing.
[Operation] The signal becomes "1" when:

- The corresponding path is executing superimposed ahead mode.

The signal becomes "0" when:

- The corresponding path is not executing superimposed ahead mode.

Parameter

	#7	#6	#5	#4	#3	#2	#1	#0
8360	CHF					CVC		ROV

[Input type] Setting input
[Data type] Bit path

#0 ROV As rapid traverse override for a section from the oscillation start point to point R:
0: Oscillation override is used.
1: Rapid traverse override is used.

#2 CVC The feedrate along the oscillation axis is changed:
0: At the upper or lower dead point immediately after the feedrate change command is issued.
1: At the upper dead point immediately after the feedrate change command is issued.

#7 CHF On the oscillation screen, the oscillation base feedrate:
0: Can be set.
1: Cannot be set.

8370	Oscillation axis

[Input type] Parameter input
[Data type] Byte path
[Valid data range] 1 to Number of controlled axes
This parameter sets which servo axis the oscillation axis corresponds to.

8371	Oscillation reference point (point R)

[Input type] Parameter input
[Data type] Real path
[Unit of data] mm, inch, deg (input unit)
[Min. unit of data] Depend on the increment system of the oscillation axis
[Valid data range] 9 digits of minimum unit of data (refer to standard parameter setting table (A))
(When the increment system is IS-B, -999999.999 to +999999.999)
The data set in this parameter is absolute coordinates.

8372	Oscillation upper dead point

[Input type] Parameter input
[Data type] Real path
[Unit of data] mm, inch, deg (input unit)
[Min. unit of data] Depend on the increment system of the oscillation axis
[Valid data range] 9 digits of minimum unit of data (refer to standard parameter setting table (A))
(When the increment system is IS-B, -999999.999 to +999999.999)
The data set in this parameter is absolute coordinates.

8373	Oscillation lower dead point

[Input type] Parameter input
[Data type] Real path
[Unit of data] mm, inch, deg (input unit)
[Min. unit of data] Depend on the increment system of the oscillation axis

[Valid data range] 9 digits of minimum unit of data (refer to standard parameter setting table (A))
(When the increment system is IS-B, -999999.999 to +999999.999)
The data set in this parameter is absolute coordinates.

8374	Oscillation base feedrate

[Input type] Parameter input
[Data type] Real path
[Unit of data] mm/min, inch/min, deg/min (input unit)
[Min. unit of data] Depend on the increment system of the oscillation axis
[Valid data range] Refer to standard parameter setting table (C).
(When the increment system is IS-B, 0.0 to +999000.0)
This parameter sets the oscillation feedrate.

8375	Maximum oscillation feedrate

[Input type] Parameter input
[Data type] Real axis
[Unit of data] mm/min, inch/min, deg/min (machine unit)
[Min. unit of data] Depend on the increment system of the applied axis
[Valid data range] Refer to standard parameter setting table (C).
(When the increment system is IS-B, 0.0 to +999000.0)
The oscillation feedrate is clamped at this parameter setting. The maximum feedrate must be set for the oscillation axis. If this parameter is set to 0, no movement is made for oscillation.

> **NOTE**
> Please set a value that is smaller than the normal rapid traverse rate (parameter No. 1420) to Maximum oscillation feedrate.

	#7	#6	#5	#4	#3	#2	#1	#0
25650								SSO

[Input type] Parameter input
[Data type] Bit

> **NOTE**
> When this parameter is set, the power must be turned off before operation is continued.

#0 SSO High precision oscillation function is
0: Disabled.
1: Enabled.

	#7	#6	#5	#4	#3	#2	#1	#0
25651					HST	SGS	FFS	OST

[Input type] Parameter input
[Data type] Bit path

#0 OST During oscillation motion, if G80 command or reset is specified,
0: Oscillation axis moves to point R and stops. (Standard specification)
1: Oscillation axis decelerates and stops.

#1 FFS When oscillation motion is started by G81.1 command,

0: Oscillation motion is begun, after the oscillation axis passes point R and the center point between upper and lower dead points are passed. (Standard specification)

1: Movements to point R and to the center point between upper and lower dead points is omitted, and oscillation motion can be immediately started.

If this parameter is set to 1, the first dead point is as follows.

State before G81.1 command	The first dead point
First command of oscillation motion after the power is turned on or in the state of reset.	Lower dead point
In the state that command of cancel was specified on the way to lower dead point at last oscillation motion.	
In the state that command of cancel was specified on the way to upper dead point at last oscillation motion.	Upper dead point

NOTE
If this parameter is effective, bit 0 (OST) of parameter No. 25651 need be set to 1. Then the tool decelerates and stops when the oscillation motion is canceled.

#2 SGS If oscillation motion is canceled by turning oscillation start signal CHPST <Gn051.6> from “1” to “0”,

0: Oscillation axis moves to point R and stops. (Standard specification)

1: Oscillation axis decelerates and stops.

If the oscillation axis decelerates and stops by oscillation start signal CHPST, use each axis workpiece coordinate system preset signal WPRST1-WPRST8<Gn358> together.
Refer to the following manual for details of the setting method and so on.

"FANUC Series 0*i*-F Plus CONNECTION MANUAL (FUNCTION)" (B-64693EN-1) "Each Axis Workpiece Coordinate System Preset Signals"

NOTE
If this parameter is effective, bit 0 (OST) of parameter No. 25651 need be set to 1.

#3 HST During oscillation motion, if oscillation hold signal *CHLD <Gn051.7> is set to"0" from "1",

0: Oscillation axis moves to point R and suspends. (Standard specification)

1: Oscillation axis decelerates and suspends.

NOTE
If this parameter is effective, bits 0 (OST) and 2 (SGS) of parameter No. 25651 need be set to 1.

25652	Maximum allowable acceleration rate of oscillation motion

[Input type] Parameter input
[Data type] Real axis
[Unit of data] mm/sec^2, inch/sec^2, deg/sec^2 (machine unit)
[Valid data range] Refer to standard parameter setting table (D). (Operating range: 0.0 to +100000.0)

Set a maximum allowable acceleration rate for oscillation axis during oscillation motion (with sine curve feedrate).

If a value greater than maximum value (100000.0) is set, the value is clamped to maximum value (100000.0).
If 0 is set, maximum value (100000.0) is assumed to be set.

25653	Acceleration rate of starting or cancellation oscillation motion

[Input type] Parameter input
[Data type] Real axis
[Unit of data] mm/sec^2, inch/sec^2, deg/sec^2 (machine unit)
[Valid data range] Refer to standard parameter setting table (D). (Operating range: 0.0 to +100000.0)

It is the linear acceleration rate of starting motion (from point R to center point between upper and lower dead points) or canceling motion.
Moreover, when override is changed during oscillation motion, the acceleration/deceleration is set by this parameter.
If a value greater than maximum value (100000.0) is set, the value is clamped to maximum value (100000.0).
If 0 is set, maximum value (100000.0) is assumed to be set.

	#7	#6	#5	#4	#3	#2	#1	#0
25655							CST	

[Input type] Parameter input
[Data type] Bit path

#1 CST When Oscillation start signal CHPST <Gn051.6> is changed to “0” or when the alarm (except BG and OH) is issued while moving to point R from the start of oscillation by Oscillation start signal CHPST:
0: Cancel of oscillation mode is executed after reaching point R.
1: Cancel of oscillation mode is executed immediately.

When reset operation is executed while moving to point R, cancel of oscillation mode is executed immediately regardless of the setting of this parameter.

> **NOTE**
> In the following case, this parameter does not affect the motion.
> 1 Start of oscillation by G81.1 command
> 2 Oscillation motion after reaching point R

Alarm and message

Number	Message	Description
PS5050	ILL-COMMAND IN G81.1 MODE	- During oscillation, a move command has been issued for the oscillation axis. - Oscillation is specified for Cs contour control axis. - Machine lock for the axis while oscillation motion is executed. - Oscillation is specified for the slave axis of superimposed control.

	Each Axis Workpiece Coordinate System Preset Signals

1.16 DUAL CONTROL AXES SWITCHING

Overview

This function makes it possible to allocate two control axes to one motor. When the allocated two control axes are in the controlled axes detach, the allocated two control axes can be switched. The reference position is not lost at the change of the control axes, when the absolute position detection is used. This function is useful for using the attachment with different gear ratio by one motor.

Explanation

Two control axes are allocated to one motor. As a result, one motor can have two independent axes setting (parameter, compensation, and custom macro system variables, etc. that related to axis).
Number of the servo axis (parameter No.1023) of these two control axes must set the consecutive values that the odd number and the even number (odd number + 1).The odd number is set to parameter No.1023 for a real axis, and the even number is set to parameter No.1023 for an imaginary axis.
It is necessary for a real axis that the setting (bit 3 (DCHx) of parameter No.2437 is set to 1) which the dual control axes switching function is enabled.
It is necessary for an imaginary axis that the setting (bit 3 (DCHx) of parameter No.2437 and bit 0 (DMYx) of parameter No.2009 are set to 1) which the dual control axes switching function and the serial feedback dummy function are enabled. And set the dummy axis for FSSB setting too.
When both a real axis and an imaginary axis are in the controlled axes detach, the selected axis and the non-selected axis can be switched by dual control axes switching signal SVMWCx <Gn687.x>.
The motor moves according to command for the selected axis.
Feedback from the motor returns to both the selected axis and the non-selected axis. A position display of the selected axis and the non-selected axis (machine position display, absolute position display and relative position display) are updated by the feedback pulses according to the setting of each axis.

Table 1.16 (a) Relationships between dual control axes switching signal and selected axis

	Dual control axes switching signal SVMWCx <Gn687.x>	
	0	1
Selected axis	Real axis	Imaginary axis
Non-selected axis	Imaginary axis	Real axis

[Example]
Real axis (C1) : Parameter No.1023 = 3
Bit 3 (DCHx) of parameter No.2437 = 1
Imaginary axis (C2) : Parameter No.1023 = 4
Bit 0 (DMYx) of parameter No.2009 = 1
Bit 3 (DCHx) of parameter No.2437 = 1

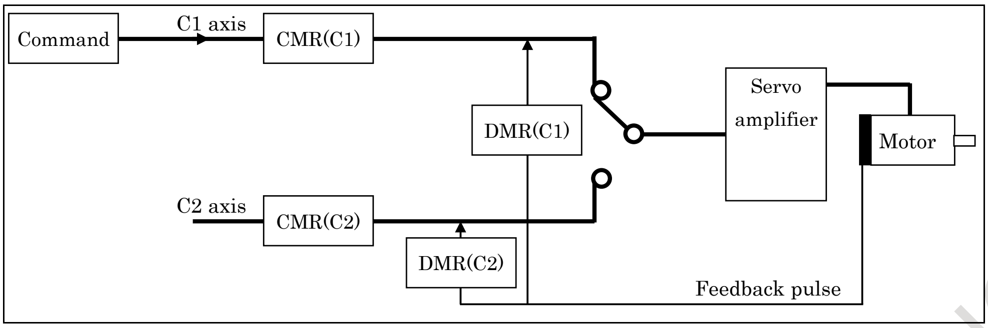

Fig. 1.16 (a) Example of dual control axes switching signal SVMWCx <Gn687.x> = "0"
(selected axis: C1, non-selected axis: C2)

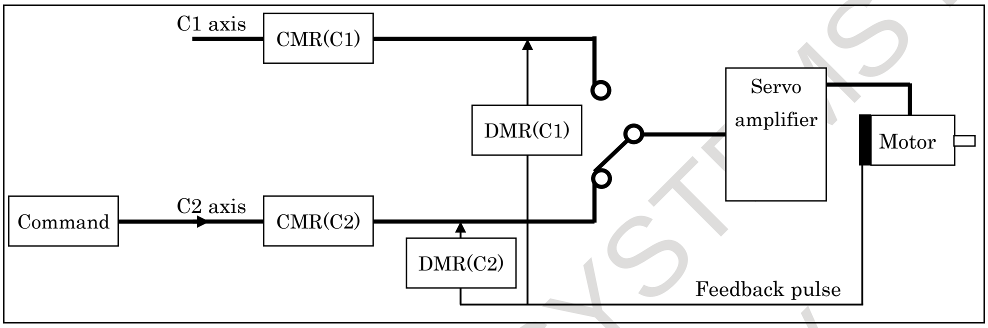

Fig. 1.16 (b) Example of dual control axes switching signal SVMWCx <Gn687.x> = "1"
(selected axis: C2, non-selected axis: C1)

Full closed system

This function can be controlled in the full closed system by using two separate position detectors. Feedback from the separate position detectors returns to each axis when the full closed system is used.
It is necessary for an imaginary axis to set 1 to bit 3 (DCFULLx) of parameter No.2570.

[Example]

Real axis (C1) : Parameter No.1023 = 3
Bit 3 (DCHx) of parameter No.2437 = 1
Parameter No.24096 (C1) = 1

Imaginary axis (C2) : Parameter No.1023 = 4
Bit 0 (DMYx) of parameter No.2009 = 1
Bit 3 (DCHx) of parameter No.2437 = 1
Bit 3 (DCFULLx) of parameter No.2570 = 1
Parameter No.24096 (C2) = 2

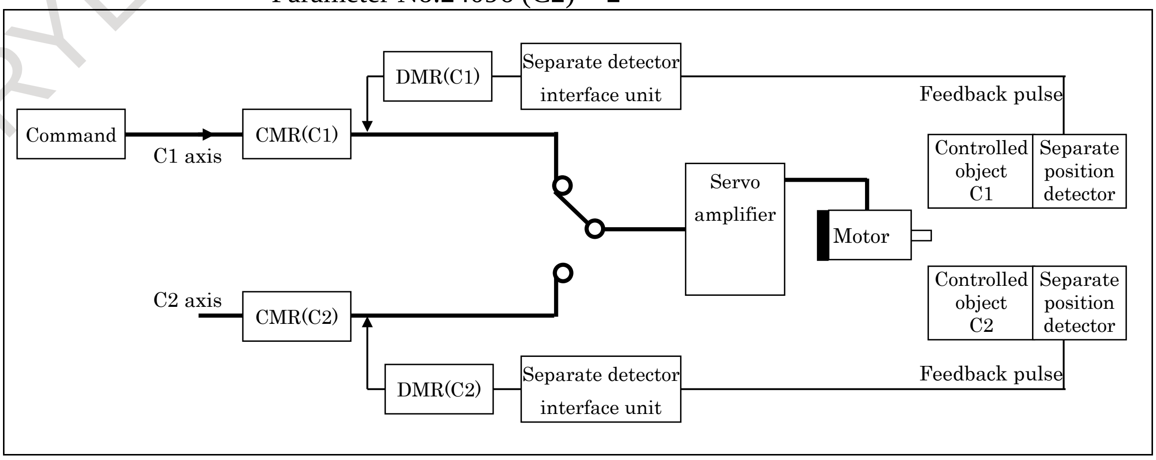

Fig. 1.16 (c) Example of dual control axes switching signal SVMWCx <Gn687.x> = "0" in full closed system
(selected axis: C1, non-selected axis: C2)

> **NOTE**
> 1 A different system (semi closed system, full closed system) cannot be used between a real axis and an imaginary axis.
> 2 When one separate position detector is shared, it is necessary to set 0 to bit 3 (DCFULLx) of parameter No.2570.

[Switch procedure of dual control axes switching signal]

To switch the dual control axes switching signal from “0” to “1”, switch the signal according to the following procedure.

(1) Set the controlled axis detach signals DTCHx <Gn124.x> for a real axis and an imaginary axis to “1”, using the M code as a trigger.
(2) Set the dual control axes switching signal SVMWCx <Gn687.x> to “1”, when the controlled axis detach status signals MDTCHx <Fn110.x> for a real axis and an imaginary axis are “1”.
(3) Set the controlled axis detach signals DTCHx <Gn124.x> for a real axis and an imaginary axis to “0”, when the dual control axes status signal SVMWSx <Fn687.x> is “1”.
(4) Perform the FIN processing for the M code.

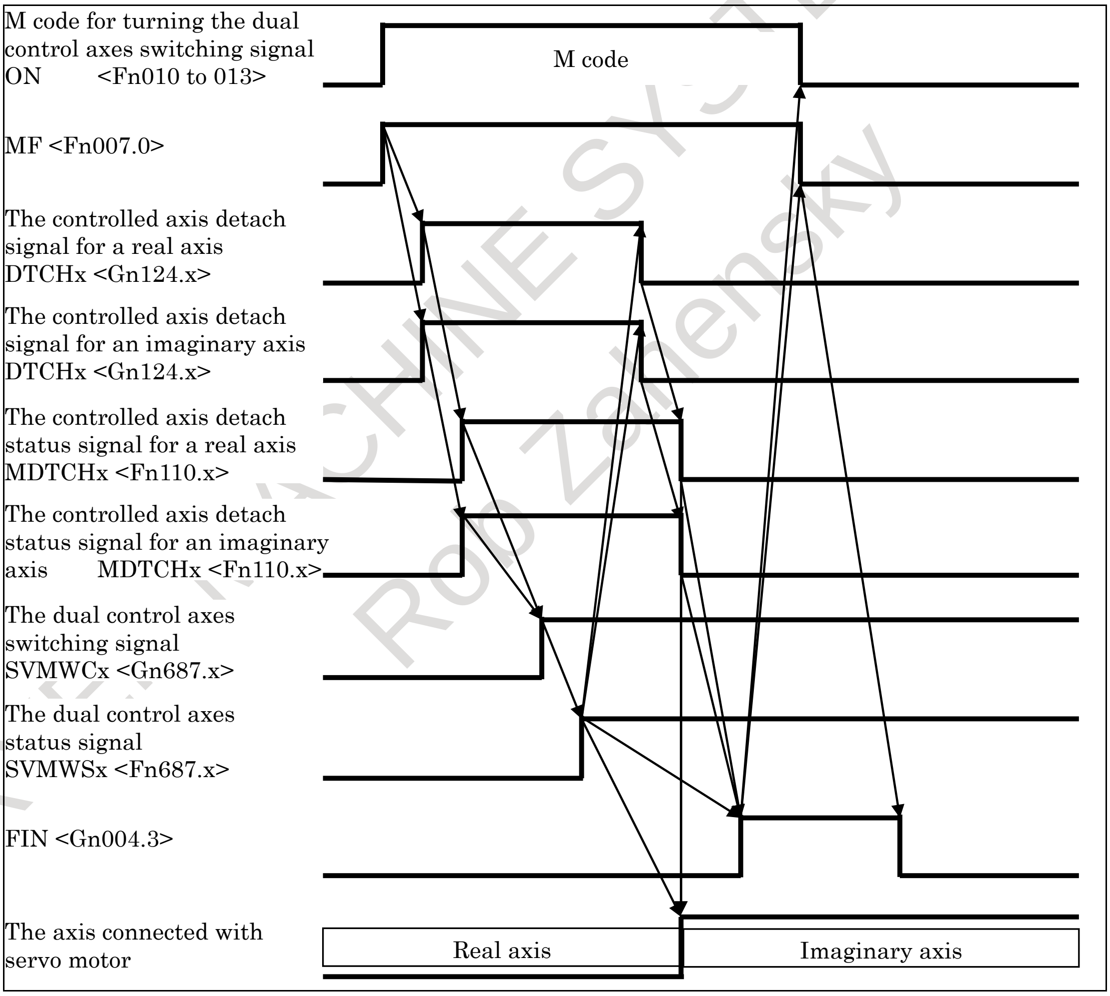

Fig. 1.16 (d) Timing chart (The dual control axes switching signal SVMWCx <Gn687.x> “0” → “1”)

To switch when the dual control axes switching signal from “1” to “0”, switch the signal according to the following procedure.

(1) Set the controlled axis detach signals DTCHx <Gn124.x> for a real axis and an imaginary axis to “1”, using the M code as a trigger.
(2) Set the dual control axes switching signal SVMWCx <Gn687.x> to “0”, if the controlled axis detach status signals MDTCHx <Fn110.x> for a real axis and an imaginary axis are “1”.

(3) Set the controlled axis detach signals DTCHx <Gn124.x> for a real axis and an imaginary axis to "0", if the dual control axes status signal SVMWSx <Fn687.x> is "0".
(4) Perform the FIN processing for the M code.

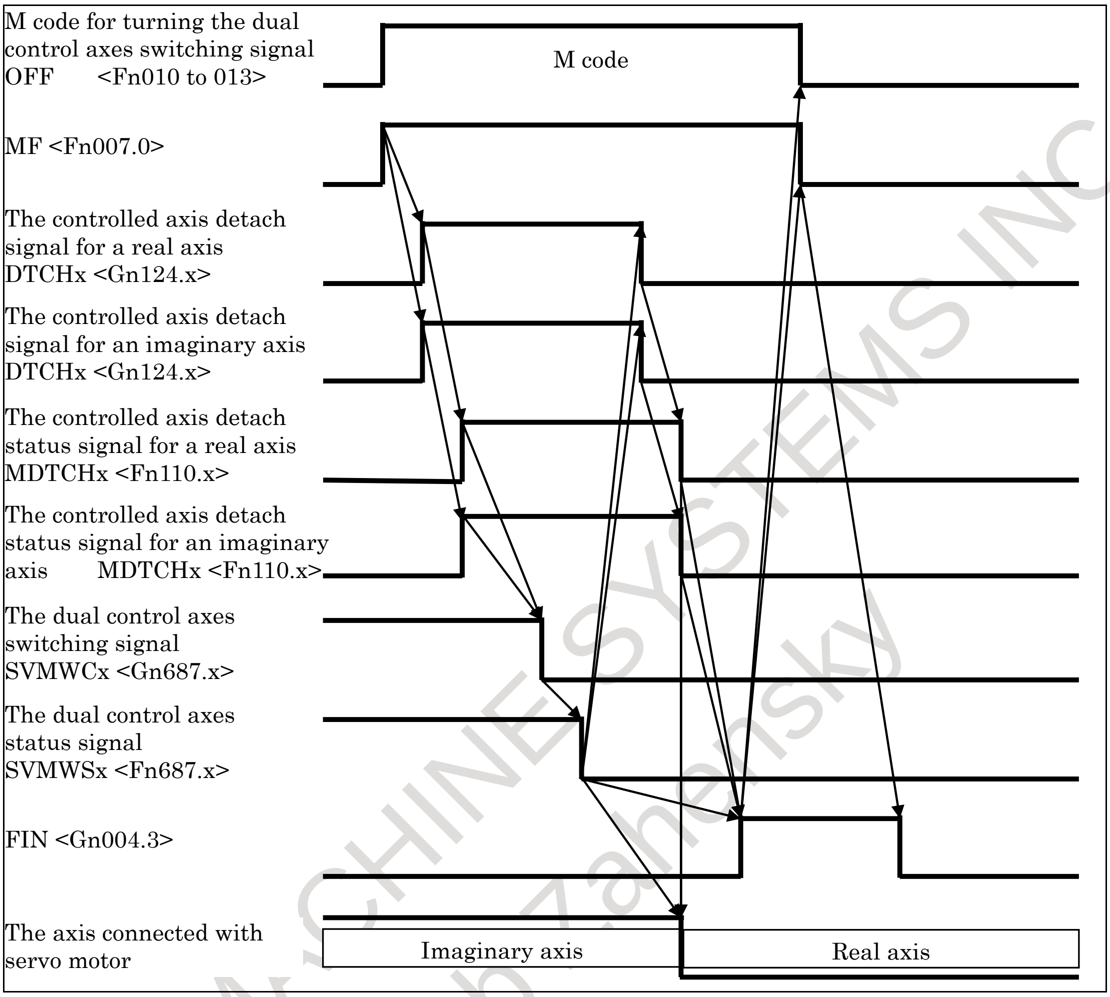

Fig. 1.16 (e) Timing chart (The dual control axes switching signal SVMWCx <Gn687.x> "1" → "0")

Use with absolute position detection

To set the zero point of an absolute position detector, perform the manual reference position return at the selected axis. Perform the manual reference position return for a real axis and an imaginary axis as the selected axis.
If the zero point of an absolute position detector is set, the manual reference position return is unnecessary when the dual control axes switching signal SVMWCx <Gn687.x> is switched.

Without absolute position detection

When the dual control axes switching signal SVMWCx <Gn687.x> is switched, the reference position is lost. The manual reference position return must be performed by the selected axis before the move command. If specifying the move command without reference position return, alarm PS0224 "ZERO RETURN NOT FINISHED" is issued.

Restrictions

Dual control axes switching cannot be used together with the following functions.

- Dual Check Safety
- Angular axis control
- Tandem control
- Dual position feedback

- Semi-Full error monitoring

The dual control axes switching cannot be used for multiple winding motor.

Disable the following functions, before the dual control axes switching signal SVMWCx <Gn687.x> is switched.

- Synchronous control and composite control
- Superimposed control
- Axis synchronous control
- Flexible synchronization control
- Electronic gear box
- Axis control by PMC
- Spindle control with servo motor

NOTE

1 To disable the display of non-selected axis, delete the current position indication for the non-selected axis by using bit 0 (NDPx) of parameter No.3115.
2 The setting of bit 0 (ROTx) and 1 (ROSx) of parameter No.1006 should be same setting for both a real axis and an imaginary axis. If the setting is different, the machine coordinates might not be correctly updated at dual control axes switching signal SVMWCx <Gn687.x> switching.
3 If the controlled axis detach status signals MDTCHx <Fn110.x> for a real axis and an imaginary axis are not “1” while dual control axes switching signal SVMWCx <Gn687.x> is switched, alarm SV0401 “IMPROPER V_READY OFF” is issued.
4 In automatic operation, set the M code for dual control axes switching signal on or off to the M code preventing buffering. (Parameters Nos.3411 to 3432)
5 An alarm occurs at the time of a mechanical adjustment, so on and off of dual control axes switching signal perform a time chart on Fig. 1.16 (d) and Fig. 1.16 (e) manually.
6 If the dual control axes switching is executed while excitation of the motor is on, alarm SV0417 “ILL DGTL SERVO PARAMETER” is issued. (Detail number of diagnosis data No.352: 4379)
7 It is necessary to change bit 1 to 4 of parameter No.2013 and bit 1 to 4 of parameter No.2014 for an axis of the dual control axes switching according to the motor model. If the standard parameters for the motor model are the same as the values described in the before change column in the below table, change to the values described in the after change column.

No.2013 #4,#3,#2#1 No.2014 #4,#3,#2,#1		
Before change		After change
1, 0, 0, 1	→	1, 0, 1, 0
0, 1, 1, 1	→	1, 0, 0, 0
0, 1, 0, 1	→	0, 1, 1, 0
0, 0, 1, 1	→	0, 1, 0, 0
0, 0, 0, 1	→	0, 0, 1, 0

8 To get the frequency response using SERVO GUIDE, because the serial feedback dummy function (bit 0 (DMYx) of parameter No.2009) is effective to an imaginary axis, it is not possible to measure. To get the frequency response with imaginary axis, temporarily invalidate the serial feedback dummy function (bit 0 (DMYx) of parameter No.2009) for an imaginary axis after power on and measure it. After completing the measurement, reset to effective the serial feedback dummy function (bit 0 (DMYx) of parameter No.2009 = 1).
9 In actual speed display, a synthetic speed of real axis and imaginary axis is displayed. In order to exclude imaginary axis speed from the actual speed display, set actual speed display axis selection signals *ACTF1 to *ACTF8 <Gn580> to “1” about the imaginary axis.

Parameter

1023	Number of the servo axis for each axis

> **NOTE**
> When this parameter is set, the power must be turned off before operation is continued.

[Input type] Parameter input
[Data type] Byte axis
[Valid data range] 0 to 80

This parameter associates each control axis with a specific servo axis. Specify values 1+8n, 2+8n, 3+8n, 4+8n, 5+8n, and 6+8n (n = 0, 1, 2, …, 9) like 1, 2, 3, 4, 5, …, 77, and 78.
The control axis number is the order number that is used for setting the axis-type parameters or axis-type machine signals
For dual control axes switching, two axes need to be specified as one pair. So, make a setting as described below.
For a real axis, set an odd (1, 3, 5, 9, ...) servo axis number. For an imaginary axis to be paired, set a value obtained by adding 1 to the value set for the real axis.

	#7	#6	#5	#4	#3	#2	#1	#0
2009								DMYx

[Input type] Parameter input
[Data type] Bit axis

#0 DMYx The serial feedback dummy function is:
0: Not used.
1: Used.
Set this parameter for the imaginary axis.

> **NOTE**
> The setting of this parameter becomes valid after the power is turned off then back on.

	#7	#6	#5	#4	#3	#2	#1	#0
2437					DCHx			

[Input type] Parameter input
[Data type] Bit axis

#3 DCHx The dual control axes switching function is:
0: Disabled.
1: Enabled.
Set this parameter to both axes of the real axis and the imaginary axis.

	#7	#6	#5	#4	#3	#2	#1	#0
2570					DCFULLx			

[Input type] Parameter input
[Data type] Bit axis

#3 DCFULLx In the dual control axes switching function, one scale is:
0: Shared with the real axis and the imaginary axis.
1: Not shared with the real axis and the imaginary axis.
Set this parameter only for the imaginary axis.

NOTE
In the case of having an individual scale with the real axis and imaginary axis, set this bit to 1.

24096	**Connector number for the 1st or 9th separate detector interface unit**
24097	**Connector number for the 2nd or 10th separate detector interface unit**
24098	**Connector number for the 3rd or 11th separate detector interface unit**
24099	**Connector number for the 4th or 12th separate detector interface unit**
24100	**Connector number for the 5th separate detector interface unit**
24101	**Connector number for the 6th separate detector interface unit**
24102	**Connector number for the 7th separate detector interface unit**
24103	**Connector number for the 8th separate detector interface unit**

NOTE
When these parameters are set, the power must be turned off before operation is continued.

[Input type] Parameter input
[Data type] Byte axis
[Valid data range] 0 to 8

Set a connector number for the connector to which a separate detector interface unit is attached if the separate detector interface unit is to be used. The following table lists the necessary settings. Be sure to specify 0 for connectors not in use.

Correspondence between connectors and connector numbers

Connector	Connector number
JF101	1
JF102	2
JF103	3
JF104	4
JF105	5
JF106	6
JF107	7
JF108	8

(Setting example)

Controlled axis	Connector to which each separate detector interface unit is attached				Parameter setting			
	1st connector	2nd connector	5th connector	6th connector	No. 24096	No. 24097	No. 24100	No. 24101
X1	JF101	–	–	–	1	0	0	0
Y1	–	JF102	–	–	0	2	0	0
Z1	–	–	JF102	–	0	0	2	0
X2	–	JF101	–	–	0	1	0	0
Y2	–	–	–	JF101	0	0	0	1
Z2	–	–	–	–	0	0	0	0
A1	–	–	JF101	–	0	0	1	0
B1	–	–	–	JF102	0	0	0	2
C1	–	JF104	–	–	0	4	0	0
A2	JF102	–	–	–	2	0	0	0
B2	–	JF103	–	–	0	3	0	0
C2	–	–	–	JF103	0	0	0	3

NOTE

1. Specify these parameters when separate detector interface units are used.
2. Parameters Nos. 24096 to 24103 are specified automatically when data is entered on the FSSB setting screen if the FSSB setting mode in use is the automatic setting mode (bit 0 (FMD) of parameter No. 1902 = 0). If the manual setting 2 mode (bit 0 (FMD) of parameter No. 1902) = 1), specify the parameters directly.

Alarm and message

Number	Message	Description
PS0224	ZERO RETURN NOT FINISHED	A reference return has not been performed before the start of automatic operation. (Only when bit 0 (ZRNx) of parameter No.1005 is 0) Perform a reference position return.
SV0401	IMPROPER V_READY OFF	Although the ready signal (PRDY) of the position control was ON, the ready signal (VRDY) of the velocity control was OFF.
SV0417	ILL DGTL SERVO PARAMETER	A digital servo parameter setting is incorrect.

Signal

Actual speed display axis selection signals *ACTF1 to *ACTF8 <Gn580>

[Classification] Input signal

[Function] These signals specify whether the movement speed of each axis is added to the display of actual speed.

[Operation] The movement speed of the axis for which 1 is set is not added to the display of actual speed.

Dual control axes switching signal SVMWC1 to SVMWC8 <Gn687>

[Classification] Input signal

[Function] These signals switch the selected axes in dual control axes.

[Operation] When this signal is set to “0”, the real axis becomes selected axis. And the imaginary axis becomes non-selected axis.
When this signal is set to “1”, the imaginary axis becomes selected axis. And the real axis becomes non-selected axis.

Dual control axes status signal SVMWS1 to SVMWS8 <Fn687>

[Classification] Output signal

[Function] This signal notifies the status of the dual control axes.

[Operation] This signal becomes “0” when:
- The real axis is selected axis, and the imaginary axis is non-selected axis.

This signal becomes “1” when:
- The imaginary axis is selected axis, and the real axis is non-selected axis.

Signal address

NOTE
The signal (Gn687, Fn687) for the real axis can be used. The signal for the imaginary axis cannot be used.

1.17 VELOCITY FEED FORWARD COMPENSATION FUNCTION

Overview

Velocity feed forward coefficient can be adjusted according to the machine coordinate value of the moving axis specified by parameter No.11821.

Explanation

Velocity feed forward coefficient of the compensation axis can be adjusted according to the machine coordinate value of the moving axis specified by parameter No.11821 with this function.

Velocity feed forward coefficient of the compensation axis is determined by the following formula.

$$VFF = \frac{K}{100} VFF_0$$

VFF : Velocity feed forward coefficient
VFF_0 : Velocity feed forward coefficient parameter (No.2069, 2145)
K : Compensation coefficient

Compensation coefficient of the compensation axis is set with the following parameters.

Table 1.17 (a) Compensation coefficient setting parameter

	Parameter
Machine coordinate of moving axis	No.14270 to No.14279
Compensation coefficient of compensation axis	No.14280 to No.14289

Example 1)
When setting the parameter in Table 1.17 (b) below, compensation coefficients of the compensation axis are as shown in Fig. 1.17 (a).

Table 1.17 (b) Setting example 1

Parameter	Setting value	Parameter	Setting value
No.14270	-3000.0	No.14280	100
No.14271	-2500.0	No.14281	150
No.14272	-2000.0	No.14282	100
No.14273	-800.0	No.14283	100
No.14274	-500.0	No.14284	50
No.14275	500.0	No.14285	50
No.14276	800.0	No.14286	100
No.14277	2000.0	No.14287	100
No.14278	2500.0	No.14288	150
No.14279	3000.0	No.14289	100

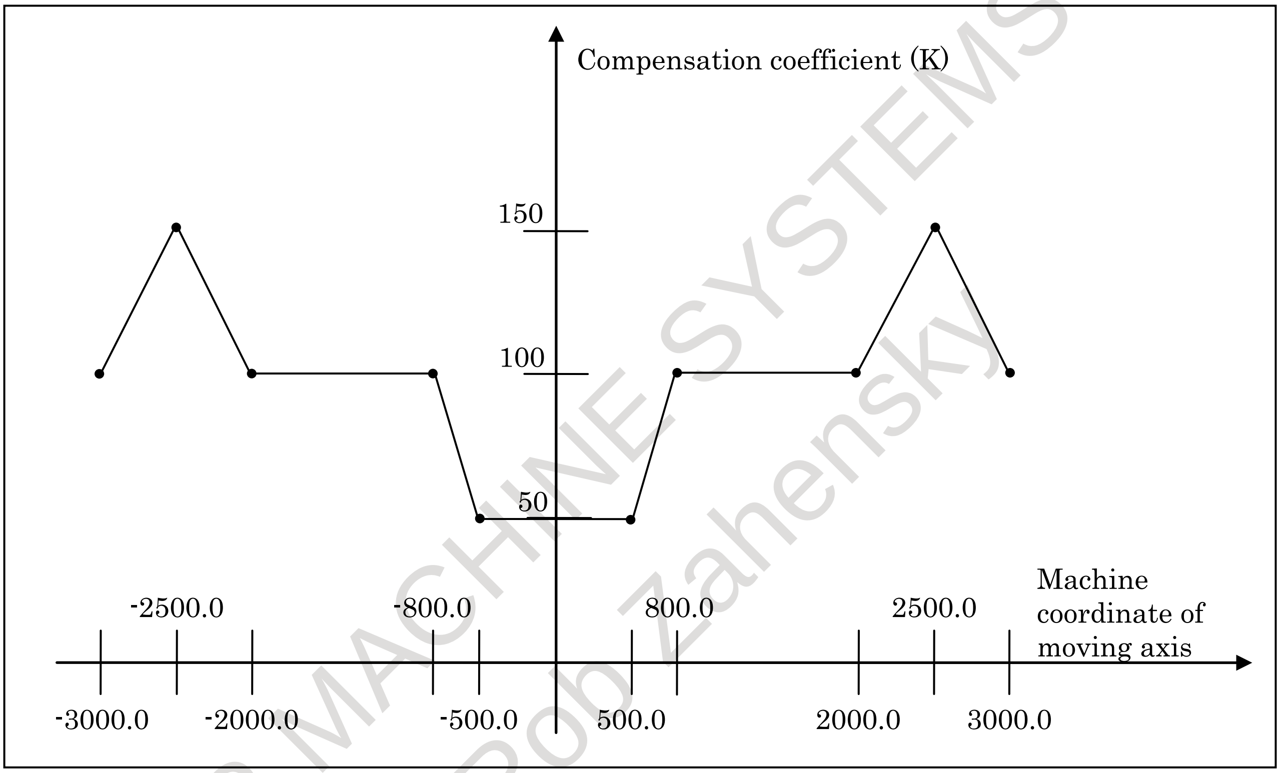

Fig. 1.17 (a) Compensation coefficient (example 1)

Example 2)
When setting the parameter in Table 1.17 (c) below, compensation coefficients of the compensation axis are as shown in Fig. 1.17 (b) .

Table 1.17 (c) Setting example 2

Parameter	Setting value	Parameter	Setting value
No.14270	-5.0	No.14280	50
No.14271	1000.0	No.14281	150
No.14272	0.0	No.14282	0
No.14273	0.0	No.14283	0
No.14274	0.0	No.14284	0
No.14275	0.0	No.14285	0
No.14276	0.0	No.14286	0
No.14277	0.0	No.14287	0
No.14278	0.0	No.14288	0
No.14279	0.0	No.14289	0

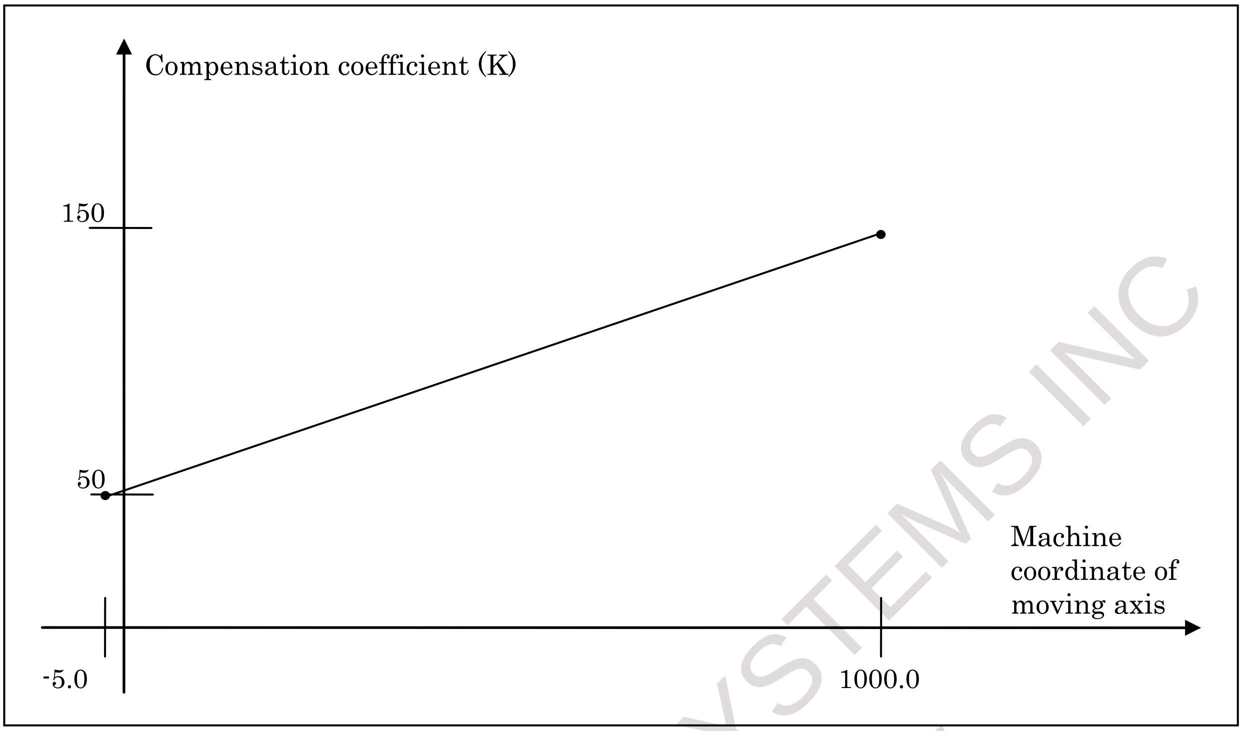

Fig. 1.17 (b) Compensation coefficient (example 2)

> **NOTE**
> 1 This function is enabled after reference position return of moving axis and compensation axis are completed.
> 2 Set the parameter No.14270 to No.14279 setting so that the set value of the small parameter number becomes smaller. (No.14270 setting value < No.14271 setting value < … < No.14279 setting value) When the magnitude relation of the setting value is not established, subsequent parameter setting becomes invalid. In the case of Table 1.17 (c), since the setting value of No.14271 is larger than the setting value of No.14272, parameter setting after No.14272 is invalid.
> 3 This function is invalid if the machine coordinate value of moving axis is out of the range of parameter No.14270 to No.14279 set value.

Limitation

- Moving axis and compensation axis must be assigned to be the same path.
- When the axis used this function, the following function cannot be used.
  - Cs contouring control
  - Spindle control with servo motor
  - Temporary absolute coordinate setting

Parameter

2069	Velocity feedforward coefficient (VFFLT)

[Input type] Parameter input
[Data type] Word axis
[Unit of data] %
[Recommendation] 50 to 200

2145	Velocity feedforward coefficient for cutting feed

[Input type] Parameter input

[Data type] Word axis
[Unit of data] %
[Recommendation] 50 to 200

11821	Controlled axis number of moving axis

[Input type] Parameter input
[Data type] Byte axis
[Valid data range] 0, 1 to 24
Specify controlled axis number.
When 0 is set, this function is invalid.

> **NOTE**
> 1 When this parameter is set, the power must be turned off before operation is continued.
> 2 Set this parameter on compensation axis.

14270	Machine coordinate 1 of moving axis
14271	Machine coordinate 2 of moving axis
14272	Machine coordinate 3 of moving axis
14273	Machine coordinate 4 of moving axis
14274	Machine coordinate 5 of moving axis
14275	Machine coordinate 6 of moving axis
14276	Machine coordinate 7 of moving axis
14277	Machine coordinate 8 of moving axis
14278	Machine coordinate 9 of moving axis
14279	Machine coordinate 10 of moving axis

[Input type] Parameter input
[Data type] Real axis
[Unit of data] mm, inch, deg (machine unit)
[Min. unit of data] Depend on the increment system of the applied axis
[Valid data range] 9digit of minimum unit of data (refer to standard parameter setting table (A))
(When the increment system is IS-B, -999999.999 to +999999.999)
Specify the machine coordinate value of the moving axis.

> **NOTE**
> 1 When this parameter is set, the power must be turned off before operation is continued.
> 2 Set this parameter on compensation axis.

14280	Compensation coefficient 1 of compensation axis

14281	Compensation coefficient 2 of compensation axis
14282	Compensation coefficient 3 of compensation axis
14283	Compensation coefficient 4 of compensation axis
14284	Compensation coefficient 5 of compensation axis
14285	Compensation coefficient 6 of compensation axis
14286	Compensation coefficient 7 of compensation axis
14287	Compensation coefficient 8 of compensation axis
14288	Compensation coefficient 9 of compensation axis
14289	Compensation coefficient 10 of compensation axis

[Input type] Parameter input
[Data type] 2-word axis
[Unit of data] %
[Valid data range] 1 to 1000

Specify the compensation coefficient of compensation axis.

NOTE
1 When this parameter is set, the power must be turned off before operation is continued.
2 Set this parameter on compensation axis.
3 When a value outside the data range is set, 100 is assumed to be set.

2 PREPARATIONS FOR OPERATION

2.1 EMERGENCY STOP

Overview

By pressing the emergency stop button on the machine operation panel, you can immediately stop the movement of the machine in case of emergency.

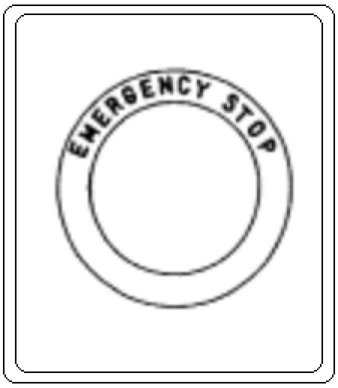

Fig. 2.1 (a) EMERGENCY STOP BUTTON

This button is locked when it is pressed. Although it varies with the machine tool builder, the button can usually be unlocked by twisting it.

Signal

Emergency stop (input)

***ESP<X008.4> (for the first machine group), <X008.0> (for the second machine group), <X008.1> (for the third machine group), <Gn008.4>**

[Classification] Input signal

[Function] Immediately stop the movement of the machine in case of emergency.

[Operation] When the emergency stop signal *ESP turns to “0”, the emergency stop is applied to the machine and the CNC is reset. In general, this signal is controlled by the B contacts of a pushbutton switch. The emergency stop signal turns the servo ready signal SA to “0”.
In this CNC, it is the basic specification that overtravel detection is performed by the stored stroke check function. A limit switch for normal overtravel detection is not needed. To prevent the machine from moving beyond the software limit through servo feedback error, always install a stroke end limit switch (shown in Fig. 2.1 (b) as follows).

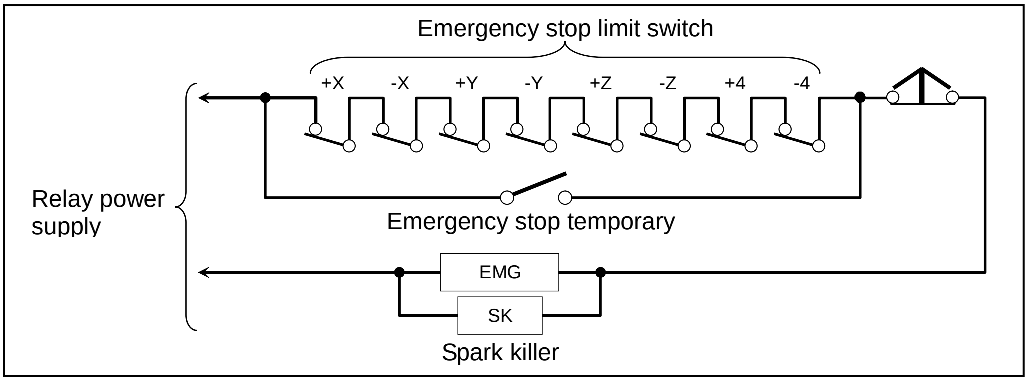

Fig. 2.1 (b) Connection of emergency stop limit switch

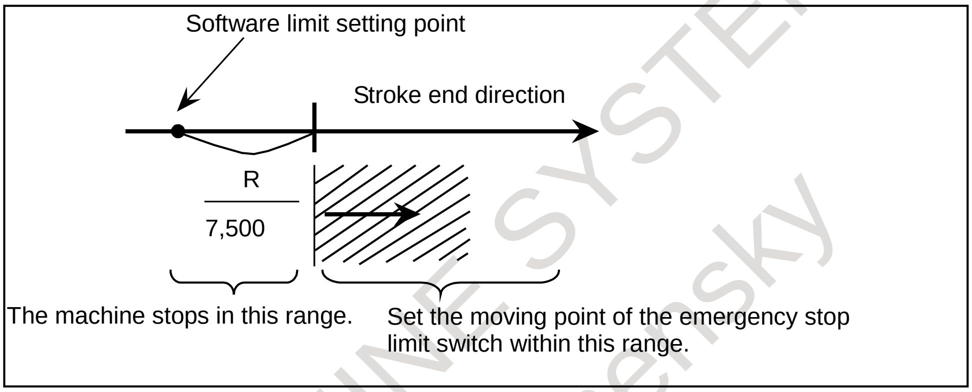
The distance from the position where the dynamic brake is applied to that where the tool stops moving is given in the "FANUC AC SERVO MOTOR α*i*-B/α*i* series DESCRIPTIONS (B-65262EN)."

> ⚠ **WARNING**
> About the software limit setting point and operating point of limit switch for emergency stop
> The stop point by the software limit goes beyond the setting point by as much as the following distance.
> The actual stopping point may exceed the position set by parameters Nos.1320 and 1321 by as much as R/7500 (mm).
> R/7,500 (mm)
> R: Rapid traverse rate (mm/min)
> Set the limit switch for emergency stop including the allowance for the above value.



Signal address

2.2 CNC READY SIGNALS

Overview

When the CNC is turned on and becomes ready for operation, the CNC ready signal is set to 1.

Signal

CNC Ready Signal MA<Fn001.7>

[Classification] Output signal

[Function] The CNC ready signal indicates that the CNC is ready.

[Output cond.] When the CNC is turned on and becomes ready for operation, the signal is set to “1”. Normally, it takes several seconds to establish this state after the power is turned on. If a system alarm is issued, the signal is set to “0”. The signal remains set to “1”, however, when an emergency stop or a similar operation is performed.

Servo Ready Signal SA<Fn000.6>

[Classification] Output signal

[Function] Signal SA turns to “1” when the servo system is ready to operate. On the machine side, for an axis that is to be braked, release the brake when this signal is “1” and apply the brake when this signal is “0”.
Time chart of this signal is as Fig. 2.2 (a).

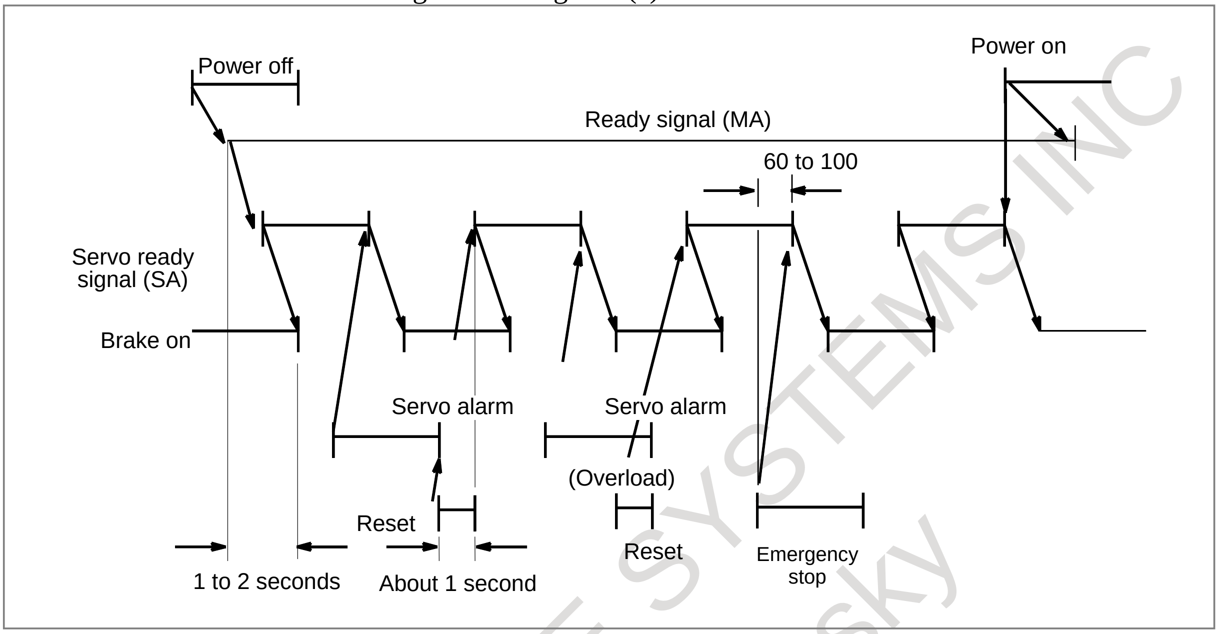

Fig. 2.2 (a) Time chart for servo ready signal

	#7	#6	#5	#4	#3	#2	#1	#0
Fn000		SA						
Fn001	MA							

2.3 OVERTRAVEL CHECK

2.3.1 Overtravel Signals

Overview

When the tool tries to move beyond the stroke end set by the machine tool limit switch, the tool decelerates and stops as a result of tripping the limit switch, and an OVER TRAVEL is displayed.

Signal

Overtravel signals *+L1 to *+L8<Gn114>, *-L1 to *-L8<Gn116>

[Classification] Input signal

[Function] Indicates that the control axis has reached its stroke limit. There are individual signals for each direction in every control axis.
The +/- in the signal name indicates the direction and the number at the end indicates the control axis number.
+Lx

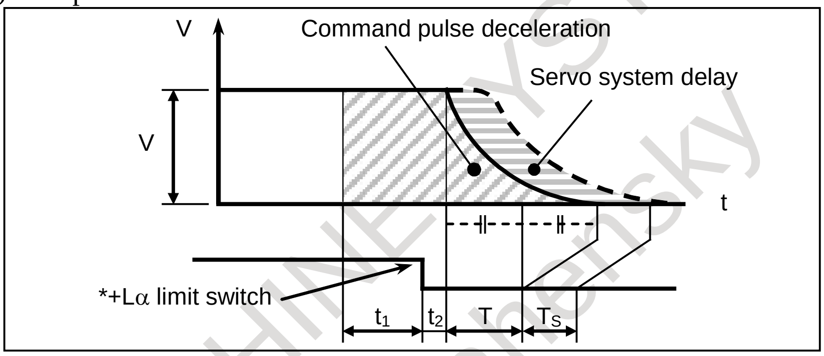
x : 1 : No. 1 axis is at stroke limit.
2 : No. 2 axis is at stroke limit.
3 : No. 3 axis is at stroke limit.
:
:
8 : No. 8 axis is at stroke limit.
+ : Limit reached in + direction.
- : Limit reached in - direction.

[Operation] When it is “0”, the control unit operates as given below.

- In automatic operation, if even one axis overtravel signal turns to “0”, all axes are decelerated to stop, an alarm is given and operation is halted.
- In manual operation, decelerates and stops movement of the axis "0" in the direction of "0" only, and the axis can be moved in the opposite direction.
- Once the axis overtravel signal has turned to “0”, the axis and direction is registered. Even if the signal returns to “1”, it is not possible to move that axis in that direction until the alarm is cleared.

The following shows the deceleration distance at overtravel.

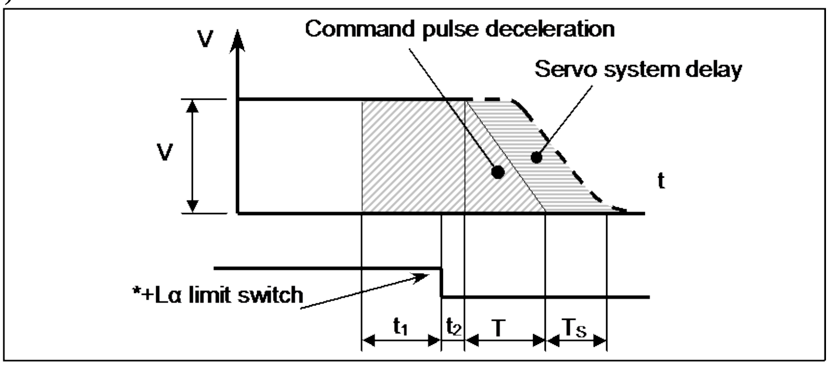
(i) Exponential acceleration/deceleration



$L=V(t_1+t_2+T+T_S)\times 1/60000$ [mm or inch]

L : Deceleration distance
V : Feedrate [mm/min or inch/min]
t_1 : Limit switch signal delay time (from limit switch operation to *+Lα signal turn off [msec])
t_2 : Receiver delay time 30msec
T : Acceleration/deceleration time [msec]
T_S : Servo system delay [msec]

(ii) Linear acceleration/deceleration



$L=V(t_1+t_2+T/2+T_S)\times 1/60000$ [mm or inch]

L : Deceleration distance
V : Feedrate [mm/min or inch/min]
t_1 : Limit switch signal delay time (from limit switch operation to *+Lα signal turn off [msec])
t_2 : Receiver delay time 30msec
T : Acceleration/deceleration time [msec]
T_S : Servo system delay [msec]

If rapid traverse is commanded and the bit 1 (LRP) of parameter No.1401 is 1, acceleration/deceleration time T is different depending on the traverse speed. T must set the value in which this is taken into consideration.

(iii) Bell-shaped acceleration/deceleration
It is similar to (ii).

> **NOTE**
> Servo system delay T_S is 33 msec when the servo unit is adjusted to the standard setting.

Releasing overtravel

First, move the tool into a safe zone under manual operation. Then press the reset button to reset the alarm.

Signal address

	#7	#6	#5	#4	#3	#2	#1	#0
Gn114	*+L8	*+L7	*+L6	*+L5	*+L4	*+L3	*+L2	*+L1

Parameter

	#7	#6	#5	#4	#3	#2	#1	#0
3004			OTH					

[Input type] Parameter input
[Data type] Bit path

#5 OTH The overtravel signal is:
0: Checked
1: Not checked

> ⚠ **WARNING**
> For safety, usually set 0 to check the overtravel signal.

Alarm and message

Number	Message	Description
OT0506	+ OVERTRAVEL (HARD)	The stroke limit switch in the positive direction was triggered. This alarm is generated when the machine reaches the stroke end. When this alarm is generated, feed of all axes is stopped during automatic operation. During manual operation, only the feed of the axis on which the alarm occurred is stopped.
OT0507	- OVERTRAVEL (HARD)	The stroke limit switch in the negative direction was triggered. This alarm is generated when the machine reaches the stroke end. When this alarm is generated, feed of all axes is stopped during automatic operation. During manual operation, only the feed of the axis on which the alarm occurred is stopped.

Reference item

Manual name	Item name
OPERATOR'S MANUAL (B-64694EN)	Overtravel

2.3.2 Stored Stroke Check 1

Overview

A machine movable range is set with coordinates in the machine coordinate system in parameters. If the machine attempts to move beyond the range, it is decelerated and stopped and an alarm is displayed.
This function is enabled after manual reference position return is performed after power-on. (In case not using absolute pulse coder)
It can be used instead of an overtravel limit switch (hardware component).
When both functions are used at the same time, both are valid.
Unlike an overtravel limit switch, this function checks whether the position at which the machine is stopped after decelerated from the current position is beyond the range.
The stroke check 1 release signal common to all axes can be set to 1 so that the control unit does not make stroke check 1.

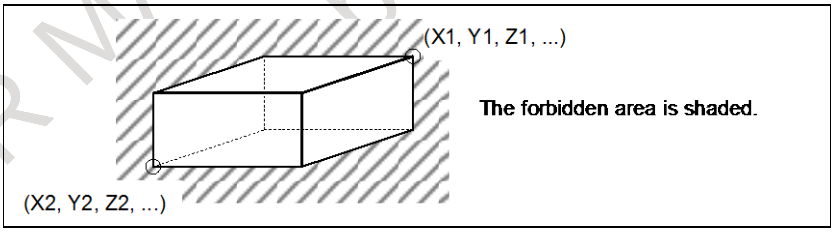

Fig. 2.3.2 (a)

Explanation

Parameters Nos. 1320, 1321 or Nos. 1326, 1327 set boundary. Outside the area of the set limits is a forbidden area. The machine tool builder usually sets this area as the maximum stroke.
When the tool enters a forbidden area and an alarm is generated, the tool can be moved in the reverse direction from which the tool came.
At this time, a signal (overtravel alarm signals +OT1 to +OT8 <Fn124>, -OT1 to -OT8 <Fn126>) can be output to the PMC if bit 6 (OTS) of parameter No. 1301 is set to 1. In addition, when the tool enters the forbidden area during manual operation, the signal (overtravel alarm signal) can be output to the PMC without generating the alarm by setting bit 1 (NAL) of parameter No. 1300 to 1. With this parameter setting, the alarm is generated when the tool enters the forbidden area during automatic operation.
When bit 2 (LMS) of parameter No. 1300 is set to 1, stored stroke check 1 select signal EXLM <Gn007.6> selects stroke check 1-I (parameter No. 1320 and 1321) or stroke check 1-II (parameter No. 1326 and 1327).

And when bit 0 (DLM) of parameter No. 1301 is set to 1, axis direction dependent stored stroke check 1 switch signals +EXL1 to +EXL8<Gn104>, -EXL1 to -EXL8<Gn105> switches stroke limit 1-I (parameter No. 1320 and No. 1321) and stroke limit 1-II (parameter No. 1326 and No. 1327) for each axis direction.

Automatically released alarm

If bit 4 (OF1) of parameter No. 1301 is set to 1, when the axis moves within the movable area, the alarm can be canceled without reset operation.

NOTE

1 When a soft OT1 alarm is issued during automatic operation, the soft OT alarm may be issued each time operation restarts after the automatic release and the tool is moved along the axis to a position within the stroke limits through manual intervention, which can prevent the operation from being continued.
Example:
Suppose that a path N1→N2→N3 is programmed as shown in the Fig. 2.3.2 (b) and that an absolute command in the N2 block causes a soft OT alarm at point a. When automatic operation is restarted after the soft OT alarm is released automatically by retracting the tool to point b by manual intervention in the manual absolute mode, the tool moves toward point d, which is the end point of the N2 block, so the soft OT alarm is issued again at point c. It is impossible to proceed to the N3 block.

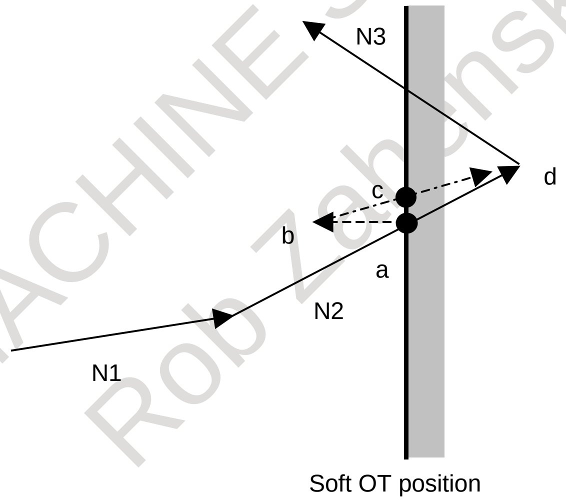

Fig. 2.3.2 (b)

2 The alarm can also be released automatically when the tool has entered the movable range by moving the tool along an axis by applying external force to the tool in the emergency stop state or servo-off state.

Simultaneous selection of stored stroke limit 1-I and -II

With the settings below, the inner area that is set for stored stroke check 1-II becomes a movement area, in addition to the inner area that is set for stored stroke check 1-I.

- Bit 2 of (LMS) of parameter No. 1300 = 1
- Bit 0 of (DLM) of parameter No. 1301 = 0
- Bit 1 of (LMA) of parameter No. 1301 = 1
- Stored stroke check 1 select signal EXLM <Gn007.6> = “1”

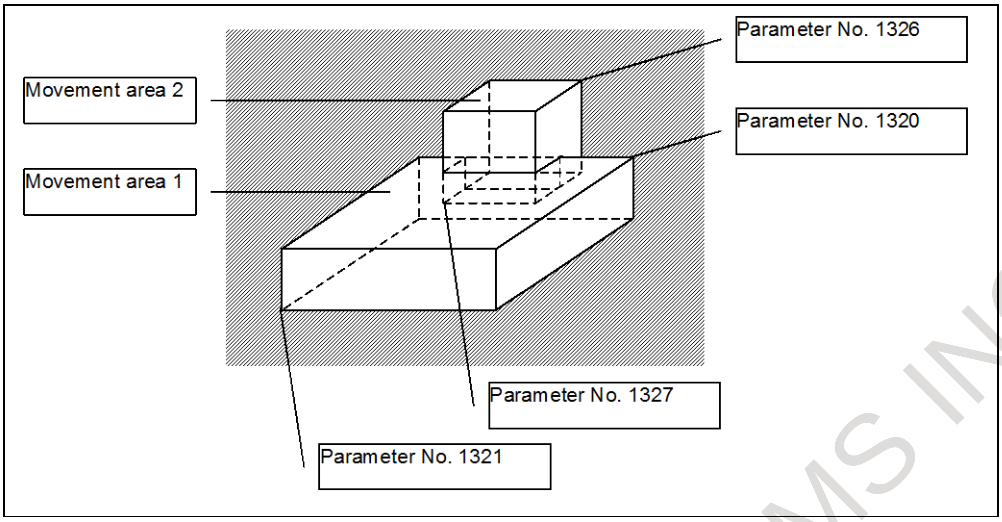

Fig. 2.3.2 (c)

> **NOTE**
> Simultaneous selection of stored stroke limit 1-I and -II cannot be used together with High precision oscillation function.

Signal

Stored stroke check 1 select signal EXLM<Gn007.6>

[Classification] Input signal

[Function] Selects stroke check 1-I (parameter Nos. 1320 and 1321) or stroke check 1-II (parameter Nos. 1326 and 1327).

[Operation] If this signal is “0”, the movement area for stroke check 1 is the inner area that is set for stroke check 1-I. (Area A in Fig. 2.3.2 (d))

If this signal is “1”, the movement area for stroke check 1 is as described below, depending on the setting of bit 1 (LMA) of parameter No. 1301.

- If bit 1 (LMA) of parameter No. 1301 is 0, the inner area that is set for stroke check 1-II. (Area B in Fig. 2.3.2 (d))
- If bit 1 (LMA) of parameter No. 1301 is 1, the inner area that is set for stored stroke check 1-II, in addition to the inner area set for stroke check 1-I. (Areas A and B in Fig. 2.3.2 (d))

This signal is effective if bit 2 (LMS) of parameter No. 1300 is 1.

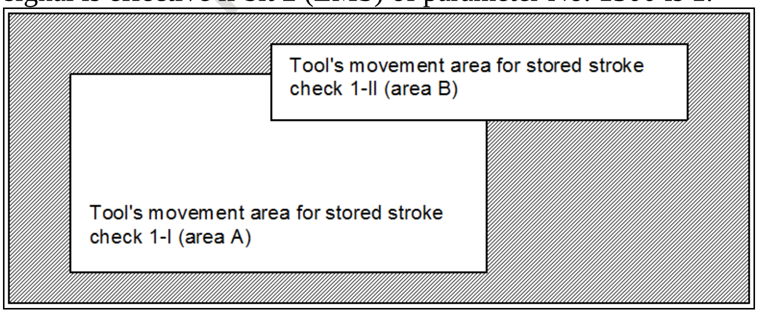

Fig. 2.3.2 (d)

Stroke check release signal RLSOT<Gn007.7>

[Classification] Input signal

[Function] Selects whether the stored stroke check 1 limits are checked or not.

[Operation] When this signal is set to “1”, does not check the stored stroke check 1 limits.

Axis direction dependent stored stroke check 1 switch signals +EXL1 to +EXL8<Gn104>, -EXL1 to -EXL8<Gn105>

[Classification] Input signal

[Function] Switches between stroke limit 1-I (parameter No. 1320 and No. 1321) and stroke limit 1-II (parameter No. 1326 and No. 1327) for each axis direction.
When this signal goes “1”, the CNC operates as described below.

1 +EXL1, +EXL2, . . .
Stroke check 1 (+ side) is checked using parameter No. 1326 instead of No. 1320.

2 -EXL1, -EXL2, . . .
Stroke limit 1 (- side) is checked using parameter No. 1327 instead of No. 1321.

Only if the bit 0 (DLM) of parameter No.1301 is set to 1, this signal is enabled.

Overtravel alarm signals +OT1 to +OT8<Fn124>, -OT1 to -OT8<Fn126>

[Classification] Output signal

[Function] Indicates whether the tool was about to enter the parameter-specified forbidden area (stored stroke limits).
This signal is valid when bit 1 (NAL) of parameter No. 1300 is set to 1 or when bit 6 (OTS) of parameter No. 1301 is set to 1. For differences in output condition between these parameter settings, see [Output cond.] below.
This signal is provided for each direction of each controlled axis. The sign + or - in the signal name indicates the direction, and the number at the end of the signal name indicates the number of a controlled axis.

* <u>x</u>OT<u>y</u>

y: 1 ….. No. 1 axis at stroke limit.
2 ….. No. 2 axis at stroke limit.
3 ….. No. 3 axis at stroke limit.

x: +: Positive direction
-: Negative direction

[Output cond.] If bit 1 (NAL) of parameter No. 1300 is set to 1, this signal is set to “1” when a move command in automatic operation or manual operation causes the tool to be about to enter the forbidden area (stored stroke limit 1) specified by parameter Nos. 1320 and 1321.
If bit 6 (OTS) of parameter No. 1301 is set to 1, this signal is set to “1” when one of the following overtravel alarms is issued:

- Alarms OT0500, OT0501 : Stored stroke check 1
- Alarms OT0502, OT0503 : Stored stroke check 2
- Alarms OT0504, OT0505 : Stored stroke check 3
- Alarms OT0506, OT0507 : Hard OT
- Alarms OT0510, OT0511 : Stored stroke check before movement

Once the signal is set to “1”, the axis and direction of the signal are stored. It is impossible to further move the tool along that axis in that direction. The tool can be moved along the axis only in the direction opposite to the stored direction. Moving the axis in the opposite direction resets the signal to “0”.

Signal address

Parameter

	#7	#6	#5	#4	#3	#2	#1	#0
1300	BFA					LMS	NAL	

[Input type] Setting input
[Data type] Bit path

#1 NAL When the tool enters the inhibition area of stored stroke limit 1:
0: The overtravel alarm signal is not output.
1: The overtravel alarm signal is output, and the tool is decelerated to a stop.
If manual operation is in progress at this time, the alarm is not output.

> **NOTE**
> Even if this parameter is set to 1, an alarm is displayed and the tool is decelerated to a stop when a move command issued during automatic operation causes the tool to get in a parameter-specified inhibition area. Also in this case, the overtravel alarm signal is output for the PMC.

#2 LMS The stored stroke check 1 select signal EXLM
0: Disabled
1: Enabled
When bit 0 (DLM) of parameter No. 1301 is set to 1, the stored stroke check 1 select signal EXLM <Gn007.6> is made invalid.

#7 BFA When the stored stroke check 1, 2, or 3 alarm is issued, an interference alarm is issued with the inter-path interference check function (T series), or a chuck/tail stock barrier (T series) alarm is issued:
0: The tool stops after entering the prohibited area.
1: The tool stops before the prohibited area.

> **NOTE**
> 1. This parameter is valid even in AI contour control.
> 2. This parameter is invalid for the slave axis under axis synchronous control.

	#7	#6	#5	#4	#3	#2	#1	#0
1301		OTS		OF1			LMA	DLM

[Input type] Setting input
[Data type] Bit path

#0 DLM The axis direction dependent stored stroke check 1 switch signals +EXLx and –EXLx are:
0: Disabled.
1: Enabled.
When this parameter is set to 1, the stored stroke check 1 select signal EXLM <Gn007.6> is made invalid.

#1 LMA When the stored stroke check 1 select signal EXLM <Gn007.6> is "1" with bit 2 (LMS) of parameter No. 1300 set to 1, the movable area for stored stroke check 1 is:
0: The inside area set for stored stroke check 1-II.
1: The inside area set for stored stroke check 1-I and the inside area set for stored stroke check 1-II as well.

#4 OF1 If the tool is moved into the range allowed on the axis after an alarm is raised by stored stroke check 1,
0: The alarm is not canceled before a reset is made.
1: The OT alarm is immediately canceled.

> **NOTE**
> In the cases below, the automatic release function is disabled. To release an alarm, a reset operation is required.
> 1 When a setting is made to issue an alarm before a stored stroke limit is exceeded (bit 7 (BFA) of parameter No. 1300 is set to 1)
> 2 When an another overtravel alarm (such as stored stroke check 2, stored stroke check 3, and interference check) is already issued
> 3 When an overtravel alarm is already issued with High precision oscillation function.

#6 OTS When the overtravel alarm is issued:
0: The overtravel alarm signal is not output to the PMC.
1: The overtravel alarm signal is output to the PMC.

1320	Coordinate value I of stored stroke check 1 in the positive direction on each axis
1321	Coordinate value I of stored stroke check 1 in the negative direction on each axis

[Input type] Parameter input
[Data type] Real axis
[Unit of data] mm, inch, deg (machine unit)
[Min. unit of data] Depend on the increment system of the applied axis
[Valid data range] 9 digit of minimum unit of data (refer to standard parameter setting table (A))
(When the increment system is IS-B, -999999.999 to +999999.999)
Set the coordinate value of stored stroke check 1 on each axis in the + or - direction in the machine coordinate system.

> **NOTE**
> 1 Specify diameter values for any axes for which diameter programming is specified.
> 2 The area outside the area set by parameters Nos. 1320 and 1321 is a prohibited area.

1326	Coordinate value II of stored stroke check 1 in the positive direction on each axis

1327	Coordinate value II of stored stroke check 1 in the negative direction on each axis

[Input type] Parameter input
[Data type] Real axis
[Unit of data] mm, inch, deg (machine unit)
[Min. unit of data] Depend on the increment system of the applied axis
[Valid data range] 9 digit of minimum unit of data (refer to standard parameter setting table (A))
(When the increment system is IS-B, -999999.999 to +999999.999)

Set the coordinate value of stored stroke check 1 on each axis in the + and - directions in the machine coordinate system.

When the stored stroke check switch signal EXLM is set to “1”, or the stored stroke check switch signals for each axis direction +EXLx and -EXLx are set to “1”, parameters Nos. 1326 and No. 1327 are used for stroke check instead of parameters Nos.1320 and No. 1321.

> **NOTE**
> 1 Specify diameter values for any axes for which diameter programming is specified.
> 2 The area outside the area set by parameter No. 1326 and No. 1327 is a prohibited area.
> 3 The EXLM signal is valid only when bit 2 (LMS) of parameter No. 1300 is set to 1.
> 4 When axis direction dependent stored stroke check 1 switch signals (+EXL1 to +EXL8, -EXL1 to -EXL8) is enabled (with bit 0 (DLM) of parameter No. 1301 set to 1), stroke parameter switching by the stored stroke check 1 select signal (EXLM3, EXLM2, EXLM) is disabled.

Alarm and message

Number	Message	Description
OT0500	+ OVERTRAVEL (SOFT 1)	A movement in the positive direction exceeded stored stroke check 1.
OT0501	- OVERTRAVEL (SOFT 1)	A movement in the negative direction exceeded stored stroke check 1.

Caution

> ⚠ **CAUTION**
> 1 If the two points for specifying a forbidden area are identical, all areas are handled as forbidden areas for stored stroke check 1.
> 2 The size of a forbidden area must be set correctly. If the size is set incorrectly, the stroke becomes infinite.

Note

NOTE

1. Bit 7 (BFA) of parameter No. 1300 can be used to specify whether to stop the tool before it enters the forbidden area or when it enters the area.
2. The stroke check is checked with finer accuracy than the displayed coordinate value. Therefore, even if the coordinates on the boundary are displayed, OT alarms may occur.

OPERATOR'S MANUAL (B-64694EN)	Stroke check

2.3.3 Stored Stroke Check 1 Area Expansion

Overview

In stored stroke check 1, up to eight different forbidden areas can be defined and selected.
Since the number of selectable forbidden areas increases, different forbidden areas can be used for different machine specifications.

Explanation

The boundary of the forbidden area in stored stroke check 1 is defined by specifying coordinate values I and II with parameters Nos. 1320, 1321, 1326, and 1327.

In this function, coordinate values III to VIII can be defined by parameters Nos. 1350 to 1361 in addition to coordinate values I and II above. The stored stroke check 1 select signal can be used to switch between these coordinate values of the forbidden area.

The relationship between the states of the signals and the stroke parameters (coordinate values) to be selected are shown below.

EXLM3	EXLM2	EXLM	Stroke parameter to be selected
0	0	0	Coordinate value I (No. 1320 / No. 1321)
0	0	1	Coordinate value II (No. 1326 / No.1327)
0	1	0	Coordinate value III (No. 1350 / No.1351)
0	1	1	Coordinate value IV (No. 1352 / No.1353)
1	0	0	Coordinate value V (No. 1354 / No.1355)
1	0	1	Coordinate value VI (No. 1356 / No.1357)
1	1	0	Coordinate value VII (No. 1358 / No.1359)
1	1	1	Coordinate value VIII (No. 1360 / No.1361)

Except for switching of forbidden areas by the signal selection above, the specification of stored stroke check 1 is used basically.
When the axis direction dependent stored stroke check 1 switch signals are enabled (when bit 0 (DLM) of parameter No.1301 is set to 1), this function is disabled.

Signal

Stored stroke check 1 select signals

EXLM<Gn007.6>, EXLM2<Gn531.6>, EXLM3<Gn531.7>

[Classification] Input signal
[Function] Switches between stroke parameters in stored stroke check 1 area expansion.
[Operation] The relationship between the states of stored stroke check 1 select signals EXLM3, EXLM2, and EXLM and the stroke parameters to be selected are shown below.

EXLM3	EXLM2	EXLM	Stroke parameter to be selected
0	0	0	Coordinate value I (No. 1320 / No. 1321)
0	0	1	Coordinate value II (No. 1326 / No.1327)
0	1	0	Coordinate value III (No. 1350 / No.1351)
0	1	1	Coordinate value IV (No. 1352 / No.1353)
1	0	0	Coordinate value V (No. 1354 / No.1355)
1	0	1	Coordinate value VI (No. 1356 / No.1357)
1	1	0	Coordinate value VII (No. 1358 / No.1359)
1	1	1	Coordinate value VIII (No. 1360 / No.1361)

1300						LMS		

[Input type] Setting input
[Data type] Bit path

#2 LMS The stored stroke check 1 select signal (EXLM3, EXLM2, or EXLM when stored stroke check 1 area expansion is used) is
0: Disabled
1: Enabled

> **NOTE**
> When bit 0 (DLM) of parameter No. 1301 is set to 1, the stored stroke check 1 select signal EXLM (EXLM3, EXLM2, or EXLM when stored stroke check 1 area expansion is used) is made invalid.

1320	Coordinate value I of stored stroke check 1 in the positive direction on each axis
1321	Coordinate value I of stored stroke check 1 in the negative direction on each axis
1326	Coordinate value II of stored stroke check 1 in the positive direction on each axis
1327	Coordinate value II of stored stroke check 1 in the negative direction on each axis
1350	Coordinate value III of stored stroke check 1 in the positive direction on each axis
1351	Coordinate value III of stored stroke check 1 in the negative direction on each axis
1352	Coordinate value IV of stored stroke check 1 in the positive direction on each axis
1353	Coordinate value IV of stored stroke check 1 in the negative direction on each axis
1354	Coordinate value V of stored stroke check 1 in the positive direction on each axis
1355	Coordinate value V of stored stroke check 1 in the negative direction on each axis
1356	Coordinate value VI of stored stroke check 1 in the positive direction on each axis
1357	Coordinate value VI of stored stroke check 1 in the negative direction on each axis
1358	Coordinate value VII of stored stroke check 1 in the positive direction on each axis

1359	Coordinate value VII of stored stroke check 1 in the negative direction on each axis
1360	Coordinate value VIII of stored stroke check 1 in the positive direction on each axis
1361	Coordinate value VIII of stored stroke check 1 in the negative direction on each axis

[Input type] Parameter input
[Data type] Real axis
[Unit of data] mm, inch, deg (machine unit)
[Min. unit of data] Depend on the increment system of the applied axis
[Valid data range] 9 digit of minimum unit of data (refer to standard parameter setting table (A))
(When the increment system is IS-B, -999999.999 to +999999.999)

Set the coordinate value of stored stroke check 1 on each axis in the + or - direction in the machine coordinate system.

The stored stroke check 1 select signal (EXLM3, EXLM2, EXLM) and the stroke parameter to be selected have the following relationships:

EXLM3	EXLM2	EXLM	Stroke parameter to be selected
0	0	0	Coordinate value I (No. 1320 / No. 1321)
0	0	1	Coordinate value II (No. 1326 / No. 1327)
0	1	0	Coordinate value III (No. 1350 / No. 1351)
0	1	1	Coordinate value IV (No. 1352 / No. 1353)
1	0	0	Coordinate value V (No. 1354 / No. 1355)
1	0	1	Coordinate value VI (No. 1356 / No. 1357)
1	1	0	Coordinate value VII (No. 1358 / No. 1359)
1	1	1	Coordinate value VIII (No. 1360 / No. 1361)

NOTE

1. Specify diameter values for any axes for which diameter programming is specified.
2. The outside of the area set with each parameter is treated as the inhibition area.
3. The stored stroke check 1 select signal (EXLM3, EXLM2, EXLM) is valid only when bit 2 (LMS) of parameter No. 1300 is 1.
4. When axis direction dependent stored stroke check 1 is enabled (with bit 0 (DLM) of parameter No. 1301 set to 1), stroke parameter switching by the stored stroke check 1 select signal (EXLM3, EXLM2, EXLM) is disabled.

Alarm and message

Number	Message	Description
OT0500	+ OVERTRAVEL (SOFT 1)	Exceeded the stored stroke check 1 when moving in the + direction.
OT0501	- OVERTRAVEL (SOFT 1)	Exceeded the stored stroke check 1 when moving in the - direction.

Note

NOTE

The basic notes are the same as those of stored stroke check 1.

2.3.4 Stored Stroke Check 2, 3

Overview

For stored stroke check 2, the outside or inside of the area specified by parameters or a program is defined as the forbidden area. As a limit position, specify a distance from the origin of the machine coordinate system. This function is enabled the after reference point establishes at power-on. When the limits are specified in a program, they can be set for the X-, Y-, and Z-axes. For this reason, the forbidden area can be changed according to the workpiece. Whether to define the inside or outside of the specified area as the forbidden area is determined by setting the corresponding parameter.

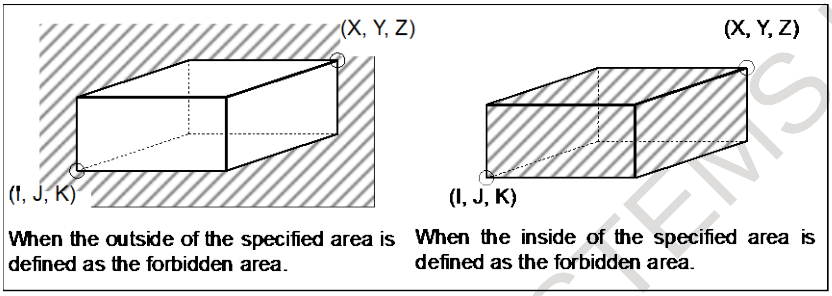

Fig. 2.3.4 (a) Stored stroke check 2

For stored stroke check 3, the inside of the area set by parameters is defined as the forbidden area.

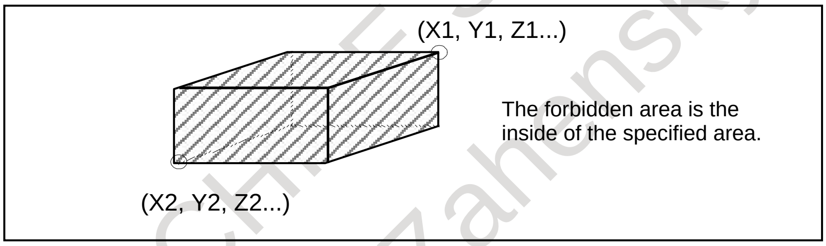

Fig. 2.3.4 (b) Stored stroke check 3

Explanation

Three areas which the tool cannot enter can be specified with stored stroke check 1, stored stroke check 2, and stored stroke check 3.

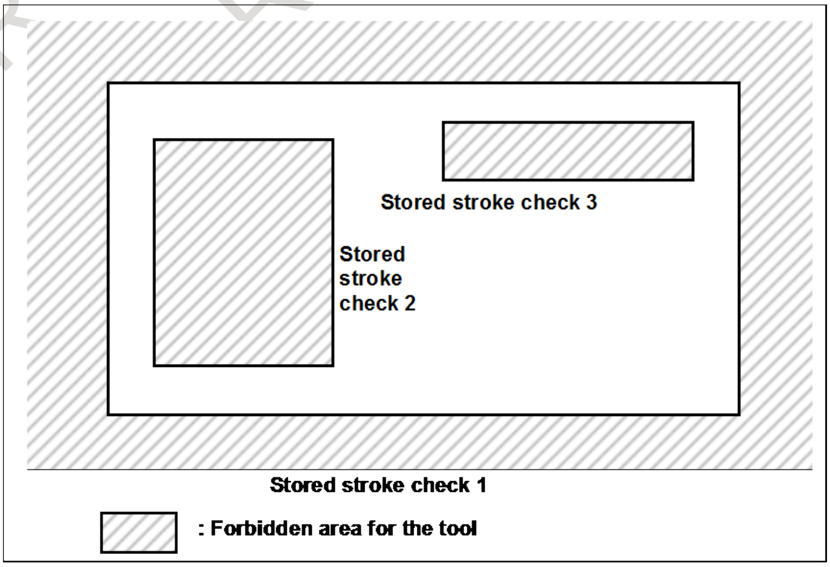

Fig. 2.3.4 (c) Stroke check

The following shows the areas which the tool cannot enter for each stored stroke check.

- Stroke check 1: Outside
- Stroke check 2: Outside or inside (switchable)
- Stroke check 3: Inside

When the tool moves into the forbidden area, an alarm is displayed and the tool is decelerated and stopped.
When the tool enters a forbidden area and an alarm is generated, the tool can be moved in the reverse direction from which the tool came.

- Stored stroke check 2

Parameters Nos. 1322 and 1323 or commands set these boundaries. Inside or outside the area of the limit can be set as the forbidden area. Bit 0 (OUT) of parameter No. 1300 selects either inside or outside as the forbidden area.
In case of program command a G22 command forbids the tool to enter the forbidden area, and a G23 command permits the tool to enter the forbidden area.
Each of G22; and G23; should be commanded independently of another commands in a block.
The command below creates or changes the forbidden area:

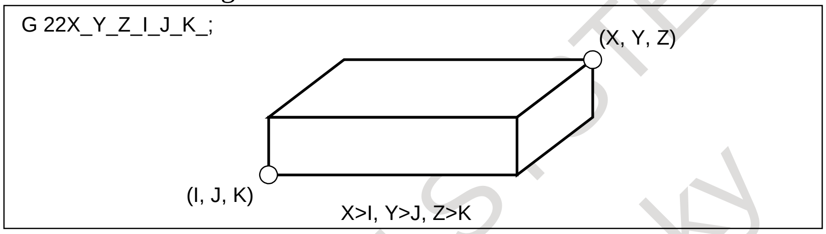

Fig. 2.3.4 (d) Creating or changing the forbidden area using a program

When setting the area by parameters, points A (Parameter No.1322) and B (Parameter No.1323) in the figure below must be set.

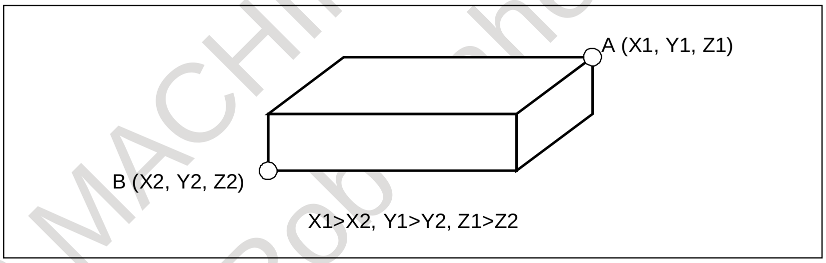

Fig. 2.3.4 (e) Creating or changing the forbidden area using a parameters

The values X1, Y1, Z1, X2, Y2, and Z2, which are set by parameters Nos. 1322 and 1323, must be specified by the distance from the machine coordinate system (machine increment). The values X, Y, Z, I, J, and K, which are set by a G22 command, must be specified by the distance in the least input increment (input increment).
When data is set by the program command, the command valued is converted in the machine increment and it set to the corresponding parameter (No.1322 and No.1323).

- Format

Stored stroke check 2 on

G22 X__ Y__ Z__ I__ J__ K__ ;

X, Y, Z:Coordinate of stored stroke check 2 in the positive direction on each axis
I, J, K: Coordinate of stored stroke check 2 in the negative direction on each axis

Use addresses X, Y, and Z or addresses I, J, and K. Addresses X and I specify the forbidden area related to the X-axis of the basic three axes. Addresses Y and J specify the forbidden area related to the Y-axis of the basic three axes. Addresses Z and K specify the forbidden area related to the Z-axis of the basic three axes. When addresses are omitted, a stroke check is made based on the values set by parameters.

Stored stroke check 2 off

G23 ;

- Stored stroke check 3

Set the boundary with parameters Nos. 1324 and 1325. The area inside the boundary becomes the forbidden area. The values X1, Y1, Z1, X2, Y2, and Z2 must be set as coordinates (machine increment) in the machine coordinate system.

- Checkpoint for the forbidden area

The parameter setting or programmed value (X, Y, Z, I, J, K) depends on which part of the tool or tool holder is checked for entering the forbidden area.
If point A is checked in Fig. 2.3.4 (f) and Fig. 2.3.4 (g), the machine coordinates value that corresponds to distance "a" should be set as the data for the stored stroke limit function. If point B is checked, the machine coordinates value that corresponds to distance "b" must be set. When checking the tool tip (like point A), and if the tool length varies for each tool, setting the forbidden area for the longest tool requires no re-setting and results in safe operation.

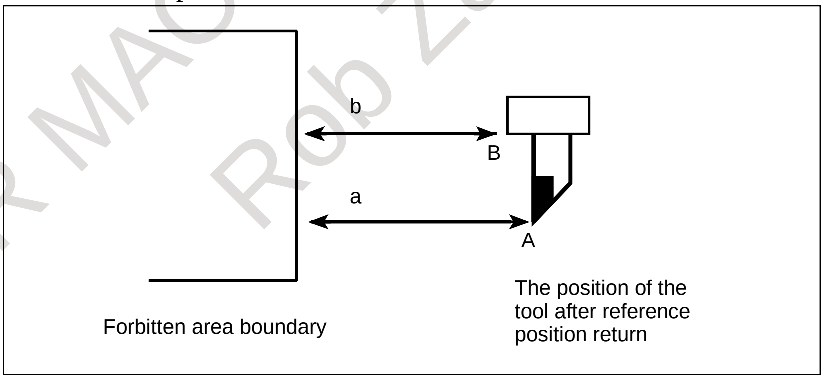

Fig. 2.3.4 (f) Setting the forbidden area (turning tool)

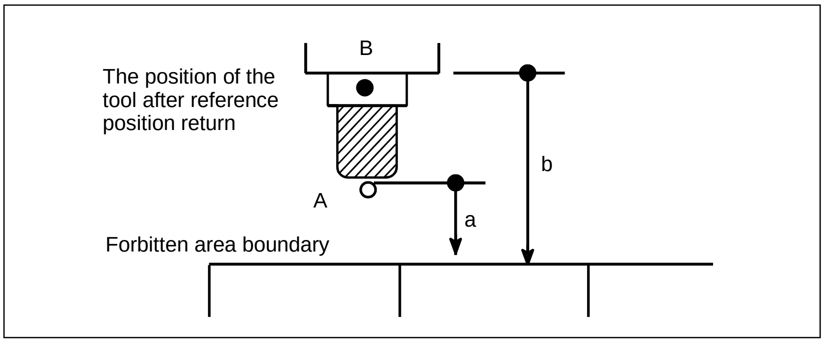

Fig. 2.3.4 (g) Setting the forbidden area (rotating tool)

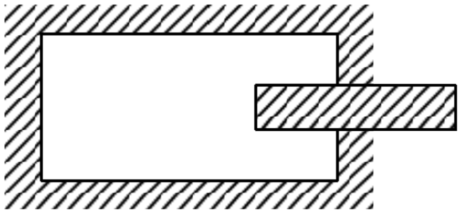
- Forbidden area overlapping

Area can be set in piles.



Setting the forbidden area overlapping

Fig. 2.3.4 (h) Setting the forbidden area overlapping

Unnecessary limits should be set beyond the machine stroke.

- Condition under which each check is enabled

Each check becomes effective after the power is turned on and after reference point establishes.
After the power is turned on, if the reference position is in the forbidden area of each limit, an alarm is generated immediately. (Only in G22 mode for stored stroke check 2).

- Releasing the alarms

If the enters a forbidden area and an alarm is generated, the tool can be moved only in the backward direction. To cancel the alarm, move the tool backward until it is outside the forbidden area and reset the system. When the alarm is canceled, the tool can be moved both backward and forward.

- Change from G23 to G22 in a forbidden area

When G23 is switched to G22 in the forbidden area, the following results.
<1> When the forbidden area is inside, an alarm is informed in the next move.
<2> When the forbidden area is outside, an alarm is informed immediately.

- Timing for displaying an alarm

In stored stroke check 1,2,3, bit 7 (BFA) of parameter No. 1300 selects whether an alarm is displayed immediately before the tool enters the forbidden area or immediately after the tool has entered the forbidden area.

Signal

Stroke check 3 release signal RLSOT3<Gn007.4>

[Classification] Input signal
[Function] Selects whether stored stroke check 3 is checked.
[Operation] When this signal is set to “1”, does not check stored stroke check 3.

1: Command value

Alarm and message

Number	Message	Description
OT0502	+ OVERTRAVEL (SOFT 2)	A movement in the positive direction exceeded stored stroke check 2. Alternatively, in the chuck and tail stock barrier, an entry to the forbidden area was made during movement in the positive direction.
OT0503	- OVERTRAVEL (SOFT 2)	A movement in the negative direction exceeded stored stroke check 2. Alternatively, in the chuck and tail stock barrier, an entry to the forbidden area was made during movement in the negative direction.
OT0504	+ OVERTRAVEL (SOFT 3)	A movement in the positive direction exceeded stored stroke check 3.
OT0505	- OVERTRAVEL (SOFT 3)	A movement in the negative direction exceeded stored stroke check 3.

Caution

⚠ **CAUTION**

1 If the two points for specifying a forbidden area are identical, all areas are handled as movable areas in case of stored stroke check 2 that the inside area is forbidden (bit 0 (OUT) of parameter No. 1300 = 0), or stored stroke check 3. And all areas except the specified point are handled as forbidden areas in case of stored stroke check 2 that the outside area is forbidden (the parameter OUT = 1).

2 Even if the two points for specifying a forbidden area are erroneously set, the rectangular parallelepiped having the points as vertices is assumed as a boundary.

3 Since an axis without the reference position return function has no forbidden areas, there are no alarms about forbidden areas for the axis.

Note

NOTE

1 For checks 1,2 and 3, bit 7 (BFA) of parameter No. 1300 can be used to specify whether to stop the tool before it enters the forbidden area or when it enters the area.

2 Because checking is made with higher precision than the precision of indicated coordinates, an OT alarm may be issued even when coordinates on a boundary is indicated.

Reference item

Manual name	Item name
OPERATOR'S MANUAL (B-64694EN)	Stroke check

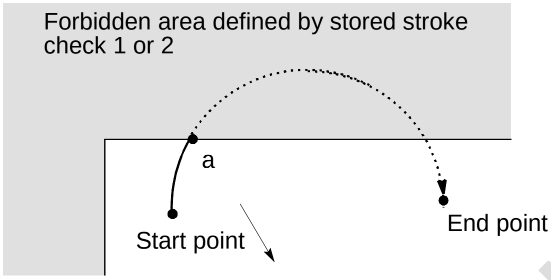
2.3.5 Stroke Limit Check before Move

During automatic operation, before the movement specified by a given block is started, whether the tool enters the forbidden area defined by stored stroke check 1, 2, or 3 is checked by determining the position of the end point from the current position of the machine and a specified amount of travel. If the tool is found to enter the forbidden area defined by a stored stroke limit, the tool is stopped immediately upon the start of movement for that block, and an alarm is displayed.

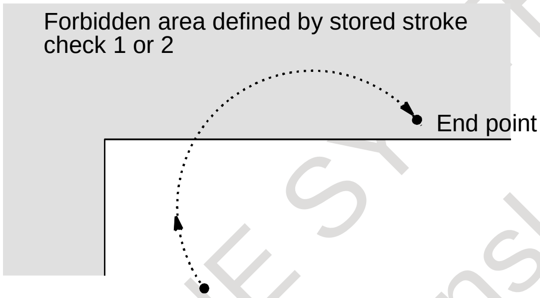
⚠ CAUTION

Whether the coordinates of the end point, reached as a result of traversing the distance specified in each block, are in a forbidden area is checked. In this case, the path followed by a move command is not checked. However, if the tool enters the forbidden area defined by stored stroke check 1, 2, or 3, an alarm is issued.

Example 1)

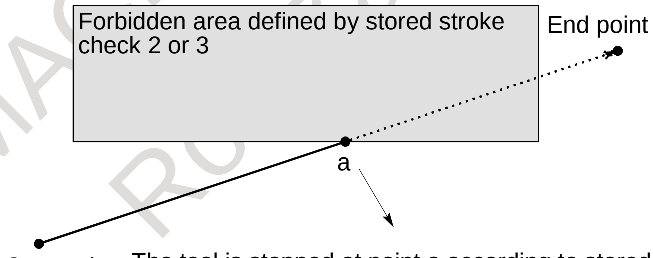


The tool is stopped at point a according to stored stroke check 1 or 2.

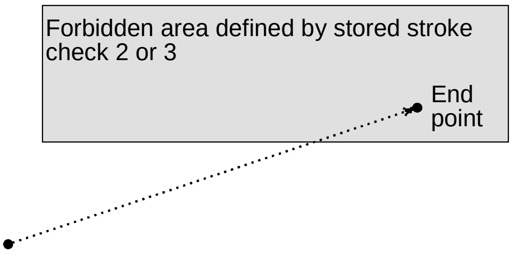


Immediately upon movement commencing from the start point, the tool is stopped to enable a stroke limit check before moving to be performed before movement.

Example 2)



The tool is stopped at point a according to stored stroke check 2 or 3.



Immediately upon movement commencing from the start point, the tool is stopped to enable a stroke limit check before moving to be performed before movement.

Explanation

This function is enabled by setting bit 7 (PLC) of parameter No. 1301 to 1.
When a stroke limit check before moving is performed, whether to check the movement performed by a G31 (skip) block and G37 (automatic tool length measurement) block can be determined using (bit 2 (NPC) of parameter No. 1301).

Limitation

- Machine lock

If machine lock is applied at the start of movement, no stroke limit check made before movement is performed.

- G23

When stored stroke check 2 is disabled (G23 mode), no check is made to determine whether the tool enters the forbidden area defined by stored stroke check 2.

- Program restart

When a program is restarted, an alarm is issued if the restart position is within a forbidden area.

- A block consisting of multiple operations

If a block consisting of multiple operations (such as a canned cycle) is executed, an alarm is issued at the start point of any operation whose end point falls within an inhibited area.

- Cylindrical interpolation mode

In cylindrical interpolation mode, no check is made.

T

- Polar coordinate interpolation mode

In polar coordinate interpolation mode, no check is made.

- 3-dimensional coordinate system conversion

In 3-dimensional coordinate system conversion mode, no check is made.

- PMC axis control

No check is made for a movement based on PMC axis control.

Parameter

	#7	#6	#5	#4	#3	#2	#1	#0
1301	PLC					NPC		

[Input type] Setting input
[Data type] Bit path

#2 NPC As part of the stroke limit check performed before movement, the movement specified in G31 (skip) and G37 (automatic tool length measurement) blocks is:
0: Checked
1: Not checked

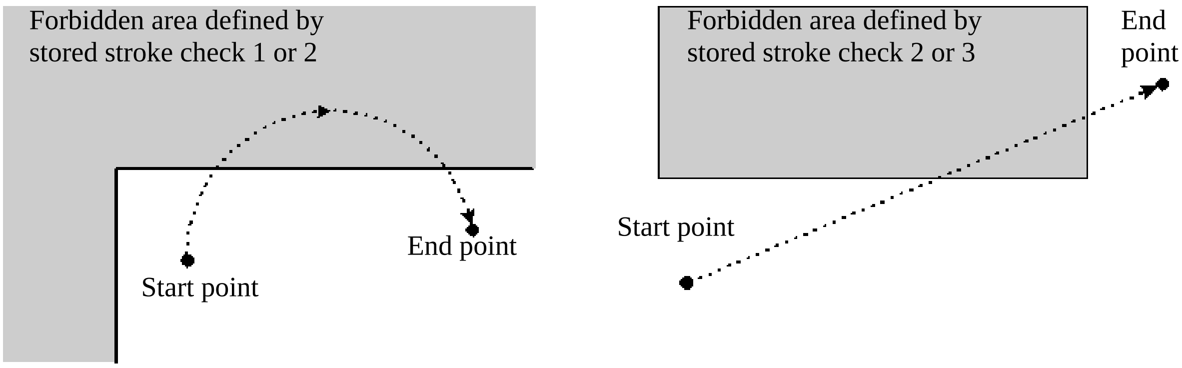
#7 PLC Stroke check before movement is:
0: Not performed
1: Performed

Alarm

Number	Message	Description
OT0510	+ OVERTRAVEL (PRE-CHECK)	The block end point was found in the + side stroke limit prohibition area during a stroke check before movement. Modify the program.
OT0511	- OVERTRAVEL (PRE-CHECK)	The block end point was found in the - side stroke limit prohibition area during a stroke check before movement. Modify the program.

2.3.6 Check of the Tool Path between Blocks by Stroke Limit Check before Move

By setting bit 0 (SBA) of parameter No.1302 to 1, whether the tool enters the forbidden area defined by Stored stroke limit 1, 2, or 3 is checked on the tool path of movement command in addition to checking the end point. (Hereinafter, this check is called “check of the tool path between blocks”.)
Check of the tool path between blocks is effective in Positioning (G00), Liner interpolation (G01), Circular interpolation (G02, G03), High-speed reference position return (G28, G30), or Selecting a machine coordinate system (G53).
If the tool enters the forbidden area defined by stored stroke check 1, 2, or 3, an alarm is issued when check of the tool path between blocks is not effective.



When forbidden area is outside. **When forbidden area is inside.**

Immediately upon movement commencing from the start point, the tool is stopped to enable a stroke limit check before moving to be performed before movement.

: Forbidden area

Fig. 2.3.6 (a) Check of the tool path between blocks

Explanation

Plane selection axes

When one axis or both axes among the selection axes of selected plane (G17, G18 or G19 plane) not exist (Hereinafter, this selection axes are called “plane selection axes”.), check of the tool path between blocks is not executed.

Target axis of check of the tool path between blocks

Check of the tool path between blocks is executed on the 3-dimension which is composed by the two axes of plane selection axes and the one axis other than plane selection axes (Hereinafter, this axis is called “plane non-selection axis”).

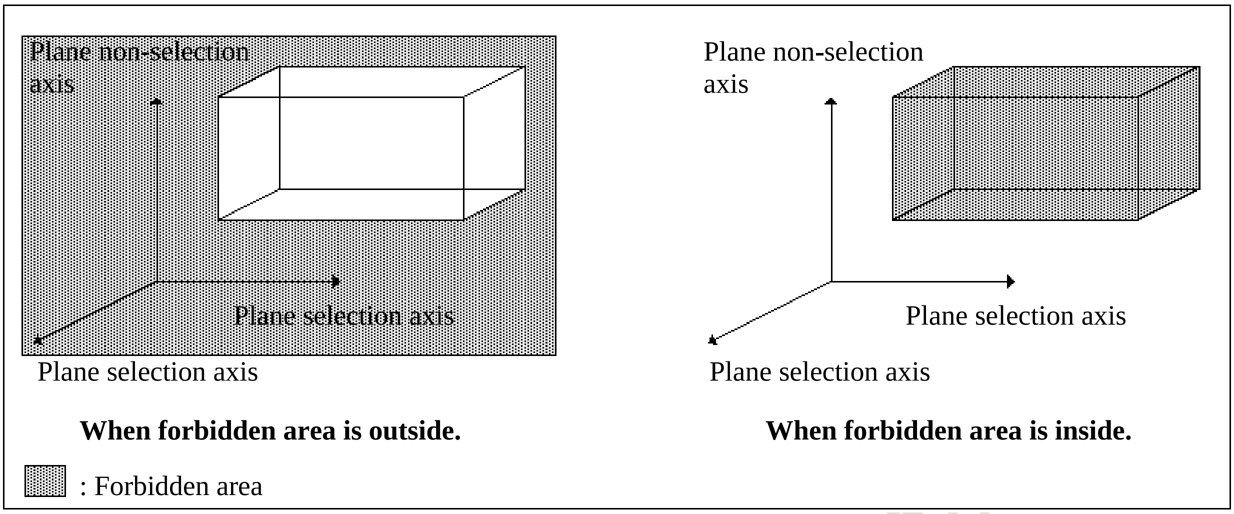


Fig. 2.3.6 (b) Target axis of check of the tool path between blocks

Normally, the basic axis other than plane selection axes in basic coordinate system is set to plane non-selection axis.

Example 1)
When X-Y plane (G17) is selected with the following axis configuration, plane selection axes are X axis and Y axis, and plane non-selection axis is Z axis. (Fig. 2.3.6 (c))
No.1022
(X)=1: X axis of the basic three axes
(Y)=2: Y axis of the basic three axes
(Z)=3: Z axis of the basic three axes
(W)=7: Axis parallel to Z axis
(A)=0: Rotary axis

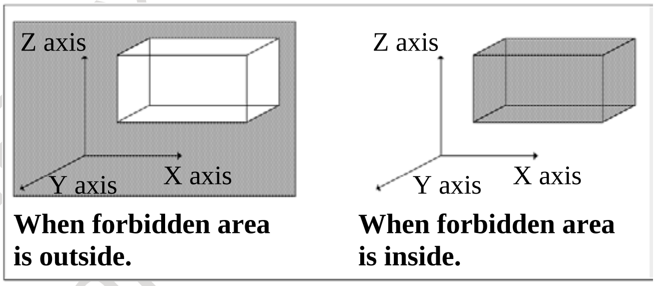

Fig. 2.3.6 (c) Target axis in Example 1

However, there are the following exceptions.

(1) The basic axis other than plane selection axes in basic coordinate system does not exist.

(1) - 1 When parallel axis does not exist.
In this case, check of the tool path between blocks is executed on the plane composed by plane selection axes.

Example 2)
When X-Y plane (G17) is selected with the following axis configuration, plane selection axes are X axis and Y axis, and plane non-selection axis does not exist. (Fig. 2.3.6 (d))
No.1022
(X)=1: X axis of the basic three axes
(Y)=2: Y axis of the basic three axes
(A)=0: Rotary axis

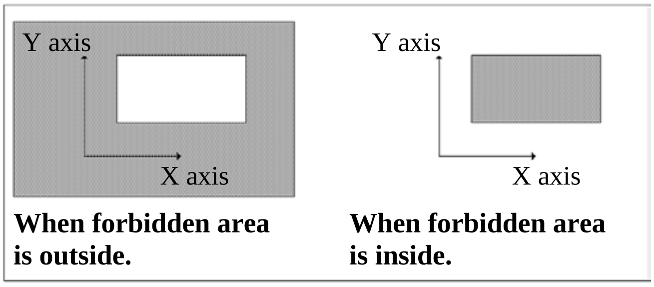

Fig. 2.3.6 (d) Target axis in Example 2

(1) - 2 When the parallel axis exists.

In this case, the parallel axis of lowest number of intra-path relative axis number which is parallel to the basic axis other than plane selection axes is set to plane non-selection axis.

Example 3)

When X-Y plane (G17) is selected with the following axis configuration, plane selection axes are X axis and Y axis, and plane non-selection axis is W axis. (Fig. 2.3.6 (e))

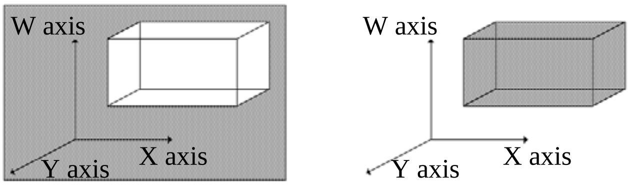
No.1022

(X)=1: X axis of the basic three axes

(Y)=2: Y axis of the basic three axes

(W)=7: Axis parallel to Z axis

(A)=0: Rotary axis



When forbidden area is outside. **When forbidden area is inside.**

Fig. 2.3.6 (e) Target axis in Example 3

(2) In the state of selecting the plane which includes the plane non-selection axis direction, the axis movement had been specified.

In this case, the axis which was specified by the plane selection is set to plane non-selection axis. However, when the axis movement by "List of modes that cannot execute check of the tool path between blocks" or "List of commands that cannot execute check of the tool path between blocks" is specified, the axis which was specified by the plane selection is not set to plane non-selection axis. And, the basic axis other than plane selection axes in the basic coordination system is set to plane non-selection axis when G code group of plane selection G code clear by reset etc. (Example 4)

Example 4)

When U-Y plane (G17) is selected after specifying the axis movement in W-X plane (G18) with the following axis configuration (Program example 1), plane selection axes are U axis and Y axis, and plane non-selection axis is W axis. (Fig. 2.3.6 (f))

No.1022

(X)=1: X axis of the basic three axes

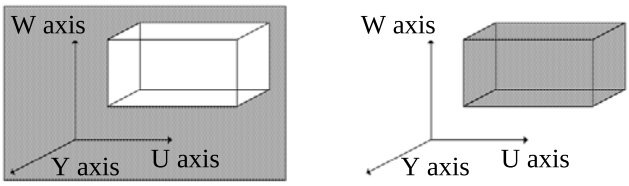
(Y)=2: Y axis of the basic three axes

(Z)=3: Z axis of the basic three axes

(U)=5: Axis parallel to X axis

(W)=7: Axis parallel to Z axis

(A)=0: Rotary axis



When forbidden area is outside. **When forbidden area is inside.**

Fig. 2.3.6 (f) Target axis in Example 4 (U-Y-W)

However, plane non-selection axis is Z axis in the following case. (Fig. 2.3.6 (g))

1. After selecting W-X plane (G18), U-Y plane (G17) is selected without specifying the axis movement (Program example 2).
2. After selecting W-X plane (G18), U-Y plane (G17) is selected after specifying only the axis movement by "List of modes that cannot execute check of the tool path between blocks" or "List of commands that cannot execute check of the tool path between blocks" (Program example 3).

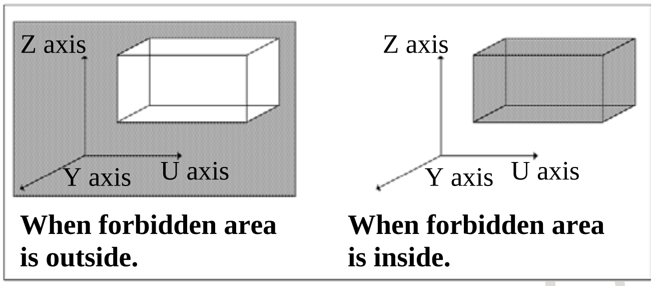


Fig. 2.3.6 (g) Target axis in Example 4 (U-Y-Z)

When G code group of plane selection G code clears by reset etc..

Afterwards, when G code group of plane selection G code clears by reset etc., plane selection axes are X axis and Y axis, and plane non-selection axis is Z axis. (Fig. 2.3.6 (h))

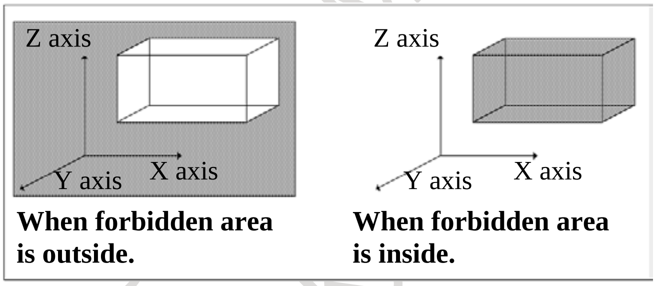

Fig. 2.3.6 (h) Target axis in Example 4 (Clear state)

G18W0X0
G31W100.0F100.0
G31X100.0F100.0 } When axis movement of W axis is specified by G31 command in case of setting bit 2 (NPC) of parameter No.1301 to 1 or etc. ,
G17U0Y0
:
: } plane selection axes are U axis and Y axis, and plane non-selection axis is Z axis.

NOTE

1. Check of the tool path between blocks is executed for forbidden area defined by stored stroke limit of plane selection axes and plane non-selection axis. Therefore, even if the axis other than plane selection axes and plane non-selection axis exceed the forbidden area defined by stored stroke limit in the tool path between blocks, the alarm is not generated by check of the tool path between blocks. (However, because stored stroke check of normal is effective, the alarm is generated when approaching the forbidden area defined by stored stroke limit during moving the axis.)
2. When the forbidden area is defined by inside of stored stroke limit, the alarm is generated if all axes to which stored stroke check is effective enter the forbidden area. However, in check of the tool path between blocks, the alarm is generated if plane selection axes and plane non-selection axis enters the forbidden area.

Limitation

Limitation of Stroke limit check before move

Limitation of Stroke limit check before move is effective for check of the tool path between blocks.

Non-linear type positioning

Check of the tool path between blocks is executed for the straight-line that connect the start position and end position of the block even if Positioning (G00), High-speed reference position return (G28, G30), or Selecting a machine coordinate system (G53) is move by non-linear type. Therefore, check of the tool path between blocks might not be able to be executed correctly, depending on the command.

Circular interpolation that is imperfect circle

When Circular interpolation that is imperfect circle is specified, check of the tool path between blocks is executed for the base circle. Therefore, check of the tool path between blocks might not be able to be executed correctly, depending on the shape of Circular interpolation.

Machine lock

For the axis which is Machine lock state when starting the block, check of the tool path between blocks is not executed.

Stored stroke check 2 off (G23)

When Stored stroke check 2 is invalid (G23 mode), check of the tool path between blocks for the forbidden area defined by Stored stroke limit 2 is not executed.

Arbitrary angular axis control

Stored stroke limit can be checked in Cartesian coordinate system by setting bit 0 (AOT), bit 1 (AO2) or bit 2 (AO3) of parameter No.8201 in Arbitrary angular axis control. By setting of checking stored stroke limit in Cartesian coordinate system, check of the tool path between blocks is effective. Check of the tool path between blocks by this stored stroke limit is not executed if angular axis or perpendicular axis to which stored stroke limit is checked by slanted coordinate system is set to plane selection axes or plane non-selection axis.

List of modes that cannot execute check of the tool path between blocks

Check of the tool path between blocks is not executed during the mode of following functions.

T

- Polar coordinate interpolation

- Cylindrical interpolation
- 3-dimensional coordinate conversion
- Skip function (However, the case of setting bit 2 (NPC) of parameter No.1301 to 0 is excluded.)
- Automatic tool length measurement (M series) / automatic tool offset (T series) (However, the case of setting bit 2 (NPC) of parameter No.1301 to 0 is excluded.)

List of commands that cannot execute check of the tool path between blocks

Check of the tool path between blocks is not executed by the following commands.

- Movement command by Real time macro commands
- Movement command by PMC axis control
- Movement command for slave axis of Tandem control

Parameter

	#7	#6	#5	#4	#3	#2	#1	#0
1302								SBA

[Input type] Parameter input
[Data type] Bit path

#0 SBA In Stroke limit check before move, check of the tool path between blocks for movement command is, :

0: Not executed.
1: Executed.

> **NOTE**
> 1 Check of the tool path between blocks is invalid for the functions to which Stroke limit check before move is invalid.
> 2 Limitation of Stroke limit check before move is valid for check of the tool path between blocks.

Alarm and message

Number	Message	Description
OT0510	+ OVERTRAVEL (PRE-CHECK)	The block end point or the tool path between blocks was found in the + side stroke limit forbidden area during Stroke limit check before move. Modify the program.
OT0511	- OVERTRAVEL (PRE-CHECK)	The block end point or the tool path between blocks was found in the - side stroke limit forbidden area during Stroke limit check before move. Modify the program.

2.3.7 Checking the Stored Stroke during the Time from Power–on to the Reference Position Establishment

This function stores the machine coordinates present immediately before the power is turned off. Therefore, immediately after the power is turned on again, this function can restore the approximate machine coordinates and enables the function for checking the stored stroke during the time from power–on to the reference position establishment. (If bit 0 (DOTx) of parameter No. 1311 is set to 1)

Even before the reference position is established by manual reference position return, the stored stroke check can be performed using approximate machine coordinates.

Absolute coordinates are set based on the machine coordinates.
Data such as workpiece offsets specified by G92, G52, and so on before the power is turned off, however, is not set.
If bit 3 (PPD) of parameter No. 3104 is set to 1, the relative position indication is preset.

The stored stroke check is enabled immediately after the power is turned on.
This stored stroke check is performed in the same way as the normal stored stroke check.

The reference position is not established until a reference position return takes place.
(Until then, reference position establishment signals ZRF1 to ZRF8<Fn120> are “0”.
Precision compensation functions such as pitch error compensation are not performed.)

- Axis synchronous control

In case of the synchronization establishment of the axis synchronous control, when the position is set by this function, the synchronization establishment is executed.

NOTE

1. This function stores machine coordinates periodically while the CNC is operating. This means that no machine coordinates are stored when the tool moves while the power is off.
   If the power to the CNC is turned off while the tool is moving along an axis, correct machine coordinates cannot be stored.
   To reflect movements made while the power is off, use temporary absolute coordinate setting.
2. Because this function stores machine coordinates by using software, load is imposed on the system.
   For axes for which this function is not required, this function should not be set.
3. When an absolute position detector (absolute Pulsecoder) is used for an axis, this function cannot be used for that axis.
4. If the tool is already beyond a stored stroke immediately after the power is turned on, an overtravel alarm (OT alarm) is issued.
   In this case, release the alarm by moving the tool along the axis in the direction that does not cause overtravel.
   If bit 6 (LZR) of parameter No. 1300 is set to 1, the function for checking the stored stroke during the time from power–on to the reference position establishment is disabled.
5. When the power is turned on while the  key and the <P> address key are held down, the stored stroke check immediately after power-on is disabled.
   (When the MDI keys are provided as standard keys)
   (When performing this operation, exercise special care.)
   In this case, machine coordinates and absolute coordinates are set.
   When the compact type MDI keys are used, the stored stroke immediately after power-on is disabled by holding down the  key and <O> address key at power-on.

Parameter

	#7	#6	#5	#4	#3	#2	#1	#0
1300		LZR						

[Input type] Setting input
[Data type] Bit path

#6 LZR When the stored stroke check immediately after power-on is enabled (bit 0 (DOTx) of parameter No. 1311 is set to 1), the stored stroke check is:
0: Performed even before a manual reference position return is made.
1: Not performed until a manual reference position return is made.

	#7	#6	#5	#4	#3	#2	#1	#0
1311								DOTx

[Input type] Parameter input
[Data type] Bit axis

> **NOTE**
> When this parameter is set, the power must be turned off before operation is continued.

#0 DOTx Stored stroke limit check immediately after power-on is:
0: Disabled.
1: Enabled.

If the stored stroke check is enabled, the machine coordinate value present immediately before the power is turned off is stored.
The machine coordinate value is set immediately after the power is turned on.
Based on the machine coordinate value, absolute coordinate and relative coordinate values are set.

> **NOTE**
> Because this function uses software to store machine coordinates, the function puts an extra load on the system. So, this function should not be set for axes that do not require this function. The amount of a movement made while the power is off is not reflected in machine coordinates immediately after the power is turned on.

2.3.8 Stroke Limit External Setting

Overview

When a tool is changed, the tool tip is aligned with the end of the limit area and signals are input. This operation sets the machine position (machine coordinates) at that time as the limit position in the parameters for coordinate values I of stored stroke check 1 (Nos.1320 and 1321). A setting signal is provided for each direction of each axis.

Signal

Stroke limit external setting signal +LM1 to +LM8<Gn110>, -LM1 to -LM8<Gn112>

[Classification] Input signal
[Function] Changes the values of the parameters for coordinate values I of stored stroke check 1 (Nos. 1320 and 1321).

[Operation] When these signals are set to "1", the control unit changes the values of the parameters Nos. 1320 and 1321 by using the machine coordinates when the signals are input as the stroke check values.

> **NOTE**
> Stroke limit external setting signal +LM1 to +LM8<Gn110>, -LM1 to -LM8<Gn112> should be set to "1" when the relevant axis is stopped. If these signals are set to "1" during axes movement, stroke limit may not be precisely.

Signal address

	#7	#6	#5	#4	#3	#2	#1	#0
Gn110	+LM8	+LM7	+LM6	+LM5	+LM4	+LM3	+LM2	+LM1
Gn112	-LM8	-LM7	-LM6	-LM5	-LM4	-LM3	-LM2	-LM1

Note

> **NOTE**
> 1 This function can not change the values of the parameters for coordinate values II to VIII of stored stroke check 1 (Nos.1326, 1327 and 1350 to 1361).

2.3.9 Stroke Limit Area Changing Function

Overview

This function can be used to rewrite the parameters that set the + side coordinate value and the - side coordinate values of the stroke limits even when the axis is traveling. The parameters can be rewritten by the PMC window function (WINDW: SUB52), FOCAS2, and a C Language Executor. The new stroke limit range is enabled immediately after the parameters are rewritten by any of these functions. The rewritable parameters are shown below.

- Parameter No. 1320:Coordinate value I of stored stroke check 1 in the positive direction on each axis
- Parameter No. 1321:Coordinate value I of stored stroke check 1 in the negative direction on each axis
- Parameter No. 1322:Coordinate value of stored stroke check 2 in the positive direction on each axis
- Parameter No. 1323:Coordinate value of stored stroke check 2 in the negative direction on each axis
- Parameter No. 1324:Coordinate value of stored stroke check 3 in the positive direction on each axis
- Parameter No. 1325:Coordinate value of stored stroke check 3 in the negative direction on each axis
- Parameter No. 1326:Coordinate value II of stored stroke check 1 in the positive direction on each axis
- Parameter No. 1327:Coordinate value II of stored stroke check 1 in the negative direction on each axis

The machining cycle time can be reduced because this function can rewrite parameters even if some axes are moving.

This function is enabled by setting bit 0 (SLM) of parameter No.1312 to 1.

Limitation

- Axis synchronous control

This function is disabled when the automatic slave axis parameter setting is enabled (bit 4 (SYP) of parameter No. 8303 = 1) in feed axis synchronous control. (Writing to the parameters is allowed only when all axes are stopped.)

Parameter

	#7	#6	#5	#4	#3	#2	#1	#0
1312								SLM

[Input type] Parameter input
[Data type] Bit

#0 SLM The stroke limit area changing function is:
0: Disabled.
1: Enabled.

Note

NOTE
If the parameters are rewritten so that the current position is included in a forbidden area during axis movement, the axis decelerates and stops, and an alarm is displayed. If an alarm occurs when the tool enters a forbidden area, the tool can move only opposite to the direction from which the tool came. After moving it outside the forbidden area in the opposite direction, release the alarm with a reset. When the alarm is released, the tool can move in both directions.

2.3.10 Stored stroke limit range switching function by signal

Overview

The range stored stroke limit can be switched by input signal of PMC. Therefore, the range stored stroke limit can easily be set again.

Explanation

- Stored stroke limit range switching

Stored stroke limit range switching function consists of the next five steps.

1) Data for switching is set.
Data for switching is set to data table (D) of PMC.
Data for switching is set from the address specified by parameter No.1313 and stored stroke limit range switching data selection signals OTD0 to OTD15<Gn594, Gn595>.

2) The offset from the head of data table (D) of PMC to which data for switching is set is specified.
The offset from the head of data table (D) of PMC that sets data for switching is specified by stored stroke limit range switching data selection signals.

3) The switched axis is specified.
The axis switched by stored stroke limit range switching axis selection signals OTA1 to OTA8 <Gn596> is specified. Two or more axes can be specified. Be careful of the compatibility of specification of axes and data for switching.

4) The switched kind of stored stroke limit is specified.
The kind of stored stroke limit is specified with stored stroke limit range switching selection signals +/-OT11,+/-OT12,+/-OT2,+/-OT3 <Gn597>. Two or more kinds can be specified at the same time.

5) Request and finish for switching
When above-mentioned steps from 1) to 4) have been prepared, stored stroke limit range switching start signal OTSW <Gn599.0> is set to "1". When stored stroke limit range switching finish signal OTSWFN <Fn599.0> becomes "1", the range of stored stroke limit of the specified axis is switched, therefore set stored stroke limit range switching start signal to "0". Other input signals can be specified until turning on stored stroke limit range switching start signal next time. The state of the signal can be held when you need not change the specified signal.

- Stored stroke limit range switching cancellation

When stored stroke limit range switching is canceled, the range of stored stroke limit of the specified axis returns to the parameter setting value. Cancellation of stored stroke limit range switching consists of the next two steps.

1) Specify the kind of the stored stroke limit that is going to cancel.
   Specify the kind of stored stroke limit that is going to cancel with stored stroke limit range switching cancellation signals +/-OT11C,+/-OT12C,+/-OT2C,+/-OT3C <Gn598>. Two or more kinds of stored stroke limit can be specified at the same time.

2) Request and finish of cancellation
   When step 1) has been prepared, set stored stroke limit range switching start signal to "1".
   When stored stroke limit range switching finish signal becomes "1", the range of stored stroke limit of the specified axis returns to the parameter setting value, therefore set stored stroke limit range switching start signal to "0".

- Data format for switching

The data format is described as follows.
- Data for switching uses 4 bytes per data.
- Set the value that becomes the multiple of four (0, 4, and 8, etc.) to data table address that sets the switching data. Therefore, the total of the offset specified by the parameter No.1313 and the stored stroke limit range switching data selection signal should be a multiple of four (0, 4, and 8, etc.).
- Set data for switching to data table by a diameter value according to diameter specification of axes.
- Set data for switching to data table by detection units.
  Example)
  Data for switching is 1000 for 1.000(IS-B).
  Data for switching is 10000 for 1.0000(IS-C).
- Please set data for switching continuously, without creating a blank area. For example, please set the data of the third axis directly soon after the data of the first axis when you would like to switch the first axis and third axis.

Fig.2.3.10 (a) Data format for switching

- Example of setting of data for switching and time chart

- Switching axes : The first axis and the second axis
- Switching kinds : Coordinate value of stored stroke check 2,3 in the positive direction, and the negative direction
- Head of data table (D) : Parameter No.1313=1000
- Offset from head of D : 100
- Switching data : Coordinate value of stored stroke check 2 in the positive direction
  The first axis = 2100.000
  The second axis = 2200.000
  Coordinate value of stored stroke check 2 in the negative direction

The first axis = -2100.000
The second axis = -2200.000
Coordinate value of stored stroke check 3 in the positive direction
The first axis = 3100.000
The second axis = -3200.000
Coordinate value of stored stroke check 3 in the negative direction
The first axis = -3100.000
The second axis = 3200.000

Example of setting the above-mentioned condition

Coordinate of stored stroke check 2 in the positive direction	D1100 = 2100000 -----	The first axis
	D1104 = 2200000 -----	The second axis
Coordinate of stored stroke check 2 in the negative direction	D1108 = -2100000 ----	The first axis
	D1112 = -2200000 ----	The second axis
Coordinate of stored stroke check 3 in the positive direction	D1116 = 3100000 -----	The first axis
	D1120 = 3200000 -----	The second axis
Coordinate of stored stroke check 3 in the negative direction	D1124 = -3100000 ----	The first axis
	D1128 = -3200000 ----	The second axis

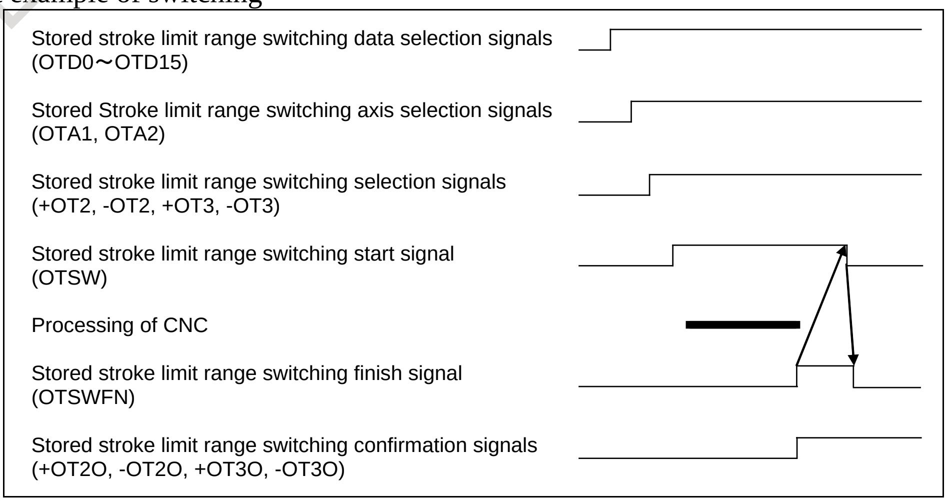
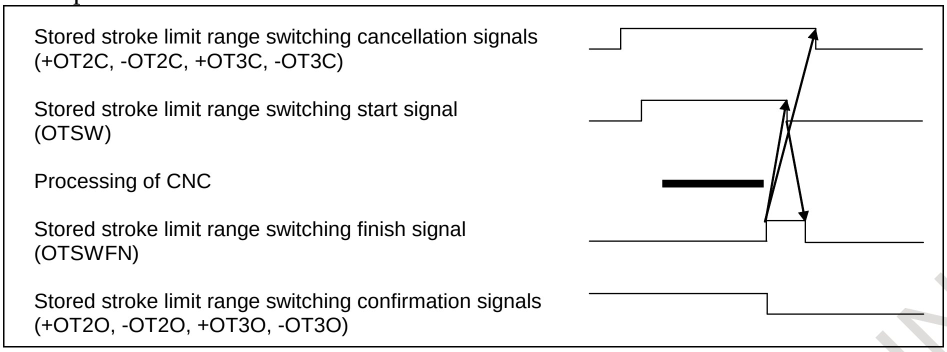
Fig.2.3.10 (b) Example of setting data for switching

Timing chart example of switching



Timing chart example of cancellation



NOTE

1. If the offset value which is added the value specified by the parameter No.1313 and the stored stroke limit range switching data selection signal is not a multiple of four (0, 4, and 8, etc.), alarm PW0041, "DATA TABLE(D) SETTING IS ILLEGAL" is generated.
2. The area of data table (D) of PMC is different depending on PMC used and its memory size. Please confirm the specification of PMC, and set it within the range that can be used.
3. A different kind of a different axis cannot be switch at the same time though two or more kinds or two or more axes can be switched at the same time. For example, it is not possible to switch the second axis to stored stroke limit 2 and switch the first axis to stored stroke limit 3 at the same time.
4. The cancellation is given to priority when the stored stroke limit range switching start signal is set to "1" in the state of the signal that both the switching and the cancellation are possible.
5. Even if other input signals are switched in the state "1" of stored stroke limit range switching start signal, it doesn't become effective immediately. It is reflected at the time of rising of the stored stroke limit range switching start signal.
6. Confirm whether to operate correctly by data and the signal that this function set beforehand.

Signal

Stored stroke limit range switching data selection signals OTD0 to OTD15 <Gn594 to Gn595>

[Classification] Input signal

[Function] The offset value from the address of head of data table (D) of PMC to which the data for switching of stored stroke limit range switching is set is specified by the binary code in two bytes. The address of head data is set to the parameter No.1313.

[Operation] When stored stroke limit range switching start signal is set to "1", the switching operation of the range of stored stroke limit starts by the specified data.

Stored stroke limit range switching axis selection signals OTA1 to OTA8<Gn596>

[Classification] Input signal

[Function] The axis that executes stored stroke limit range switching is specified.
These signals are provided for each control axis; the affixed number of the signal name shows the control axis number.

OTAx
x : 1 ..... Stored stroke limit switching to the first axis
2 ..... Stored stroke limit switching to 2nd axis
3 ..... Stored stroke limit switching to the 3rd axis
: :

[Operation] When stored stroke limit range switching start signal is set to "1", the range of the stored stroke limit of the specified axis is switched.

Stored stroke limit range switching selection signals
+OT11, -OT11, +OT12, -OT12, +OT2, -OT2, +OT3, -OT3 <Gn597>

[Classification] Input signal

[Function] The range switching of which stored stroke limit is executed is specified.

+OT11 ..... Coordinate value I of stored stroke check 1 in the positive direction
-OT11 ..... Coordinate value I of stored stroke check 1 in the negative direction
+OT12 ..... Coordinate value II of stored stroke check 1 in the negative direction
-OT12 ..... Coordinate value II of stored stroke check 1 in the negative direction
+OT2 ..... Coordinate value of stored stroke check 2 in the positive direction
-OT2 ..... Coordinate value of stored stroke check 2 in the negative direction
+OT3 ..... Coordinate value of stored stroke check 3 in the positive direction
-OT3 ..... Coordinate value of stored stroke check 3 in the negative direction

[Operation] When stored stroke limit range switching start signal is set to "1", the range of the specified stored stroke limit is switched.

Stored stroke limit range switching cancellation signals
+OT11C, -OT11C, +OT12C, -OT12C, +OT2C, -OT2C, +OT3C, -OT3C <Gn598>

[Classification] Input signal

[Function] The range switching of which stored stroke limit is canceled is specified.

[Operation] The range of the specified stored stroke limit switches to the parameter setting value when stored stroke limit range switching start signal switches "1".

Stored stroke limit range switching start signal OTSW<Gn599.0>

[Classification] Input signal

[Function] The range switching of which stored stroke limit is started.

[Operation] When this signal is set to "1", the range of the specified stored stroke limit is switched. Or, it is canceled.
When stored stroke limit range switching finish signal is set to "0", it is accepted.

Stored stroke limit range switching confirmation signals
+OT11O, -OT11O, +OT12O, -OT12O, +OT2O, -OT2O, +OT3O, -OT3O<Fn598>

[Classification] Output signal

[Function] These signals indicate that the range of stored stroke limit specified has been switched.

[Operation] These signals are set to "1" when:
- In the same kind of stored stroke limit, the range switching has become effective even one axis.

These signals are set to "0" when:
- In the same kind of stored stroke limit, the range switching of all axes has become ineffective.

Stored stroke limit range switching finish signal OTSWFN<Fn599.0>

[Classification] Output signal

[Function] The signal indicates that stored stroke limit range switching has been completed.

[Operation] These signals are set to "1" when:
- Stored stroke limit, the range switching has been completed.

These signals are set to "0" when:

- After having completed stored stroke limit range switching, stored stroke limit range switching start signal has been become "0".

Signal address

Fn599								OTSWFN

Parameter

1313	The first address of data table (D) that sets data that switches stored stroke limit

[Input type] Parameter input
[Data type] 2 word path
[Valid data range] 0 to 59996

The first address of data table (D) of PMC that sets data that switches stored stroke limit is set.

NOTE
1 1When this parameter is set, the power must be turned off before operation is continued.
2 When this parameter is 0, a data table from address D0 is used.

⚠ **WARNING**
If a data table of the set address in this parameter is used by another usage, it may cause an unexpected machine behavior. Be careful enough that you must prevent the competition of the used data table.

Alarm and message

Number	Message	Description
PW0041	DATA TABLE(D) SETTING IS ILLEGAL	The address of data table (D) PMC calculated from parameter No.1313, stored stroke limit range switching data selection signal (OTD0-OTD15), and the switching data area is illegal. (1) The specified first address is illegal. (2) It is not a multiple of four. (3) The range of the specified data table is illegal.

Diagnosis data

3710	Coordinate value I of stored stroke check 1 in the positive direction
3711	Coordinate value I of stored stroke check 1 in the negative direction
3712	Coordinate value II of stored stroke check 1 in the positive direction
3713	Coordinate value II of stored stroke check 1 in the negative direction
3714	Coordinate value of stored stroke check 2 in the positive direction
3715	Coordinate value of stored stroke check 2 in the negative direction
3716	Coordinate value of stored stroke check 3 in the positive direction
3717	Coordinate value of stored stroke check 3 in the negative direction

[Data type] Real axis
[Unit of data] Machine unit

Machine coordinates value of effective, various kind of stored stroke limits are displayed now.

Note

NOTE

1. Stroke limit check before move also becomes effective in the switched area.
2. The range of stored stroke limit returns to the state set to the parameter at power on.
3. When the number of control axes in the system increases and decreases by flexible path axis assignment, it is necessary to consider it.
4. Stored stroke check 1 area expansion (coordinate value III - VIII) cannot be rewritten by this function.
5. When the range of stored stroke limit is switched by this function, even if the parameters Nos.1320 to 1327 are rewritten by the G10 instruction, the PMC window, and the G22 instruction, it is not effective immediately.
6. Stroke limit area changing function is a function to rewrite the parameters Nos.1320 to 1327. This function is a function that switches the range of stroke limit to the value that is set to data table (D) of PMC without rewriting the parameters Nos.1320 to 1327.

2.3.11 Chuck and Tail Stock Barrier

T

Overview

The chuck/tail stock barrier function prevents damage to the machine by checking whether the tool tip interferes with either the chuck or tail stock.

Specify an area into which the tool may not enter (entry-inhibition area). This is done using the special setting screen, according to the shapes of the chuck and tail stock. If the tool tip should enter the set area during a machining operation, this function stops the tool and outputs an alarm message.

The tool can be removed from the entry-inhibition area only by retracting it in the direction from which the tool entered the area.

Explanation

- Settings process for Chuck and Tail stock barrier

Refer to the "Chuck and Tail Stock Barriers" in the Operator's Manual (For Lathe System) (B-64694EN-1) for the details of setting process for Chuck and Tail stock barrier.

- Setting the entry-inhibition area for a chuck

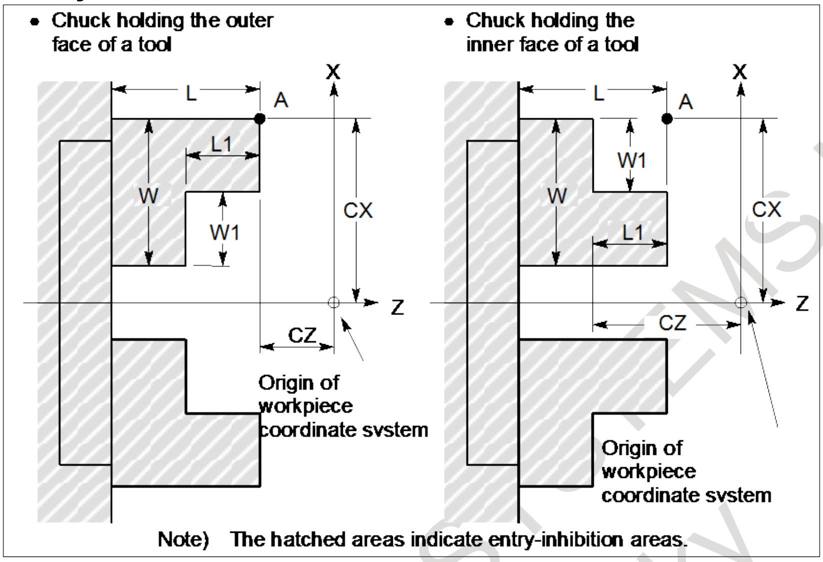

Fig. 2.3.11 (a)

Table 2.3.11 (a)

Symbol	Description	Parameter
TY	Chuck-shape selection (0: Holding the inner face of a tool, 1: Holding the outer face of a tool)	No.1330
CX	Chuck position (along X-axis)	No.1335
CZ	Chuck position (along Z-axis)	No.1336
L	Length of chuck jaws	No.1331
W	Depth of chuck jaws (radius)	No.1332
L1	Holding length of chuck jaws	No.1333
W1	Holding depth of chuck jaws (radius)	No.1334

TY : Selects a chuck type, based on its shape. Specifying 0 selects a chuck that holds the inner face of a tool. Specifying 1 selects a chuck that holds the outer face of a tool. A chuck is assumed to be symmetrical about its Z-axis.

CX, CZ : Specify the coordinates of a chuck position, point A, in the workpiece coordinate system. These coordinates are not the same as those in the machine coordinate system.

The direction of the chuck and of the tail stock is defined by a big and small relation between CZ and TZ (Z coordinate of a tail stock). Please refer to "Setting of direction of chuck and of tail stock" for details.

L, L1 : Defines the length of chuck jaws.

W, W1 : Defines the width of chuck jaws

NOTE

1. For CX and CZ, whether diameter programming or radius programming is used for the axis determines the programming system. When diameter programming is used for the axis, use diameter programming to enter data for the axis.
2. Always specify W and W1 in radius. When radius programming is used for the Z-axis, specify L and L1 in radius.
3. If you not use the entry-inhibition area for a chuck, please set 0 to L, L1, W and W1.
4. The CZ is used to define the direction of the chuck and of the tail stock. Even when you not use the entry-inhibition area for a chuck, please set to CZ.

- Setting the entry-inhibition area for a tail stock

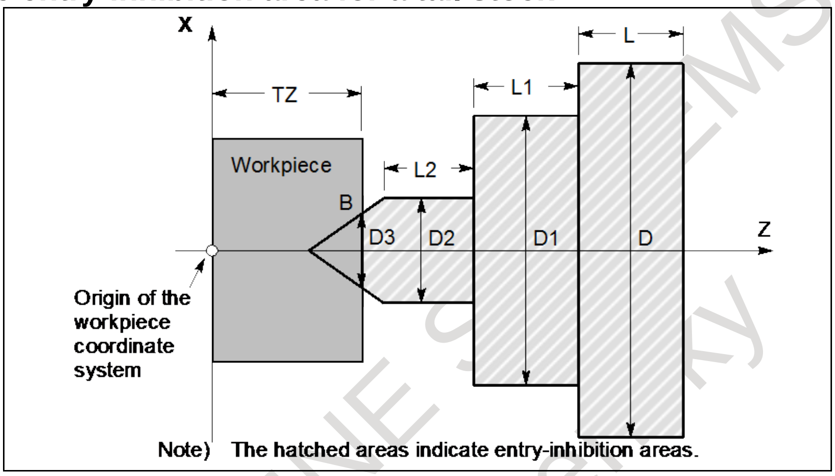

Fig. 2.3.11 (b)

Table 2.3.11 (b)

Symbol	Description	Parameter
TZ	Tailstock position (along the Z-axis)	No.1348
L	Tailstock length	No.1341
D	Tailstock diameter	No.1342
L1	Tailstock length (1)	No.1343
D1	Tailstock diameter (1)	No.1344
L2	Tailstock length (2)	No.1345
D2	Tailstock diameter (2)	No.1346
D3	Hole diameter of tailstock (3)	No.1347

TZ : Specifies the Z coordinate of the chuck position, point B (Fig. 2.3.11 (b)), in the workpiece coordinate system. These coordinates are not the same as those in the machine coordinate system. A tail stock is assumed to be symmetrical about its Z-axis. The direction of the chuck and of the tail stock is defined by a big and small relation between CZ (Z coordinate of a chuck) and TZ. Please refer to "Setting of direction of chuck and of tail stock" for details.

L, L1, L2 : Defines the tail stock length.

D, D1, D2, D3 : Defines the tail stock diameter.

NOTE
1 For TZ, whether diameter programming or radius programming is used for the Z-axis determines the programming system.
2 Always specify D, D1, D2, and D3 in diameter programming. When radius programming is used for the Z-axis, specify L, L1, and L2 in radius.
3 If you not use the entry-inhibition area for a tail stock, please set 0 to L, L1, L2, D, D1, D2 and D3.
4 The TZ is used to define the direction of the chuck and of the tail stock. Even when you not use the entry-inhibition area for a tail stock, please set to TZ.

- Setting the entry-inhibition area for the tail stock tip

The tip angle of the tail stock is 60 degrees. The entry-inhibition area is set around the tip, assuming the angle to be 90 degrees, as shown below.

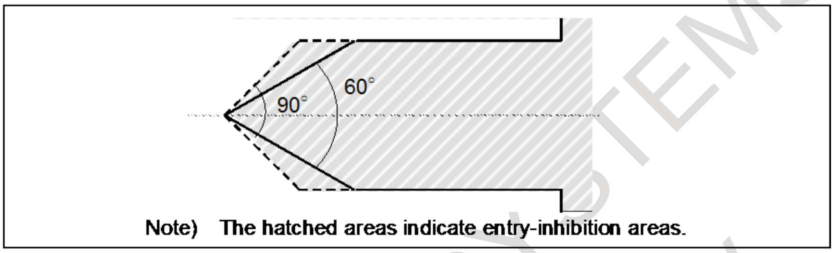

Fig. 2.3.11 (c)

- Setting of direction of chuck and of tail stock

Setting of direction of entry-inhibition area for a chuck and of entry-inhibition area for a tail stock is decided by a big and small relation between parameter No.1336 (CZ) and parameter No.1348 (TZ). When set to CZ<TZ, the direction of the chuck and of the tail stock becomes direction shown in Fig. 2.3.11 (d). When set to CZ>TZ, the direction of the chuck and of the tail stock becomes direction shown in Fig. 2.3.11 (e).

When you use only entry-inhibition area for a chuck, please set the following to parameter No.1348 (TZ).

- When you set the direction of the chuck as shown in Fig. 2.3.11 (d), please set a value that is larger than CZ to TZ
- When you set the direction of the chuck as shown in Fig. 2.3.11 (e), please set a value that is smaller than CZ to TZ

When you use only entry-inhibition area for a tail stock, please set the following to parameter No.1336 (CZ).

- When you set the direction of the tail stock as shown in Fig. 2.3.11 (d), please set a value that is smaller than TZ to CZ
- When you set the direction of the tail stock as shown in Fig. 2.3.11 (e), please set a value that is larger than TZ to CZ

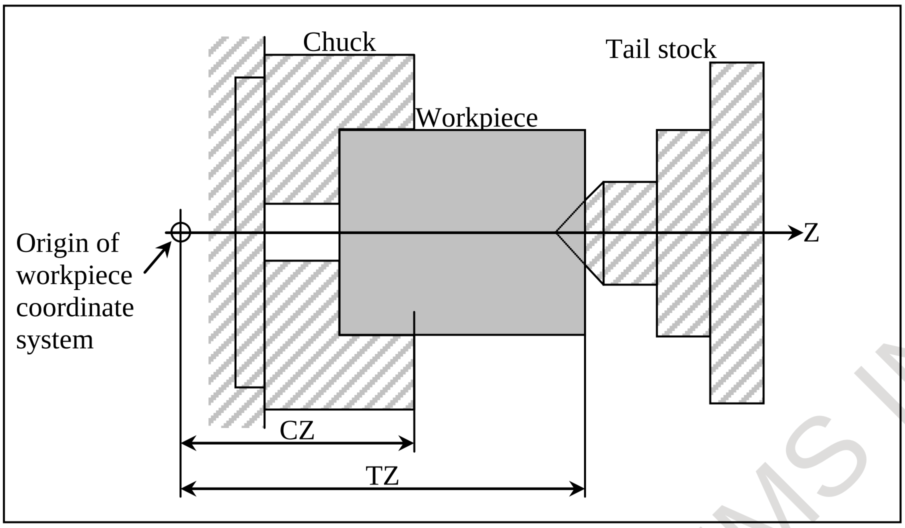

Fig. 2.3.11 (d) For parameter No.1336(CZ) < parameter No.1348(TZ)

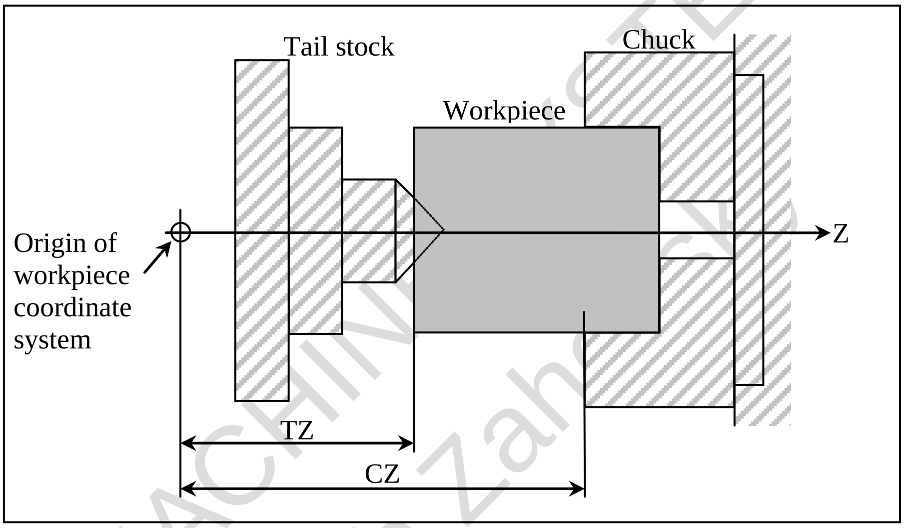

Fig. 2.3.11 (e) For parameter No.1336(CZ) > parameter No.1348(TZ)

Signal

Tailstock barrier select signal *TSB<Gn060.7>

[Classification] Input signal

[Function] Enables or disables the tail stock barrier.

[Operation] When this signal is set to “1”, the control unit operates as follows:
Disables the tail stock barrier, even when the G22 command (stored stroke check on) is specified in the program.

Table 2.3.11 (c)

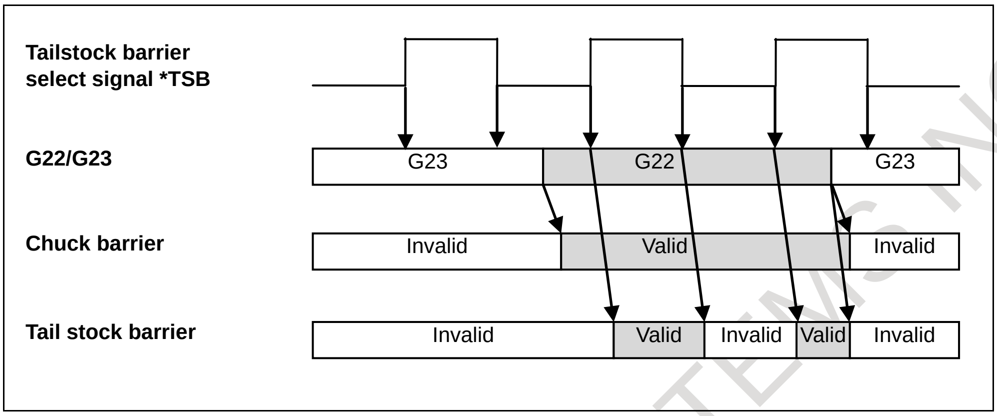
G code	*TSB	Tail stock barrier	Chuck barrier (reference)
G22	0	Enabled	Enabled
	1	Disabled	Enabled
G23	0	Disabled	Disabled
	1	Disabled	Disabled

When the G23 command (stored stroke check off) is specified, the tail stock barrier is disabled regardless of the signal *TSB. When the G22 command (stored stroke check on) is specified, the tail stock can be disabled by setting the signal to “1”.
This signal is used to select whether the tail stock area is a entry-inhibition area.
It is used whenever M commands are applied, resulting in the tail stock being attached to the workpiece or detached from the workpiece while the workpiece is being machined.

Signal address

		#7	#6	#5	#4	#3	#2	#1	#0
Gn060		*TSB							

Timing chart



Limitation

- Correct setting of an entry-inhibition area

If an entry-inhibition area is incorrectly set, it may not be possible to make the area effective. Avoid making the following settings:

- L < L1 or W < W1 in the chuck-shape settings.
- D2 < D3 in the tail stock-shape settings.
- A chuck setting overlapping that of the tail stock.

- When you use only the chuck or only the tail stock

Setting of direction of entry-inhibition area for a chuck and of entry-inhibition area for a tail stock is decided by a big and small relation between CZ and TZ. Even when you use only the chuck or only the tail stock, please set a big and small relation between CZ and TZ appropriately. Please refer to "Setting of direction of chuck and of tail stock" for details.

If you not use the entry-inhibition area for a chuck, please set 0 to L, L1, W and W1 of the chuck-shape settings.
If you not use the entry-inhibition area for a tail stock, please set 0 to L, L1, L2, D, D1, D2 and D3 of the tail stock-shape settings.

- Retraction from the entry-inhibition area

If the tool enters the entry-inhibition area and an alarm is issued, switch to manual mode, retract the tool manually, then reset the system to release the alarm. In manual mode, the tool can be moved only in the opposite direction to that in which the tool entered the area.
The tool cannot be moved in the same direction (further into the area) as it was traveling when the tool entered the area.
When the entry-inhibition areas for the chuck and tail stock are enabled, and the tool is already positioned within those areas, an alarm is issued when the tool moves.
When the tool cannot be retracted, change the setting of the entry-inhibition areas, such that the tool is outside the areas, reset the system to release the alarm, then retract the tool. Finally, reinstall the original settings.

- Coordinate system

An entry-inhibition area is defined using the workpiece coordinate system. Note the following.

<1> When the workpiece coordinate system is shifted by means of a command or operation, the entry-inhibition area is also shifted by the same amount.

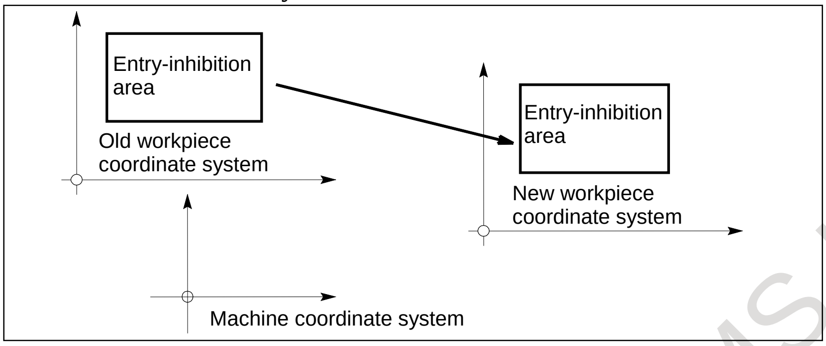


Fig. 2.3.11 (f)

Use of the following commands and operations will shift the workpiece coordinate system.
Commands:
G54 to G59, G52, G50 (G92 in G code system B or C)
Operations:
Manual handle interrupt, change in offset relative to the workpiece reference point, change in tool offset (tool geometry compensation), operation with machine lock, manual operation with manual absolute signal off

<2> When the tool enters an entry-inhibition area during automatic operation, set the manual absolute signal, *ABSM <Gn006.2>, to 0 (on), then manually retract the tool from the area. If this signal is "1", the distance the tool moves in manual operation is not counted in the tool coordinates in the workpiece coordinate system. This results in the state where the tool can never be retracted from the entry-inhibition area.

Parameter

- Profile of a chuck

1330	Profile of a chuck

[Input type] Parameter input
[Data type] Byte path
[Valid data range] 0 to 1
Select a chuck figure.
0 : Chuck which holds a workpiece on the inner surface
1 : Chuck which holds a workpiece on the outer surface

1331	Dimensions of the claw of a chuck (L)

[Input type] Parameter input
[Data type] Real path
[Unit of data] mm, inch (input unit)
[Min. unit of data] Depend on the increment system of the applied axis
[Valid data range] 0 or positive 9 digit of minimum unit of data (refer to the standard parameter setting table (B))
(When the increment system is IS-B, 0.0 to +999999.999)
Set the length (L) of the claw of the chuck.

> **NOTE**
> Whether to specify this parameter by using a diameter value or radius value depends on whether the corresponding axis is based on diameter specification or radius specification.

1332	Dimensions of the claw of a chuck (W)

[Input type] Parameter input
[Data type] Real path
[Unit of data] mm, inch (input unit)
[Min. unit of data] Depend on the increment system of the applied axis
[Valid data range] 0 or positive 9 digit of minimum unit of data (refer to the standard parameter setting table (B))
(When the increment system is IS-B, 0.0 to +999999.999)
Set the width (W) of the claw of the chuck.

> **NOTE**
> Specify this parameter by using a radius value at all times.

1333	Dimensions of the claw of a chuck (L1)

[Input type] Parameter input
[Data type] Real path
[Unit of data] mm, inch (input unit)
[Min. unit of data] Depend on the increment system of the applied axis
[Valid data range] 0 or positive 9 digit of minimum unit of data (refer to the standard parameter setting table (B))
(When the increment system is IS-B, 0.0 to +999999.999)
Set the length (L1) of the claw of the chuck.

> **NOTE**
> Whether to specify this parameter by using a diameter value or radius value depends on whether the corresponding axis is based on diameter specification or radius specification.

1334	Dimensions of the claw of a chuck (W1)

[Input type] Parameter input
[Data type] Real path
[Unit of data] mm, inch (input unit)
[Min. unit of data] Depend on the increment system of the applied axis
[Valid data range] 0 or positive 9 digit of minimum unit of data (refer to the standard parameter setting table (B))
(When the increment system is IS-B, 0.0 to +999999.999)
Set the width (W1) of the claw of the chuck.

> **NOTE**
> Specify this parameter by using a radius value at all times.

1335	X coordinate of a chuck (CX)

[Input type] Parameter input
[Data type] Real path
[Unit of data] mm, inch (input unit)
[Min. unit of data] Depend on the increment system of the applied axis
[Valid data range] 9 digit of minimum unit of data (refer to standard parameter setting table (A))
(When the increment system is IS-B, -999999.999 to +999999.999)
Set the chuck position (X coordinate) in the workpiece coordinate system.

> **NOTE**
> Whether to specify this parameter by using a diameter value or radius value depends on whether the corresponding axis is based on diameter specification or radius specification.

1336	Z coordinate of a chuck (CZ)

[Input type] Parameter input
[Data type] Real path
[Unit of data] mm, inch (input unit)
[Min. unit of data] Depend on the increment system of the applied axis
[Valid data range] 9 digit of minimum unit of data (refer to standard parameter setting table (A))
(When the increment system is IS-B, -999999.999 to +999999.999)
Set the chuck position (Z coordinate) in the workpiece coordinate system.

> **NOTE**
> 1 Whether to specify this parameter by using a diameter value or radius value depends on whether the corresponding axis is based on diameter specification or radius specification.
> 2 The direction of the chuck and of the tail stock is decided by a big and small relation between this parameter and parameter No.1348 (Z coordinate of a tail stock (TZ)). Even when you not use the chuck, please set to this parameter.

- Profile of a tail stock

1341	Length of a tail stock (L)

[Input type] Parameter input
[Data type] Real path
[Unit of data] mm, inch (input unit)
[Min. unit of data] Depend on the increment system of the applied axis
[Valid data range] 0 or positive 9 digit of minimum unit of data (refer to the standard parameter setting table (B))
(When the increment system is IS-B, 0.0 to +999999.999)
Set the length (L) of the tail stock.

> **NOTE**
> Whether to specify this parameter by using a diameter value or radius value depends on whether the corresponding axis is based on diameter specification or radius specification.

1342	Diameter of a tail stock (D)

[Input type] Parameter input
[Data type] Real path
[Unit of data] mm, inch (input unit)
[Min. unit of data] Depend on the increment system of the applied axis
[Valid data range] 0 or positive 9 digit of minimum unit of data (refer to the standard parameter setting table (B))
(When the increment system is IS-B, 0.0 to +999999.999)
Set the diameter (D) of the tail stock.

> **NOTE**
> Specify this parameter by using a diameter value at all times.

1343	Length of a tail stock (L1)

[Input type] Parameter input
[Data type] Real path
[Unit of data] mm, inch (input unit)
[Min. unit of data] Depend on the increment system of the applied axis
[Valid data range] 0 or positive 9 digit of minimum unit of data (refer to the standard parameter setting table (B))
(When the increment system is IS-B, 0.0 to +999999.999)
Set the length (L1) of the tail stock.

> **NOTE**
> Whether to specify this parameter by using a diameter value or radius value depends on whether the corresponding axis is based on diameter specification or radius specification.

1344	Diameter of a tail stock (D1)

[Input type] Parameter input
[Data type] Real path
[Unit of data] mm, inch (input unit)
[Min. unit of data] Depend on the increment system of the applied axis
[Valid data range] 0 or positive 9 digit of minimum unit of data (refer to the standard parameter setting table (B))
(When the increment system is IS-B, 0.0 to +999999.999)
Set the diameter (D1) of the tail stock.

> **NOTE**
> Specify this parameter by using a diameter value at all times.

1345	Length of a tail stock (L2)

[Input type] Parameter input
[Data type] Real path
[Unit of data] mm, inch (input unit)

[Min. unit of data] Depend on the increment system of the applied axis
[Valid data range] 0 or positive 9 digit of minimum unit of data (refer to the standard parameter setting table (B))
(When the increment system is IS-B, 0.0 to +999999.999)
Set the length (L2) of the tail stock.

> **NOTE**
> Whether to specify this parameter by using a diameter value or radius value depends on whether the corresponding axis is based on diameter specification or radius specification.

1346	Diameter of a tail stock (D2)

[Input type] Parameter input
[Data type] Real path
[Unit of data] mm, inch (input unit)
[Min. unit of data] Depend on the increment system of the applied axis
[Valid data range] 0 or positive 9 digit of minimum unit of data (refer to the standard parameter setting table (B))
(When the increment system is IS-B, 0.0 to +999999.999)
Set the diameter (D2) of the tail stock.

> **NOTE**
> Specify this parameter by using a diameter value at all times.

1347	Diameter of a tail stock (D3)

[Input type] Parameter input
[Data type] Real path
[Unit of data] mm, inch (input unit)
[Min. unit of data] Depend on the increment system of the applied axis
[Valid data range] 0 or positive 9 digit of minimum unit of data (refer to the standard parameter setting table (B))
(When the increment system is IS-B, 0.0 to +999999.999)
Set the diameter (D3) of the tail stock.

> **NOTE**
> Specify this parameter by using a diameter value at all times.

1348	Z coordinate of a tail stock (TZ)

[Input type] Parameter input
[Data type] Real path
[Unit of data] mm, inch (input unit)
[Min. unit of data] Depend on the increment system of the applied axis
[Valid data range] 9 digit of minimum unit of data (refer to standard parameter setting table (A))
(When the increment system is IS-B, -999999.999 to +999999.999)
Set the tail stock position (Z coordinate) in the workpiece coordinate system.

> **NOTE**
> 1 Whether to specify this parameter by using a diameter value or radius value depends on whether the corresponding axis is based on diameter specification or radius specification.
> 2 The direction of the chuck and of the tail stock is decided by a big and small relation between this parameter and parameter No.1336 (Z coordinate of a chuck (CZ)). Even when you not use the tail stock, please set to this parameter.

1370								CTA

[Input type] Parameter input
[Data type] Bit path

> **NOTE**
> When this parameter is set, the power must be turned off before operation is continued.

#0 CTA The overtravel alarm of Chuck and Tail Stock Barrier is,
0: Conventional specification. (Alarm OT0502, OT0503)
1: New specification. (Alarm OT0520, OT0521)

	#7	#6	#5	#4	#3	#2	#1	#0
3402	G23							

[Input type] Parameter input
[Data type] Bit path

#7 G23 When the power is turned on
0: G22 mode (stored stroke check on)
1: G23 mode (stored stroke check off)

Alarm and message

Number	Message	Description
OT0502	+ OVERTRAVEL (SOFT 2)	Exceeded the positive side stored stroke limit 2. Or, in the chuck tail stock barrier, an entry to the entry-inhibition area was made during movement in the positive direction.
OT0503	- OVERTRAVEL (SOFT 2)	Exceeded the negative side stored stroke limit 2. Or, in the chuck tail stock barrier, an entry to the entry-inhibition area was made during movement in the negative direction.
OT0520	+ OVERTRAVEL (CHUCK TAIL BARRIER)	In the chuck tail stock barrier, an entry to the entry-inhibition area was made during movement in the positive direction.
OT0521	- OVERTRAVEL (CHUCK TAIL BARRIER)	In the chuck tail stock barrier, an entry to the entry-inhibition area was made during movement in the negative direction.

Warning

> ⚠ **WARNING**
>
> 1 If an alarm is issued, the tool stops before it enters the entry-inhibition area when bit 7 (BFA) of parameter No. 1300 is set to 1.
> When bit 7 (BFA) of parameter No. 1300 is set to 0, an actual stop position can be in the entry-inhibition area beyond the specified profile because the CNC and machine system stop with some delay in time. For this reason, for safety, set profile data a little larger than the actual profile. The extra distance, L, required for this purpose is calculated from a rapid traverse rate as follows:
> L = (rapid-traverse-rate) $\times$ 1/7500
> For example, when a rapid traverse rate of 15 m/min is used, set profile data 2 mm larger than the actual profile.
> The profile of a chuck or tail stock can also be set using parameters Nos. 1330 to 1348.

OPERATOR'S MANUAL (B-64694EN)	Check/tail stock barrier

2.4 ALARM SIGNALS

When an alarm is triggered in the CNC, the alarm is displayed on the screen, and the alarm signal is set to "1".
If the voltage level of the memory backup battery falls to below a specified level while the CNC is turned off, the battery alarm signal is set to "1".

Signal

Alarm signal AL<Fn001.0>

[Classification] Output signal
[Function] The alarm signal reports that the CNC is in an alarm state.
The following are the alarms that may be issued:
(a) TH alarm
(b) TV alarm
(c) P/S alarm
(d) Overtravel alarm
(e) Overheat alarm
(f) Servo alarm
[Output cond.] The alarm signal is set to "1" when:
- The CNC is placed in the alarm state.
The alarm signal is set to "0" when:
- The alarm has been released by resetting the CNC.

Battery alarm signal BAL<Fn001.2>

[Classification] Output signal
[Function] The battery alarm signal indicates that the voltage of the battery for the memory has fallen to below a specified level while the CNC is off. In general, this signal is used to turn on an LED to notify the operator.
[Output cond.] The signal is set to "1" when:
- The battery voltage has fallen to below the specified level.
The signal is set to "0" when:
- The battery voltage has risen to the specified level or higher.

2.5 START LOCK / INTERLOCK

These signals disable machine movement along axes. When any of these signals is activated during movement, tool movement along the affected axis (or axes) is decelerated, then stopped.

Signal

Start lock signal STLK<Gn007.1>

[Classification] Input signal

[Function] This signal disables movement along axes during automatic operation (memory operation, DNC operation, or MDI operation).

[Operation] When the start lock signal STLK is set to “1”, a movement along an axis decelerates and stops. In this case, the automatic operation mode is maintained (with the cycle start lamp signal STL set to “1” and the feed hold lamp signal SPL set to “0”) while the movement is stopped. Therefore, when blocks containing only M, S, T, and B (second auxiliary functions) commands with no axis move commands are specified successively, the M, S, T, and B functions are executed one after another until a block specifying an axis move command is encountered. When an axis move command and M, S, T, and B functions are both specified, only the M, S, T, and B functions are sent, and a stop occurs in the automatic operation mode. Setting the start lock signal STLK to “0” restarts the operation. (Fig. 2.5 (a) and Fig. 2.5 (b)).

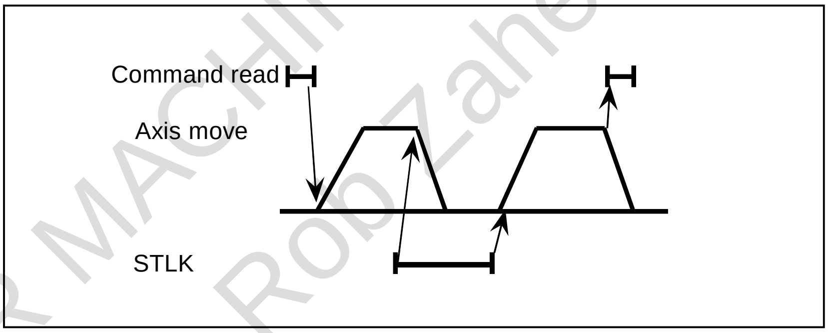

Fig. 2.5 (a) Interlock when only axis move commands are specified

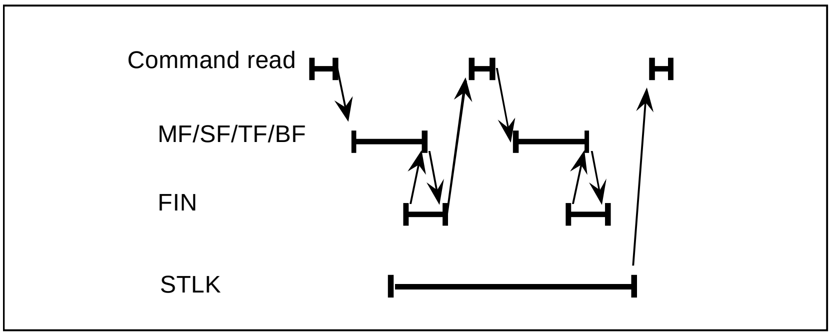

Fig. 2.5 (b) Interlock when a block containing auxiliary functions only is specified

All axes interlock signal *IT<Gn008.0>

[Classification] Input signal

[Function] This signal is used to inhibit the machine from moving, and is effective regardless of the selected mode.

[Operation] When the all axes interlock signal *IT is set to “0”, the axis movement is decelerated and stopped regardless of the selected mode. In this case, the automatic operation mode is maintained (with the cycle start lamp signal STL set to “1”and the feed hold lamp signal SPL set to “0”) while the movement is stopped. Therefore, when blocks containing only M, S, T, and B (second auxiliary functions) commands with no axis move commands are specified successively, the M, S, T, and B functions are executed one after another until a block specifying an axis move command is encountered. When an axis move command and M, S, T, and B functions are both specified, only the M, S, T, and B functions are sent, and a stop occurs in the automatic operation mode. Setting the axes interlock signal *IT to “1” restarts the operation. (Fig. 2.5 (c) and Fig. 2.5 (d)).

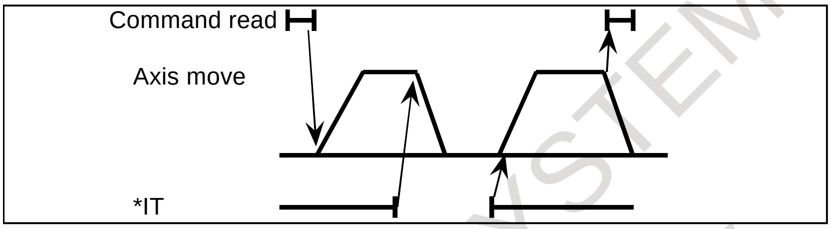

Fig. 2.5 (c) Block containing axis move commands only (manual and automatic operation)

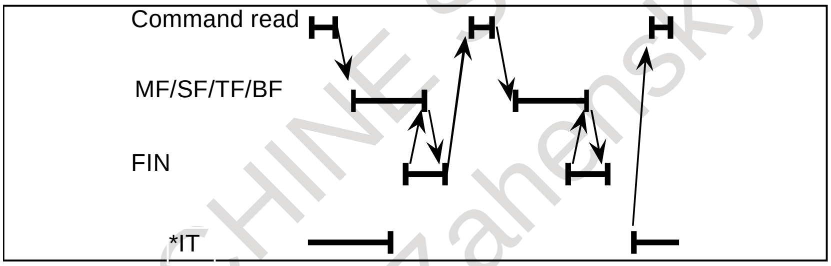

Fig. 2.5 (d) Block containing auxiliary functions only (automatic operation)

> **NOTE**
> 1 The overtravel distance of the motor after turning the all axes interlock signal *IT to “0” is represented by the following formula.
> Where
> $Qmax=Fm\times 1/60\times(A/1000+Tc/1000+Ts/1000)$
> Qmax : Overtravel quantity (mm or inch)
> Fm : Feedrate (mm/min or inch/min)
> Tc : Cutting time constant (ms)
> Ts : Servo time constant (Ts = 33ms normally)
> A : Processing time of CNC
> A = 50ms
> When acceleration/deceleration before read-ahead interpolation is used, the distance required for deceleration using look-ahead acceleration/deceleration before interpolation is added to the above formula.
> 2 Interlock signal for each axis might become invalid by the function to use. Please refer to note at this paragraph end.

Interlock signal for each axis*IT1 to *IT8<Gn130>

[Classification] Input signal

[Function] These signals disable feed along axes on an axis-by-axis basis.
A separate interlock signal is provided for each controlled axis. The number at the end of each signal name denotes the number of the corresponding controlled axis.

*IT x

x : 1 ..... Interlock for the first axis
2 ..... Interlock for the second axis
3 ..... Interlock for the third axis
: :

[Operation]
a) In manual operation
The movement of an interlocked axis is inhibited, but the other axes are movable. If an axis is interlocked during movement, it stops after being decelerated, and it starts moving again when it is released from interlock.
b) In automatic operation (MEM, RMT, or MDI mode)
If an axis is interlocked while its movement is being commanded (the move amount is not 0, inclusive of the tool offset), movement in all axes is prevented.
If a moving axis is interlocked, all axes stop moving after being decelerated, and they start moving again when interlock is released.
This function is also effective during dry run.

NOTE
Interlock signal for each axis might become invalid by the function to use. Please refer to note at this paragraph end.

Interlock signal for each axis direction
(M series) +MIT1 to +MIT8<Gn132>,-MIT1 to -MIT8<Gn134>
(T series) +MIT1<X004.2>,-MIT1<X004.3>,+MIT2<X004.4>,-MIT2<X004.5>

[Classification] Input signal

[Function] An axis direction interlock can be applied for each axis.

[Operation] When an interlock signal for each axis direction is set to “1”, the CNC applies an interlock to the specified axis direction only. However, when the interlock is done to the axis of movement instructing, the feed of all axes is prohibited regardless of axis direction.

NOTE
1 With the T series, if bit 4 (DAU) of parameter No. 3003 is set to 0, an axis direction interlock is applied only during manual operation. To apply axis direction interlock also during automatic operation, set bit 4 (DAU) of parameter No. 3003 to 1.
2 With the T series, if bit 0 (GSC) of parameter No. 5009 is set to 1, the same signal addresses as the M series (<Gn132> and <Gn134>) can be set. When using these signals in a system using four or more paths, set bit 0 (GSC) of parameter No. 5009 to 1 to use signal addresses <Gn132> and <Gn134>.
3 Interlock signal for each axis might become invalid by the function to use. Please refer to note at this paragraph end.

Block start interlock signal *BSL<Gn008.3>

[Classification] Input signal

[Function] This signal disables the start of the next block during automatic operation

[Operation] While this signal is 0, the execution of the next block during automatic operation is not started. This signal does not affect a block that has already started, and that block is continuously executed until its end. This signal does not halt automatic operation. The command in the next block is ready for execution as a valid command, so execution restarts as soon as the signal is set to “1”.

> **NOTE**
> 1 When blocks for cycle operation are internally created by a canned cycle and so on, only the first block is generally interlocked by this signal. The intermediate blocks are executed continuously even if this signal is set to “0”.
> 2 This signal is invalid to the axis movement by the real-time custom macro sentence.

Cutting block start interlock signal *CSL<Gn008.1>

[Classification] Input signal

[Function] This signal disables the start of blocks specifying move commands other than positioning during automatic operation.

[Operation] While this signal is “0”, the execution of blocks specifying movement other than positioning during automatic operation is not started. This signal does not affect a block that has already started, and that block is continuously executed until its end. This signal does not halt automatic operation. The command in the next block is ready for execution as a valid command, so execution restarts as soon as the signal is set to “1”.

[Usage] When the spindle has been specified, or when the spindle speed has been changed, this signal can be held 0 until a target spindle speed is achieved. Then, the next cutting block can be executed at the target spindle speed.

> **NOTE**
> 1 This signal is effective for any blocks including blocks for cycle operation internally created by a canned cycle and so on.
> 2 This signal is invalid to the axis movement by the real-time custom macro sentence.

Signal address

	#7	#6	#5	#4	#3	#2	#1	#0

X013			-MIT2[#2]	+MIT2[#2]	-MIT1[#2]	+MIT1[#2]		
X011			-MIT2[#3]	+MIT2[#3]	-MIT1[#3]	+MIT1[#3]		

NOTE

For the T series, the +MIT1, -MIT1, +MIT2, and -MIT2 signals are placed in X004 (path 1), X013 (path 2), and X011 (path 3) shown above when bit 2 (XSG) of parameter No. 3008 is 0. When bit 2 (XSG) of parameter No. 3008 is 1, they are placed in the X addresses set by parameter No. 3019. (The bit positions do not change.) If bit 0 (GSC) of parameter No. 5009 is set to 1, an input signal can be input from the PMC side (Gn132 (- direction), Gn134 (+ direction)). In this case, the bit positions are the same as those in the M series.

Parameter

	#7	#6	#5	#4	#3	#2	#1	#0
1002				XIK				

[Input type] Parameter input
[Data type] Bit path

#4 XIK When bit 1 (LRP) of parameter No. 1401 is set to 0, namely, when positioning is performed using non-linear type positioning, if an interlock is applied to the machine along one of axes in positioning,

0: The machine stops moving along the axis for which the interlock is applied and continues to move along the other axes.
1: The machine stops moving along all the axes.

	#7	#6	#5	#4	#3	#2	#1	#0
3003				DAU	DIT	ITX		ITL
					DIT	ITX		ITL

[Input type] Parameter input
[Data type] Bit path

#0 ITL Interlock signal for all axes

0: Enabled
1: Disabled

#2 ITX Interlock signals for each axis

0: Enabled
1: Disabled

#3 DIT The interlock signal for each axis direction is:

0: Valid.
1: Invalid.

#4 DAU When bit 3 (DIT) of parameter No. 3003 is set to 0, the interlock signal for each axis direction is:

0: Valid only in manual operation, and invalid in automatic operation.
1: Valid in either manual operation or automatic operation.

	#7	#6	#5	#4	#3	#2	#1	#0
3004							BCY	BSL

[Input type] Parameter input
[Data type] Bit path

#0 BSL The block start interlock signal *BSL and cutting block start interlock signal *CSL are:
0: Disabled.
1: Enabled.

#1 BCY When more than one operation is performed by one block command such as a canned cycle, the block start interlock signal *BSL is:
0: Checked only at the beginning of the first cycle.
1: Checked at the beginning of every cycle.

	#7	#6	#5	#4	#3	#2	#1	#0
3008						XSG		

[Input type] Parameter input
[Data type] Bit path

> **NOTE**
> When this parameter is set, the power must be turned off before operation is continued.

#2 XSG A signal assigned to an X address is:
0: Fixed at the address.
1: Able to be reassigned to an arbitrary X address.

> **NOTE**
> When this parameter is set to 1, set parameter No. 3013, No. 3014, No. 3012, and No. 3019. If parameter No. 3013 and No. 3014 are not set, the deceleration signal for reference position return *DEC is assigned to bit 0 of <Xn000>. If parameter No. 3012 and No. 3019 are not set, the skip signal, the PMC axis control skip signal, the measurement position arrival signal, the interlock signal for each axis direction, and the tool compensation value write signal are assigned to <Xn000>.

	#7	#6	#5	#4	#3	#2	#1	#0
5009								GSC

[Input type] Parameter input
[Data type] Bit path

> **NOTE**
> When this parameter is set, the power must be turned off before operation is continued.

#0 GSC When the function for direct input of offset value measured B is used, an offset write input signal is input from:

0: Machine side
1: PMC side

> **NOTE**
> When the interlock function for each axis direction is enabled (when bit 3 (DIT) of parameter No. 3003 is set to 0), switching can also be made between input from the machine side and input from PMC side for the interlock function for each axis direction.

	#7	#6	#5	#4	#3	#2	#1	#0
11600						D3IT		

[Input type] Parameter input
[Data type] Bit path

#2 D3IT In the 3-dimensional coordinate system conversion mode, the valid interlock signals (interlock signal for each axis (*ITx) or interlock signal for each axis direction (MITx, PITx)) are:

0: The signals for all of the target axes for 3-dimensional coordinate system conversion.
1: The signals for axes along which a movement is made during 3-dimensional coordinate system conversion.

Note

NOTE

1 The interlock signal for each axis direction (T series) can be used regardless of whether the function for direct input of offset value measured B is provided or not.

2 When an interlock is being applied to an axis, "I" appears on the left side of the axis address of the axis on the coordinate position display screen.

3 There are the following functions to invalidate each interlock signal temporarily.
   - (1) Interlock signal is invalid to the axes engaged in the synchronization establishment of axis synchronous control.
   - (2) Interlock signal is invalid to slave axis in axis synchronous control.
   - (3) In arbitrary angular axis control, when a movement is made along the angular axis only, interlocking the perpendicular axis does not interlock a movement along the perpendicular axis made by a movement along the angular axis.
   - (4) Interlock signal is invalid to slave axis in EGB synchronization.
   - (5) All axes interlock signal and interlock signal for each axis are invalid to a spindle during arbitrary speed threading.
   - (6) Interlock signal of the slave axis is invalid to the superimposed control pulse added from the master axis during superimposed control.
   - (7) In spindle orientation, all axes interlock signal and interlock signal for each axis are checked only when a block is started. A signal is ignored if input during the execution of the block.
   - (8) Interlock signal is invalid to the axis control command of the real-time custom macro.
   - (9) In polygon turning, interlock signal is invalid to the tool rotation axis while synchronous operation.
   - (10) Interlock signals are invalid for PMC axis control.
   - (11) Interlock signal is invalid to the synchronous slave axis of synchronous control. Interlock signal is invalid to the composite side of composite control.

5 If interlock is applied to the oscillation axis during oscillation motion, the oscillation axis stops immediately.

6 In synchronous control, interlock signals on the synchronous master side are effective for the synchronous slave axes.
   In composite control, interlock signals in the specified path are effective.

7 The behavior of interlock signals in each axis or interlock signal for each axis direction during 3-dimensional coordinate system conversion mode follows the setting of bit 2 (D3IT) of parameter No.11600 and bit 5 (ITM) of parameter No.11223. For details, see the sections on "3-dimensional coordinate conversion".

2.6 MODE SELECTION

Overview

The mode selection signal is a code signal consisting of the three bits MD1, MD2, and MD4. The following five modes can be selected depending on the combination of these signals.

- Memory edit (EDIT)
- Memory operation (MEM)
- Manual data input (MDI)
- Manual handle/incremental feed (HANDLE/INC)
- Manual continuous feed (JOG)

And in addition, DNC operation mode can be selected by combining the memory operation (MEM) mode setting and the DNCI signal. Manual reference position return mode can be selected by combining the manual continuous feed (JOG) mode setting and the ZRN signal.
The currently selected operation mode can be posted by outputting the operation mode check signal.

Signals

Signals for mode selection

Select the desired mode by setting signals for mode selection listed below according to the setting shown in Table 2.6 (a).

Mode selection signals MD1,MD2,MD4<Gn043.0 to .2>

DNC operation selection signal DNCI<Gn043.5>

Signal for selecting manual reference position return ZRN<Gn043.7>

Signals for mode check

Check the current mode by reading the mode check signal(s) according to the setting shown in Table 2.6 (a).

Signal for checking incremental feed selection MINC<Fn003.0>

Signal for checking manual handle feed selection MH<Fn003.1>

Signal for checking jog feed selection MJ<Fn003.2>

Signal for checking manual data input selection MMDI<Fn003.3>

Signal for checking DNC operation selection MRMT<Fn003.4>

Signal for checking memory operation selection MMEM<Fn003.5>

Signal for checking program edit selection MEDT<Fn003.6>

Signal for checking teach-in selection MTCHIN<Fn003.7>

Signal for checking manual reference position return selection MREF<Fn004.5>

Table 2.6 (a) Mode selection signals and corresponding check signals
(A hyphen (-) indicates that the mode is not related to the status of the signal.)

Mode		Input signal					Output signal
		MD4	MD2	MD1	DNCI	ZRN	
Automatic operation	Manual data input (MDI)	0	0	0	-	-	MMDI
	Memory operation (MEM)	0	0	1	0	-	MMEM
	DNC operation (RMT)	0	0	1	1	-	MRMT
Memory edit (EDIT)		0	1	1	-	-	MEDT
Manual operation Manual	Manual handle/ incremental feed (HANDLE/INC)	1	0	0	-	-	MH,MINC
	Jog feed	1	0	1	-	0	MJ
	Manual reference position return	1	0	1	-	1	MREF
	Teach-in handle feed	1	1	1	-	-	MTCHIN
	Teach-in jog feed	1	1	0	-	-	MTCHIN

Signal address

	#7	#6	#5	#4	#3	#2	#1	#0
Gn043	ZRN		DNCI			MD4	MD2	MD1

Fn003	MTCHIN	MEDT	MMEM	MRMT	MMDI	MJ	MH	MINC
Fn004			MREF					

Note

Precautions on modes and mode switching

NOTE

1 In MDI mode, the cycle start lamp signal STL turns to “0” and the CNC stops as soon as the commands entered via the MDI have been executed. But the feed hold lamp signal SPL does not turn to “1”. Therefore, another command can be entered from the manual data input unit under this condition.

2 Manual operation in jog feed mode
   (1) When bit 0 (JHD) of parameter No. 7100 is set to 0
       Only jog feed is possible.
   (2) When bit 0 (JHD) of parameter No. 7100 is set to 1
       Both jog feed and manual handle feed are possible, provided the manual handle feed function is installed.

3 Manual operation in manual handle/incremental feed mode.
   (1) When the manual handle feed function is not used
       Incremental feed is valid.
   (2) When the manual handle feed function is used and bit 0 (JHD) of parameter No. 7100 is set to 0
       Only manual handle feed is valid.
   (3) When the manual handle feed function is used and bit 0 (JHD) of parameter No. 7100 is set to 1
       Incremental feed and manual handle feed are valid.

4 When switching to manual data input mode is made during operation in memory operation mode, the CNC enters the automatic operation stop state after executing the command in the current block. Cycle start lamp signal STL is then set to “0”.
   In this case, feed hold lamp signal SPL is not set to “1” (Fig. 2.6 (a)).
   When switching to memory operation mode is made during operation in manual data input mode, the CNC enters memory operation mode after executing the currently executed command. To perform memory operation at this time, the program for MDI operation must have been executed (Fig. 2.6 (b))

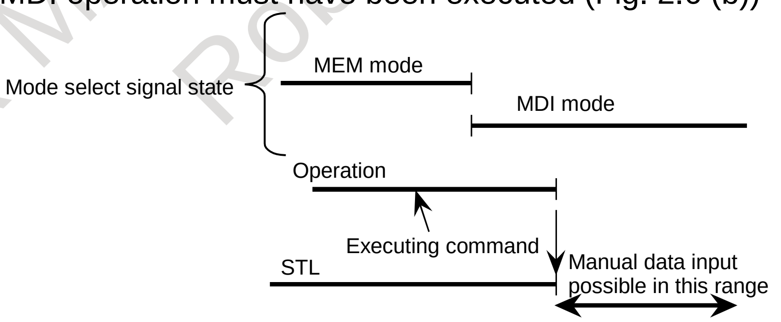

Fig. 2.6 (a)

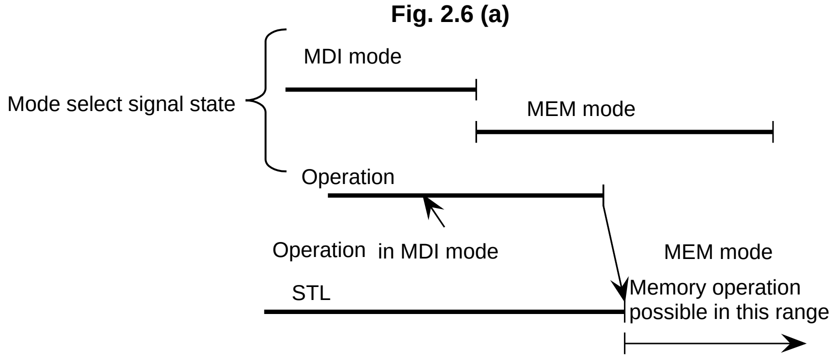

Fig. 2.6 (b)

NOTE

5 When the HANDLE/INC mode is selected while the CNC is operating in the MEM, RMT or MDI mode, the automatic or MDI operation stops, the Cycle time lamp signal STL turns to “0”, the feed hold lamp signal SPL simultaneously turns to “1”, and the CNC enters the HANDLE/INC mode. Under these conditions, manual handle feed or incremental feed by axis direction select signal is permitted. Since the MEM, RMT or MDI mode commands are held, operation can be restarted by the cycle start signal and by selecting the MDI, RMT or MEM mode. However, if operation was stopped by switching to the HANDLE/INC mode during manual data input or during automatic operation, it can be restarted only by reactivating the mode in use before the operation was stopped (Fig. 2.6 (c)).

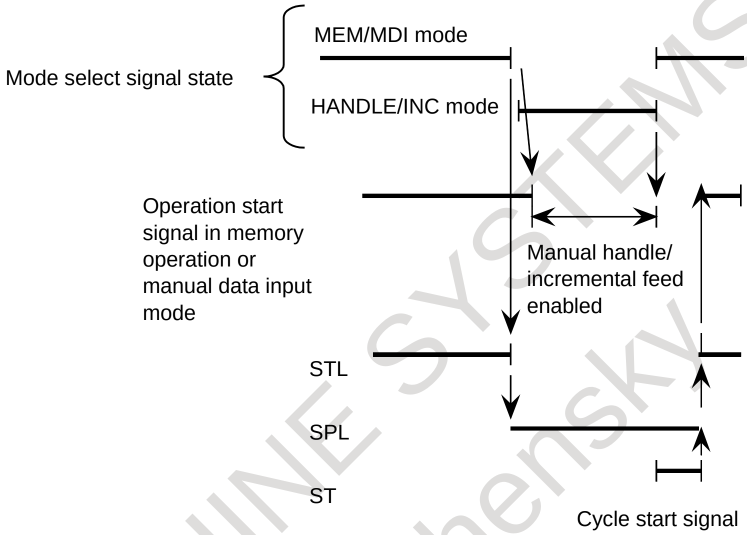

Fig. 2.6 (c)

NOTE

6 When the JOG mode is selected during MEM, RMT or MDI mode operation, operation stops, the cycle time lamp signal STL turns to “0”, the feed hold lamp signal SPL simultaneously turns to “1”, and the CNC enters the JOG mode. Under these conditions, manual feed by feed axis direction select signal is permitted. Operation can be restarted by returning to the original mode, as described for HANDLE/INC mode (Fig. 2.6 (d)). When the mode is switched to the JOG mode during manual handle feed or during incremental feed operation, the CNC ignores the manual handle feed or incremental feed command and manual jog feed becomes effective. If a feed axis direction select signal turns to 1 before the JOG mode is selected, that signal is ignored. The feed axis select signal is selected by turning the necessary feed axis direction signal to “1” after turning all the feed axis direction select signals to “0” (Fig. 2.6 (e)).
It is possible to perform handle feed in JOG mode by activating bit 0 (JHD) of parameter No. 7100. For details, refer to Note 2.

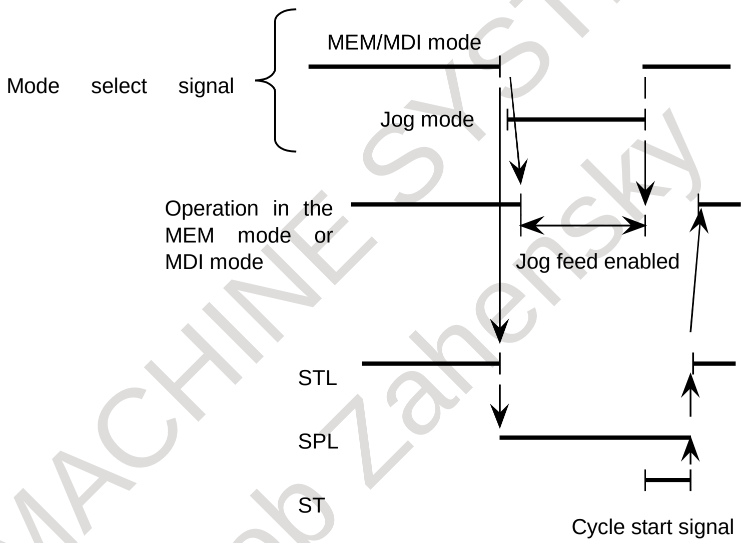

Fig. 2.6 (d)

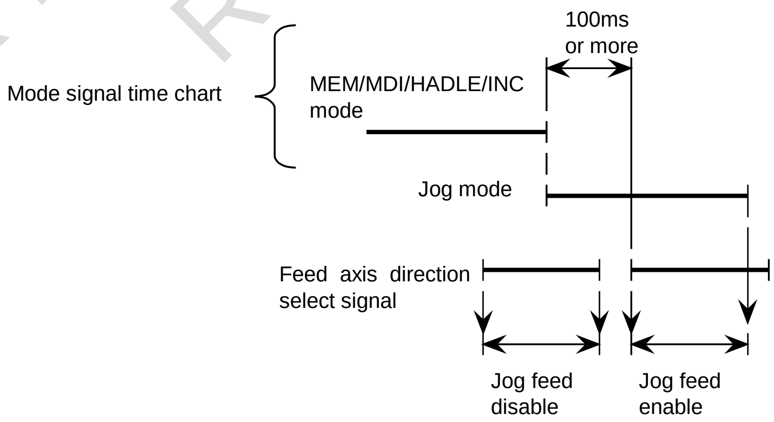

Fig. 2.6 (e)

NOTE

7 The mode switching operation is summarized in the time chart below (Fig. 2.6 (f)).

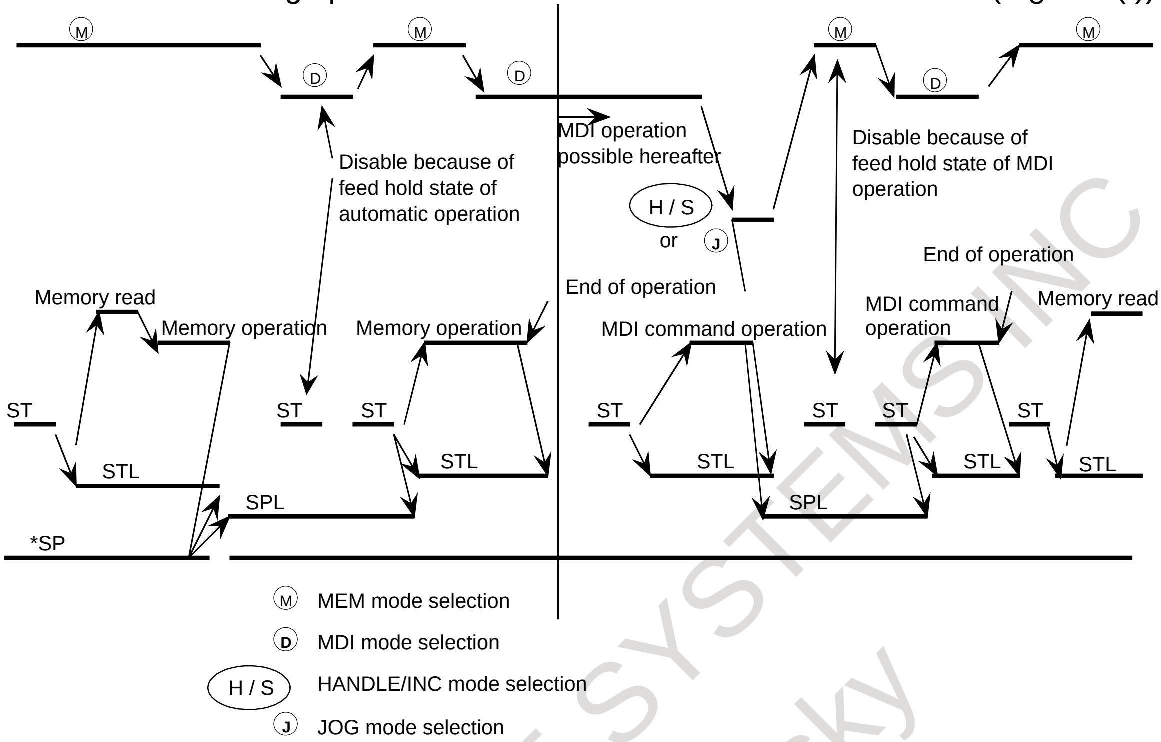

Fig. 2.6 (f) Mode signal time chart

8 Invalid mode selection signals
When mode selection signals MD4, MD2, and MD1 are set to “0”, “1”, and “0”, respectively, the mode before the signals are changed is selected. When mode selection signals MD4, MD2, and MD1 have been set to “0”, “1”, and “0”, respectively, since power-on, the MDI mode is selected.

9 Notes on output signals:
When bit 0 (JHD) of parameter No. 7100 is set to 1:
(1) In the jog feed mode, the output signals are set as follows:
MJ=”1”, MH=”0”
(2) In the manual handle feed mode, the output signals are set as follows:
MH=”1”, MINC=”0”

10 Teach-in handle/Jog mode selection output signal
(1) In teach-in handle feed mode (mode selection signals MD4, MD2, and MD1 are “1”, ”1”, and “1”), signal for checking teach-in selection MTCHIN<Fn003.7> and signal for checking manual handle feed selection MH<Fn003.1> turn to "1".
The status displayed on the bottom right on screen changes to "THND".
(2) In teach-in jog feed mode (mode selection signals MD4, MD2, and MD1 are “1”, “1”, and “0”), signal for checking teach-in selection MTCHIN<Fn003.7> and signal for checking jog feed selection MJ<Fn003.2> turn to "1".
The status displayed on the bottom right on screen changes to "TJOG".

Parameter

	#7	#6	#5	#4	#3	#2	#1	#0
7100								JHD

[Input type] Parameter input
[Data type] Bit path

#0 JHD Manual handle feed in JOG feed mode or incremental feed in the manual handle feed is:
0: Invalid.
1: Valid.

2.7 STATUS OUTPUT SIGNAL

The table below lists the status output signals. They indicate the state of the CNC. See the sections listed in the Table 2.7 (a) for details of each signal.

Table 2.7 (a)

Signal name	Symbol	Reference section
Alarm signal	AL	Alarm signals
Battery alarm signal	BAL	Alarm signals
Reset signal	RST	Reset & rewind
Rewinding signal	RWD	Reset & rewind
Tapping signal	TAP	Canned cycle for drilling
Moving signals	MV1 to MV8	Axis moving status output
Moving direction signals	MVD1 to MVD8	Axis moving status output
In-position signals	INP1 to INP8	In-position check
Rapid traversing signal	RPDO	This section
Cutting feed signal	CUT	This section
Threading signal	THRD	Threading
Constant surface speed signal	CSS	Constant surface speed control
Inch input signal	INCH	Inch/metric switching
Dwell status signal	DWL	This section

Signal

Rapid traversing signal RPDO<Fn002.1>

[Classification] Output signal
[Function] This signal indicates that a move command is being executed at rapid traverse.
[Output cond.] "1" indicates an axis starts moving after rapid traverse has been selected; 0 indicates that an axis starts moving after a feedrate other than rapid traverse has been selected. This holds true for both automatic and manual operation modes.

NOTE
1. Rapid traverse in automatic operation includes all rapid traverses in canned cycle positioning, automatic reference position return, etc., as well as the move command G00. Rapid traverse in manual operation also includes rapid traverse in reference position return.
2. Once rapid traverse has been selected, this signal remains "1", including during a stop, until another feedrate has been selected and movement has been started.

Cutting feed signal CUT<Fn002.6>

[Classification] Output signal

[Function] Signals that cutting feed is being performed by automatic operation.

[Output cond.] This signal is set to “1” in the following case:

- When cutting feed is being performed by automatic operation (cutting feed for linear interpolation, circular interpolation, helical interpolation, thread cutting, skip cutting, or cutting in canned cycle)

> ⚠ **CAUTION**
> This signal is not set to “1” in the feed hold state.

> **NOTE**
> This signal is set to “1” even when the feedrate override is 0%, and even during interlock.

Dwell status signal DWL <Fn526.5>

[Classification] Output signal

[Function] This signal indicates that dwell (G04) is in progress at the automatic operation.

[Output cond.] This signal is set to “1” in the following case:

- When dwell (G04) is being performed

This signal is set to 0 in the following case.

- When dwell (G04) is not performed

When bit 2 (DWS) of parameter No.10351 is 1, dwell status signal DWL <Fn526.5> can be used.

Signal address

	#7	#6	#5	#4	#3	#2	#1	#0
Fn002		CUT					RPDO

Parameter

	#7	#6	#5	#4	#3	#2	#1	#0
10351						DWS		

[Input type] Parameter input

[Data type] Bit

> **NOTE**
> When this parameter is set, the power must be turned off before operation is continued.

#2 DWS Dwell status signal DWL <Fn526.5> is:

0: Disabled.

1: Enabled.

2.8 VRDY OFF ALARM IGNORE SIGNAL

Overview

The German VDE safety standard requires that the motor be deactivated when the safety guard is opened. By using the VRDY OFF Alarm Ignore signal, however, the CNC can be restarted without resetting, even if the safety guard has been opened.

Signal

All-axis VRDY OFF alarm ignore signal IGNVRY<Gn066.0>

[Classification] Input signal

[Function] Disables the detection of servo alarm SV0401, "IMPROPER V_READY OFF", for all axes.

[Operation] When this signal is set to logical "1", the control unit operates as follows:

- The control unit does not issue servo alarm SV0401, "IMPROPER V_READY OFF", even when the servo amplifier ready signal goes off. The control unit, however, sets servo ready signal SA to "0". The SA signal can remain set to "1", depending on the setting of bit 6 (SAK) of parameter No. 1804.

Each-axis VRDY OFF alarm ignore signal IGVRY1 to IGVRY8<Gn192>

[Classification] Input signal

[Function] Disables the detection of servo alarm SV0401, "IMPROPER V_READY OFF", for the corresponding axis. These signals correspond to the controlled axes. The suffixed number of each signal corresponds to the number of the controlled axis.

[Operation] When this signal is set to logical "1", the control unit operates as follows:

- The control unit does not issue servo alarm SV0401, "IMPROPER V_READY OFF", even when the servo amplifier ready signal for the corresponding axis goes off. The servo ready signal SA, however, is set to "0". The SA signal, however, can remain set to "1" depending on the setting of bit 6 (SAK) of parameter No. 1804.

Signal address

	#7	#6	#5	#4	#3	#2	#1	#0
Gn066								IGNVRY
Gn192	IGVRY8	IGVRY7	IGVRY6	IGVRY5	IGVRY4	IGVRY3	IGVRY2	IGVRY1

Parameter

	#7	#6	#5	#4	#3	#2	#1	#0
1804		SAK		IVO				

[Input type] Parameter input
[Data type] Bit path

#4 IVO When an attempt is made to release an emergency stop while the VRDY OFF alarm ignore signal is "1":

0: The emergency stop state is not released until the VRDY OFF alarm ignore signal is set to "0".

1: The emergency stop state is released.

> **NOTE**
> When a reset is issued while the VRDY OFF alarm ignore signal is set to 1 and the motor activating current is low, the reset state can also be released, provided this parameter is set to 1.

#6 SAK When the VRDY OFF alarm ignore signal IGNVRY is "1", or when the VRDY OFF alarm ignore signals IGNVRYn are 1:

0: Servo ready signal SA is set to "0".

1: Servo ready signal SA remains set to "1".

Alarm and message

Number	Message	Description
SV0401	IMPROPER V_READY OFF	Although the ready signal (PRDY) of the position control was ON, the ready signal (VRDY) of the velocity control was OFF.

Caution

⚠ **CAUTION**

1. When the VRDY OFF alarm ignore signal IGNVRY is "1" and the control enters NOT READY status due to emergency stop or a servo alarm and then the control is reset, reset processing is not terminated until the VRDY OFF alarm ignore signal is set to "0".
2. When the VRDY OFF alarm ignore signal is set to "1" and the servo amplifier ready signal is set to off, the motor is freed from the drive, but follow up is not performed. To perform follow up, set the servo off signal SVFx to "1".

Note

NOTE

While the VRDY OFF alarm ignore signal is set to "1", and a servo alarm other than alarm SV0401 occurs, the control unit detects the alarm.

2.9 UNEXPECTED DISTURBANCE TORQUE DETECTION FUNCTION

Overview

Machine collision, defective, and damaged cutters cause a large load torque on the servo and spindle motors, compared with normal rapid traverse or cutting feed. This function detects the disturbance torque on the motors and sends this value as an estimated load torque to the PMC. If the detected disturbance torque value is abnormally great compared with the value specified in the parameter, the function stops the servo/spindle motor as early as possible or reverses the motor by an appropriate value specified in a parameter, in order to minimize possible damage to the machine. (The function to reverse motors is effective only for servo motors.)

Explanation

The unexpected disturbance torque detection function is further divided as follows:

(1) Estimated disturbance torque output function
The CNC is always calculating the estimated disturbance torque for the motor (excluding acceleration/deceleration torque). The estimated disturbance torque output function enables the PMC to read the calculated torque using the window function.

(2) Unexpected disturbance torque detection alarm function
This function stops motors or reverses them by an amount specified in a parameter, causing the CNC to output an alarm, whenever the disturbance torque is greater than the value specified in a parameter. (The function to reverse motors is effective only for servo motors.)]
This function can be used for the trigger condition of recording CNC information by Machine state monitoring function.

(3) Unexpected disturbance torque detection group function
This function allows you to divide servo axes into desired groups. When the disturbance torque obtained by the estimated disturbance torque output function is greater than a parameter-set value, this function stops motors immediately. The function immediately stops all axes that are set for the same group by parameter setting (including axes of which group number set to 0) then places them in the interlock state. When a value is set in parameter No. 2103, this function reverses the motors by the set amount in a direction opposite to the advance direction, then places all the axes of the same group in the interlock state.

NOTE

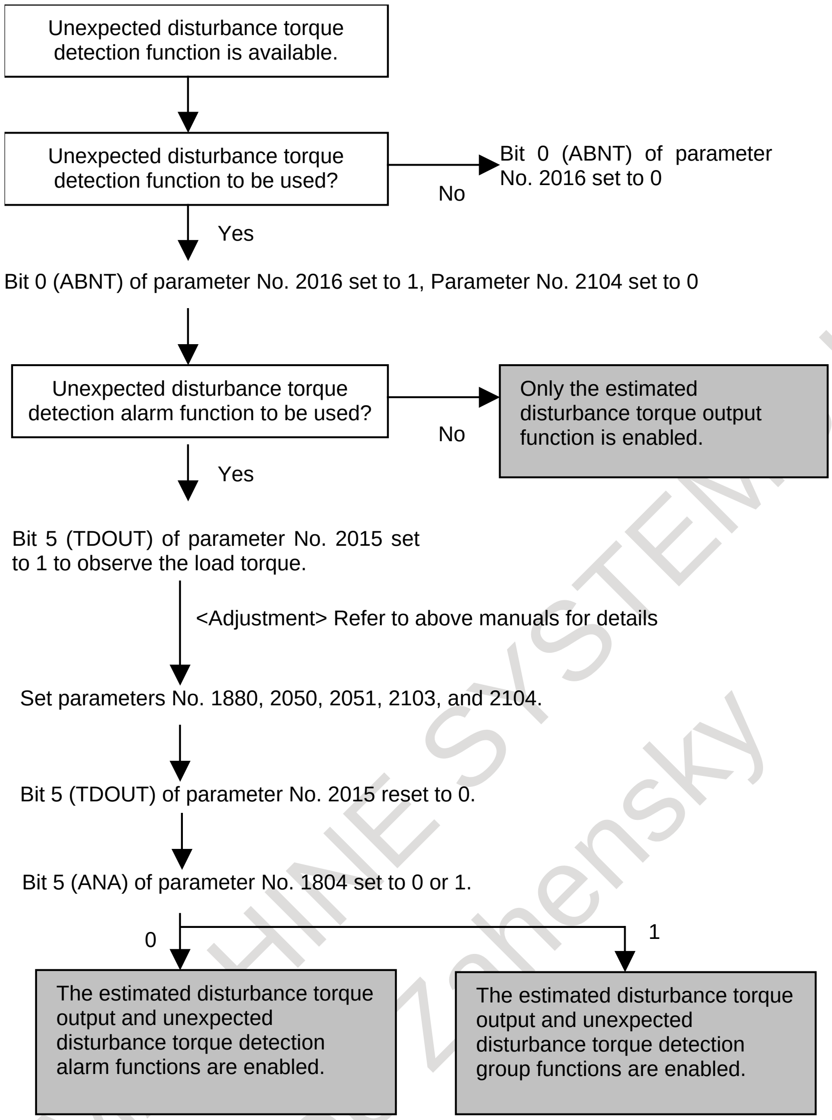
Select the unexpected disturbance torque detection alarm function or unexpected disturbance torque detection group function by setting bit 5 (ANA) of parameter No. 1804.
You cannot use these functions at the same time.

Unexpected disturbance torque detection can also be disabled only for specific axes by using bit 5 (ABDSW) of parameter No. 2215 for the unexpected disturbance torque detection function and unexpected disturbance torque detection ignore signals IUDD1 to IUDD8 <Gn125>. (This function is effective only for servo motors.)

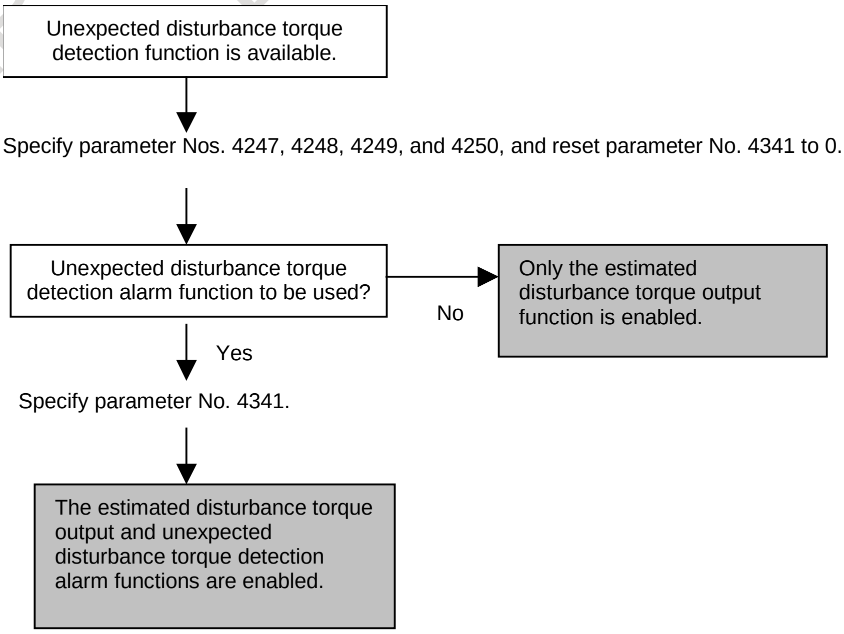
Procedure for parameter setting

The following flowcharts explain how to specify parameters for the unexpected disturbance torque detection function.
Refer to following manuals for details :
FANUC AC SERVO MOTOR α*i* series PARAMETER MANUAL B-65270EN
FANUC AC SPINDLE MOTOR α*i* series PARAMETER MANUAL B-65280EN

(1) Servo axis



(2) Spindle



- Timing chart when the unexpected disturbance torque detection group function is used

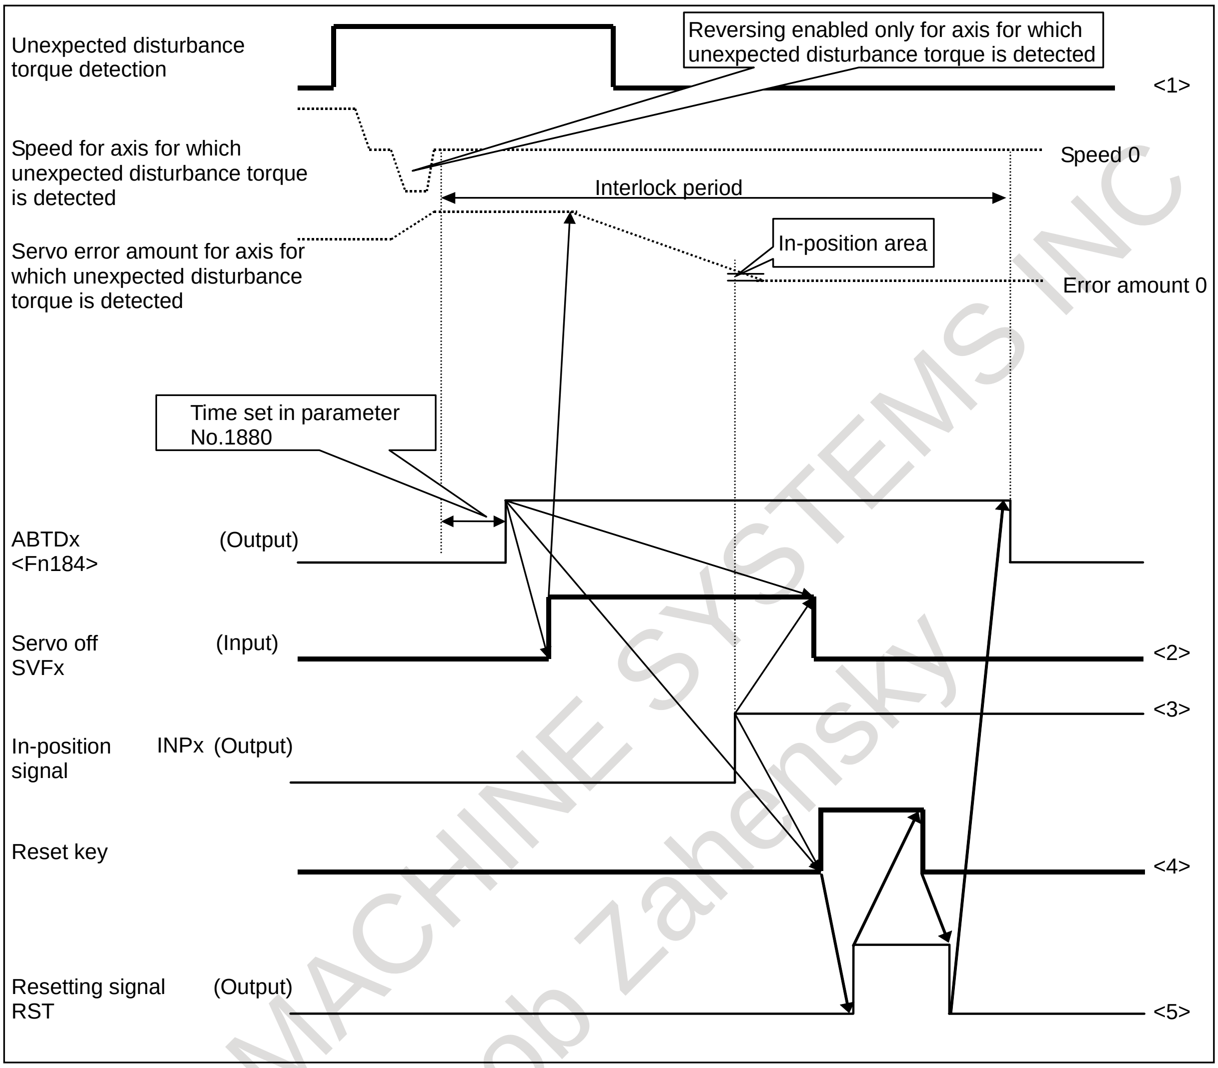


Fig. 2.9 (a) Timing chart of the unexpected disturbance torque detection group function

<1> When an unexpected disturbance torque is detected, servo motors are stopped immediately. Axes with the same group number set in parameter No. 1881 and axes with 0 set in the parameter are all stopped immediately then placed in the interlock state. At this time, axis movements are stopped regardless of commands of the CNC, so there is a difference between the coordinates held by the CNC and the actual motor position. This difference is accumulated as a servo error amount.

<2> When the operation is restarted, a follow-up operation is performed by inputting the servo off signal SVFx to match the coordinates held by the CNC and the actual motor position. Input the servo off signals SVFx for all axes of the same group (the axes with the same group number set and axes with group number 0 set). When servo off signals SVFx are input, the follow up signal *FLWU <Gn007.5> must be set to “0”, and bit 0 (FUPx) of parameter No. 1819 must be set to 0.

<3> After input servo off signal SVFx, in-position signal INPx <Fn104> becomes “1” on when the error amount enters the in-position width.

<4> Check that the in-position signals INPx for all axes that belong to the same group have became “1”, then input a reset (ERS or a reset key).

> ⚠ **CAUTION**
> When an unexpected disturbance torque is detected using the unexpected disturbance torque detection group function, be sure to follow the timing chart shown above to input servo off signals SVFx then perform a reset operation. If a reset is made without inputting the servo off signals SVFx, a shock may apply to the machine.

> **NOTE**
> 1 The servo off signal SVFx must be input with follow up signal *FLWU <Gn007.5> set to “0” and bit 0 (FUPx) of parameter No. 1819 set to 0.
> 2 Input the servo off signals SVFx for all axes of the group to which the axis with an unexpected disturbance torque detected belongs. Also for axes for which 0 is set in parameter No. 1881, input the corresponding servo off signals SVFx.
> 3 When an unexpected disturbance torque is detected for a PMC axis or when an axis for which an unexpected disturbance torque is detected belongs to a group that includes a PMC axis, all axes of the cluster to which that PMC axis belongs are placed in the interlock state.
> 4 When an unexpected disturbance torque is detected for a spindle (serial spindle), ABTSP1 <Fn090.1> or ABTSP2 <Fn090.2> is output immediately. The setting of parameter No. 1880 is ignored.
> 5 When an unexpected disturbance torque is detected for a spindle (serial spindle), servo axes are not stopped. When the servo axes must be stopped, stop them by using ladder.

Signal

Servo axis unexpected disturbance torque detection signal ABTQSV <Fn090.0>

[Classification] Output signal

[Function] Informs the PMC that an unexpected disturbance torque was detected on a servo axis.

[Output cond.] This signal becomes “1” if:

- An Unexpected disturbance torque is detected for a servo axis, Cs axis, spindle positioning axis, or spindle axis during rigid tapping.

First-spindle unexpected disturbance torque detection signal ABTSP1 <Fn090.1>

[Classification] Output signal

[Function] Informs the PMC that an unexpected disturbance torque was detected on the first spindle axis.

[Output cond.] This signal becomes “1” if:

- An unexpected disturbance torque is detected for the first spindle under speed control.

Second-spindle unexpected disturbance torque detection signal ABTSP2 <Fn090.2>

[Classification] Output signal

[Function] Informs the PMC that an unexpected disturbance torque was detected on the second spindle axis.

[Output cond.] This signal becomes “1” if:

- An unexpected disturbance torque is detected for the second spindle under speed control.

Third-spindle unexpected disturbance torque detection signal ABTSP3 <Fn090.3>

[Classification] Output signal

[Function] Informs the PMC that an unexpected disturbance torque was detected on the third spindle axis.

[Output cond.] This signal becomes “1” if:

- An unexpected disturbance torque is detected for the third spindle under speed control.

Fourth-spindle unexpected disturbance torque detection signal ABTSP4 <Fn091.4>

[Classification] Output signal

[Function] Informs the PMC that an unexpected disturbance torque was detected on the fourth spindle axis.

[Output cond.] This signal becomes “1” if:

- An unexpected disturbance torque is detected for the fourth spindle under speed control.

Unexpected disturbance torque detection signals ABDT1 to ABDT8 <Fn184>

[Classification] Output signal

[Function] Notifies the PMC of the axis on which an unexpected disturbance torque was detected. The number at the end indicates the control axis number.

[Output cond.] This signal becomes “1” if:

- An unexpected disturbance torque is detected. (At this time, the servo axis unexpected disturbance torque detection signal ABTQSV<Fn090.0> also becomes “1”.)

The Table 2.9 (a) summarizes the alarms and signals output by each function.

Table 2.9 (a)

	Signal output		Alarm	
	ABTQSV	ABTSP1 ABTSP2 ABTSP3 ABTSP4	SV0409	SP0754
Servo axis	O	-	O	-
Cs contour control	O	-	O	-
Spindle positioning axis	O	-	O	-
Rigid tapping	O	-	-	O
Spindle axis for speed control	-	O	-	O

Unexpected disturbance torque detection ignore signal IUDD1 to IUDD8<Gn125>

[Classification] Input signal

[Function] Disables the unexpected disturbance torque detection function for each axis. This signal is provided for each control axis and the value at the end indicates the control axis number.

[Output cond.] If this signal is “1”, the unexpected disturbance torque of the target axis is not detected. Before using this signal, set bit 5 (ABDSW) of the parameter No. 2215, used for the unexpected disturbance torque detection function, to 1.

Signal address

	#7	#6	#5	#4	#3	#2	#1	#0
Fn090					ABTSP3	ABTSP2	ABTSP1	ABTQSV
Fn091				ABTSP4				
Fn184	ABDT8	ABDT7	ABDT6	ABDT5	ABDT4	ABDT3	ABDT2	ABDT1

	#7	#6	#5	#4	#3	#2	#1	#0
Gn125	IUDD8	IUDD7	IUDD6	IUDD5	IUDD4	IUDD3	IUDD2	IUDD1

Parameters

- Common to servo axis and spindle

	#7	#6	#5	#4	#3	#2	#1	#0
1804			ANA					

[Input type] Parameter input
[Data type] Bit path

#5 ANA When an unexpected disturbance torque is detected for an axis:
0: Movement along all axes is stopped, and a servo alarm is output.
1: No servo alarm is output, and movement along only the axes of the group containing the axis with the unexpected disturbance torque is stopped in interlock mode. Each unexpected disturbance torque detection signal is output. The unexpected disturbance torque detection signal that has been output is cleared by a reset. The group number of each axis is set in parameter No.1881.

	#7	#6	#5	#4	#3	#2	#1	#0
1805				TSM	TSA			

[Input type] Parameter input
[Data type] Bit path

#3 TSA As the unexpected disturbance torque detection level during dwell, M code execution, and automatic operation halt state:
0: The threshold value for rapid traverse is used. (parameter No. 2142)
1: The threshold value for cutting feed is used. (parameter No. 2104)
If this parameter is set to 1, bit 3 (ABG0) of parameter No.2200 and bit 7 (ABT) of parameters No.2215 need to be set to 1.

#4 TSM As the unexpected disturbance torque detection level in the jog feed mode (excluding manual rapid traverse) and manual handle feed mode:
0: The threshold value for rapid traverse is used. (parameter No. 2142)
1: The threshold value for cutting feed is used. (parameter No. 2104)
This parameter is valid when bit 3 (ABG0) of parameter No. 2200 is set to 1.

1880	Abnormal load detection alarm timer

[Input type] Parameter input
[Data type] Word path
[Unit of data] msec
[Valid data range] 0 to 32767
This parameter sets the time from the detection of an unexpected disturbance torque until a servo alarm is issued.
When 0 is set, however, the specification of 200 msec is assumed.

1881	Group number when an unexpected disturbance torque is detected

[Input type] Parameter input
[Data type] Byte axis
[Valid data range] 0 to 32
Set the group number on each axis when an unexpected disturbance torque is detected.

When an unexpected disturbance torque is detected on an axis, only the movements on those axes that belong to the same group as the axis are stopped.
If 0 is set for an axis, the movement on the axis is stopped when an unexpected disturbance torque is detected on any other axis.
This parameter is valid when bit 5 (ANA) of parameter No. 1804 is set to 1.

[Example] When the settings indicated below are made, and an unexpected disturbance torque is detected on the 6th axis, the movements on the 2nd axis, 4th axis, 6th axis, and 7th axis are stopped. When an unexpected disturbance torque is detected on the 4th axis, the movements on the 4th axis and the 7th axis are stopped.

Parameter No. 1881	Setting value
(1st axis)	1
(2nd axis)	2
(3rd axis)	1
(4th axis)	0
(5th axis)	3
(6th axis)	2
(7th axis)	0

- Servo axis

	#7	#6	#5	#4	#3	#2	#1	#0
2015			TDOUT					

[Input type] Parameter input
[Data type] Bit axis

#5 TDOUT Select output to the check board (for each axis)
0: Output the torque command to the check board.
1: Output the estimated load torque to the check board.

	#7	#6	#5	#4	#3	#2	#1	#0
2016								ABNT

[Input type] Parameter input
[Data type] Bit axis

#0 ABNT Unexpected disturbance torque detection function (for each axis) is
0: Disabled
1: Enabled
When using the unexpected disturbance torque detection alarm function and estimated disturbance torque output function, enable the unexpected disturbance torque detection function.

2050	Velocity control observer

[Input type] Parameter input
[Data type] Word axis
[Valid data range] 0 to 32767
Be sure to set this parameter to 3559.
When using the velocity loop observer (by setting bit 2 (OBEN) of parameter No. 2003 to 1), set 956 in this parameter.

2051	Velocity control observer

[Input type] Parameter input

[Data type] Word axis
[Valid data range] 0 to 32767
Be sure to set this parameter to 3329.
When using the velocity loop observer (by setting bit 2 (OBEN) of parameter No. 2003 to 1), set 510 in this parameter.

2103	Retraction distance upon the detection of an unexpected disturbance torque

[Input type] Parameter input
[Data type] Word axis
[Unit of data] Detection unit
[Valid data range] 0 to 32767
This parameter specifies the distance by which the tool is to be retracted, by reversing the motor, if an unexpected disturbance torque is detected.
When the motor is rotating at low speed, however, the tool may be retracted too far. To prevent this, the motor is stopped, instead of being reversed, while the specified feedrate is less than the value listed in the table below.
When this parameter is set to value A, the detection of an unexpected disturbance torque causes the tool to be retracted in the reverse direction by the distance A, then stopped, if the specified feedrate is equal to or greater than the value listed below.

Detection unit	Feedrate
10 μm	A / 0.8 mm/ min
1 μm	A / 8 mm/ min
0.1 μm	A / 80 mm/ min
0.01 μm	A / 800 mm/ min
0.001 μm	A / 8000 mm/ min

When this parameter is set to 0, the motor stops immediately upon the detection of unexpected disturbance torque.

2104	Threshold for unexpected disturbance torque detection alarm

[Input type] Parameter input
[Data type] Word axis
[Unit of data] Torque command unit
[Valid data range] 0 to 7282 (The maximum motor torque is 7282, regardless of the motor type.)
This parameter specifies the threshold load torque at which an unexpected disturbance torque detection alarm is issued.
Monitor the load torque by setting bit 5 (TDOUT) of parameter No. 2015 to 1 then, for this parameter No. 2104, set a value larger than the maximum monitored torque. An output of 4.4 V is equivalent to 7282 in the units of this parameter.

2142	Threshold for unexpected disturbance torque detection alarm for rapid traverse

[Input type] Parameter input
[Data type] Word axis
[Unit of data] Torque command unit
[Valid data range] 0 to 7282 (The maximum motor torque is 7282, regardless of the motor type.)
This parameter specifies the threshold load torque at which an unexpected disturbance torque detection alarm is issued.
Monitor the load torque by setting bit 5 (TDOUT) of parameter No. 2015 to 1 then, for this parameter No. 2104, set a value larger than the maximum monitored torque. An output of 4.4 V is equivalent to 7282 in the units of this parameter.
This parameter is enabled when bit 3 (ABG0) of parameter No. 2200 = 1.

	#7	#6	#5	#4	#3	#2	#1	#0
2200					ABG0			

[Input type] Parameter input
[Data type] Bit axis

#3 ABG0 The unexpected disturbance torque detection function for cutting or rapid traverse is:
0: Disabled.
1: Enabled.
When this function is disabled, the threshold value during cutting feed is used (parameter No. 2104).

	#7	#6	#5	#4	#3	#2	#1	#0
2215			ABDSW					

[Input type] Parameter input
[Data type] Bit axis

#5 ABDSW The Unexpected disturbance torque detection function for a specified axis:
0: Cannot be disabled.
1: Can be disabled.

- Parameters for spindle

	#7	#6	#5	#4	#3	#2	#1	#0
4015							SPLDMT	

[Input type] Parameter input
[Data type] Bit spindle

#1 SPLDMT Spindle load torque monitor function
0: The spindle load torque monitor function is disabled.
1: The spindle load torque monitor function is enabled.

4247	Magnetic flux compensation time constant for spindle load torque monitor

[Input type] Parameter input
[Data type] Word spindle
[Unit of data] msec
[Valid data range] 0 to 8192

This parameter is used to compensate the delay in the generation of magnetic flux in the spindle motor relative to the specified value. When 0 is set, it is assumed that the generation of magnetic flux is not delayed.
Standard setting depends of the motor model.

4248	Spindle load torque monitor constant

[Input type] Parameter input
[Data type] Word spindle
[Valid data range] 0 to 32767

This constant is determined by the maximum output torque and inertia of the motor. It is used for observer processing.
Standard setting depends of the motor model.

4249	Observer gain 1 for spindle load torque monitor

[Input type] Parameter input
[Data type] Word spindle
[Valid data range] 0 to 32767
Standard setting is 500.

4250	Observer gain 2 for spindle load torque monitor

[Input type] Parameter input
[Data type] Word spindle
[Valid data range] 0 to 32767
Standard setting is 500.

4341	Threshold for unexpected disturbance torque detection alarm

[Input type] Parameter input
[Data type] Word spindle
[Unit of data] 0.01%
[Valid data range] 0 to 10000
This parameter specifies the threshold load torque at which an unexpected disturbance torque detection alarm is issued for the spindle. Set a percentage (in units of 0.01 %) for the maximum output torque of the motor. When 0 is set, no Unexpected disturbance torque detection alarm is issued for the spindle.

Alarm and message

- Alarm related to servo axis

Number	Message	Description
SV0409	DETECT ABNORMAL TORQUE	An abnormal load was detected on the servo motor, or during Cs axis or spindle positioning. The alarm can be canceled by RESET.

- Alarm related to spindle

Number	Message	Description
SP0754	ABNORMAL TORQUE	An abnormal load was detected in a spindle motor. The alarm can be canceled by RESET.

Limitation

The following limitations are imposed on the abnormal load detection group function:
<1> Cannot be used with axes on which inter-path synchronous/composite control or inter-path superimposed control is performed.
<2> Cannot be used with axes belonging to different paths.
<3> Cannot be used with rigid tapping with spindles belonging to different paths.
<4> Does not support the inter-path flexible synchronization control function.
<5> Does not support the 3-dimensional rigid tapping function.

2.10 MACHINING CONDITION SELECTION FUNCTION

Overview

For AI contour control function, parameters which place importance on feedrate or precision are set and a precision level is specified according to the machining condition during machining. By using these parameters and level, parameters which satisfy the condition can automatically be calculated for machining.

Format

- Changing the precision level by programming

The precision level can be changed not only by using the precision level selection screen but also by programming the following format:

G05.1 Q1 Rx ;
x : Level (1 to 10)

Also with the format used for, high precision contour control, and AI high precision contour control, the precision level can be changed.

G05 P10000 Rx ;
x : Level (1 to 10)
G08 P1 Rx ;
x : Level (1 to 10)

⚠ **CAUTION**
Once a level is specified, it is kept valid even after the AI contour control mode is canceled.

Default level

By setting the default level for the precision level in parameter No. 11687, a return to the level set in parameter No. 11687 is made during power-off or a reset.
Set the default level to an integer from 1 to 10.
When the default level is set to 0, the current level is maintained.

Parameter

11687	Standard value of precision level when AI contour control is used

[Input type] Parameter input
[Data type] Byte path
[Valid data range] 0 to 10

Set standard value of precision level when AI contour control is used.
When the power is turned on or the system is reset, the precision level
0 : keeps its value.
1 to 10 : becomes the level set to this parameter.

	#7	#6	#5	#4	#3	#2	#1	#0
13600	MSA							MCR

[Input type] Parameter input
[Data type] Bit path

#0 MCR When an allowable acceleration rate adjustment is made with the machining condition selection function or (machining parameter adjustment screen, precision level selection screen), parameter No. 1735 for the deceleration function based on acceleration in circular interpolation is:
0: Modified.
1: Not modified.

#7 MSA When the machining condition selection function or is used, the acceleration rate change time (bell-shaped) (LV1, LV10) is:

0: Set using parameter Nos. 13612 and 13613.
1: Set using parameter Nos. 13662 and 13663.

	#7	#6	#5	#4	#3	#2	#1	#0
13601								MPR

[Input type] Parameter input
[Data type] Bit

> **NOTE**
> When this parameter is set, the power must be turned off before operation is continued.

#0 MPR The machining parameter adjustment screen is:
0: Displayed.
1: Not displayed.
Even if 1 is set in this parameter bit, the precision level selection screen for the machining condition selecting function are displayed.

13610	**Acceleration rate for look-ahead acceleration/deceleration before interpolation in AI contour control (precision level 1)**
13611	**Acceleration rate for look-ahead acceleration/deceleration before interpolation in AI contour control (precision level 10)**

[Input type] Parameter input
[Data type] Real axis
[Unit of data] mm/sec^2, inch/sec^2, deg/sec^2 (machine unit)
[Min. unit of data] Depend on the increment system of the applied axis
[Valid data range] Refer to the standard parameter setting table (D)
(When the machine system is metric system, 0.0 to +100000.0. When the machine system is inch system, machine, 0.0 to +10000.0)
Each of these parameters sets an acceleration rate for look-ahead acceleration/deceleration before interpolation in AI contour control. Set a value (precision level 1) with emphasis placed on speed, and a value (precision level 10) with emphasis on precision.

13612	**Acceleration rate change time (bell-shaped) when AI contour control is used (precision level 1)**
13613	**Acceleration rate change time (bell-shaped) when AI contour control is used (precision level 10)**

[Input type] Parameter input
[Data type] Byte path
[Unit of data] msec
[Valid data range] 0 to 127
Each of these parameters sets an acceleration rate change time (bell-shaped) in AI contour control. Set a value (precision level 1) with emphasis placed on speed, and a value (precision level 10) with emphasis on precision.

13614	**Allowable acceleration rate change amount for each axis in speed control based on acceleration rate change under control on the rate of change of acceleration (precision level 1)**
13615	**Allowable acceleration rate change amount for each axis in speed control based on acceleration rate change under control on the rate of change of acceleration (precision level 10)**

[Input type] Parameter input
[Data type] Real axis
[Unit of data] mm/sec^2, inch/sec^2, deg/sec^2 (machine unit)
[Min. unit of data] Depend on the increment system of the applied axis
[Valid data range] Refer to the standard parameter setting table (D)
(When the machine system is metric system, 0.0 to +100000.0. When the machine system is inch system, machine, 0.0 to +10000.0)

Each of these parameters sets an allowable acceleration rate change amount per 1 ms for each axis in speed control based on acceleration rate change under control on the rate of change of acceleration during AI contour control.

Set a value (precision level 1) with emphasis placed on speed, and a value (precision level 10) with emphasis on precision.

13616	**Allowable acceleration rate change amount for each axis in speed control based on acceleration rate change under control on the rate of change of acceleration in successive linear interpolation operations (precision level 1)**
13617	**Allowable acceleration rate change amount for each axis in speed control based on acceleration rate change under control on the rate of change of acceleration in successive linear interpolation operations (precision level 10)**

[Input type] Parameter input
[Data type] Real axis
[Unit of data] mm/sec^2, inch/sec^2, deg/sec^2 (machine unit)
[Min. unit of data] Depend on the increment system of the applied axis
[Valid data range] Refer to the standard parameter setting table (D)
(When the machine system is metric system, 0.0 to +100000.0. When the machine system is inch system, machine, 0.0 to +10000.0)

Each of these parameters sets an allowable acceleration rate change amount per 1 ms for each axis in speed control based on acceleration rate change under control on the rate of change of acceleration in successive linear interpolation operations during AI contour control.

Set a value (precision level 1) with emphasis placed on speed, and a value (precision level 10) with emphasis on precision.

NOTE

1 For an axis with 0 set in this parameter, parameter No. 13614 and No. 13615 (allowable acceleration rate change amount in speed control based on acceleration rate change under control on the rate of change of acceleration) are valid.

2 For an axis with 0 set in parameter No. 13614 and No. 13615 (allowable acceleration rate change amount in speed control based on acceleration rate change under control on the rate of change of acceleration), speed control based on acceleration rate change is disabled, so that the specification of this parameter has no effect.

13618	**Rate of change time of the rate of change of acceleration in smooth bell-shaped acceleration/deceleration before interpolation when AI contour control is used (precision level 1)**
13619	**Rate of change time of the rate of change of acceleration in smooth bell-shaped acceleration/deceleration before interpolation when AI contour control is used (precision level 10)**

[Input type] Parameter input
[Data type] Byte path

[Unit of data] %

[Valid data range] 0 to 50

Each of these parameters sets the rate (percentage) of the change time of the rate of change of acceleration to the change time of acceleration rate change in look-ahead smooth bell-shaped acceleration/deceleration before interpolation during AI contour control.

Set a value (precision level 1) with emphasis placed on speed, and a value (precision level 10) with emphasis on precision.

NOTE

When 0 or a value not within the valid data range is set in this parameter, look-ahead smooth bell-shaped acceleration/deceleration before interpolation is not performed.

13620	**Allowable acceleration rate when AI contour control is used (precision level 1)**
13621	**Allowable acceleration rate when AI contour control is used (precision level 10)**

[Input type] Parameter input

[Data type] Real axis

[Unit of data] mm/sec^2, inch/sec^2, deg/sec^2 (machine unit)

[Min. unit of data] Depend on the increment system of the applied axis

[Valid data range] Refer to the standard parameter setting table (D)

(When the machine system is metric system, 0.0 to +100000.0. When the machine system is inch system, machine, 0.0 to +10000.0)

Each of these parameters sets an allowable acceleration rate in AI contour control. Set a value (precision level 1) with emphasis placed on speed, and a value (precision level 10) with emphasis on precision.

13622	**Time constant for acceleration/deceleration after interpolation when AI contour control is used (precision level 1)**
13623	**Time constant for acceleration/deceleration after interpolation when AI contour control is used (precision level 10)**

[Input type] Parameter input

[Data type] Word axis

[Unit of data] msec

[Valid data range] 1 to 512

Each of these parameters sets a time constant for acceleration/ deceleration after interpolation when AI contour control is used. Set a value (precision level 1) with emphasis placed on speed, and a value (precision level 10) with emphasis on precision.

13624	**Corner speed difference when AI contour control is used (precision level 1)**
13625	**Corner speed difference when AI contour control is used (precision level 10)**

[Input type] Parameter input

[Data type] Real axis

[Unit of data] mm/min, inch/min, deg/min (machine unit)

[Min. unit of data] Depend on the increment system of the applied axis

[Valid data range] Refer to the standard parameter setting table (C)

(When the increment system is IS-B, 0.0 to +999000.0)

Each of these parameters sets an allowable speed difference for speed determination based on corner speed difference in AI contour control. Set a value (precision level 1) with emphasis placed on speed, and a value (precision level 10) with emphasis on precision.

13626	Maximum cutting speed when AI contour control is used (precision level 1)
13627	Maximum cutting speed when AI contour control is used (precision level 10)

[Input type] Parameter input
[Data type] Real axis
[Unit of data] mm/min, inch/min, deg/min (machine unit)
[Min. unit of data] Depend on the increment system of the applied axis
[Valid data range] Refer to the standard parameter setting table (C)
(When the increment system is IS-B, 0.0 to +999000.0)
Each of these parameters sets a maximum cutting speed in AI contour control. Set a value (precision level 1) with emphasis placed on speed, and a value (precision level 10) with emphasis on precision.

13628	Parameter number corresponding to arbitrary item 1 when AI contour control is used
13629	Parameter number corresponding to arbitrary item 2 when AI contour control is used

[Input type] Parameter input
[Data type] 2-word path
[Valid data range] 1 to 65535
These parameters set the parameter numbers corresponding to arbitrary items 1 and 2.

NOTE

1 The parameter numbers corresponding to the following cannot be specified:
   - Bit parameters
   - Spindle parameters Nos. 4000 to 4799
   - Parameters of real number type
   - Parameters that require power-off (for which the alarm PW0000 is issued)
   - Nonexistent parameters

2 When these parameters are set, the power must be turned off before operation is continued.

13630	Value with emphasis on speed (precision level 1) of the parameter corresponding to arbitrary item 1 when AI contour control is used
13631	Value with emphasis on speed (precision level 1) of the parameter corresponding to arbitrary item 2 when AI contour control is used
13632	Value with emphasis on precision (precision level 10) of the parameter corresponding to arbitrary item 1 when AI contour control is used
13633	Value with emphasis on precision (precision level 10) of the parameter corresponding to arbitrary item 2 when AI contour control is used

[Input type] Parameter input
[Data type] 2-word axis
[Unit of data] Depend on the type of parameter for an arbitrary item
[Valid data range] Depend on the type of parameter for an arbitrary item

Each of these parameters sets a value with emphasis placed on speed or precision for a parameter.

13634	Precision level currently selected when AI contour control is used

[Input type] Parameter input
[Data type] Byte path
[Valid data range] 1 to 10
This parameter sets the level currently selected.

13662	Acceleration rate change time (bell-shaped) when AI contour control is used (precision level 1), range extended
13663	Acceleration rate change time (bell-shaped) when AI contour control is used (precision level 10), range extended

[Input type] Parameter input
[Data type] 2-word path
[Unit of data] msec
[Valid data range] 0 to 200
Each of these parameters sets an acceleration rate change time (bell-shaped) in AI contour control. Set a value (precision 1) with emphasis placed on speed, and a value (precision level 10) with emphasis on precision.

2.11 MALFUNCTION PREVENT FUNCTIONS

Overview

These functions monitor the CNC internal status and check that related data is within the allowable range. If an invalid state due to a deteriorated hardware component or noise is detected, these functions stop the machine with an alarm to prevent any malfunction.

Explanation

Each function is detailed below.

- Checking the maximum speed of the servo motor

This function checks whether the maximum speed specified in parameter No. 12255 is exceeded. If the maximum speed is exceeded, this function issues alarms DS0004 and PW0006 and stops the machine. When the parameter is set to 0, this function checks whether the maximum speed (999000 for IS-B) is exceeded.

- Checking the maximum acceleration of the servo motor

This function checks whether the maximum acceleration specified in parameter No. 12256 is exceeded. If the maximum acceleration is exceeded, this function issues alarms DS0005 and PW0006 and stops the machine. When the parameter is set to 0, this function does not check the maximum acceleration.

- Checking the maximum speed of the spindle motor

This function checks whether the maximum speed of the spindle motor is exceeded. If the maximum speed is exceeded, this function issues alarms IE0007 and PW0006 and outputs S0. The parameter which specifies the maximum speed of each spindle is used.

- Checking the stored stroke limit at the end point

This function makes a stored stroke check immediately before pulses are output in addition to a normal stored stroke check. If the stored stroke limit is exceeded, this function issues one of alarms IE0001 to

IE0006 and alarm PW0006 and stops the machine. The parameters for normal stored stroke checks are used.

- Monitoring execution of NC command analysis

This function monitors NC command analysis to check the execution counter and reference area for validity. If invalid data is detected, this function issues one of alarms DS0006 to DS0013 and alarm PW0006 and stops the machine.

- Monitoring execution of acceleration/deceleration after interpolation

This function monitors the execution counter during execution of linear/bell-shaped acceleration/deceleration after interpolation to check the counter for validity. If invalid data is detected, this function issues alarms IE0008 and PW0006 and stops the machine.

Parameter

12255	Maximum servo motor speed

[Input type] Parameter input
[Data type] Real axis
[Unit of data] mm/min, inch/min, deg/min (machine unit)
[Min. unit of data] Depend on the increment system of the applied axis
[Valid data range] Refer to the standard parameter setting table (C)
(When the increment system is IS-B, 0.0 to +999000.0)

This parameter sets a maximum servo motor speed. When the value set in this parameter is exceeded, the servo motor stops with the alarm DS0004. When 0 is set in this parameter, the specification of a maximum allowable value (999000 for IS-B) is assumed.

12256	Maximum servo motor acceleration rate

[Input type] Parameter input
[Data type] Real axis
[Unit of data] mm/sec^2, inch/sec^2, deg/sec^2 (machine unit)
[Min. unit of data] Depend on the increment system of the applied axis
[Valid data range] Refer to the standard parameter setting table (D)
(When the machine system is metric system, 0.0 to +100000.0. When the machine system is inch system, machine, 0.0 to +10000.0)

This parameter sets a maximum servo motor acceleration rate. When the value set in this parameter is exceeded, the servo motor stops with the alarm DS0005. When 0 is set in this parameter, alarm check is not performed.

Alarm and message

The machine is decelerated and stopped when a DS alarm is issued or is immediately stopped when an IE alarm is issued to prevent any malfunction.
Check the block in which the machine is stopped. If you cannot find the cause, contact FANUC without releasing the alarm state.

Number	Message	Description
DS0004	EXCESS MAXIMUM FEEDRATE	The malfunction prevention function detected the command in which a value exceeding the maximum speed was specified.
DS0005	EXCESS MAXIMUM ACCELERATION	The malfunction prevention function detected the command in which a value exceeding the maximum acceleration was specified.
DS0006	ILLEGAL EXECUTION SEQUENCE	The malfunction prevention function detected an illegal execution sequence.
DS0007	ILLEGAL EXECUTION SEQUENCE	The malfunction prevention function detected an illegal execution sequence.

Number	Message	Description
DS0008	ILLEGAL EXECUTION SEQUENCE	The malfunction prevention function detected an illegal execution sequence.
DS0009	ILLEGAL EXECUTION SEQUENCE	The malfunction prevention function detected an illegal execution sequence.
DS0010	ILLEGAL REFERENCE AREA	The malfunction prevention function detected an illegal reference area.
DS0011	ILLEGAL REFERENCE AREA	The malfunction prevention function detected an illegal reference area.
DS0012	ILLEGAL REFERENCE AREA	The malfunction prevention function detected an illegal reference area.
DS0013	ILLEGAL REFERENCE AREA	The malfunction prevention function detected an illegal reference area.
IE0001	+ OVERTRAVEL (SOFT 1)	The malfunction prevention function detected that stored stroke check 1 on the positive side was exceeded.
IE0002	- OVERTRAVEL (SOFT 1)	The malfunction prevention function detected that stored stroke check 1 on the negative side was exceeded.
IE0003	+ OVERTRAVEL (SOFT 2)	The malfunction prevention function detected that stored stroke check 2 on the positive side was exceeded.
IE0004	- OVERTRAVEL (SOFT 2)	The malfunction prevention function detected that stored stroke check 2 on the negative side was exceeded.
IE0005	+ OVERTRAVEL (SOFT 3)	The malfunction prevention function detected that stored stroke check 3 on the positive side was exceeded.
IE0006	- OVERTRAVEL (SOFT 3)	The malfunction prevention function detected that stored stroke check 3 on the negative side was exceeded.
IE0007	EXCESS MAXIMUM REV. DATA	The malfunction prevention function detected the command in which a value exceeding the maximum speed was specified.
IE0008	ILLEGAL ACC/DEC	The malfunction prevention function detected the acceleration/deceleration error.

2.12 OPERATOR ERROR PREVENT FUNCTIONS

Overview

If an invalid value is set for tool offset or the machine is operated improperly, a workpiece may be cut incorrectly or a tool may be damaged. If data is lost due to an operator error, time is required for recovery. The operator error prevent functions include the following functions to prevent an unintentional operator operation (called an operator error below).

1. Functions operating during data setting
   - Checking whether offset data is within the valid setting range
   - Reconfirming incremental input operation
   - Disabling absolute input using soft keys to prevent an operator error related to absolute and incremental input
   - Reconfirming deletion of a program or all data
   - Reconfirming data update during setting
2. Functions operating during execution
   - Highlighting updated modal data
   - Displaying the status of the execution block before execution of a program
   - Displaying the axis status such as the mirror image enable state or interlock enable state
   - Checking the start of a program from a midpoint
   - Checking whether offset data is within the valid setting range
   - Checking the maximum incremental amount

Explanation

- Functions operating during data setting

The following functions are provided to prevent an operation error during data setting.

- Checking of the input data range
- Reconfirming of incremental input
- Prohibiting of soft key absolute input
- Reconfirming of program deletion
- Reconfirming of all data deletion
- Reconfirming of data update during setting

For details on these functions, refer to the OPERATOR’S MANUAL.

- Functions related to checking before execution

The following functions are provided to prevent an operation error during execution.

- Update display of modal information
- Start check signal
- Status display of axes
- Reconfirming of midway block start
- Checking of the execution data range
- Checking of the maximum incremental amount

For details of functions other than the start check signal and bit 0 of diagnosis information No. 3570, refer to the OPERATOR’S MANUAL.

- Start check signal

If cycle start is performed when the start check signal STCHK <Gn408.0> is 1, the stop state is entered with the remaining traverse distance and modal of the execution block indicated. Performing cycle start again starts the execution.
An operation error is prevented because the status of the execution block can be checked before execution.
Using the start check signal together with the update display of modal information shown above makes checking easier.

- During a memory operation stop

If memory operation is stopped due to the reconfirming of midway block start, bit 0 of diagnosis information No. 3570 is set to 1, so that the state can be confirmed.
In a multi-path system, bit 0 of diagnosis information No. 3570 is set to 1 on only the path on the cursor is position in the middle of the program.

Signal

Start check signal STCHK<Gn408.0>

[Classification] Input signal

[Function] The traverse distance and modal can be checked before execution.

[Operation] When this signal is “1”, the remaining traverse distance and modal is displayed before executing a block and then execution stops. Performing cycle start again starts the execution.

Middle block start signal MBSO<Fn534.4>

[Classification] Output signal

[Function] Indicates that memory operation is stopped by the reconfirming of middle block start of the operator error prevent function.

[Output cond.] The signal is set to “1” when:

- Memory operation is stopped by the reconfirming of middle block start of Operator error prevent function.

In a multi-path system, the bit is set to 1 on only the path on which the cursor is position in the middle of the program.

The signal is set to “0” when:

- Memory operation is not stopped by the reconfirming of middle block start of Operator error prevent function.

When bit 0 (MBO) of parameter No.10336 is set to 1, this signal is enabled.

Signal address

	#7	#6	#5	#4	#3	#2	#1	#0
Gn408								STCHK

10000	Lower limit 1 of tool offsets No. 01
to	to
10019	Lower limit 1 of tool offsets No. 20

[Input type] Parameter input
[Data type] Real path
[Unit of data] mm, inch, deg (input unit)
[Min. unit of data] Depend on the increment system of the applied axis
[Valid data range] 9 digit of minimum unit of data (refer to standard parameter setting table (A))
(When the increment system is IS-B, -999999.999 to +999999.999)

These parameters set the lower limits of the following offset values:

- T series, without tool geometry/wear offsets, X-axis offset
- T series, with tool geometry/wear offsets, X-axis and geometry offsets
- M series, tool offset memory A offset
- M series, tool offset memory C, geometry, and length offsets

10020	**Upper limit 1 of tool offsets No. 01**
to	**to**
10039	**Upper limit 1 of tool offsets No. 20**

[Input type] Parameter input
[Data type] Real path

[Data type] Real path
[Unit of data] mm, inch, deg (input unit)
[Min. unit of data] Depend on the increment system of the applied axis
[Valid data range] 9 digit of minimum unit of data (refer to standard parameter setting table (A))
(When the increment system is IS-B, -999999.999 to +999999.999)
These parameters set the lower limits of the following offset values:
- T series, with tool geometry/wear offsets, tool noise radius and wear offsets

10220	**Upper limit 6 of tool offsets No. 01**
to	**to**
10239	**Upper limit 6 of tool offsets No. 20**

[Input type] Parameter input
[Data type] Real path
[Unit of data] mm, inch, deg (input unit)
[Min. unit of data] Depend on the increment system of the applied axis
[Valid data range] 9 digit of minimum unit of data (refer to standard parameter setting table (A))
(When the increment system is IS-B, -999999.999 to +999999.999)
These parameters set the upper limits of the following offset values:
- T series, with tool geometry/wear offsets, tool noise radius and wear offsets

10240	**Lower limit 1 of a tool offset number range No. 01**
to	**to**
10259	**Lower limit 1 of a tool offset number range No. 20**

[Input type] Parameter input
[Data type] Word path
[Valid data range] 0 to maximum number of offset sets
Each of these parameters sets the lower limit of a tool offset number range.

These parameters correspond to the tool offset lower/upper limits set in parameters Nos. 10000 to 10239.

10260	**Upper limit 1 of a tool offset number range No. 01**
to	**to**
10279	**Upper limit 1 of a tool offset number range No. 20**

[Input type] Parameter input
[Data type] Word path
[Valid data range] 0 to maximum number of offset sets

Each of these parameters sets the upper limit of a tool offset number range.
These parameters correspond to the tool offset lower/upper limits set in parameters Nos. 10000 to 10239.

10280	**Lower limit 7 of tool offsets No. 01**
to	**to**
10283	**Lower limit 7 of tool offsets No. 04**

[Input type] Parameter input
[Data type] Real path
[Unit of data] mm, inch, deg (input unit)
[Min. unit of data] Depend on the increment system of the applied axis
[Valid data range] 9 digit of minimum unit of data (refer to standard parameter setting table (A))
(When the increment system is IS-B, -999999.999 to +999999.999)

These parameters set the lower limits of the following offset values:

- T series, without tool geometry/wear offsets, Y-axis offset
- T series, with tool geometry/wear offsets, Y-axis and geometry offsets

10284	**Upper limit 7 of tool offsets No. 01**
to	**to**
10287	**Upper limit 7 of tool offsets No. 04**

[Input type] Parameter input
[Data type] Real path
[Unit of data] mm, inch, deg (input unit)
[Min. unit of data] Depend on the increment system of the applied axis
[Valid data range] 9 digit of minimum unit of data (refer to standard parameter setting table (A))
(When the increment system is IS-B, -999999.999 to +999999.999)

These parameters set the upper limits of the following offset values:

- T series, without tool geometry/wear offsets, Y-axis offset
- T series, with tool geometry/wear offsets, Y-axis and geometry offsets

10288	**Lower limit 8 of tool offsets No. 01**
to	**to**
10291	**Lower limit 8 of tool offsets No. 04**

[Input type] Parameter input
[Data type] Real path
[Unit of data] mm, inch, deg (input unit)
[Min. unit of data] Depend on the increment system of the applied axis
[Valid data range] 9 digit of minimum unit of data (refer to standard parameter setting table (A))
(When the increment system is IS-B, -999999.999 to +999999.999)

These parameters set the lower limits of the following offset values:

- T series, with tool geometry/wear offsets, Y-axis and wear offsets

10292	**Upper limit 8 of tool offsets No. 01**
to	**to**
10295	**Upper limit 8 of tool offsets No. 04**

[Input type] Parameter input
[Data type] Real path
[Unit of data] mm, inch, deg (input unit)
[Min. unit of data] Depend on the increment system of the applied axis
[Valid data range] 9 digit of minimum unit of data (refer to standard parameter setting table (A))
(When the increment system is IS-B, -999999.999 to +999999.999)

These parameters set the upper limits of the following offset values:

- T series, with tool geometry/wear offsets, Y-axis and wear offsets

10296	**Lower limit 2 of a tool offset number range No. 01**
to	**to**
10299	**Lower limit 2 of a tool offset number range No. 04**

[Input type] Parameter input
[Data type] Word path
[Valid data range] 0 to maximum number of offset sets

Each of these parameters sets the lower limit of a tool offset number range.
These parameters correspond to the tool offset lower/upper limits set in parameters Nos. 10280 to 10295.

10300	**Upper limit 2 of a tool offset number range No. 01**
to	**to**
10303	**Upper limit 2 of a tool offset number range No. 04**

[Input type] Parameter input
[Data type] Word path
[Valid data range] 0 to maximum number of offset sets

Each of these parameters sets the upper limit of a tool offset number range.
These parameters correspond to the tool offset lower/upper limits set in parameters Nos. 10280 to 10295.

10304	**Lower limit of workpiece zero point offsets No. 01**
to	**to**
10309	**Lower limit of workpiece zero point offsets No. 06**

[Input type] Parameter input
[Data type] Real axis
[Unit of data] mm, inch, deg (input unit)
[Min. unit of data] Depend on the increment system of the applied axis
[Valid data range] 9 digit of minimum unit of data (refer to standard parameter setting table (A))
(When the increment system is IS-B, -999999.999 to +999999.999)

Each of these parameters sets the lower limit of workpiece zero point offset values.

10310	**Upper limit of workpiece zero point offsets No. 01**
to	**to**
10315	**Upper limit of workpiece zero point offsets No. 06**

[Input type] Parameter input
[Data type] Real axis
[Unit of data] mm, inch, deg (input unit)
[Min. unit of data] Depend on the increment system of the applied axis

[Valid data range] 9 digit of minimum unit of data (refer to standard parameter setting table (A))
(When the increment system is IS-B, -999999.999 to +999999.999)
Each of these parameters sets the upper limit of workpiece zero point offset values.

10316	**Lower limit of a workpiece zero point offset range No. 01**
to	**to**
10321	**Lower limit of a workpiece zero point offset range No. 06**

[Input type] Parameter input
[Data type] Word path
[Valid data range] 0 to maximum number of offset sets
Each of these parameters sets the lower limit of a workpiece zero point offset range. For an additional workpiece coordinate system, set a value after adding 1000.
These parameters correspond to the workpiece zero point offset lower/upper limits set in parameters Nos. 10304 to 10315.

10322	**Upper limit of a workpiece zero point offset range No. 01**
to	**to**
10327	**Upper limit of a workpiece zero point offset range No. 06**

[Input type] Parameter input
[Data type] Word path
[Valid data range] 0 to maximum number of offset sets
Each of these parameters sets the upper limit of a workpiece zero point offset range. For an additional workpiece coordinate system, set a value after adding 1000.
These parameters correspond to the workpiece zero point offset lower/upper limits set in parameters Nos. 10304 to 10315.

10328	**Lower limit of workpiece shifts**

[Input type] Parameter input
[Data type] Real axis
[Unit of data] mm, inch, deg (input unit)
[Min. unit of data] Depend on the increment system of the applied axis
[Valid data range] 9 digit of minimum unit of data (refer to standard parameter setting table (A))
(When the increment system is IS-B, -999999.999 to +999999.999)
This parameter sets a workpiece shift lower limit.

10329	**Upper limit of workpiece shifts**

[Input type] Parameter input
[Data type] Real axis
[Unit of data] mm, inch, deg (input unit)
[Min. unit of data] Depend on the increment system of the applied axis
[Valid data range] 9 digit of minimum unit of data (refer to standard parameter setting table (A))
(When the increment system is IS-B, -999999.999 to +999999.999)
This parameter sets a workpiece shift upper limit.

#0 MSC The reconfirming of midway block start of operator error prevent function is:
0: Enabled independently for each path.
1: Enabled for the local path and those paths for this parameter is set to 1.

- Additional information

Parameters for input data range checks are assigned as follows:

- Tool offset
  - <1> No tool geometry/wear offset for a lathe system
    Nos. 10000 to 10119, Nos. 10240 to 10279
  - <2> With tool geometry/wear offset for a lathe system
    Nos. 10000 to 10279
  - <3> Tool offset memory A for a machining center system
    Nos. 10000 to 10039, Nos. 10240 to 10279
  - <4> Tool offset memory C (geometry/wear, length/radius) for a machining center system
    Nos. 10000 to 10079, Nos. 10120 to 10199, Nos. 10240 to 10279
- Y-axis tool offset
  Nos. 10280 to 10303
- Workpiece origin offset
  Nos. 10304 to 10327
- Workpiece shift
  Nos. 10328 and 10329

	#7	#6	#5	#4	#3	#2	#1	#0

1: Enabled.

Alarm and message

Number	Message	Description
PS0334	OFFSET IS OUT OF EFFECTIVE RANGE	An offset data which was out of the effective range was specified. (operator error prevention function)
PS0337	EXCESS MAXIMUM INCREMENTAL VALUE	The command value exceeded the maximum amount of incremental. (operator error prevention function)

Diagnosis display

	#7	#6	#5	#4	#3	#2	#1	#0
3570								MSC

#0 MSC Memory operation is stopped due to the reconfirming of midway block start.
In a multi-path system, the bit is set to 1 on only the path on which the cursor is position in the middle of the program.

Caution

> ⚠ **CAUTION**
> The input data range check function does not check the values related to the second geometry offset function. The second geometry offset function, which is used to set values specific to the machine, is not assumed to be modified by end users.

2.13 Improvement of stop distance reduction function at power failure

Overview

Improvement of stop distance reduction function at power failure becomes effective by setting bit 1 (PFSx) of parameter No.11820 to 1. When the power supply detects a power failure, the axis immediately stops (alarm SV1094) by this function.
Stop method of the axis can be changed to deceleration stop (alarm DS0099) by setting bit 2 (PFD) of parameter No.11808 and bit 1 (PFSx) of parameter No.11820 to 1.
To stop the axis at power failure, conventional stop distance reduction function at power failure requires the PMC ladder or the wiring.
This function makes the PMC ladder and the wiring unnecessary.

Explanation

If the power failure is detected by the power supply, the power failure detection signals XPFL1 – XPFL8 <Fn374> is set to “0”.
When the power failure detection signals XPFL1 – XPFL8 is “0”, the axis immediately stops (alarm SV1094) by setting bit 1 (PFSx) of parameter No.11820 to 1
Stop method of the axis can be changed to deceleration stop (alarm DS0099) by setting bit 2 (PFD) of parameter No.11808 and bit 1 (PFSx) of parameter No.11820 to 1.

Table 2.13 (a) Stop method of improvement of stop distance reduction function at power failure

Bit 1 (PFSx) of parameter No.11820	Bit 2 (PFD) of parameter No.11808	Stop method
0	0	This function is invalid
0	1	This function is invalid
1	0	Immediately stop (alarm SV1094)
1	1	Deceleration stop (alarm DS0099)

As for this function, immediately stop or deceleration stop is executed by the power failure detection signals from the power supply. Therefore, the PMC ladder and the wiring become unnecessary by this function.

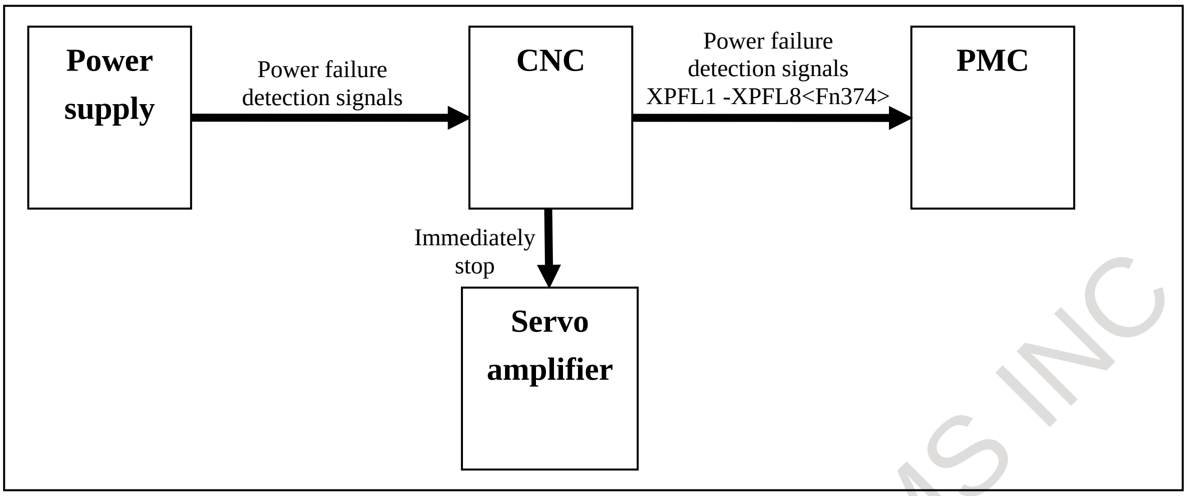

Fig. 2.13 (a) Immediately stops by this function (alarm SV1094)

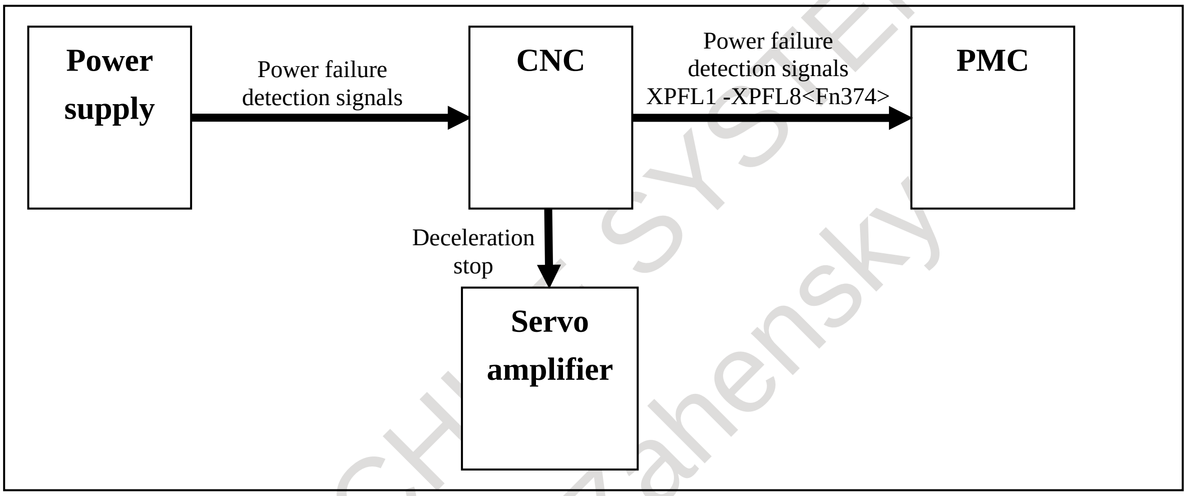

Fig. 2.13 (b) Deceleration stops by this function (alarm DS0099)

To stop the axis at power failure, conventional stop distance reduction function at power failure required like following 1 – 3 the PMC ladder or the wiring.

1 If immediately stops of the axis are executed by emergency stop, it was necessary to make the PMC ladder. The PMC ladder executes the emergency stop by making emergency stop *ESP <Gn008.4> to 0 when the power failure detection signals XPFL1 – XPFL8 <Fn374> is 0.

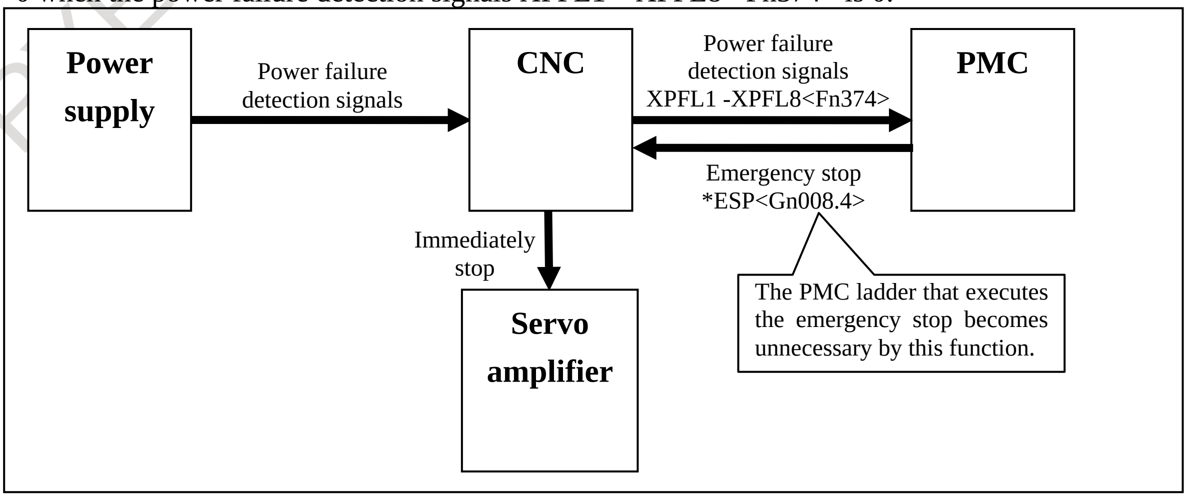

Fig. 2.13 (c) Immediately stops of the axis by emergency stop (PMC ladder)

2 If deceleration stops of the axis are executed by feed hold signal, it was necessary to make the PMC ladder. The PMC ladder executes the feed hold stop by making feed hold signal *SP <Gn008.5> to 0 when the power failure detection signals XPFL1 – XPFL8 <Fn374> is 0.

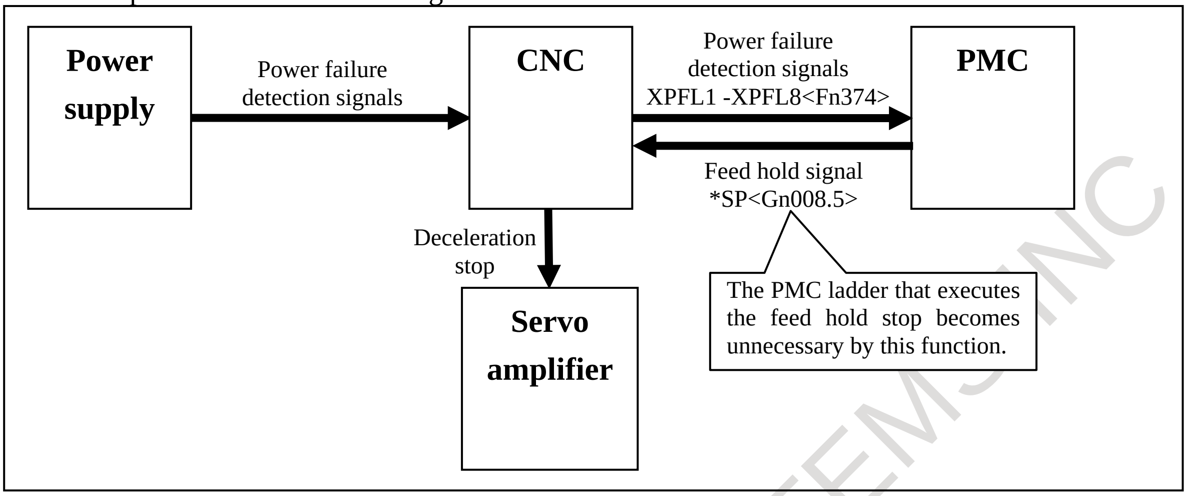

Fig. 2.13 (d) Deceleration stops of the axis by feed hold signal (PMC ladder)

3 If immediately stops of the axis are executed by emergency stop that uses power failure detection signal (contact signal) from the power supply, it was necessary to make the wiring. The wiring wires emergency stop *ESP <X8.4>,<X8.0>,<X8.1> of PMC for the power failure detection signal (contact signal) from the power supply.
Wiring effort can be reduced by using this function though immediately stops of the axis by the following wiring can be achieve the stop at power failure earlier than stop time that used this function.

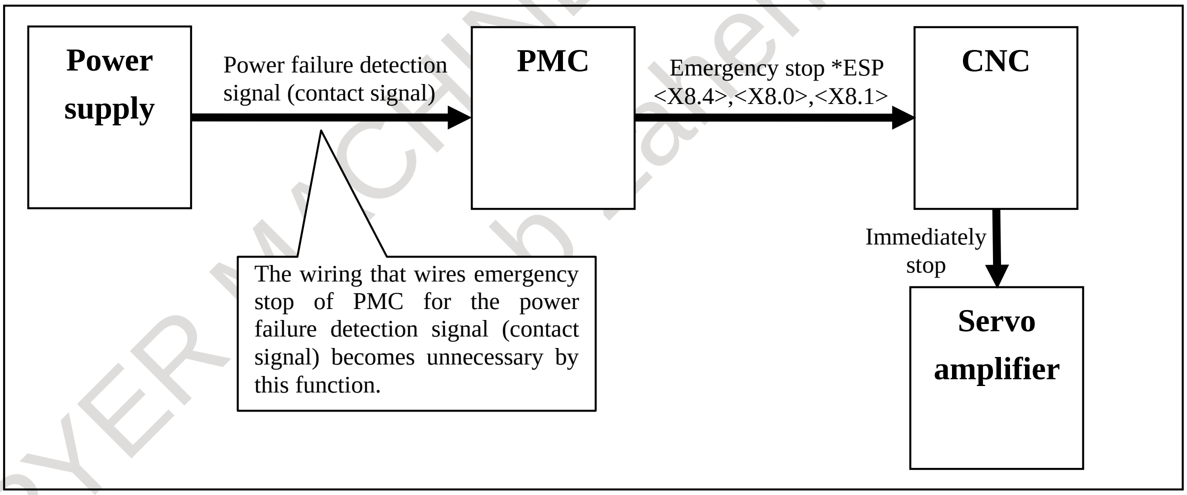

Fig. 2.13 (e) Immediately stops of the axis by emergency stop (Wiring for contact signal)

NOTE
- Improvement of stop distance reduction function at power failure is valid after the servo ready signal SA <Fn000.6> is set to “1” for the first time after power on.
- It enters the servo off state at the same time as generating the alarm at the immediately stops (alarm SV1094), and it shifts to deceleration stop operation with the dynamic brake. In this case, the stopping distance can be shortened by using brake control function (bit 6 (BRKCx) of parameter No.2005) and quick stop at emergency stop (bit 0 (DBSTx) of parameter No.2017). Refer to Servo motor parameter manual (B-65270EN) for details of brake control function and quick stop at emergency stop.
- This function executes the axis stop directly according to the power failure detection signal from power supply without using PMC. Therefore, timing in which the axis stop begins is different from conventional stop distance reduction function at power failure. Use conventional stop distance reduction function at power failure if the axis should stop after operating the machine side according to the power failure detection signals XPFL1 – XPFL8 <Fn374>.

Parameter

	#7	#6	#5	#4	#3	#2	#1	#0

[Input type] Parameter input
[Data type] Bit axis

#6 BRKCx Brake control function is:
0: Disabled.
1: Enabled.

	#7	#6	#5	#4	#3	#2	#1	#0
2017								DBSTx

[Input type] Parameter input
[Data type] Bit axis

#0 DBSTx Specifies whether to enable quick stop type 1 at emergency stop as follows:
0: To disable.
1: To enable.
When using the quick stop at emergency stop function, make the brake control setting for all the axes to which thus function is applied.

NOTE
When only the brake control function is set, a gradual stop occurs with the torque limit set by the torque limit setting function during brake control.
When the quick stop at emergency stop is enabled, a gradual stop occurs with the torque limit set to 100%, so that the stop distance is reduced.

Signal

Emergency stop (input)

*ESP<X008.4> (for the first machine group), <X008.0> (for the second machine group), <X008.1> (for the third machine group), <Gn008.4>

[Classification] Input signal
[Function] Activating an emergency stop signal stops the machine instantly.
[Operation] When the emergency stop signal *ESP turns to "0", the emergency stop is applied to the machine and the CNC is reset. This signal is controlled by the B contacts of a pushbutton switch. The emergency stop signal turns the servo ready signal SA to "0".

Feed hold signal *SP<Gn008.5>

[Classification] Input signal
[Function] Halts automatic operation.
[Operation] When signal *SP is set to 0 during automatic operation, the CNC enters the feed hold state and stops operation. Automatic operation cannot be started when signal *SP is set to 0.
MEM, RMT, or MDI mode

Servo Ready Signal SA<Fn000.6>

[Classification] Output signal
[Function] Signal SA turns to "1" when the servo system is ready to operate. For an axis that is to be braked, release the brake when this signal is "1" and apply the brake when this signal is "0".

Power Failure Detection Signals XPFL1 to XPFL8<Fn374>

[Classification] Output signal
[Function] This signal indicates that power failure is detected by the power supply.
[Operation] This signal turns to 1 at:
- Normal

The signal turns to 0 at:
- Power failure status

Signal address

	#7	#6	#5	#4	#3	#2	#1	#0

Alarm and message

Number	Message	Description
SV1094	STOP DISTANCE REDUCTION ENABLE	The axis stop is executed by stop distance reduction function at power failure.
DS0099	STOP DISTANCE REDUCTION ENABLE	The axis stop is executed by stop distance reduction function at power failure.

3 MANUAL OPERATION

3.1 JOG FEED/INCREMENTAL FEED

Overview

- Jog feed

In jog mode, setting a feed axis and direction selection signal to “1” moves the tool along the selected axis in the selected direction continuously.
Manual operation is allowed one axis at a time. Up to 3 axes can be selected at a time by setting bit 0 (JAX) of parameter No.1002.
By using bit 6 of parameter No. 7001, the number of axes that can be selected can be increased up to the maximum number of simultaneously controlled axes.

- Incremental feed

In incremental feed mode, setting a feed axis and direction selection signal to “1” moves the tool one step along the selected axis in the selected direction. The minimum distance the tool is moved, is the least input increment. The step can be 10, 100, or 1000 times the least input increment.
Bit 2 (HNT) of parameter No. 7103 can be used to multiply the obtained step by 10.

- Feedrate

The jog feedrate is specified in parameter No.1423.
The jog feedrate can be adjusted with the jog feedrate override dial.
With manual rapid traverse selection signal, the tool can be moved at the rapid traverse rate regardless of the jog feedrate override signal.

Explanation

- Manual per revolution feed

The manual per revolution feed is enabled for jog feed and incremental feed by setting bit 4 (JRV) of parameter No.1402 to 1. During the manual per revolution feed, jog feed and incremental feed is performed at the feedrate that is obtained by multiplying the spindle speed and the jog feedrate override value by the feed amount per revolution specified with the parameter No. 1423. In the case of linear axis (metric input), during manual per revolution feed, the tool is jogged at the following feedrate:
Parameter setting value (mm/rev) × JOG feedrate override × actual spindle speed (rev/min).

NOTE
1 Manual per revolution feed is not available at the setting of without the position coder (setting bit 0 (NPC) of parameter No.1402 to 1 or bit 1 (FPR) of parameter No.3729 to 1).
2 When multi spindle control is enabled and the multiple position coders are used, the target feedback pulses from the position coder for manual per revolution feed is selected with a position coder select signal (PC2SLC<Gn028.7>, PC3SLC<Gn026.0>, PC4SLC <Gn026.1>). And in addition, when multi path control is enabled, an arbitrary position coder can be selected by combining a path spindle feedback selection signals (SLPCA<Gn064.2>, SLPCB<Gn064.3>, SLPCC<Gn403.4>, SLPCD<Gn403.5>). For the selection of a position coder, see the section of "Multi spindle" and "Path spindle control".

Signal

The following signals determine that way the jog feed or incremental feed is executed.

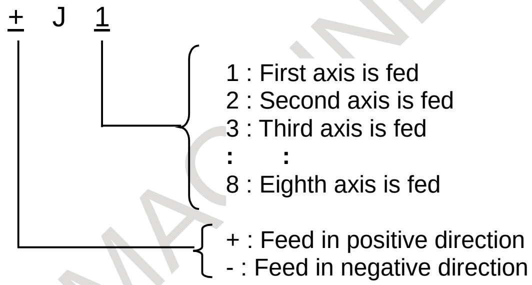
Selection	Jog feed	Incremental feed
Mode selection	MD1, MD2, MD4, MJ	MD1, MD2, MD4, MINC
Selection of the axis to move	+J1, -J1, +J2, -J2, +J3, -J3, ...	
Selection of the direction to move the axis		
Selection of the move amount		MP1, MP2
Selection of feedrate	*JV0 to *JV15, RT, ROV1, ROV2	

The only difference between jog feed and incremental feed is the method of selecting the feed distance. In jog feed, the tool continues to be fed while feed axis and direction selection signals are 1: +J1, -J1, +J2, -J2, +J3, -J3, etc. In incremental feed, the tool is fed by one step.
The distance of the step is selected by the manual handle feed move distance selection signals MP1 and MP2.
For the signals selecting the mode, see "Mode Selection Signals." In selection of the move amount, for manual handle feed amount selection signals MP1 and MP2, see "MANUAL HANDLE FEED". In selection of feedrate, for rapid traverse override signals ROV1 and ROV2, see “Feedrate Override Signals.”
Other signals are described below.

Feed Axis and Direction Selection Signal +J1 to +J8<Gn100>-J1 to -J8<Gn102>

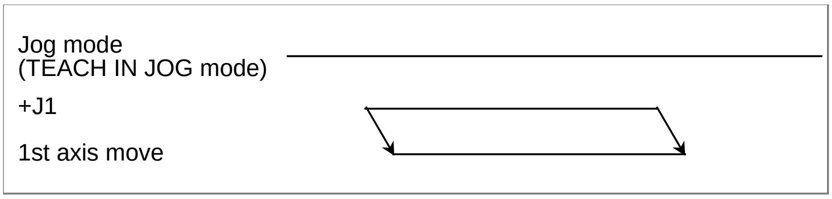
[Classification] Input signal

[Function] Selects a desired feed axis and direction in jog feed or incremental feed. The sign (+ or -) in the signal name indicates the feed direction. The number following J indicates the number of the control axis.



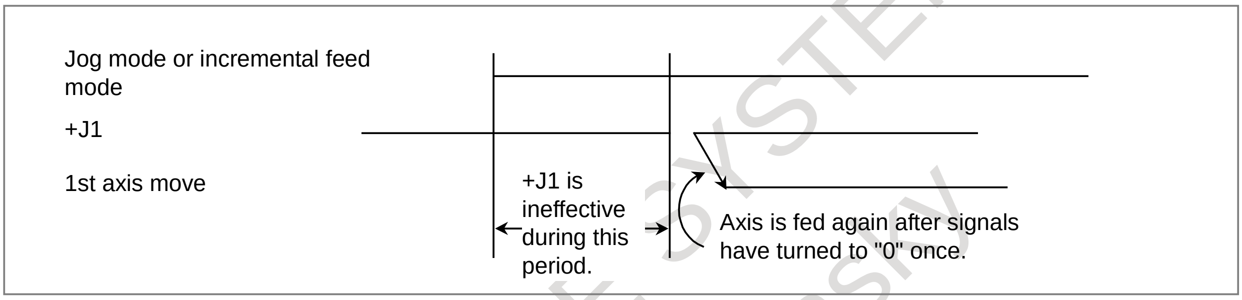
[Operation] When the jog bit is “1”, the control unit operates as described below.

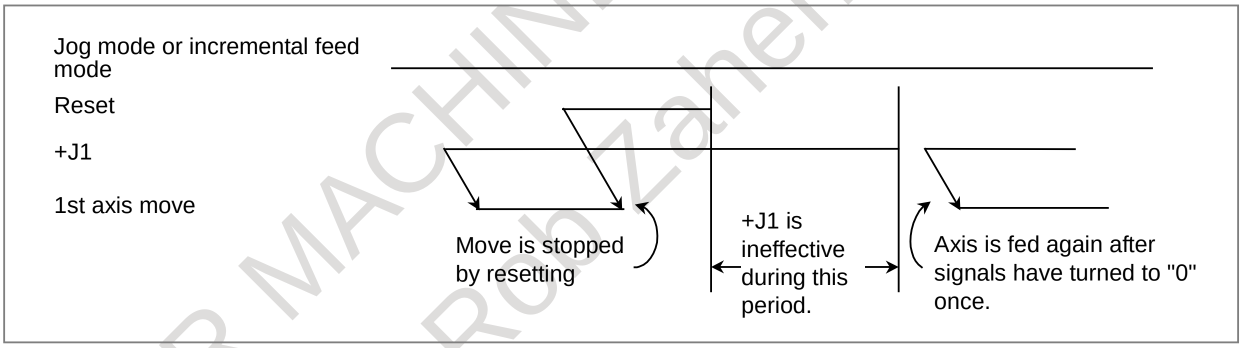
- When jog feed or incremental feed is allowed, the control unit moves the specified axis in the specified direction. In jog feed, the control unit continues to feed the axis while the bit is “1”.



- In incremental feed, the control unit feeds the requested axis by the step distance which is specified by the manual handle feed move distance selection signals MP1, MP2, then the axis stops. Even if the signal is set to “0” while the axis is being fed, the control unit does not stop moving.
  To feed the axis again, set the signal to “0”, then to “1” again.

> ⚠ **CAUTION**
>
> 1 If both the positive direction and negative direction signals of the same axis are simultaneously set to “1”, neither the positive direction nor the negative direction is selected. The control unit assumes that both these signals are set to “0”.
>
> 2 If the feed axis and direction selection signals are set to “1” before the jog feed mode or incremental feed mode is selected, these signals are invalidated. After the jog feed mode or incremental feed mode is selected, set these signal to “0”, then set them to “1” again.
>
> 3 If the control unit is reset while the feed axis and direction selection signals are set to “1” or if a feed axis and direction signal turns to “1” while the control unit is in the reset state, the signal will be ignored even after releasing reset. After the reset state is released, set these signals to “0”, then set them to “1” again.





Manual feedrate override signal *JV0 to *JV15<Gn010,Gn011>

[Classification] Input signal

[Function] Selects a feedrate in jog feed or incremental feed. These signals are in sixteen bit binary code, which corresponds to the override values as follows:

$$\text{Override value (\%)} = 0.01\% \times \sum_{i=0}^{15} \left| 2^i \times Vi \right|$$

where Vi=0 when *JVi is “1”.
Vi=1 when *JVi is “0”.

The override value is assumed to be zero when all of the signals, (*JV0 to *JV15) are set to “1” or “0”. When this occurs, the feed is stopped. The override value can be specified in the range of 0% to 655.34% in units of 0.01%. Some examples are listed below.

*JV0 to *JV15				Override value
12	8	4	0	
1 1 1 1	1 1 1 1	1 1 1 1	1 1 1 1	0
1 1 1 1	1 1 1 1	1 1 1 1	1 1 1 0	0.01
1 1 1 1	1 1 1 1	1 1 1 1	0 1 0 1	0.10
1 1 1 1	1 1 1 1	1 0 0 1	1 0 1 1	1.00
1 1 1 1	1 1 0 0	0 0 0 1	0 1 1 1	10.00
1 1 0 1	1 0 0 0	1 1 1 0	1 1 1 1	100.00
0 1 1 0	0 0 1 1	1 0 1 1	1 1 1 1	400.00
0 0 0 0	0 0 0 0	0 0 0 0	0 0 0 1	655.34
0 0 0 0	0 0 0 0	0 0 0 0	0 0 0 0	0

[Operation] If rapid traverse selection signal RT is “0” during jog feed or incremental feed, actual feedrate is manual feedrate set by parameter No.1423 multiplied by override value selected by this signals.

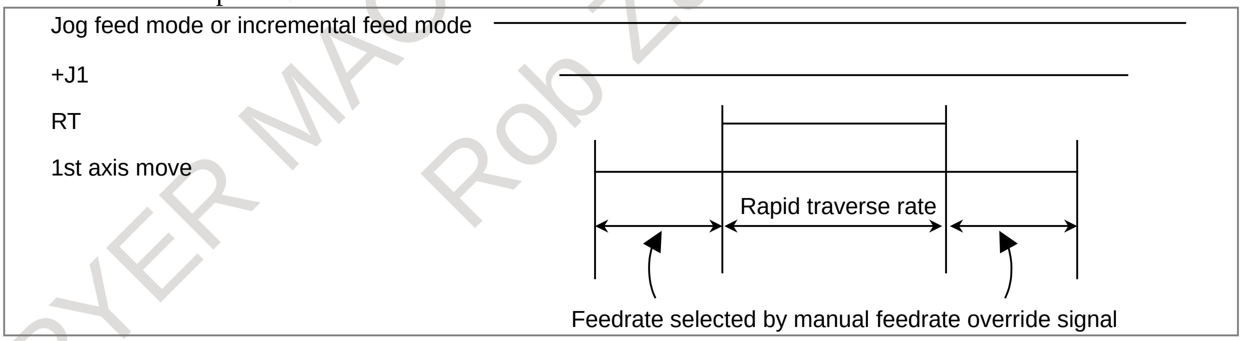
NOTE
The *JVi signals also serve as the override signals during dry run in automatic operation mode.

Manual rapid traverse selection signal RT<Gn019.7>

[Classification] Input signal

[Function] Selects a rapid traverse rate for jog feed or incremental feed.

[Operation] When the signal turns to “1”, the control unit operates as described below:
The control unit executes the jog feed or incremental feed at a rapid traverse rate. The rapid traverse override is validated.
When the signal is switched from “1” to “0” or vice versa during jog feed or incremental feed, the feedrate is decelerated until it reaches zero, then increased to the specified value. During acceleration and deceleration, the feed axis and direction selection signal can be kept “1”.



⚠ WARNING
After the power is turned on, stored stroke check function does not work until the reference position return is completed. During this period, the control unit ignores manual rapid traverse selection signal RT, if it is set to “1”, and keeps moving the tool at a feedrate selected by the manual feedrate override signal. The bit 0 (RPD) of parameter No. 1401 can be set so the rapid traverse is validated before the reference position return is completed.

Signal address

	#7	#6	#5	#4	#3	#2	#1	#0
Gn010	*JV7	*JV6	*JV5	*JV4	*JV3	*JV2	*JV1	*JV0

Parameter

	#7	#6	#5	#4	#3	#2	#1	#0
1002								JAX

[Input type] Parameter input
[Data type] Bit path

#0 JAX Number of axes controlled simultaneously in jog feed, manual rapid traverse and manual reference position return
0: 1 axis
1: 3 axes

	#7	#6	#5	#4	#3	#2	#1	#0
1401								RPD

[Input type] Parameter input
[Data type] Bit path

#0 RPD Manual rapid traverse during the period from power-on time to the completion of the reference position return.
0: Disabled (Jog feed is performed.)
1: Enabled

	#7	#6	#5	#4	#3	#2	#1	#0
1402				JRV			JOV	NPC

[Input type] Parameter input
[Data type] Bit path

#0 NPC Feed per revolution without the position coder (function for converting feed per revolution F to feed per minute F in the feed per revolution mode (G95)) is:
0: Not used
1: Used

#1 JOV Jog override is:
0: Enabled
1: Disabled (tied to 100%)

#4 JRV Jog feed or incremental feed is
0: Performed at feed per minute.
1: Performed at feed per rotation.

NOTE
1 Specify a feedrate in parameter No. 1423.
2 For the machining center system, the threading/synchronous feed is required.

1423	Jog feedrate for each axis

[Input type] Parameter input
[Data type] Real axis
[Unit of data] mm/min, inch/min, deg/min (machine unit)
[Min. unit of data] Depend on the increment system of the applied axis
[Valid data range] Refer to the standard parameter setting table (C)
(When the increment system is IS-B, 0.0 to +999000.0)
(1) When bit 4 (JRV) of parameter No. 1402 is set to 0 set jog feedrate (feed per minute) for each axis when manual feedrate override is 100%.
(2) When bit 4 (JRV) of parameter No. 1402 is set to 1set jog feedrate (feed per revolution) for each axis when manual feedrate override is 100%.

NOTE
This parameter is clamped to the axis-by-axis manual rapid traverse rate (parameter No. 1424).

1424	Manual rapid traverse rate for each axis

[Input type] Parameter input
[Data type] Real axis
[Unit of data] mm/min, inch/min, deg/min (machine unit)
[Min. unit of data] Depend on the increment system of the applied axis
[Valid data range] Refer to the standard parameter setting table (C)
(When the increment system is IS-B, 0.0 to +999000.0)
Set the rate of manual rapid traverse when the rapid traverse override is 100% for each axis.

NOTE
1 If 0 is set, the rate set in parameter No. 1420 (rapid traverse rate for each axis) is assumed.
2 When manual rapid traverse is selected (bit 0 (RPD) of parameter No. 1401 is set to 1), manual feed is performed at the feedrate set in this parameter, regardless of the setting of bit 4 (JRV) of parameter No. 1402.

	#7	#6	#5	#4	#3	#2	#1	#0
1610				JGLx				

[Input type] Parameter input
[Data type] Bit axis

#4 JGLx Acceleration/deceleration in jog feed
0: Exponential acceleration/deceleration is applied.
1: The same acceleration/deceleration as for cutting feedrate is applied.
(Depending on the settings of bits 1 (CTBx) and 0 (CTLx) of parameter No. 1610)

1624	Time constant of acceleration/deceleration in jog feed for each axis.

[Input type] Parameter input
[Data type] Word axis
[Unit of data] msec
[Valid data range] 0 to 4000

Set the time constant used for acceleration/deceleration in jog feed for each axis.

1625	FL rate of acceleration/deceleration in jog feed for each axis

[Input type] Parameter input
[Data type] Real axis
[Unit of data] mm/min, inch/min, deg/min (machine unit)
[Min. unit of data] Depend on the increment system of the applied axis
[Valid data range] Refer to the standard parameter setting table (C)
(When the increment system is IS-B, 0.0 to +999000.0)

Set the FL rate of acceleration/deceleration in jog feed for each axis.
This parameter allows only the exponential type.

	#7	#6	#5	#4	#3	#2	#1	#0
3729							FPRs	

[Input type] Parameter input
[Data type] Bit spindle

#1 FPRs Feed per revolution (without a position coder) is:
0: Not used for a spindle.
1: Used for a spindle.

In a machine that does not use a position coder, by setting bit 1 (FPRs) of parameter No.3729 to 1for each axis, feed per revolution can be performed with a spindle command.
A feed per revolution is
specified with G95 (G99 for lathe systems) in the same way as for normal operation.
When multispindle control is performed, the target spindle for feed per revolution is selected with a position coder select signal (PC2SLC<Gn028.7>, PC3SLC<Gn026.0>, PC4SLC <Gn026.1>).

NOTE
Enable the constant surface speed control (bit 0 (SSC) of parameter No.8133 is 1).

	#7	#6	#5	#4	#3	#2	#1	#0
7001		JEX						

[Input type] Parameter input
[Data type] Bit path

#6 JEX The number of axes controlled simultaneously in jog feed, manual rapid traverse, and manual reference position return is:
0: Set by bit 0 (JAX) of parameter No. 1002.
1: The maximum number of simultaneously controlled axes.

	#7	#6	#5	#4	#3	#2	#1	#0
7103						HNT		

[Input type] Parameter input
[Data type] Bit path

#2 HNT When compared with the travel distance magnification selected by the manual handle feed travel distance selection signals (incremental feed signals) (MP1, MP2), the travel distance magnification for incremental feed/manual handle feed is:
0: Same.
1: 10 times greater.

Warning

⚠ **WARNING**
In incremental feed, when axis is diameter specification, travel distance is diameter value.

Note

NOTE
1 Time constant and method of automatic acceleration/deceleration for manual rapid traverse are the same as rapid traverse in programmed command (positioning by G00).
2 If a manual pulse generator is provided, the manual handle feed mode is enabled instead of incremental feed mode. However, using bit 0 (JHD) of parameter No. 7100 enables both manual handle and incremental feed in the manual handle feed mode.

Reference item

Manual name	Item name
OPERATOR'S MANUAL (B-64694EN)	Jog feed
	Incremental feed

3.2 MANUAL HANDLE FEED

Overview

In the handle mode, when the manual pulse generator on the machine operator's panel is rotated, the axis moves accordingly. Select the axis along which the tool is to be moved with the handle feed axis selection switches.
The minimum distance the tool is moved when the manual pulse generator is rotated by one graduation is equal to the least input increment.
The distance the tool is to be move can be multiplied by one of 4 magnifications selected by manual handle feed movement selection signals MP1, MP2<Gn019.4,5>. The distance can be further multiplied by 10 using bit 2 (HNT) of parameter No. 7103.
The number of manual pulse generators that can be attached is maximum 5. When using the fourth or fifth manual pulse generator, the function "Manual handle feed 4/5-unit" is needed.

NOTE
To use manual handle feed, set 1 in bit 0 (HPG) of parameter No.8131.

Explanation

- Manual handle feed in the jog feed mode

- Incremental feed in the manual handle feed mode

The following states can be selected using bit 0 (JHD) of parameter No. 7100.

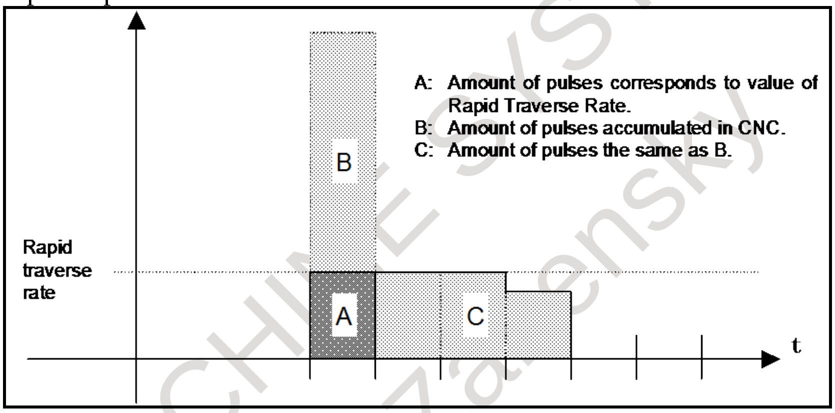
	JHD=0		JHD=1	
	Jog feed mode	**Manual handle feed mode**	**Jog feed mode**	**Manual handle feed mode**
Jog feed	Enabled	Disabled	Enabled	Disabled
Manual handle feed	Disabled	Enabled	Enabled	Enabled
Incremental feed	Disabled	Disabled	Disabled	Enabled

- Manual handle feed in TEACH IN JOG mode

By setting bit 1 (THD) of parameter No. 7100, manual handle feed in TEACH IN JOG mode can be enabled or disabled.

- When manual handle feed exceeding the rapid traverse rate is specified

The amount of pulses exceeding the rapid traverse rate can be saved by CNC as B. And amount of pulses B will be output as pulses C.



Amount of pulses output by CNC in Manual Handle Feed

For pulses exceeding rapid traverse rate, amount of pulses B is calculated in 2 cases as following:

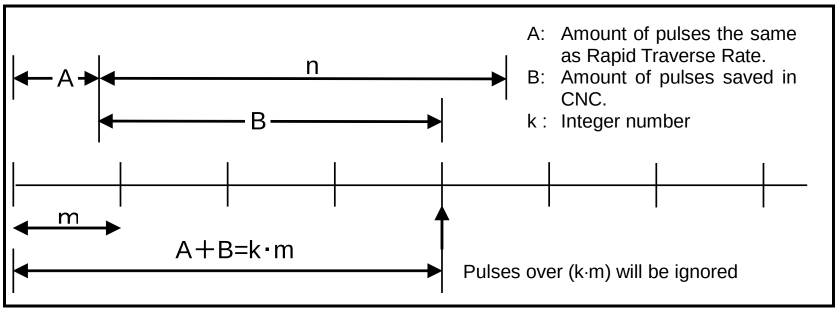
1) In case of parameter No.7117 = 0
The feedrate is clamped at the Rapid Traverse Rate and generated pulses exceeding the Rapid Traverse Rate are ignored (B=0).

2) In case of parameter No.7117 > 0
The feedrate is clamped as the Rapid Traverse Rate, but the pulses exceeding the Rapid Traverse Rate is not ignored. Amount of pulses accumulated in CNC is calculated as following. (Although the rotation of manual pulse generator is stopped, if there is pulses accumulated in CNC, it will be output and the tool will move as long as amount of it. Then the tool stops.)

Magnification set by manual handle feed movement selection signals MP1, MP2<Gn019.4,5> is m, value of parameter No.7117 is n.

n < m: Clamping is set performed at value of parameter No.7117.

n ≥ m: It is clamped in a range not exceeding n so that A+B shown in the following figure is an integral multiple of m. As a result, movement of the axis can be stopped at an integral multiple of the handle feed moving magnification.



Amount of pulses exceeding the Rapid Traverse Rate (n ≥ m)

> **NOTE**
> Due to change of mode, clamping can be performed not as an integral multiple of the selected magnification.
> The distance the tool moves may not match the graduations on the manual pulse generator.

- Upper limit of the feedrate in manual handle feed

The upper limit of the feedrate is determined as follows depending on the input signal (maximum manual handle feedrate switch signal HNDLF) from PMC.

- If HNDLF is “0”, clamping is performed at the manual rapid traverse rate (parameter No. 1424).
- If HNDLF is “1”, clamping is performed at the rate set in parameter No. 1434.

- Movement direction of an axis to the rotation of MPG

Bit 0 (HNGx) of parameter No. 7102 switches the direction of MPG in which the tool moves along an axis, corresponding to the direction in which the handle of the manual pulse generator is rotated.

Manual handle feed direction inversion signal HDN<Gn347.1> inverts the axis movement direction in relation to the rotation direction of the manual handle. The axis whose movement direction is to be inverted can be selected using bit 1 (HNAx) of parameter No. 7102.

The parameter and signal take effect only on the following functions:

- Manual handle feed
- Manual handle interruption

Warning

> ⚠ **WARNING**
> Rotating the handle quickly with a large magnification such as × 100 moves the tool too fast. The feedrate is clamped at the rapid traverse feedrate.

Note

> **NOTE**
> Rotate the manual pulse generator at a rate of five rotations per second or lower. If the manual pulse generator is rotated at a rate higher than five rotations per second, the tool may not stop immediately after the handle is no longer rotated or the distance the tool moves may not match the graduations on the manual pulse generator.

Signal

Manual Handle Feed Axis Selection Signals

HS1A to HS1D<Gn018.0 - 3>, HS1E<Gn411.0>,
HS2A to HS2D<Gn018.4 - 7>, HS2E<Gn411.1>,
HS3A to HS3D<Gn019.0 - 3>, HS3E<Gn411.2>,
HS4A to HS4D<Gn020.0 - 3>, HS4E<Gn411.3>,
HS5A to HS5D<Gn379.0 - 3>, HS5E<Gn412.0>

[Classification] Input signal

[Function] Selects the axis of manual handle feed. A set of five code signals, A, B, C, D and E is provided for each manual pulse generator. (Up to 5 generators can be used.) (For multi-path control, there is a set of code signals for each path for each manual pulse generator.) The number in the signal name indicates the number of the manual pulse generator to be used.

HS1A

1 : Selection of axis to be moved by 1st. manual pulse generator
2 : Selection of axis to be moved by 2nd. manual pulse generator
3 : Selection of axis to be moved by 3rd. manual pulse generator
4 : Selection of axis to be moved by 4th. manual pulse generator
5 : Selection of axis to be moved by 5th. manual pulse generator

Code signals A, B, C, D, and E correspond to the feed axes listed in following table:

Manual handle feed axis selection signals					Feed axis
HSnE	HSnD	HSnC	HSnB	HSnA	
0	0	0	0	0	No selection (None of axis is fed)
0	0	0	0	1	1st axis
0	0	0	1	0	2nd axis
0	0	0	1	1	3rd axis
		to			to
1	0	1	1	0	22nd axis
1	0	1	1	1	23rd axis
1	1	0	0	0	24th axis

Manual handle feed amount selection signals (Incremental feed signals)

MP1, MP2<Gn019.4,5>, MP21, MP22 <Gn087.0,1>, MP31, MP32 <Gn087.3,4>,
MP41, MP42 <Gn087.6,7>, MP51, MP52 <Gn380.0,1>

[Classification] Input signal

[Function] This signal selects the distance traveled per pulse from the manual pulse generator during the manual handle feed or manual handle interrupt. It also selects the distance traveled per incremental feed step.

The table below lists the signal-to-distance correspondence.

Manual Handle Feed Amount Selection signals		Distance Traveled		
MP2	MP1	Manual Handle Feed	Manual Handle Interruption	Incremental Feed
0	0	Minimum unit × 1	Minimum unit × 1	Minimum unit × 1
0	1	Minimum unit × 10	Minimum unit × 10	Minimum unit × 10
1	0	Minimum unit × m[*1]	Minimum unit × m[*1]	Minimum unit × 100
1	1	Minimum unit × n[*1]	Minimum unit × n[*1]	Minimum unit × 1000

*1 Scale factors m and n are specified using parameter No.7113 and 7114.

Scale factors m and n of each axis are specified using parameter No.12350 and 12351.

> ⚠ **CAUTION**
> 1 Because the least input increment is used as the units for manual handle and incremental feed, the same value represents a different distance depending on whether the metric or inch input system is used.
> 2 For an axis under diameter programming, the tool moves by the diameter value.

Furthermore, Manual Handle Feed Amount Selection Signals of each Manual Pulse Generator can be used by setting bit 5 (MPX) of parameter No.7100. The relation between Manual Handle Feed Amount Selection signals of each Manual Pulse Generator and parameter to set magnification is showed in the next table.

Value of bit 5 (MPX) of parameter No. 7100	Manual Pulse Generator	Manual Handle Feed Amount Selection signals	Parameter of Magnification	
			m_x	n_x
MPX=0	1st.-5th. Manual Pulse Generator	MP1,MP2	No.7113	No.7114
MPX=1	1st. Manual Pulse Generator	MP1,MP2	No.7113	No.7114
	2nd. Manual Pulse Generator	MP21,MP22	No.7131	No.7132
	3rd. Manual Pulse Generator	MP31,MP32	No.7133	No.7134
	4th. Manual Pulse Generator	MP41,MP42	No.7135	No.7136
	5th. Manual Pulse Generator	MP51,MP52	No.7137	No.7138

Maximum manual handle feedrate switch signal HNDLF<Gn023.3>

[Classification] Input signal

[Function] Selects the maximum feedrate in manual handle feed. The maximum feedrate in manual handle feed is determined according to the state of this signal as follows.

Maximum manual handle feedrate switch signal	Maximum feedrate
0	Manual rapid traverse rate (parameter No. 1424)
1	Maximum manual handle feedrate (parameter No. 1434)

Manual handle feed direction inversion signal HDN<Gn347.1>

[Classification] Input signal

[Function] Inverts the rotation direction of the manual pulse generator and the axis movement direction in manual handle feed.

0: Does not invert the axis movement direction in relation to the rotation direction of the manual pulse generator.

1: Inverts the axis movement direction in relation to the rotation direction of the manual pulse generator.

The axis whose movement direction is to be inverted by this signal can be selected using bit 1 (HNAx) of parameter No. 7102. This signal does not work on the rotation direction of manual linear/circular interpolation.

Parameter

1424	Manual rapid traverse rate for each axis

[Input type] Parameter input
[Data type] Real axis
[Unit of data] mm/min, inch/min, deg/min (machine unit)
[Min. unit of data] Depend on the increment system of the applied axis
[Valid data range] Refer to the standard parameter setting table (C)
(When the increment system is IS-B, 0.0 to +999000.0)

Set the rate of manual rapid traverse when the rapid traverse override is 100% for each axis.

NOTE
1. If 0 is set, the rate set in parameter No. 1420 (rapid traverse rate for each axis) is assumed.
2. When manual rapid traverse is selected (bit 0 (RPD) of parameter No. 1401 is set to 1), manual feed is performed at the feedrate set in this parameter, regardless of the setting of bit 4 (JRV) of parameter No. 1402.

1434	Maximum manual handle feedrate for each axis

[Input type] Parameter input
[Data type] Real axis
[Unit of data] mm/min, inch/min, deg/min (machine unit)
[Min. unit of data] Depend on the increment system of the applied axis
[Valid data range] Refer to the standard parameter setting table (C)
(When the increment system is IS-B, 0.0 to +999000.0)

Set a maximum manual handle feedrate for each axis in case of maximum manual handle feedrate switch signal HNDLF<Gn023.3>=1.

	#7	#6	#5	#4	#3	#2	#1	#0
7100			MPX				THD	JHD

[Input type] Parameter input
[Data type] Bit path

#0 JHD Manual handle feed in JOG feed mode or incremental feed in the manual handle feed is:
0: Invalid.
1: Valid.

#1 THD In the TEACH IN JOG mode, the manual pulse generator is:
0: Disabled.
1: Enabled.

#5 MPX In Manual handle feed mode:
0 : Manual handle feed amount selection signals MP1 and MP2 <Gn019.4 and Gn019.5> for the 1st manual pulse generator are used as signals common to all manual pulse generators.
1 : Manual handle feed amount selection signals differ depending on the manual pulse generator as follow:
1st. Manual Pulse Generator : MP1, MP2 <Gn019.4, Gn019.5>
2nd. Manual Pulse Generator : MP21, MP22 <Gn087.0, Gn087.1>
3rd. Manual Pulse Generator : MP31, MP32 <Gn087.3, Gn087.4>
4th. Manual Pulse Generator : MP41, MP42 <Gn087.6, Gn087.7>
5th. Manual Pulse Generator : MP51, MP52 <Gn380.0, Gn380.1>

	#7	#6	#5	#4	#3	#2	#1	#0
7102							HNAx	HNGx

[Input type] Parameter input
[Data type] Bit axis

#0 HNGx Axis movement direction for rotation direction of manual pulse generator
0: Same in direction
1: Reverse in direction

#1 HNAx When manual handle feed direction inversion signal HDN <Gn0347.1> is set to "1", the direction of movement is set for each axis with respect to the rotation direction of the manual pulse generator.
0: The axis movement direction is the same as the direction in which the manual pulse generator rotates.
1: The axis movement direction is opposite to the direction in which the manual pulse generator rotates.
When the rotation direction is reversed by manual handle feed direction inversion signal HDN <Gn0347.1>, the rotation axis direction obtained by the setting of bit 0 (HNGx) of parameter No. 7102 is reversed.

	#7	#6	#5	#4	#3	#2	#1	#0
7103						HNT		

[Input type] Parameter input
[Data type] Bit path

#2 HNT When compared with the travel distance magnification selected by the manual handle feed travel distance selection signals (incremental feed signals MP1, MP2), the travel distance magnification for incremental feed/manual handle feed is:

0: Same.
1: 10 times greater.

	#7	#6	#5	#4	#3	#2	#1	#0
7105							HDX	

[Input type] Parameter input
[Data type] Bit

> **NOTE**
> When this parameter is set, the power must be turned off before operation is continued.

#1 HDX Manual handle for I/O Link connection is:

0: Automatically set.
1: Manually set.

> **NOTE**
> In manual setting, parameters Nos. 12300 to 12304 and 12340 to 12344 must be set by manual to connect Manual Pulse Generator with I/O Link.

7113	Manual handle feed magnification m

[Input type] Parameter input
[Data type] Word path
[Valid data range] 1 to 2000

This parameter sets the magnification m when manual handle feed movement selection signals MP1 and MP2 are set to "0" and "1".

7114	Manual handle feed magnification n

[Input type] Parameter input
[Data type] Word path
[Valid data range] 1 to 2000

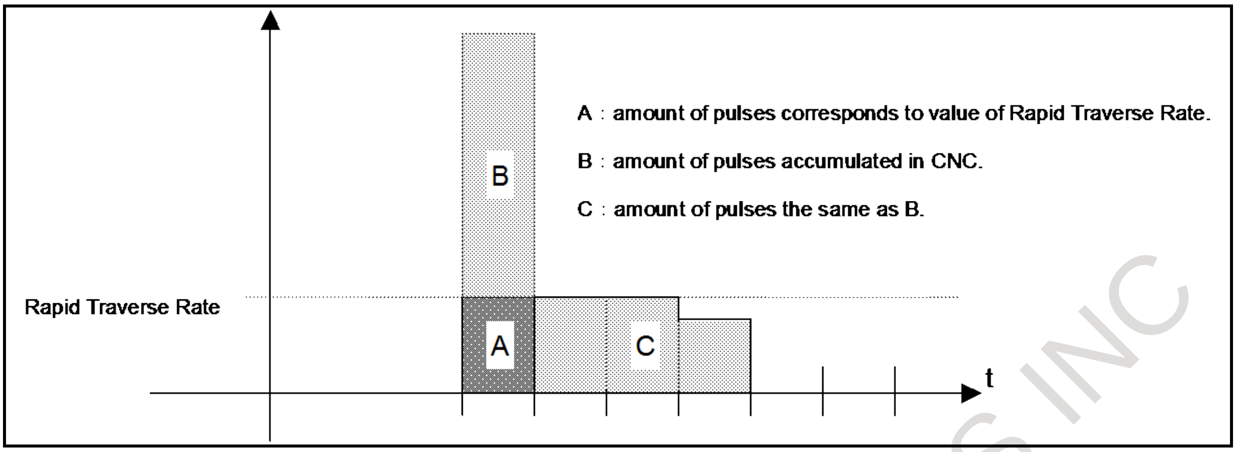
This parameter sets the magnification when manual handle feed movement selection signals MP1 and MP2 are set to "1".

7117	Allowable number of pulses that can be accumulated during manual handle feed

[Input type] Parameter input
[Data type] 2-word path
[Unit of data] Pulse
[Valid data range] 0 to 999999999

This parameter sets the number of pulses from the manual pulse generator that exceed the rapid traverse rate and can be accumulated without being discarded if manual handle feed faster than the rapid traverse rate is specified.

The amount of pulses exceeding the rapid traverse rate can be saved by CNC as B. And amount of pulses B will be exported as pulses C.



Amount of pulses exported by CNC in Manual Handle Feed

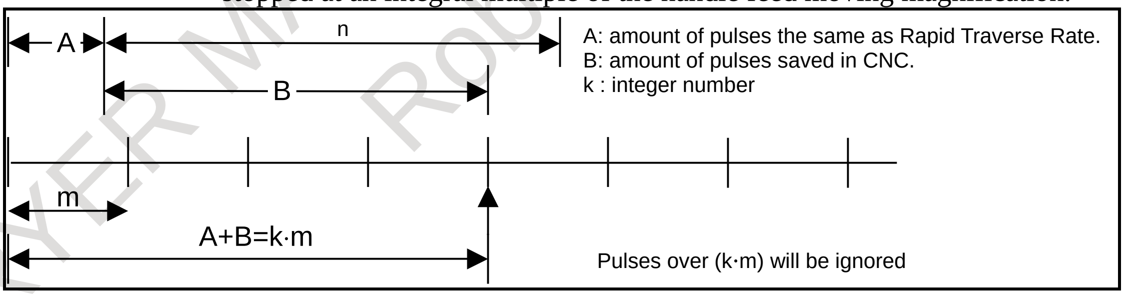
Amount of pulses B is calculated in 2 cases as following:

1) In case of parameter No.7117 = 0
   The feedrate is clamped at the Rapid Traverse Rate and generated pulses exceeding the Rapid Traverse Rate are ignored (B=0)
2) In case of parameter No.7117 > 0
   The feedrate is clamped as the Rapid Traverse Rate, but the handle pulses exceeding the Rapid Traverse Rate is not ignored. Amount of pulses accumulated in CNC is calculated as following. (Although the rotation of manual pulse generator is stopped, if there is pulses accumulated in CNC, it will be output and the tool will move as long as amount of it. Then the tool stops.)

Magnification set by manual handle feed amount selection signals MP1, MP2 <Gn019.4, Gn019.5> is m, value of parameter No.7117 is n.

n < m: Clamping is set performed at value of parameter No.7117.

n ≥ m: It is clamped in a range not exceeding n so that A+B shown in the following figure is an integral multiple of m. As a result, movement of the axis can be stopped at an integral multiple of the handle feed moving magnification.



Amount of pulses exceeding the Rapid Traverse Rate (n ≥ m)

> **NOTE**
> Due to change of mode, clamping can be performed not as an integral multiple of the selected magnification.
> The distance the tool moves may not match the graduations on the manual pulse generator.

7131	**Manual handle feed magnification m2 / 2nd. manual pulse generator**
7132	**Manual handle feed magnification n2 / 2nd. manual pulse generator**
7133	**Manual handle feed magnification m3 / 3rd. manual pulse generator**

7134	**Manual handle feed magnification n3 / 3rd. manual pulse generator**
7135	**Manual handle feed magnification m4 / 4th. manual pulse generator**
7136	**Manual handle feed magnification n4 / 4th. manual pulse generator**
7137	**Manual handle feed magnification m5 / 5th. manual pulse generator**
7138	**Manual handle feed magnification n5 / 5th. manual pulse generator**

[Input type] Parameter input
[Data type] Word path
[Valid data range] 1 to 2000

The 'mx' sets magnification when manual handle feed amount selection signals MPx1 = 0, MPx2 = 1. The 'nx' sets magnification when manual handle feed amount selection signals MPx1 = 1, MPx2 = 1.

12300	**X address of the 1st. manual pulse generator**
12301	**X address of the 2nd. manual pulse generator**
12302	**X address of the 3rd. manual pulse generator**
12303	**X address of the 4th. manual pulse generator**
12304	**X address of the 5th. manual pulse generator**

> **NOTE**
> When these parameters are set, the power must be turned off before operation is continued.

[Input type] Parameter input
[Data type] Word
[Valid data range] -1, 0 to 127, 200 to 327, 400 to 527, 600 to 727

To set X address of manual pulse generator connected with I/O Link in PMC.
When the manual pulse generator is not connected, set -1 to this parameter.

	PMC Path	X Address
1st. manual pulse generator	No. 12340	No. 12300
2nd. manual pulse generator	No. 12341	No. 12301
3rd. manual pulse generator	No. 12342	No. 12302
4th. manual pulse generator	No. 12343	No. 12303
5th. manual pulse generator	No. 12344	No. 12304

Setting of PMC path set with parameters Nos.12340 to 12344 is as follows.

Value	PMC Path
0	1st. PMC
1	
2	2nd. PMC
3	3rd. PMC

> **NOTE**
> Set these parameters when bit 1 (HDX) of parameter No. 7105 is set to 1. When HDX = 0, these parameters are automatically set. If a manual handle is not connected when HDX = 0, -1 is set automatically.

12340	PMC path of the 1st. manual pulse generator connected with I/O Link
12341	PMC path of the 2nd. manual pulse generator connected with I/O Link
12342	PMC path of the 3rd. manual pulse generator connected with I/O Link
12343	PMC path of the 4th. manual pulse generator connected with I/O Link
12344	PMC path of the 5th. manual pulse generator connected with I/O Link

NOTE
When these parameters are set, the power must be turned off before operation is continued.

[Input type] Parameter input
[Data type] Byte
[Valid data range] 0 to 3
Referring to parameters Nos. 12300 to 12304.

12350	Manual handle feed magnification m in each axis

[Input type] Parameter input
[Data type] Word axis
[Valid data range] 0 to 2000
For each axis, this parameter sets the magnification m when manual handle feed movement selection signals MP1 = 0, MP2 = 1.

NOTE
When value is set to 0 for this parameter, the parameter No. 7113 is valid.

12351	Manual handle feed magnification n in each axis

[Input type] Parameter input
[Data type] Word axis
[Valid data range] 0 to 2000
For each axis, this parameter sets the magnification when manual handle feed movement selection signals MP1 = “1”, MP2 = “1”.

NOTE
When value is set to 0 for this parameter, the parameter No. 7114 is valid.

Reference item

Manual name	Item name
OPERATOR’S MANUAL (B-64694EN)	Manual handle feed

3.2.1 Jog and Handle Simultaneous Mode

Overview

Usually, manual handle feed is enabled only when the operation mode is set to the manual handle feed mode. By setting bit 0 (JHD) of parameter No. 7100, however, manual handle feed can be performed even in Jog feed mode. At this setting, moreover, incremental feed can be performed even in the manual handle feed mode.

Explanation

When bit 0 (JHD) of parameter No. 7100 is set to 1 (jog and handle simultaneous mode), the enabled feed in each mode is as follows.

	Jog feed	Manual handle feed	Incremental feed
Jog feed mode (JOG mode)	Enabled	Enabled	Disabled
Manual handle feed mode (HND mode)	Disabled	Enabled	Enabled

- Superimposed feed of the jog feed and the manual handle feed

When bit 0 (JHD) of parameter No. 7100 is set to 1 (jog and handle simultaneous mode), the jog feed and the manual handle feed can be superimposed in jog feed mode. In order to perform superimposed operation, type of acceleration/deceleration and the time constant are the same in the jog feed and the manual handle feed. The type of acceleration/deceleration and the time constant in manual handle feed follow the type of acceleration/deceleration and the time constant in previous commanded feed (either jog feed or manual rapid traverse).

Fig. 3.2.1 (a) and (b) show the following operation in JOG mode.
(1) Jog feed
(2) Jog feed and manual handle feed
When the manual rapid traverse selection signal RT<Gn019.7> is set to "0", the type of acceleration/deceleration and the time constant in jog feed are the same as those in jog feed. The type of acceleration/deceleration and the time constant in manual handle feed is the same as those in previous commanded jog feed.

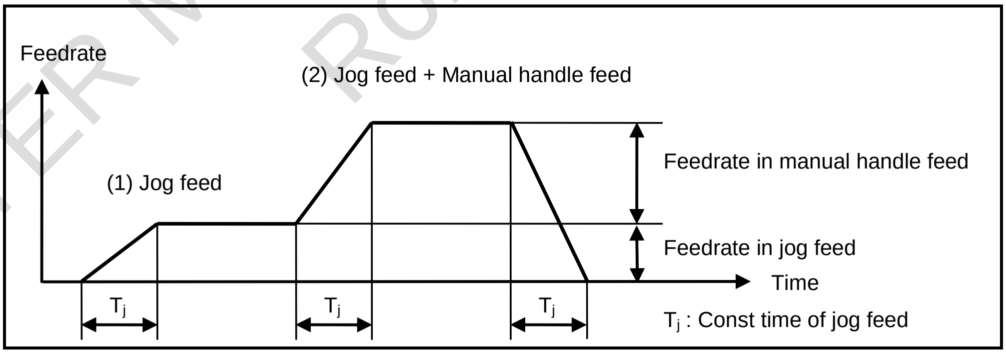


Fig. 3.2.1 (a) Superimposed operation (when RT<Gn019.7> is "0")

When the manual rapid traverse selection signal RT<Gn019.7> is set to "1", the type of acceleration/deceleration and the time constant in jog feed are the same as those in rapid traverse. The type of acceleration/deceleration and the time constant in manual handle feed is the same as those in previous commanded manual rapid traverse.

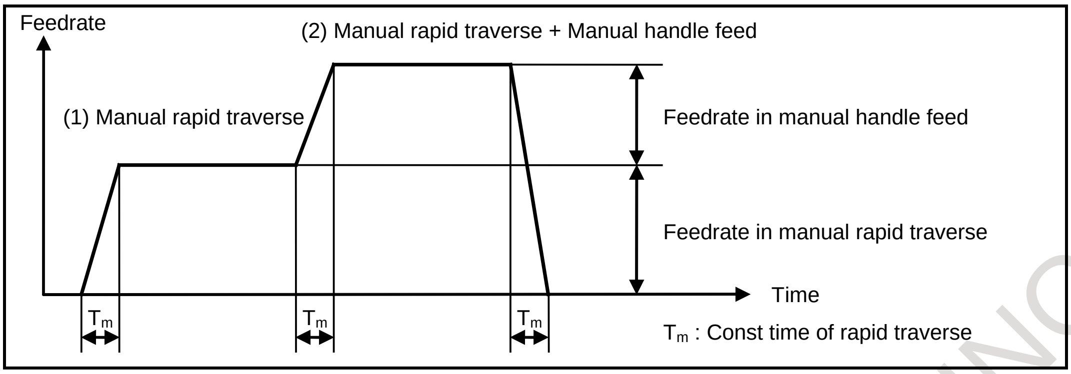

Fig. 3.2.1 (b) Superimposed operation (when RT<Gn019.7> is "1")
(Acceleration/deceleration of time fixed type is used for positioning of linear interpolation type.)

Fig. 3.2.1 (c) and (d) show the operation which commanded in the following order in JOG mode.
(1) Manual handle feed
(2) Jog feed
(3) Manual handle feed
The type of acceleration/deceleration and the time constant in the manual handle feed are switched after the jog feed.

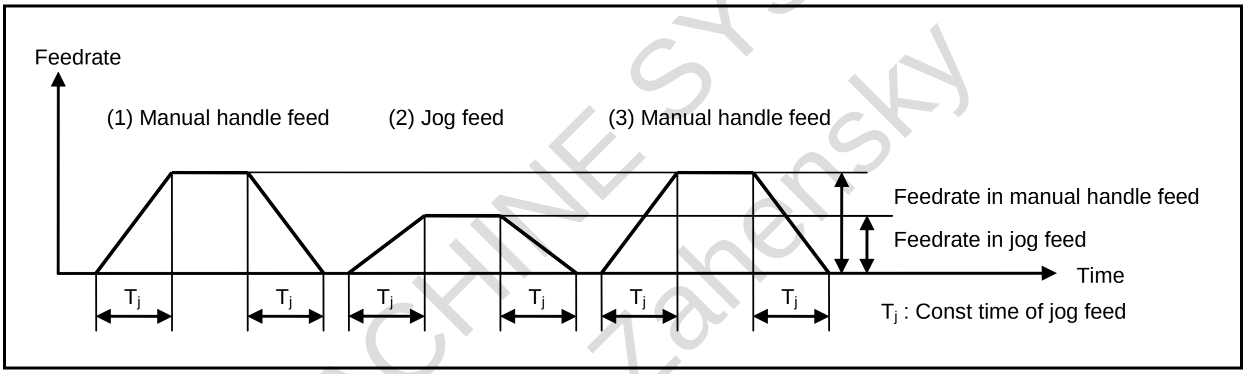

Fig. 3.2.1 (c) Switch of the jog feed and the manual handle feed (when RT<Gn019.7> is "0")

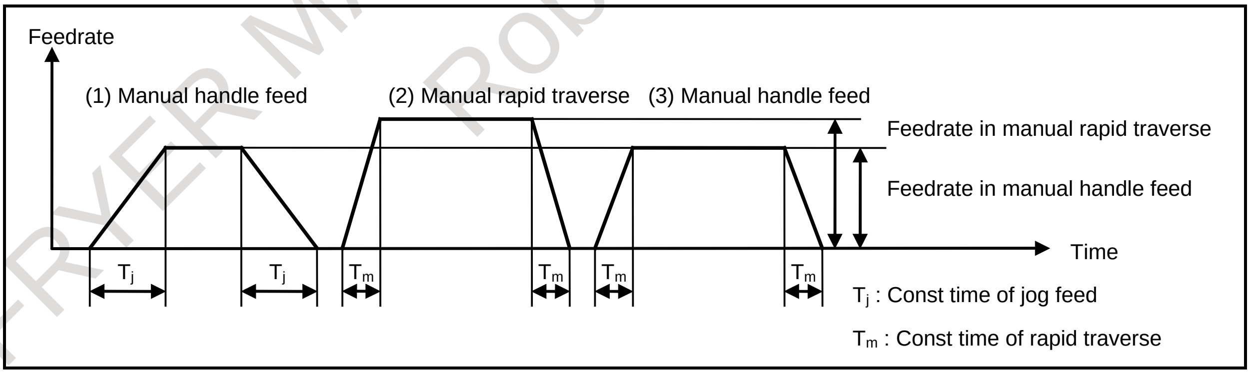

Fig. 3.2.1 (d) Switch of the jog feed and the manual handle feed (when RT<Gn019.7> is "1")

Fig.3.2.1 (e)and (f) show the operation which started (2) manual handle feed immediately after (1) jog feed. Feed can be switched without deceleration stop because the same type of acceleration/deceleration and time constant are used.

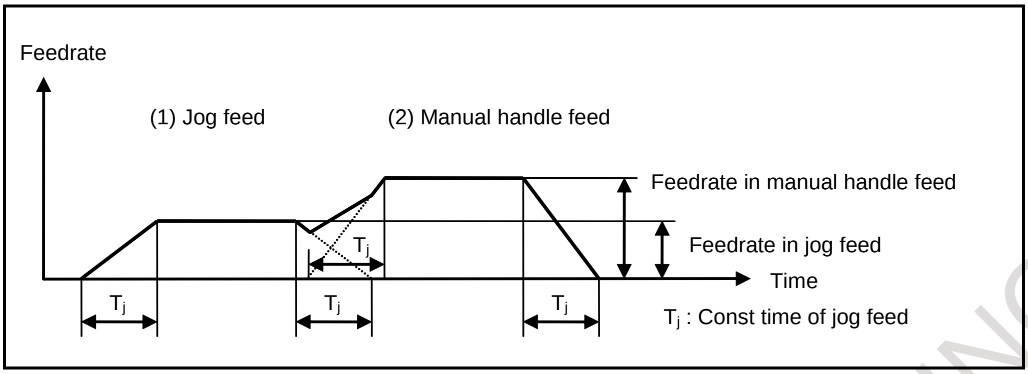

Fig.3.2.1 (e) Switch from the jog feed to the manual handle feed (when RT<Gn019.7> is "0")

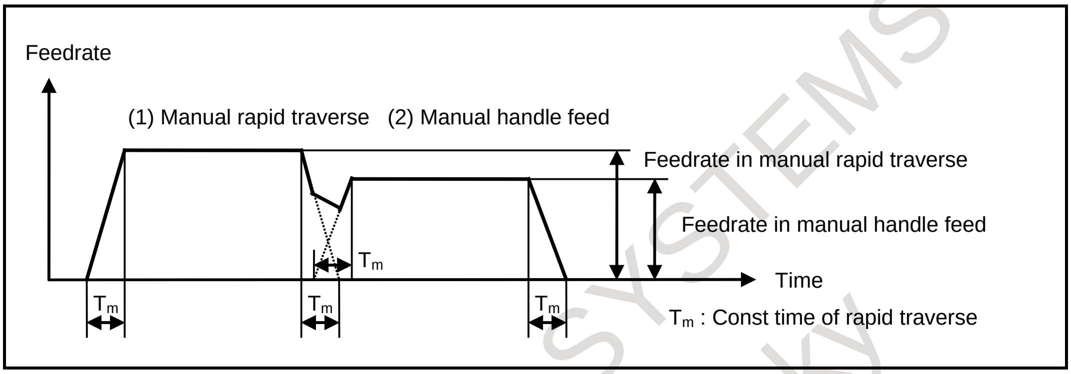

Fig.3.2.1 (f) Switch from the jog feed to the manual handle feed (when RT<Gn019.7> is "1")

- Prohibition of superimposed feed of the jog feed and the manual handle feed (Bit 1 (FJH) of parameter No. 7107)

When bit 1 (FJH) of parameter No. 7107 is set to 1, the jog feed and the manual handle feed are not superimposed. Priority can be placed on the jog feed if both are executed at the same time.

Fig. 3.2.1 (g) and (h) show the operation which commanded in the following order in JOG mode.
(1) Manual handle feed
(2) Jog feed
(3) Manual handle feed
When manual rapid traverse selection signal RT <Gn019.7> is set to "0", the type of acceleration/deceleration and the time constant in jog feed and manual handle feed are those of jog feed.

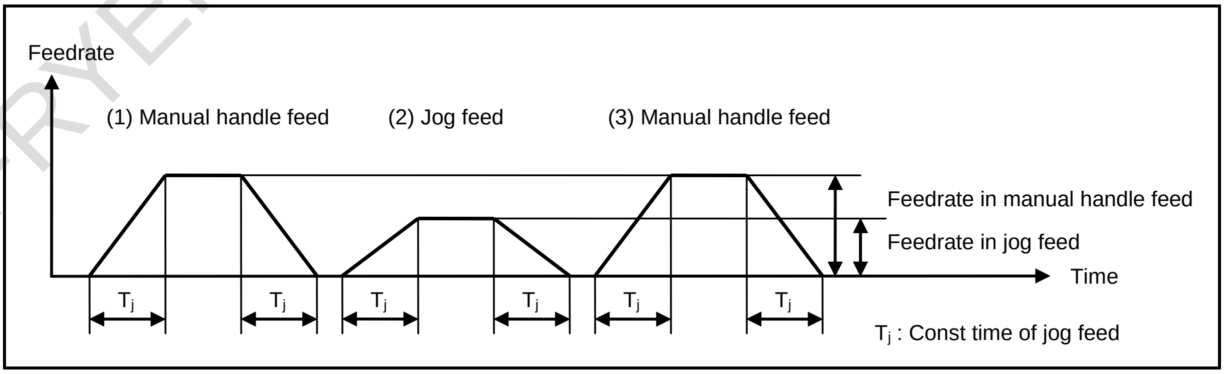

Fig. 3.2.1 (g) Switch of the jog feed and the manual handle feed (when RT<Gn019.7> is "0")

When manual rapid traverse selection signal RT <Gn019.7> is set to "1", the type of acceleration/deceleration and the time constant in jog feed are those of rapid traverse, the type of acceleration/deceleration and the time constant in manual handle feed are those of jog feed.

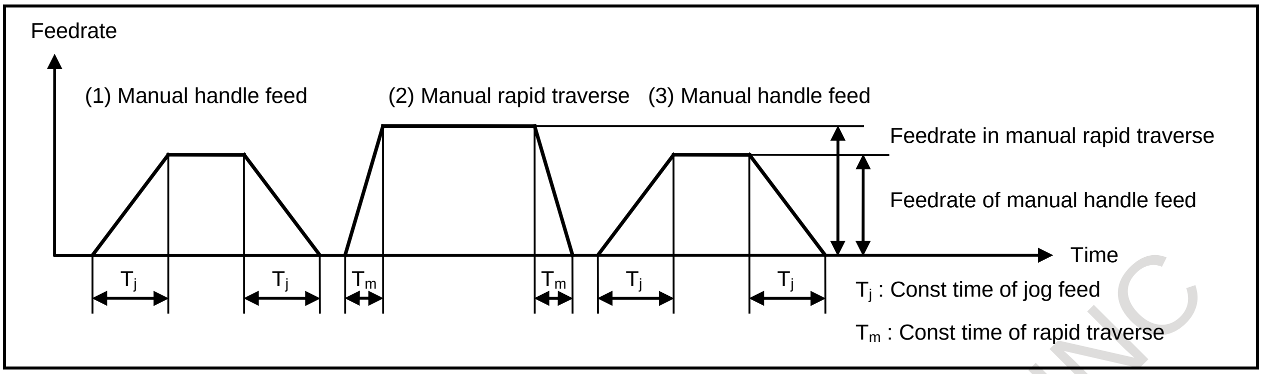

Fig. 3.2.1 (h) Switch of the jog feed and the manual handle feed (when RT<Gn019.7> is "1")

Fig.3.2.1 (i) and (j) show the operation which started (2) manual handle feed immediately after (1) jog feed.
The type of acceleration/deceleration and the time constant are switched after checking that delay in acceleration/deceleration is 0.

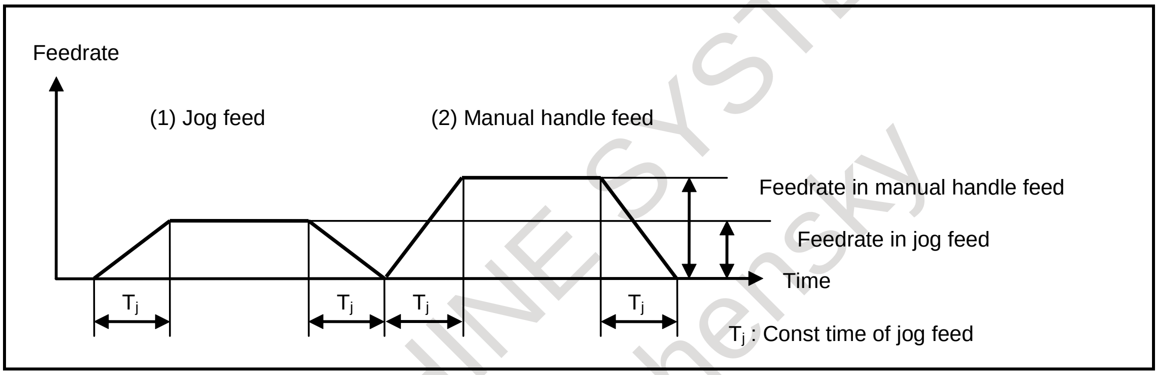

Fig.3.2.1 (i) Switch from the jog feed to the manual handle feed (when RT<Gn019.7> is "0")

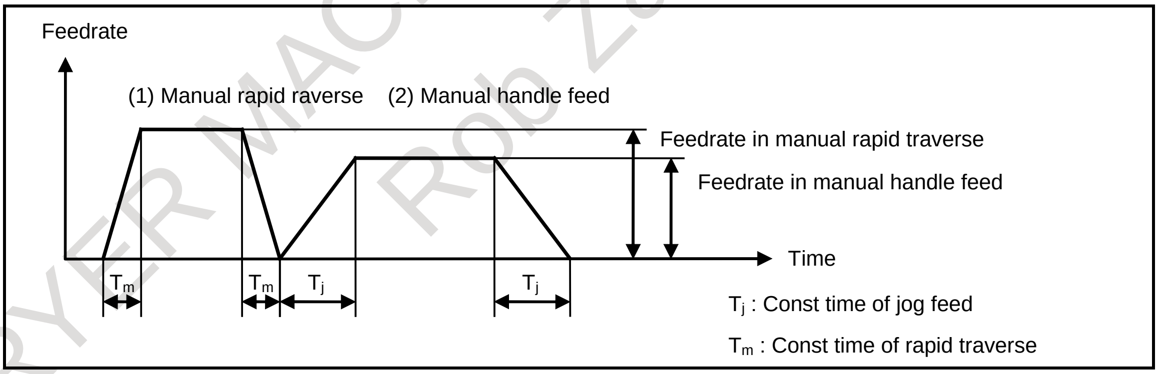

Fig.3.2.1 (j) Switch from the jog feed to the manual handle feed (when RT<Gn019.7> is "1")

- TEACH IN JOG mode

When bit 1 (THD) of parameter No.7100 is set to 1, manual handle can be effective in TEACH IN JOG mode. Bit 1 (FJH) of parameter No.7107 is effective in this case.

Parameter

	#7	#6	#5	#4	#3	#2	#1	#0
7100							THD	JHD

[Input type] Parameter input
[Data type] Bit path

#0 JHD Manual handle feed in JOG feed mode or incremental feed in the manual handle feed is:
0: Invalid.
1: Valid.

#1 THD In the TEACH IN JOG mode, the manual pulse generator is:
0: Disabled.
1: Enabled.

	#7	#6	#5	#4	#3	#2	#1	#0
7107							FJH	

[Input type] Parameter input
[Data type] Bit

#1 FJH When bit 0 (JHD) of parameter No. 7100 is 1, jog feed and manual handle feed in jog feed mode, or incremental feed and manual handle feed in manual handle feed are:
0: superimposed. The type of acceleration/deceleration and the time constant in manual handle feed are the type of acceleration/deceleration and the time constant in previous commanded feed (either jog feed or manual rapid traverse).
1: not superimposed. Priority can be placed on jog feed or incremental feed if they and manual handle feed are executed at the same time. If there is an axis for jog feed or incremental feed even for one axis in the path, handle feed is invalid for all axes in the path. The type of acceleration/deceleration and the time constant in manual handle feed are always those of jog feed.

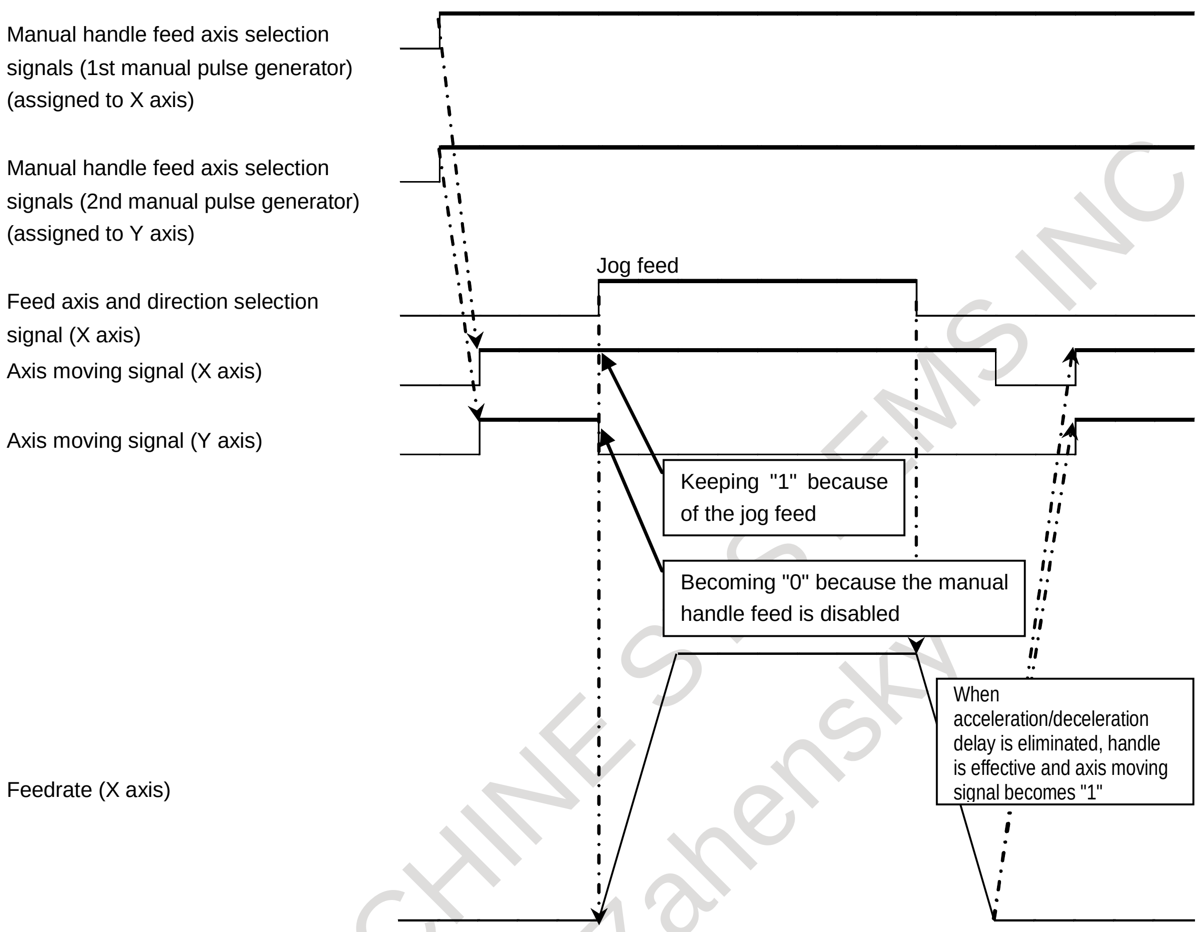
> **NOTE**
> When bit 1 (THD) of parameter No.7100 is set to 1, this parameter is effective to jog feed and manual handle feed in TEACH IN JOG mode.

Notes

1) Axis moving signals MVx<Fn102> of axes that manual handle feed is effective become "1". When bit 1 (FJH) of parameter No. 7107 is set to 1, even if the manual handle is allocated in axes other than the jog feed axes, the signals MVx<Fn102> of those axes does not become "1" because manual handle feed of those axes is not effective. When the manual handle feed become effective after checking that delay in acceleration/deceleration is 0, the signals MVx<Fn102> become "1".

Example of timing diagram of MVx<Fn102> when bit 1 (FJH) of parameter No. 7107 is 1

Jog feed with X axis is executed when the manual handle is allocated in X axis and Y axis.



*Above-mentioned timing that Axis moving signal becomes "1" after jog feed is one example.
That is different according to the specified speed and the in-position width.

3.3 MANUAL HANDLE INTERRUPT

Overview

In the automatic operation mode (manual data input, DNC operation, or memory operation) or memory edit mode, by rotating the manual pulse generator, handle feed can be performed by superimposing on the movement by automatic operation. The axis to which the handle interrupt is applied is selected using the manual handle interrupt axis selection signal. The minimum travel distance per graduation is the least command increment. The distance can be scaled by one of four types of magnification that is selected using manual handle feed movement selection signals MP1 and MP2 <Gn019 .4 and .5>.
The scaled distance can be multiplied by 10 using bit 3 (HIT) of parameter No. 7103. Each scale factor can be selected using the manual handle travel distance selection signals (refer to "Manual Handle Feed").

> ⚠ **WARNING**
> The amount of movement per graduation for manual handle interrupt is equal to the least input increment like that for manual handle feed. For example, for metric input on an inch machine, the tool moves by 0.01 inches for 254 graduations; for inch input on a millimeter machine, it moves by 0.254 mm for 100 graduations.

Signal

Manual Handle Interrupt Axis Selection Signals

HS1IA to HS1ID<Gn041.0 to 3>, HS1IE<Gn411.4>
HS2IA to HS2ID<Gn041.4 to 7>, HS2IE<Gn411.5>
HS3IA to HS3ID<Gn042.0 to 3>, HS3IE<Gn411.6>
HS4IA to HS4ID<Gn088.4 to 7>, HS4IE<Gn411.7>
HS5IA to HS5ID<Gn379.4 to 7>, HS5IE<Gn412.4>

[Classification] Input signal

[Function] These signals select an axis to which the manual handle interrupt is applied. There are five sets of signals, each corresponding to a manual pulse generator (up to five). Each set consists of five code signals A, B, C, D and E. The number in the signal name indicates the number of the manual pulse generator to be used.

HSxIA

x : 1 Selects the axis for which manual pulse generator No. 1 is used
2 Selects the axis for which manual pulse generator No. 2 is used
3 Selects the axis for which manual pulse generator No. 3 is used
4 Selects the axis for which manual pulse generator No. 4 is used
5 Selects the axis for which manual pulse generator No. 5 is used

The correspondence between code signals A, B, C, D, and E and selected feed axes is similar to the correspondence of the manual handle feed axis selection signals. See "Manual Handle Feed Axis Selection signals."

Parameter

1466	Feedrate for retraction in threading cycle G92 or G76
	Feedrate for retraction in threading cycle G76.7

[Input type] Parameter input
[Data type] Real path
[Unit of data] mm/min, inch/min (machine unit)
[Min. unit of data] Depend on the increment system of the reference axis
[Valid data range] Refer to the standard parameter setting table (C)
(When the increment system is IS-B, 0.0 to +999000.0)
When threading cycle G92, G76 or G76.7 is specified, retraction is performed after threading. Set a feedrate for this retraction.

> ⚠ **WARNING**
> When the manual handle interruption is valid, set the same value as the parameter No.1430 to the parameter No.1466.

> **NOTE**
> When this parameter is set to 0 or bit 1 (CFR) of parameter No. 1611 is set to 1, the rapid traverse rate set in parameter No. 1420 is used.

	#7	#6	#5	#4	#3	#2	#1	#0
1606								MNJx

[Input type] Parameter input
[Data type] Bit axis

#0 MNJx In manual handle interrupt or automatic manual simultaneous operation (interrupt type):
0: Only cutting feed acceleration/deceleration is enabled, and jog feed acceleration/deceleration is disabled.
1: Both cutting feed acceleration/deceleration and jog feed acceleration/deceleration are applied.

	#7	#6	#5	#4	#3	#2	#1	#0
6004						VHD		

[Input type] Parameter input
[Data type] Bit path

#2 VHD With system variables #5121 to #5140:
0: The tool offset value (geometry offset value) in the block currently being executed is read. (This parameter is valid only when tool geometry/tool wear compensation memories are available.)
1: An interrupt travel distance based on manual handle interrupt is read.

	#7	#6	#5	#4	#3	#2	#1	#0
7100					HCL			

[Input type] Parameter input
[Data type] Bit path

#3 HCL The clearing of handle interruption amount display by soft key [INTRPT CANCEL] operation is:
0: Disabled.
1: Enabled.

	#7	#6	#5	#4	#3	#2	#1	#0
7102								HNGx

[Input type] Parameter input
[Data type] Bit axis

#0 HNGx Axis movement direction for rotation direction of manual pulse generator
0: Same in direction
1: Reverse in direction

	#7	#6	#5	#4	#3	#2	#1	#0
7103					HIT		RTH	

[Input type] Parameter input
[Data type] Bit path

#1 RTH By a reset or emergency stop, the amount of manual handle interruption is:
0: Not canceled.
1: Canceled.

#3 HIT When compared with the travel distance magnification selected by the manual handle feed travel distance selection signals (incremental feed signals MP1, MP2 <Gn019.4, Gn019.5>), the travel distance magnification for manual handle interrupt is:
0: Same.
1: 10 times greater.

7113	Manual handle feed magnification m

[Input type] Parameter input
[Data type] Word path
[Valid data range] 1 to 2000
This parameter sets the magnification m when manual handle feed movement selection signals MP1 and MP2 are set to “0” and “1”.

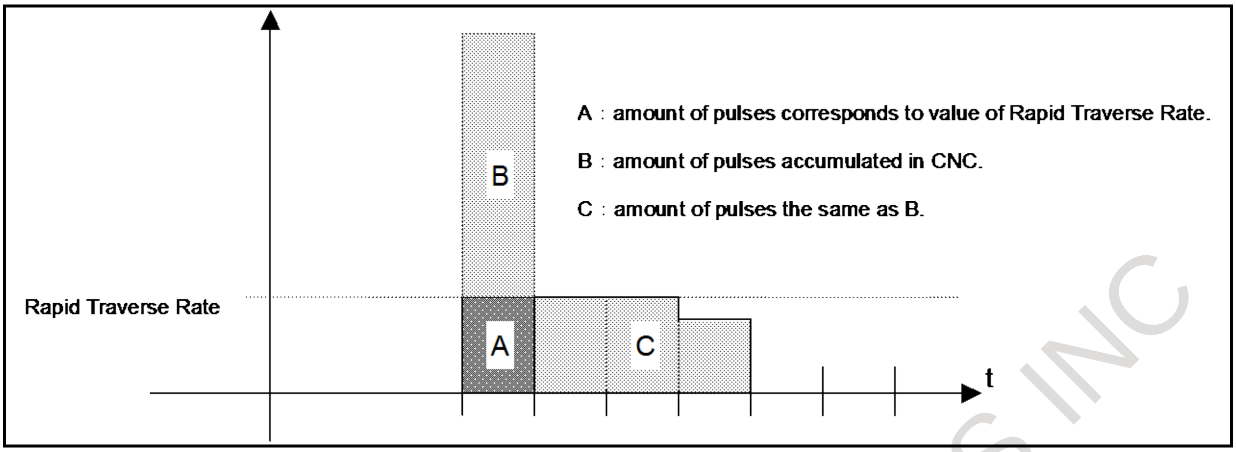
7114	Manual handle feed magnification n

[Input type] Parameter input
[Data type] Word path
[Valid data range] 1 to 2000
This parameter sets the magnification when manual handle feed movement selection signals MP1 and MP2 are set to “1”.

7117	Allowable number of pulses that can be accumulated during manual handle feed

[Input type] Parameter input
[Data type] 2-word path
[Unit of data] Pulse
[Valid data range] 0 to 999999999
This parameter sets the number of pulses from the manual pulse generator that exceed the rapid traverse rate and can be accumulated without being discarded if manual handle feed faster than the rapid traverse rate is specified.

The amount of pulses exceeding the rapid traverse rate can be saved by CNC as B. And amount of pulses B will be exported as pulses C.



Amount of pulses exported by CNC in Manual Handle Feed

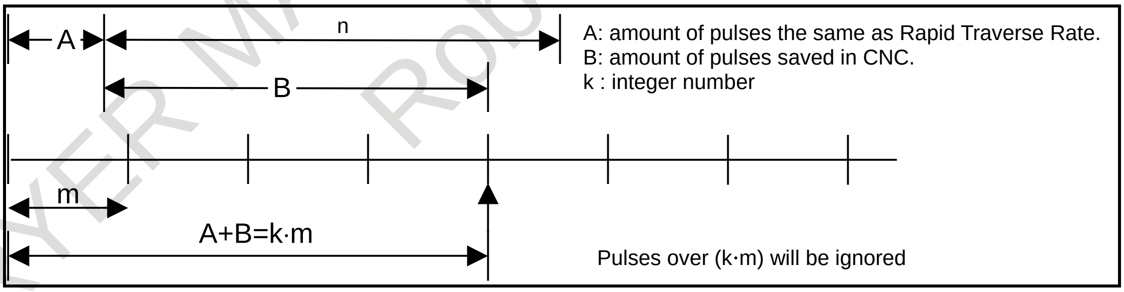
Amount of pulses B is calculated in 2 cases as following:

1) In case of parameter No.7117 = 0
   The feedrate is clamped at the Rapid Traverse Rate and generated pulses exceeding the Rapid Traverse Rate are ignored (B=0)
2) In case of parameter No.7117 > 0
   The feedrate is clamped as the Rapid Traverse Rate, but the pulses exceeding the Rapid Traverse Rate is not ignored. Amount of pulses accumulated in CNC is calculated as following. (Although the rotation of manual pulse generator is stopped, if there is pulses accumulated in CNC, it will be output and the tool will move as long as amount of it. Then the tool stops.)

Magnification set by manual handle feed amount selection signals MP1, MP2 <Gn019.4, Gn019.5> is m, value of parameter No.7117 is n.

n < m: Clamping is set performed at value of parameter No.7117.

n ≥ m: It is clamped in a range not exceeding n so that A+B shown in the following figure is an integral multiple of m. As a result, movement of the axis can be stopped at an integral multiple of the handle feed moving magnification.



Amount of pulses exceeding the Rapid Traverse Rate (n ≥ m)

NOTE
Due to change of mode, clamping can be performed not as an integral multiple of the selected magnification.
The distance the tool moves may not match the graduations on the manual pulse generator.

	#7	#6	#5	#4	#3	#2	#1	#0
10480							**RMI**	

[Input type] Parameter input
[Data type] Bit path

#1 RMI Manual handle interrupt for an axis specified in rapid traverse (G00) mode is:
0: Disabled.
1: Enabled.

> **NOTE**
> 1 Travel distance of manual handle interrupt depends on the setting of allowable number of pulses that can be accumulated during manual handle feed (parameter No.7117)
> 2 During axis movement at rapid traverse rate, axis movement by manual handle interrupt is output during deceleration so as not to exceed rapid traverse rate.

12350	Manual handle feed magnification m in each axis

[Input type] Parameter input
[Data type] Word axis
[Valid data range] 0 to 2000
For each axis, this parameter sets the magnification m when manual handle feed movement selection signals MP1 = “0”, MP2 = “1”.

> **NOTE**
> When value is set to 0 for this parameter, the parameter No. 7113 is valid.

12351	Manual handle feed magnification n in each axis

[Input type] Parameter input
[Data type] Word axis
[Valid data range] 0 to 2000
For each axis, this parameter sets the magnification when manual handle feed movement selection signals MP1 = “1”, MP2 = “1”.

> **NOTE**
> When value is set to 0 for this parameter, the parameter No. 7114 is valid.

Warning

> ⚠ **WARNING**
> When the manual handle interruption is valid, set the same value as the parameter No.1430 to the parameter No.1466.

Note

> **NOTE**
> 1 In the manual operation mode (such as the jog feed mode, manual handle feed mode, or TEACH IN HANDLE mode), handle interrupt is disabled.
> 2 When the machine lock or interlock is on, the tool is not moved by handle interrupt.
> 3 Manual handle interrupt is not effective for an axis in either of the following states:
> - Follow-up
> - PMC axis control

> **NOTE**
> 4 Manual handle interrupt is not allowed for an axis specified in G00 mode. But manual handle interrupt is enabled within the rapid traverse rate of the specified axis by setting bit 1 (RMI) of parameter No.10480.

OPERATOR'S MANUAL (B-64694EN)	Manual handle interrupt
CONNECTION MANUAL (FUNCTION) (B-64693EN-1) (This manual)	Manual handle feed

3.3.1 Manual Interruption of 3-dimensional Coordinate System Conversion

Overview

When the manual pulse generator is rotated in the 3-dimensional coordinate conversion mode, the travel distance specified by the manual pulse generator is superposed on the travel distance by automatic operation in the direction of the selected handle feed axis on the coordinate (program coordinate) system after 3-dimensional coordinate conversion.

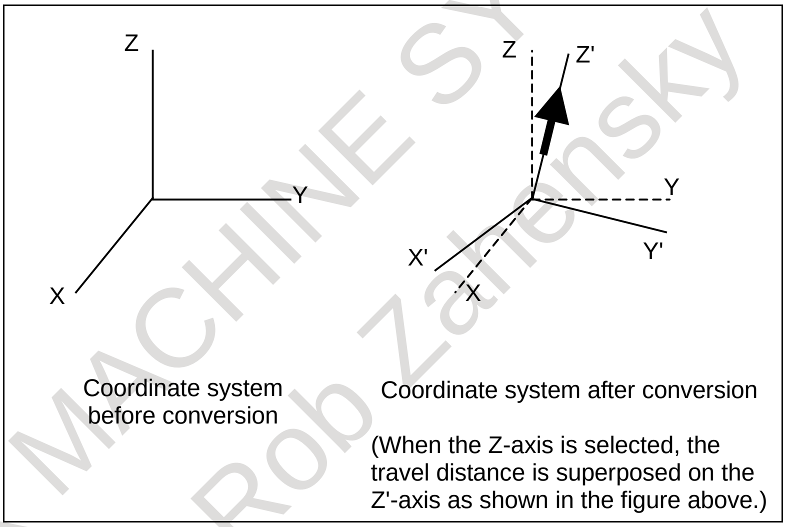

Fig. 3.3.1 Manual interruption of 3-dimensional coordinate system conversion

Explanation

- Interruption

This function performs interruption only when all of conditions 1 to 6 below are met. Otherwise, interruption does not occur.

1. During the automatic operation mode (MEM mode, MDI mode, or RMT mode)
2. During the 3-dimensional coordinate conversion mode
3. During the cutting mode (G01, G02, G03, or other G code for cutting is being executed.)
4. When interrupt is done to three axes of the target as 3-dimensional coordinate conversion
5. When 3-dimensional coordinate conversion manual interrupt enable/disable switch signal NOT3DM is set to 0
6. When the tool axis direction, the tool axis right-angle direction, or the tool tip center rotation is not selected for the 3-dimensional manual feed (when input signals ALNGH, RGHTH, and RNDH are all "0")

The feedrate superposed along the 3-dimensional coordinate conversion mode does not exceed the maximum cutting speed of each axis.

- Manual interruption and coordinate system

When this function operates, the absolute coordinate values do not include the travel distance by manual interruption. The absolute coordinate values are therefore not updated even when the manual pulse generator is rotated.
The machine coordinate values and relative coordinate values include the travel distance by manual interruption. However, the values are represented on the coordinate system before being converted. As shown in Fig. 3.3.1, the travel distance of the manual handle interruption is superposed along the Z'-axis. The travel distance is displayed using the X, Y, and Z coordinates of the coordinate system before being converted.
The travel distance by this function can be monitored on the manual handle interruption screen. Bit 3 (DMK) of parameter No. 5402 specifies whether the coordinate system (X, Y, Z) before being converted or the coordinate system (X', Y', Z') or after being converted is used to display the amount of interruption by the manual handle.

Signals

3-dimensional coordinate system conversion manual interrupt enable/disable switch signal NOT3DM<Gn347.7>

[Classification] Input signal
[Function] Enables or disables the 3-dimensional coordinate conversion manual interrupt function.
[Operation] When this signal is set to “0”, the 3-dimensional coordinate conversion manual interrupt function is enabled.
When this signal is set to “1”, the 3-dimensional coordinate conversion manual interrupt function is disabled.

3-dimensional coordinate conversion manual interrupt mode in-progress signal D3MI<Fn347.7>

[Classification] Output signal
[Function] Reports the state of the 3-dimensional coordinate conversion manual interrupt.
[Operation] The signal is set to “1” when all of the following conditions are met.
- During the automatic operation mode (MEM mode, MDI mode, or RMT mode)
- During 3-dimensional coordinate system conversion mode
- During cutting mode (G01, G02, G03, or other G code for cutting is being executed.)
- When 3-dimensional coordinate conversion manual interrupt enable/disable switch signal NOT3DM is set to 0

[Input type] Parameter input
[Data type] Bit path

#3 DMK The manual handle interruption screen is displayed:
0: Using the program coordinate system (post-conversion coordinate system).
1: Using the workpiece coordinate system (pre-conversion coordinate system).
This parameter is valid only in 3-dimensional coordinate conversion mode.

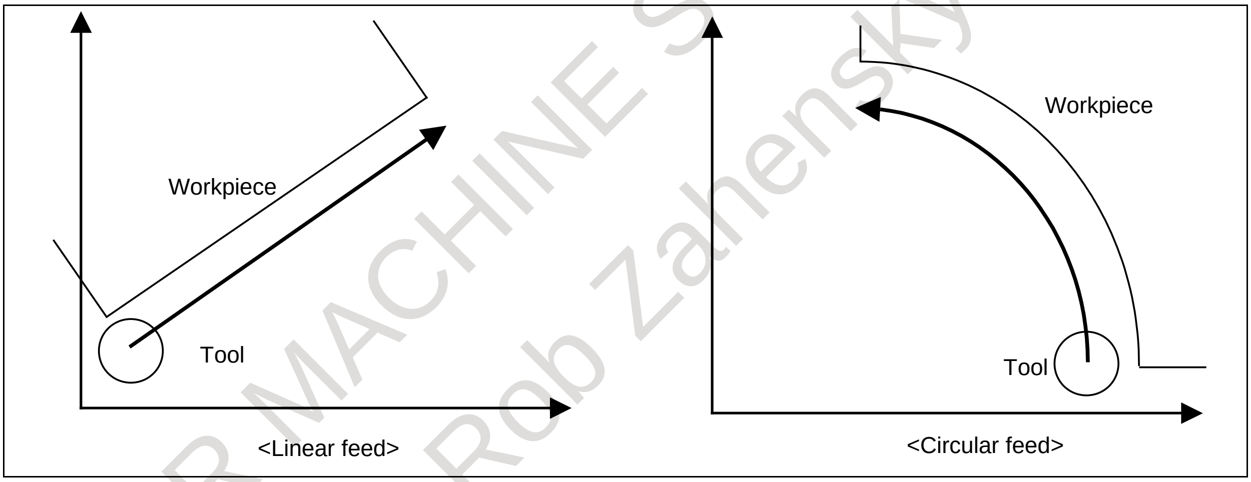
Note
Handle interruption is disabled during execution of a G68 or G69 block.

3.4 MANUAL LINEAR/CIRCULAR INTERPOLATION

Overview
In manual handle feed or jog feed, the following types of feed operations are possible along with the conventional feed operation with simultaneous single-axis control (for X, Y, Z, or other axis).

- Feed along a tilted straight line in the XY, YZ, or ZX plane based on simultaneous 2-axis control (linear feed)
- Feed along a circle in the XY, YZ, or ZX plane based on simultaneous 2-axis control (circular feed)

When using this function, please enable "Manual handle feed (bit 0 (HPG) of parameter No.8131 is 1)". When using the fourth or fifth manual pulse generator, the function "Manual handle feed 4/5-unit" is needed.



NOTE
1 Two control axes should be included in the three standard axes.
2 In the following, only the case of the XY plane is described. If any other plane is used, replace XY with YZ or ZX. (Refer to the table below.)

XY plane	YZ plane	ZX plane
X	Y	Z
Y	Z	X

3 Either of two control axes should be reference axis (parameter No. 1031).
Example) Parameter setting of the machine which has X-axis, Y-axis and Z-axis
- When performing manual linear/circular interpolation on X-Y plane
- When performing manual linear/circular interpolation on Y-Z plane
- When performing manual linear/circular interpolation on Z-X plane

The setting of the reference axis (parameter No. 1031) influences functions other than this function, and set it carefully enough.

Explanations

- Line/circle definition

A line or circle definition is not required for axis direction feed. For linear or circular feed, however, a line or circle must be defined, using the interface described later. (For example, in the case of circular feed, the center and radius of the circle must be specified.)

- Interface area

Part of the R area in the PMC is used for line and circle definitions. Set the necessary data in this area using the PMC or macro executor. See "Data setting" below for information about what data needs to be set at each address.

- Data setting

This function uses R960 to R979 of PMC as input data and R980 to R989 as output data for line and circle definitions.
When bit 3 (MRI) of parameter No. 7106 is set to 1, an arbitrary R signal can be assigned to input data. Likewise, an arbitrary R signal can be assigned to output data by setting bit 4 (MRO) of parameter No. 7106 to 1. In the case of input data, the head address of the R signal used is set in parameter No. 13541. In the case of output data, the head address of the R signal used is set in parameter No. 13542. (Input data uses an area of 20 bytes, and output data uses an area of 10 bytes.)

(a) Input data (PMC -> CNC)

A straight line or circle is defined by setting the following data.
By default, add "960". When bit 3 (MRI) of parameter No. 7106 is set to 1, add the value set in parameter No. 13541.

<table>
<tr><th rowspan="2">Data address</th><th rowspan="2">Number of bytes</th><th colspan="2">Setting</th></tr>
<tr><th>Linear feed</th><th>Circular feed</th></tr>
<tr><td>+0</td><td>1</td><td colspan="2">(Reserve) Do not use.</td></tr>
<tr><td>+1</td><td>1</td><td colspan="2">Linear or circular feed selection

<tr><td>Bit 6</td><td>Prohibited area when the limit function is enabled (Bit 7 is ”1”)
0: Area in the same direction as approach direction
1: Area in the opposite direction as approach direction</td></tr>
<tr><td>Bit 7</td><td>Whether the limit function is enabled or disabled
0: Disabled
1: Enabled</td></tr>
</table></td></tr>
<tr><td>+16</td><td>1</td><td colspan="2">Plane selection</td></tr>
<tr><td>+17 and +18</td><td>2</td><td colspan="2">(Reserve) Do not use. (Must be set to 0.)</td></tr>
<tr><td>+19</td><td>1</td><td colspan="2">Setting change notification</td></tr>
</table>

(b) Output data (CNC -> PMC)

By default, add "980". When bit 4 (MRO) of parameter No. 7106 is set to 1, add the value set in parameter No. 13542.

Data address	Number of bytes	Setting	
		Linear feed	Circular feed
+0 to +3	4	The distance from the current position to the given line is output.	The distance from the current position to the given circle is output.
+4 to +9	6	(Reserve) Do not use.	

NOTE

1 When the multi-PMC function is used, only the first PMC R address is available.

2 About the settings of parameters No. 13541 and No.13542

<1>Set a value that is a multiple of 4 (0, 4, 8, etc.).

<2>The addresses of input data and output data must not overlap.

<3>When a multi-path system is used, set a value that does not overlap the data address used in any other path.

<4>The range of the R address differs depending on the PMC used and the memory size. Check the specifications of the PMC, and set a value within the valid range.

If any setting other than the above items (<1> to <4>) is made, alarm PW5390 "R-ADDRESS SETTING IS ILLEGAL" is issued.

3 Hereinafter, the default data addresses (R960 to R979 for input data and R980 to R989 for output data) are used in the explanation of the setting data.

Setting for the plane selection (R976)
Set each plane as follows.

R976	#7	#6	#5	#4	#3	#2	#1	#0	Hexadecimal number
XY plane	0	0	1	0	0	0	0	1	21H
YZ plane	0	0	1	1	0	0	1	0	32H
ZX plane	0	0	0	1	0	0	1	1	13H

Setting for setting change notification (R979)
The definition of a straight line or circle (data of R961 to R975) can be set or changed in the manual operation mode (manual handle feed mode or jog feed mode). This data notifies the CNC that the definition has been changed.
After setting the data of R961 to R975, set 0 in the setting change notification (R979). When the value of R979 is changed to 0, the CNC judges that the data has been changed. After reading the data of R961 to R975, the CNC sets 1 in the setting change notification (R979). Afterwards, the linear feed or the circular feed is executed based on the read data until the setting change notification (R979) is changed to 0 again.

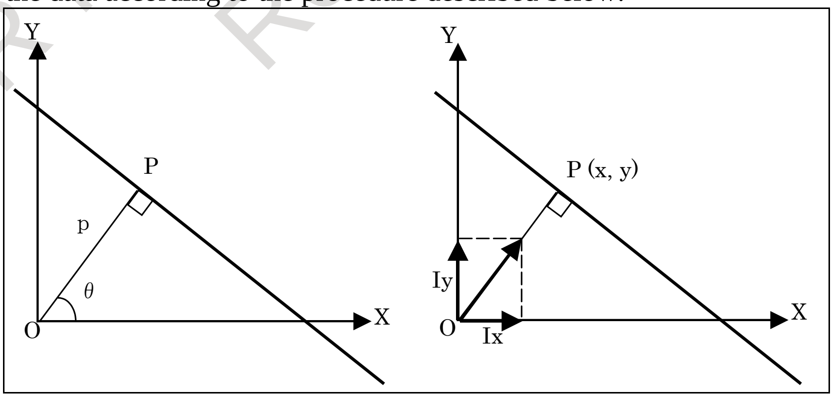
NOTE
1. When setting the setting change notification (R979), make sure that each axis is stopped.
2. While the setting change notification (R979) is set to "0", do not change the data.

- Setting for linear feed

Assuming that p is the length of a perpendicular line between the origin (O) and the straight line, that P(x,y) is the intersection of the straight line and the perpendicular line, and that θ is the angle formed by the perpendicular line and the positive X-axis, the straight line can be defined as:
$x \cdot \cos\theta + y \cdot \sin\theta = p$

NOTE
The "origin" refers to that in the absolute coordinate system. Coordinates X and Y used in this description represent the center of the tool.

Based on this, set the data according to the procedure described below.



Setting data

<1>	R961	:	Linear feed
<2>	R962 - R965	:	Approach direction Ix · 2^{30}
<3>	R966 - R969	:	Approach direction Iy · 2^{30}
<4>	R970 - R973	:	Distance between origin and straight line p
<5>	R974	:	Direction in which the guidance handle moves
<6>	R975	:	Whether the limit function is enabled or disabled
<7>	R979	:	Setting change notification

<1> Select linear feed. (R961)
Set R961 to "1".

<2> <3> Specify the approach direction. (R962 to R969)
Specify the X and Y components (Ix, Iy) of a unit vector (±cosθ, ±sinθ), which is parallel to perpendicular line OP, each with four bytes. Set a value multiplied by 2^{30}.
R962 to R965 = $Ix \cdot 2^{30}$
R966 to R969 = $Iy \cdot 2^{30}$
The tool moves in the direction indicated with this unit vector when the approach handle is rotated in the forward direction. The unit of data is the least input increment set for the reference axis by parameter No. 1031. (For example, when metric input is used for IS-B, the unit is 0.001 mm.)

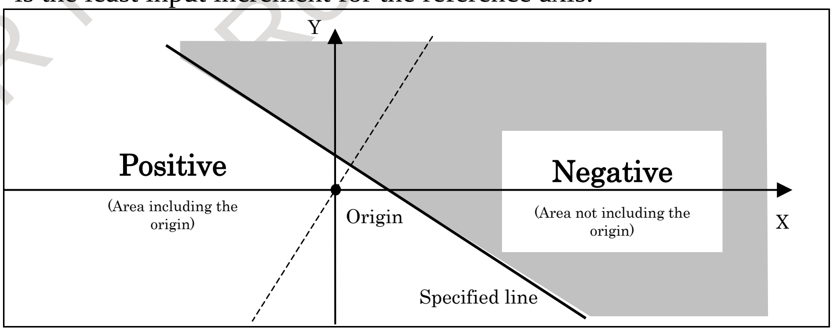
<4> Specify length P of the perpendicular line from the origin to the straight line with four bytes. (R970 to R973)
Length P must satisfy the following equation:

$P = \pm| \overrightarrow{OP} |$

According to the side of the specified straight line on which the approach is started, the sign changes as follows.
(Refer to the following figure.)

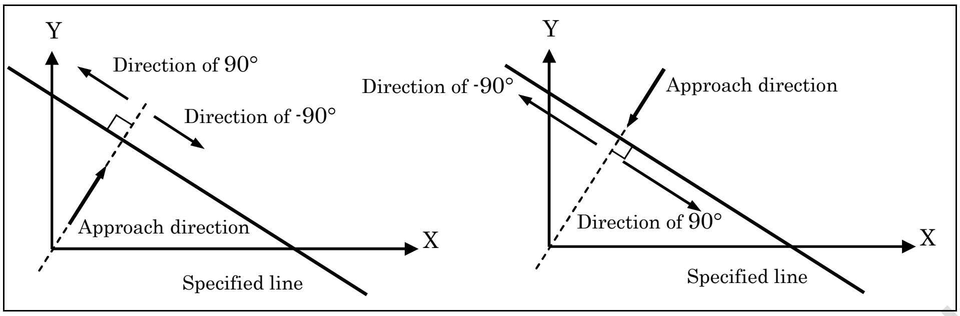
Area including the origin : Positive
Area not including the origin : Negative

(Set a "negative" value when the tool is approached from the direction opposite to the direction set in <2> and <3>.)
The unit of P is the least input increment for the reference axis.



<5> Specify the cutting direction. (R974)
Specify the direction of travel for the forward rotation of the guidance handle, using R974.
The meaning of the setting is as follows:

0: Direction towards +90° from the approach direction
1: Direction towards -90° from the approach direction



<6> Specify whether to enable the limit function. (Bit 7 of R975)

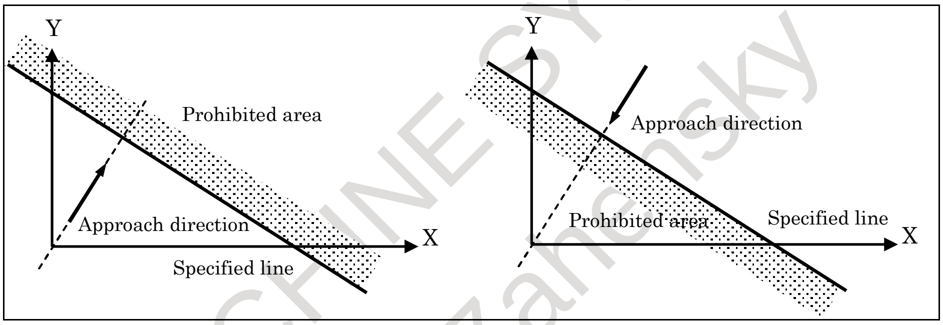
To disable the limit function, set bit 7 of R975 to "0".

To enable the limit function, set bit 7 of R975 to "1".

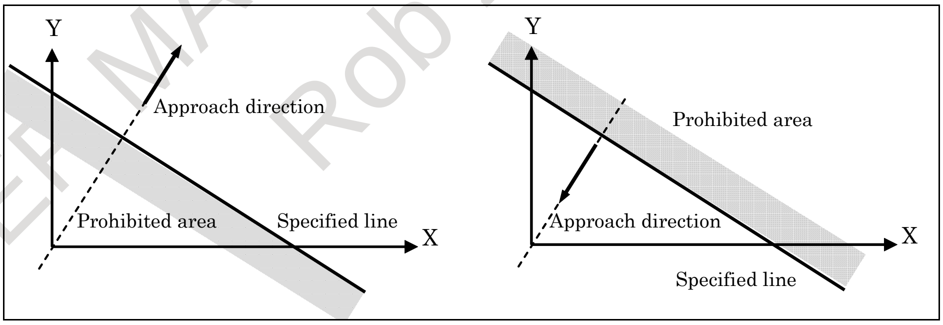
When the limit function is enabled, an area is set where the tool is not allowed to enter. The area is delimited with a specified line. When you attempt to bring the tool into the prohibited area, using manual handle feed or jog feed, the tool decelerates and stops. Operation on the specified line is possible.

The prohibited area is set as shown below, according to the setting of the approach direction (R962 to R965, R966 to R969) and the setting of the prohibited area (Bit 6 of R975).

- When bit 6 of R975 is set to "0"



- When bit 6 of R975 is set to "1"



<7> Set the setting change notification. (R979)

Set R979 to "0".

This completes the straight line definition.

During linear feed, the distance to the specified line is calculated, using the following equation, and output to R980 to R983 (4 bytes).

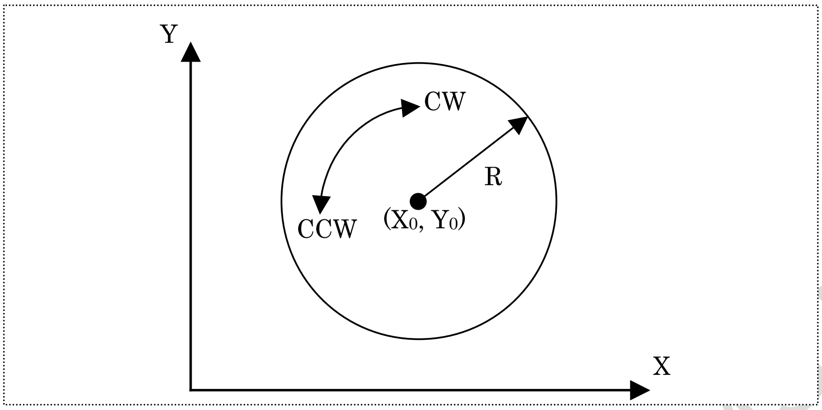
The unit of the data is the least input increment for the reference axis.

$F(X,Y) = p - (Ix \cdot X + Iy \cdot Y)$

(Where X, Y = Current X- and Y-axis positions)

- Setting for circular feed

Specify the data according to the procedure below.



Setting data

<1> R961 : Circular feed and direction of rotation (CW/CCW)
<2> R962 to R965 : Center of the circle X_0
<3> R966 to R969 : Center of the circle Y_0
<4> R970 to R973 : Radius R
<5> R974 : Which side to be machined (inside or outside)
<6> R975 : Whether the limit function is enabled or disabled
<7> R979 : Setting change notification

<1> Specify circular feed and the direction of rotation. (R961)
Set R961 to "2" or "3".
If R961 is set to "2", the tool moves along the circle clockwise, when the guidance handle is rotated in the forward direction.
If R961 is "3", the tool moves along the circle counterclockwise, when the guidance handle is rotated in the forward direction.

<2> <3> Specify the coordinates (X_0, Y_0) of the center of the circle. (R962 to R965, R966 to R969)

NOTE
X and Y used in this description refer to coordinates in the absolute coordinate system.

R962 to R965 = X_0
R966 to R969 = Y_0
Each coordinate is four bytes. The unit of the data is the least input increment for the reference axis.

<4> Specify radius R. (R970 to R973)
R970 to R973 = R
The radius R is four bytes. The unit of the data is the least input increment for the reference axis.

<5> Specify which side is to be machined, the inside or outside of the circle. (R974)
Set R974 to "0" or "1".
If R974 is 0, the inside of the circle is machined.
If R974 is 1, the outside of the circle is machined.
When the approach handle is rotated, the tool moves along a straight line normal to the specified circle. The direction of the tool movement is determined according to the setting of R974.

When the approach handle is rotated in the forward direction, the direction of the tool movement (approach direction) is as follows:

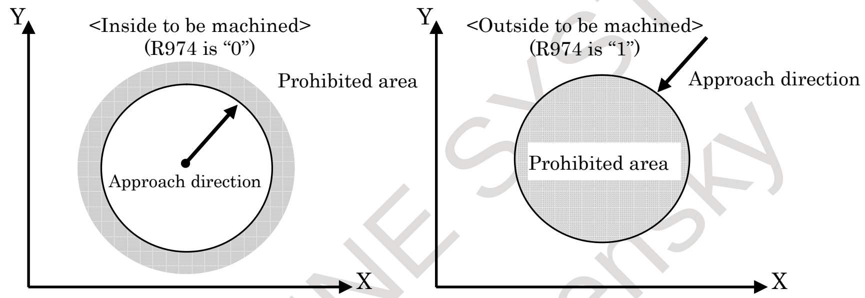
- When the inside of the circle is to be machined (R974 = “0”), the tool moves from the center of the circle to the circumference.
- When the outside of the circle is to be machined (R974 = “1”), the tool moves toward the center of the circle.

<6> Specify whether to enable or disable the limit function. (Bit 7 of R975)

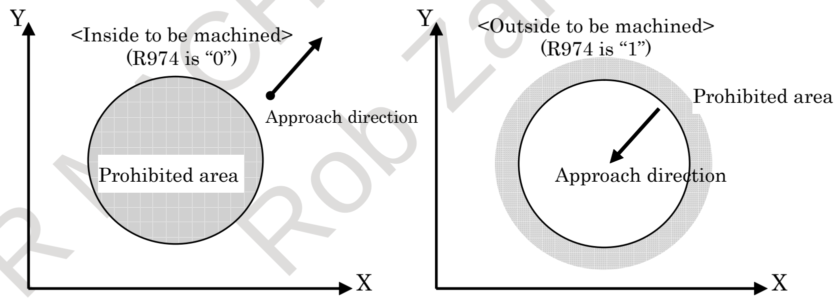
To disable the limit function, set bit 7 of R975 to 0.
To enable the limit function, set bit 7 of R975 to 1.

When the limit function is enabled, an area is set where the tool is not allowed to enter. The area is either inside or outside of the specified circle. When you attempt to bring the tool into the prohibited area, using manual handle feed or jog feed, the tool decelerates and stops. Operation on the specified circle is possible.
Whether the inside or outside of the circle is set as the prohibited area is determined according to the setting of R974 that specifies which side (inside or outside of the circle) is to be machined and the setting of the prohibited area (Bit 6 of R975).

- When bit 6 of R975 is set to "0"



- When bit 6 of R975 is set to "1"



<7> Set the setting change notification. (R979)

Set R979 to "0".

This completes the circle definition.

During circular feed, the distance to the specified circle is calculated, using the following equation, and output to R980 to R983 (4 bytes). The unit of the data is the least input increment for the reference axis.
When the inside of the circle is to be machined:

$$F(X,Y) = R - \sqrt{(X - X_0)^2 + (Y - Y_0)^2}$$

When the outside of the circle is to be machined:

$$F(X,Y) = \sqrt{(X - X_0)^2 + (Y - Y_0)^2} - R$$

- When neither linear nor circular feed is carried out

Specify the following data.

Setting data

<1> R961	: 0 (Neither linear nor circular feed is carried out)
<2> R962 to R965	: (Need not be specified)
<3> R966 to R969	: (Need not be specified)
<4> R970 to R973	: (Need not be specified)
<5> R974	: (Need not be specified)
<6> R975	: (Need not be specified)
<7> R976	: (Need not be specified)
<8> R979	: Setting change notification

<1> Linear or circular feed selection
Reset R961 to "0".
If R961 is set to 0, both the guidance and approach handles become ineffective.
The tool will not move, even if these handles are rotated.

<2> to <7> It is unnecessary to set R962 to R976.

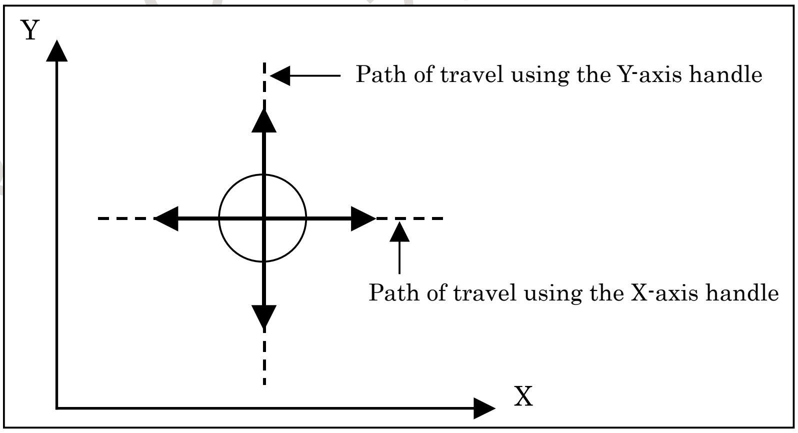
<8> Set the setting change notification. (R979)
Set R979 to "0".

The values of R980 to R983 (distance to a given line or circle) are output as "0".

- Manual handle feed

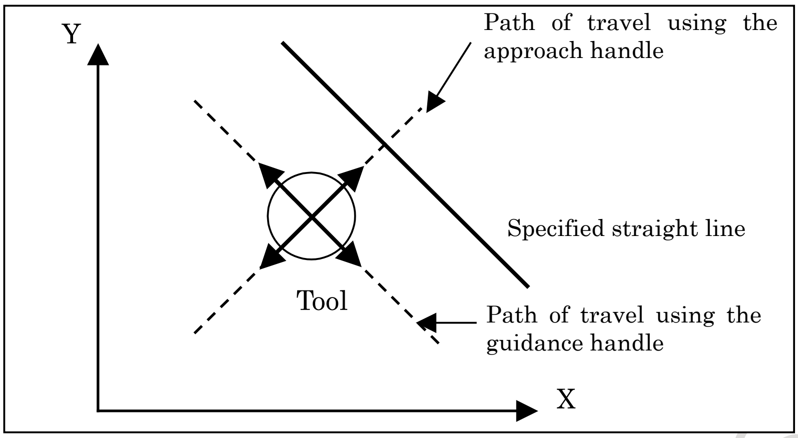
In manual handle feed, the tool can be moved along a specified axis (X-axis, Y-axis, Z-axis, or N^{th}-axis), along a rotated straight line (linear feed), or along a circle (circular feed).

(1) Feed along a specified axis (simultaneous 1-axis control)
A single manual handle operation can move the tool along the desired axis, such as X-axis, Y-axis, or Z-axis, on a simultaneous 1-axis control basis.



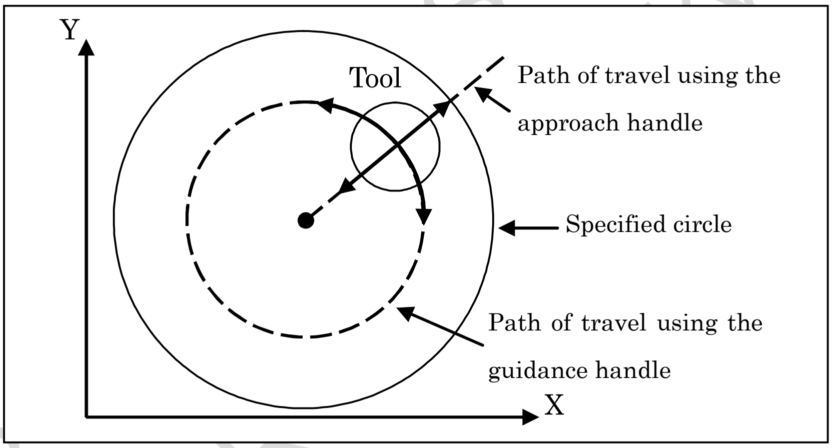
Feed along a specified axis

(2) Linear feed (simultaneous 2-axis control)
A single manual handle operation can move the tool in parallel to the straight line on a simultaneous 2-axis control basis. This manual handle is referred to as the "guidance handle". Also, the tool can be moved at right angles to a specified straight line on a simultaneous 2-axis control basis. This manual handle is referred to as the "approach handle". When the guidance handle or approach handle is turned clockwise or counterclockwise, the tool travels forward or backward along the respective path.



Linear feed

(3) Circular feed (simultaneous 2-axis control)
A single manual handle operation can move the tool from the current position along a concentric circle that has the same center as a specified circle on a simultaneous 2-axis control basis. This manual handle is referred to as the guidance handle. Also, a single manual handle operation can move the tool along a straight line normal to a specified circle on simultaneous 2-axis control. This manual handle is referred to as the approach handle. When the guidance handle or approach handle is turned clockwise or counterclockwise, the tool travels forward or backward along the respective path.



Circular feed

- Feedrate for manual handle feed

The feedrate depends on the speed at which a manual handle is turned. The distance to be traveled by the tool (along a tangent in the case of linear or circular feed) per manual handle pulse can be selected using the manual handle feed travel distance magnification signal MP1<Gn019.4> or MP2<Gn019.5>.
The approach handle clamp feedrate can be set using parameter No. 7160. The guidance handle clamp feedrate can be set using parameter No. 7161. Set the parameter No. 7117 to 0.

- Manual handle selection

Five manual pulse generator interfaces are provided to allow up to five manual handles to be connected. The mode of the manual handles connected to the interfaces (whether to use the manual handle as a handle for feed along an axis, as a guidance handle, or as an approach handle) can be selected by the manual linear/circular interpolation signal MHLCn<Gn544.0 to Gn544.4> and manual handle usage selection signal MHUSn<Gn545.0 to Gn545.4>, which are provided for each interface. By switching these signals, a single manual handle can be used for multiple purposes.

- Direction of movement using manual handles

When the tool is moved along a straight line or circle using the guidance handle or approach handle, the direction of the tool movement (for example, whether to make a clockwise or counterclockwise movement along a circle) when the handle is turned clockwise or counterclockwise can be specified using the interfaces described above.

- Jog feed

In jog feed, the tool can be moved along a specified axis (X-axis, Y-axis, Z-axis, etc.), along a rotated straight line (linear feed), or along a circle (circular feed).

(1) Feed along a specified axis (simultaneous 1-axis control)

While a feed axis and its direction are specified with the feed axis direction selection signals +J1~+J8 <Gn100> and -J1~-J8 <Gn102>, the tool moves in the specified axis direction.

When feeding the axis of selected plane (R976) of manual linear/circular interpolation in each axis direction, feedrate is the value of parameter No.1410 (parameter No.1415 is used when bit 4 (JRV) of parameter No.1402 is set to 1). The feedrate can be overridden (0.01% to 655.34%) using the manual feedrate override signal *JV0 to *JV15 <Gn010,Gn011>.

NOTE

1. Two axes of the selected plane cannot be fed at the same time in each axis direction. (When feed axis direction selection signals of two axes are set to "1" simultaneously, the two axes decelerate and stop.)
2. The manual rapid traverse selection signal RT <Gn019.7> is invalid for two axes of selected plane. (Even if RT is set to "1", a rapid traverse rate is not selected.)

When the axis excluding the plane axis selected by R976 of manual linear/circular interpolation is fed in each axis direction, the feederate is the value of parameter No. 1423. The feedrate can be overridden (0.01% to 655.34%) using the manual feedrate override signal *JV0~*JV15 <Gn010, Gn011>.

(2) Linear feed (simultaneous 2-axis control)

By defining a straight line, the tool can be moved as follows:

- While a feed axis and its direction are selected using the feed axis direction selection signal +Jg<Gn086.0> or –Jg<Gn086.1>, the tool moves along a straight line parallel to the specified straight line on a simultaneous 2-axis control basis.
- While a feed axis and its direction are selected using the feed axis direction selection signal +Ja<Gn086.2> or -Ja<Gn086.3>, the tool moves along a straight line perpendicular to the specified straight line on a simultaneous 2-axis control basis.

The feedrate in the tangential direction is specified in parameter No. 1410 (Parameter No.1415 is used when bit 4 (JRV) of parameter No. 1402 is set to 1). The feedrate can be overridden (0.01% to 655.34%) using the manual feedrate override signal *JV0 to *JV15 <Gn010, Gn011>. The manual rapid traverse selection signal RT<Gn019.7> is invalid. (Even if RT is set to "1", a rapid traverse rate is not selected.)

(3) Circular feed (simultaneous 2-axis control)

By defining a circle, the tool can be moved as follows:

- While a feed axis and its direction are selected using the feed axis direction selection signal +Jg<Gn086.0> or –Jg<Gn086.1>, the tool moves from the current position along the concentric circle that has the same center as the specified circle.
- While a feed axis and its direction are selected using the feed axis direction selection signal +Ja<Gn086.2> or -Ja<Gn086.3>, the tool moves along a straight line normal to the specified circle.

The feedrate in the tangential direction is specified in parameter No. 1410 (Parameter No.1415 is used when bit 4 (JRV) of parameter No. 1402 is set to 1). The feedrate can be overridden (0.01% to 655.34%) using the manual feedrate override signal *JV0 to *JV15<Gn010, Gn011>. The manual rapid traverse selection signal RT<Gn019.7> is invalid. (Even if RT is set to "1", a rapid traverse rate is not selected.)

- Manual handle feed in JOG mode

Even in JOG mode, manual handle feed can be enabled using bit 0 (JHD) of parameter No. 7100. In this case, however, manual handle feed is enabled only when the tool is not moved using jog feed.

Basic procedure

(1) Select the manual operation mode.
To perform manual handle feed, select manual handle feed mode. To perform jog feed, select jog feed mode.

(2) Define a line or circle.
See the "Line/circle definition" in the Explanations section.

(3) Move the tool using manual handle feed or jog feed.

To perform the manual handle feed

First, select either single-axis feed along the X-, Y- or Z-axis, or simultaneous two-axis feed along a specified line or circle in the specified plane, using manual linear/circular interpolation signal MHLCn.

To execute single-axis feed along the X-, Y- or Z-axis, select the axis along which the tool will move when the manual handle is turned, using the manual handle feed axis selection signals HSnA, HSnB, HSnC, HSnD, and HSnE.

To execute simultaneous two-axis feed in the specified plane, select either approach handle or guidance handle, using the manual handle usage selection signal (MHUSn). By selecting the plane, the two axes along which the tool will move when the manual handle is turned are selected.

Turning the manual handle will move the tool along the selected axis. The feedrate varies with the speed at which the manual handle is turned.

The amount the tool will be moved when the manual handle is turned by one pulse can be specified using manual handle feed amount selection signals MP1 and MP2.

To perform the jog feed

Select the feed axis and the direction in which the tool is to be moved, using the feed axis and direction selection signals +Jg, -Jg, +Ja, -Ja. While the feed axis is specified, the tool is moved along the specified axis or specified line or circle at the parameter-set feedrate (jog feedrate).

The manual feedrate override signals *JV0 to *JV15 can be used to apply an override to the feedrate. The manual rapid traverse selection signal RT is invalid.

To stop the feed of manual linear/circular interpolation

When jog feed is performed without carrying out the feed of manual linear/circular interpolation, specify the following data.

- Specify the R area in the PMC which is describe in the above-mentioned "When neither linear nor circular feed is carried out"
- Set Feed axis and direction selection signal +Jg, -Jg, +Ja, -Ja to “0”
- Set Manual linear/circular interpolation signal MHLC1 to MHLC5 to “0”

Limitations

- Mirror image

The mirror image function is not available during the manual operation. (Operate when the mirror image signal MI1 to MI3<Fn108> is set to "0" and the mirror image setting is off.)

> **NOTE**
> If the tool is operated with the mirror image function activated, the normal operation will not be guaranteed.

- Rotation direction

When this function is effective, bit 0 (HNGx) of parameter No. 7102 is invalid which is used to change the axis movement direction with respect to the rotation direction of the manual pulse generator. (The rotation direction of the manual pulse generator is always the same as the axis movement direction; that is, the operation is the same as when bit 0 (HNGx) of parameter No. 7102 is set to 0.)

- The amount of the shift for manual handle feed

When this function is effective, parameters No. 12350 and No. 12351 used to determine the magnification of manual handle feed for each axis are invalid and the values of parameter No. 7113 and No. 7114 are used. (Parameters No. 7131 and No. 7132 are used for the second manual pulse generator, parameters No. 7133 and No. 7134 for the third, parameters No. 7135 and No. 7136 for the fourth, and parameters No. 7137 and No. 7138 for fifth.)

- Incremental feed

This function is invalid for the incremental feed.

- Synchronous/composite control

If the axis is set as the synchronous/composite control axis, this function is invalid.

Note

> **NOTE**
> When using this function, please enable "Manual handle feed (bit 0 (HPG) of parameter No.8131 is 1)". When using the fourth or fifth manual pulse generator, the function "Manual handle feed 4/5-unit" is needed.

Signal

The following signals are related to jog feed and manual handle feed.

Feed axis and direction selection signal +Jg, -Jg, +Ja, -Ja <Gn086.0 to Gn086.3>

[Classification] Input signal

[Function] Selects a desired feed axis and direction in jog feed. The sign (+ or -) in the signal name indicates the feed direction. "g" and "a" after J indicates Guidance JOG and Approach JOG, respectively.

[Operation] For operation, these signals are the same as feed axis and direction selection signal +J1 to +J8, -J1 to –J8 <Gn100, Gn102>.
Refer to section "JOG FEED/ INCREMENTAL FEED".

Manual linear/circular interpolation signal MHLC1 to MHLC5 <Gn544.0 to Gn544.4>

[Classification] Input signal

[Function] Each of these signals selects the manual linear/circular interpolation function for the n-th manual pulse generator.

[Operation]
0: Manual linear/circular interpolation is disabled. The manual handle is used for axis direction feed.
1: Manual linear/circular interpolation is enabled. The manual handle is used for the purpose selected by the usage selection of manual linear/circular interpolation signal (MHUSn).

Usage selection of manual linear/circular interpolation signal MHUS1 to MHUS5 <Gn545.0 to Gn545.4>

[Classification] Input signal

[Function] Selects the guidance handle or approach handle for the n-th manual pulse generator when the manual linear/circular interpolation signal MHLCn is set to "1" for the manual linear/circular interpolation function.

[Operation] 0: The manual handle is used as the approach handle.
1: The manual handle is used as the guidance handle.

Selection of usage of the nth manual handle

MHLCn	MHUSn	Usage
0	-	Axis direction feed
1	0	Approach handle
1	1	Guidance handle

Signal address

	#7	#6	#5	#4	#3	#2	#1	#0
Gn086					-Ja	+Ja	-Jg	+Jg
Gn544				MHLC5	MHLC4	MHLC3	MHLC2	MHLC1
Gn545				MHUS5	MHUS4	MHUS3	MHUS2	MHUS1

Alarm and message

Number	Message	Description
PW5390	R-ADDRESS SETTING IS ILLEGAL	Either the R address range of the PMC set by parameters No. 13541 and No. 13542 or the first address of the range is invalid.

Parameter

1031	Reference axis

[Input type] Parameter input
[Data type] Byte path
[Valid data range] 1 to Number of controlled axes

The unit of some parameters common to all axes such as those for dry run feedrate and single-digit F1 feedrate may vary according to the increment system. An increment system can be selected by a parameter on an axis-by-axis basis. So, the unit of those parameters is to match the increment system of a reference axis. Set which axis to use as a reference axis.

Among the basic three axes, the axis with the finest increment system is generally selected as a reference axis.

> **NOTE**
> When this parameter is set to 0, the reference axis is 1'st axis.

	#7	#6	#5	#4	#3	#2	#1	#0
1402				JRV				

[Input type] Parameter input
[Data type] Bit path

#4 JRV Jog feed or incremental feed is
0: Performed at feed per minute.

1: Performed at feed per rotation.

NOTE
1 Specify a feedrate in parameter No. 1423.
2 For the machining center system, the threading/synchronous feed is required.

1410	Dry run rate

[Input type] Parameter input
[Data type] Real path
[Unit of data] mm/min, inch/min, deg/min (machine unit)
[Min. unit of data] Depend on the increment system of the reference axis
[Valid data range] Refer to the standard parameter setting table (C)
(When the increment system is IS-B, 0.0 to +999000.0)
Set the dry run rate at the 100% position on the jog feedrate specification dial. The unit of data depends on the increment system of the reference axis. Setting this parameter to 0 results in alarm PS5009, "PARAMETER ZERO (DRY RUN)", being issued.

1415	Manual synchronous feedrate for manual linear/circular interpolation continuous feed at override 100%

[Input type] Parameter input
[Data type] Real path
[Unit of data] mm/min, inch/min, deg/min (machine unit)
[Min. unit of data] Depend on the increment system of the reference axis
[Valid data range] Refer to the standard parameter setting table (C)
(When the increment system is IS-B, 0.0 to +999000.0)

NOTE
This parameter is valid only when bit 4 (JRV) of parameter No. 1402 is 1 (manual per revolution feed is enabled). If manual per revolution feed is disabled, the manual linear/circular interpolation continuous feedrate follows the dry run rate (parameter No. 1410). For a machining center system, the manual linear/circular interpolation continuous feedrate follows the dry run rate (parameter No. 1410) (feed per minute) even though bit 4 (JRV) of parameter No. 1402 is set to 1 when the threading/synchronous feed function is not specified.

1423	Jog feedrate for each axis

[Input type] Parameter input
[Data type] Real axis
[Unit of data] mm/min, inch/min, deg/min (machine unit)
[Min. unit of data] Depend on the increment system of the applied axis
[Valid data range] Refer to the standard parameter setting table (C)
(When the increment system is IS-B, 0.0 to +999000.0)
(1) When bit 4 (JRV) of parameter No. 1402 is set to 0, set jog feedrate (feed per minute) for each axis when manual feedrate override is 100%.
(2) When bit 4 (JRV) of parameter No. 1402 is set to 1, set jog feedrate (feed per revolution) for each axis when manual feedrate override is 100%.

> **NOTE**
> This parameter is clamped to the axis-by-axis manual rapid traverse rate (parameter No. 1424).

	#7	#6	#5	#4	#3	#2	#1	#0
7001	MFM							

[Input type] Parameter input
[Data type] Bit path

#7 MFM For the manual linear/circular interpolation function, modifying a value specified with a command during jog feed in the guidance direction (approach direction):
0: Immediately starts moving according to the new value.
1: Stops moving.

	#7	#6	#5	#4	#3	#2	#1	#0
7100							THD	JHD

[Input type] Parameter input
[Data type] Bit path

#0 JHD Manual handle feed in JOG feed mode or incremental feed in the manual handle feed is:
0: Invalid.
1: Valid.

#1 THD In the TEACH IN JOG mode, the manual pulse generator is:
0: Disabled.
1: Enabled.

	#7	#6	#5	#4	#3	#2	#1	#0
7106				MRO	MRI			

[Input type] Parameter input
[Data type] Bit path

#3 MRI Internal relay (the R signal) of PMC that uses it with input data in manual linear/circular interpolation:
0: R960 to R979 are used.
1: The address set by parameter No.13541 is used as the start address.

> ⚠ **WARNING**
> Set an appropriate value to parameter No.13541 beforehand when you set 1 to this parameter.
> If the set address in parameter No.13541 is used by another usage, it may cause an unexpected machine behavior. Be careful enough that you must prevent the competition of the used internal relay.

#4 MRO Internal relay (the R signal) of PMC that uses it with output data in manual linear/circular interpolation:
0: R980 to R989 are used.
1: The address set by parameter No.13542 is used as the start address.

> ⚠ **WARNING**
> Set an appropriate value to parameter No.13542 beforehand when you set 1 to this parameter.
> If the set address in parameter No.13542 is used by another usage, it may cause an unexpected machine behavior. Be careful enough that you must prevent the competition of the used internal relay.

7113	Manual handle feed magnification m

[Input type] Parameter input
[Data type] Word path
[Valid data range] 1 to 2000

This parameter sets the magnification m when manual handle feed movement selection signals MP1 and MP2 are set to "0" and "1".

7114	Manual handle feed magnification n

[Input type] Parameter input
[Data type] Word path
[Valid data range] 1 to 2000

This parameter sets the magnification when manual handle feed movement selection signals MP1 and MP2 are set to "1".

7131	Manual handle feed magnification m2 / 2nd. manual pulse generator
7132	Manual handle feed magnification n2 / 2nd. manual pulse generator
7133	Manual handle feed magnification m3 / 3rd. manual pulse generator
7134	Manual handle feed magnification n3 / 3rd. manual pulse generator
7135	Manual handle feed magnification m4 / 4th. manual pulse generator
7136	Manual handle feed magnification n4 / 4th. manual pulse generator
7137	Manual handle feed magnification m5 / 5th. manual pulse generator
7138	Manual handle feed magnification n5 / 5th. manual pulse generator

[Input type] Parameter input
[Data type] Word path
[Valid data range] 1 to 2000

The 'mx' sets magnification when manual handle feed amount selection signals MPx1 = 0, MPx2 = 1. The 'nx' sets magnification when manual handle feed amount selection signals MPx1 = 1, MPx2 = 1.

7160	Approach handle clamp feedrate

[Input type] Parameter input
[Data type] Real path
[Unit of data] mm/min, inch/min, deg/min (machine unit)
[Min. unit of data] Depend on the increment system of the reference axis。
[Valid data range] Refer to standard parameter setting table (C)

Approach handle clamp feedrate is set.

7161	Guidance handle clamp feedrate

[Input type] Parameter input
[Data type] Real path
[Unit of data] mm/min, inch/min, deg/min (machine unit)
[Min. unit of data] Depend on the increment system of the reference axis。
[Valid data range] Refer to standard parameter setting table (C)

Guidance handle clamp feedrate is set.

13541	The head address of the R signal used by the input data in the manual linear/circular interpolation

[Input type] Parameter input
[Data type] 2-word path
[Valid data range] 0 to 59999

The head address of the internal relay(R signal) of PMC used by the input data in the manual linear/circular interpolation is set. 20-byte area is required for input data from the set address.

NOTE

1 When this parameter is set, the power must be turned off before operation is continued.
2 This parameter is valid when bit 3 (MRI) of parameter No.7106 is set to 1.
3 About setting parameters Nos. 13541 and 13542
   (1) Set the value which becomes the multiple of four. (0, 4, 8, …)
   (2) The address of output data and input data must not be duplicated.
   (3) When the multi-path system is used, set the value which does not duplicate the data address used in other path systems.
   (4) The range in R address is different depending on PMC used and the memory. Confirm the specification of PMC, and set the value within the range which can be used. (Example: First PMC memory B -> R0 to R7999)

   When the settings other than the above-mentioned ((1) to (4)) were done, the alarm PW5390, "R-ADDRESS SETTING IS ILLEGAL" is issued.
4 When this parameter is 0, an internal relay from address R0 is used.

⚠ WARNING

If the set address in this parameter is used by another usage, it may cause an unexpected machine behavior. Be careful enough that you must prevent the competition of the used internal relay.

13542	Head address of the R signal used by the output data in the manual linear/circular interpolation

[Input type] Parameter input
[Data type] 2-word path
[Valid data range] 0 to 59999

The head address of the internal relay(R signal) of PMC used by the output data in the manual linear/circular interpolation is set. 10-byte area is required for output data from the set address.

NOTE

1 When this parameter is set, the power must be turned off before operation is continued.
2 This parameter is valid when bit 4 (MRO) of parameter No.7106 is set to 1.
3 About setting parameters Nos. 13541 and 13542
 (1) Set the value which becomes the multiple of four. (0, 4, 8, …)
 (2) The address of output data and input data must not be duplicated.
 (3) When the multi-path system is used, set the value which does not duplicate the data address used in other path systems.
 (4) The range in R address is different depending on PMC used and the memory. Confirm the specification of PMC, and set the value within the range which can be used. (Example: First PMC memory B -> R0 to R7999)
 When the settings other than the above-mentioned ((1) to (4)) were done, the alarm PW5390, “R-ADDRESS SETTING IS ILLEGAL” is issued.
4 When this parameter is 0, an internal relay from address R0 is used.

⚠ **WARNING**

If the set address in this parameter is used by another usage, it may cause an unexpected machine behavior. Be careful enough that you must prevent the competition of the used internal relay.

Standard parameter setting table (C) velocity and angular velocity parameters

Unit of data	Increment system	Minimum data unit	Valid data range
mm/min degree/min	IS-A	0.01	0.00 to +999000.00
	IS-B	0.001	0.000 to +999000.000
	IS-C	0.0001	0.0000 to +99999.9999
inch/min	IS-A	0.001	0.000 to +96000.000
	IS-B	0.0001	0.0000 to +9600.0000
	IS-C	0.00001	0.00000 to +4000.00000

3.5 HANDLE-SYNCHRONOUS FEED

Overview

The tool is fed at a program-specified feedrate or at a feedrate that matches a dry run feedrate in cutting feed blocks (such as linear interpolation (G01) and circular interpolation (G02 and G03)) during automatic operation. This function enables the tool to be fed in synchronization with the rotation of a manual handle (manual pulse generator).

The manual linear/circular interpolation signals MHLCn <Gn544.0-4> and the usage selection of manual linear/circular interpolation signals MHUSn <Gn545.0-4> select the manual handle with which the tool is to be synchronized.

The feedrate for handle-synchronous feed is controlled in such a way that the tangential feedrate is commensurate with the rotation speed of the manual handle.

The travel distance of the tool per manual handle pulse (travel distance amount of tangential movement) is determined by the manual handle feed travel distance selection signals MP1 <Gn019.4> and MP2 <Gn019.5>.

The combination of signals determines which feedrate (program-specified feedrate (F command), a dry run feedrate, or a feedrate synchronized with the rotation of the manual handle) is to be used in a cutting feed block, as shown in the table below.
These signals can be switched even in the middle of a block.

Dry run signal DRN	Handle-synchronous feed signal HREV	Cutting feedrate
0	0	Program-specified feedrate
0	1	Feedrate synchronized with the rotation of the manual handle
1	0	Dry run feedrate
1	1	Dry run feedrate

It is possible to make effective only one direction of rotation of a manual handle. When bit 5 (HSR) of parameter No. 7106 is set to 1, the effective direction of the manual pulse generator is only CW (clockwise) if the handle rotation direction selection signal HDSR <Gn193.3> is set to 0. Also, the effective direction of the manual pulse generator is only CCW (counterclockwise) if the handle rotation direction selection signal HDSR <Gn193.3> is set to 1.
When bit 5 (HSR) of parameter No. 7106 is set to 0, both directions of the manual pulse generator are effective as usual.

Limitations

- Unit system of the control axis

The unit system of the control axis is decided by the setting for the reference axis selected by parameter No. 1031.

- Manual mode

This function cannot be used in manual mode.

- Different magnification in each axis

Manual handle feed axis is not applied when this function is executing, it is not possible to apply a different magnification to the manual handle pulse on a per-axis basis.

Note

NOTE

1 The direction of manual handle rotation does not influence the direction of tool movement. That is to say, rotating the manual handle backward does not cause the tool to reverse.
Handle-synchronous feed disregards the sign of the pulse from the manual pulse generator. (The absolute values of pulses are used.) Therefore, the tool moves along a programmed path through a distance that matches the rotation number of the manual handle, regardless of the direction of rotation.

2 If the maximum feedrate of the handle is set to the setting of parameter No. 1434 (maximum manual handle feedrate switch signal HNDLF <Gn023.3> = “1”), the maximum feedrate for the basic axes is effective.
The setting of parameter No. 1434 for any other axis is not effective.

3 It is not possible to make the maximum feedrate effective on an axis-by-axis basis.

4 When using this function, enable “Manual linear/circular interpolation” and "Manual handle feed (bit 0 (HPG) of parameter No.8131 is 1)". When using the fourth or fifth manual pulse generator, the function "Manual handle feed 4/5-units" is needed.

Signal

Manual handle feed amount selection signals (Incremental feed signals) MP1, MP2 <Gn019.4, Gn019.5>

[Classification] Input signal

[Function] This signal selects the distance traveled per pulse from the manual pulse generator during the manual handle feed or manual handle interrupt. It is also used for incremental feed.
The following table shows the correspondence between the signals and travel distances.

Manual handle feed amount selection signals		Distance traveled
MP2	MP1	Manual handle feed
0	0	Least input increment x 1
0	1	Least input increment x 10
1	0	Least input increment x m *1
1	1	Least input increment x n *1

*1 Magnifications m and n are specified using parameters No. 7113 and 7114.

> ⚠ **CAUTION**
> 1 Because the least input increment is used as the units for manual handle feed and incremental feed, the same value represents a different distance depending on whether the metric or inch input system is used.
> 2 For an axis under diameter programming, the tool moves by the diameter value.

Handle-synchronous feed signal HREV <Gn023.4>

[Classification] Input signal

[Function] This signal selects handle-synchronous feed. That is to say, it causes the cutting feedrate used during automatic operation to be synchronized with the rotation of the manual handle (manual pulse generator).

[Operation] When this signal is set to “1”, the machine tool behaves as follows:
The cutting feedrate used during automatic operation is caused to synchronize with the rotation of the manual pulse generator; instead of being a program-specified feedrate.

- The manual linear/circular interpolation signals MHLCn <Gn544.0-4> and the usage selection of manual linear/circular interpolation signals MHUSn <Gn545.0-4> select the manual pulse generator with which the tool is to be synchronized.
- The feedrate varies with the rotation speed of the manual pulse generator. The travel distance of the tool per pulse of the manual pulse generator (travel distance amount of tangential movement) is determined by the manual handle feed amount selection signals MP1 <Gn019.4> and MP2 <Gn019.5>.

Manual linear/circular interpolation signals
MHLC1 to MHLC5 <Gn544.0 to Gn544.4>

[Classification] Input signal

[Function] Each of these signals selects the manual pulse generator for which the manual linear/circular interpolation function is to be executed. The number at the end of the signal name corresponds to the manual pulse generator number.

[Operation] When this signal is set to “0”

- Manual linear/circular interpolation is disabled. The manual pulse generator is used as a regular manual handle.

When this signal is set to “1”

- Manual linear/circular interpolation is enabled. The usage of the manual handle is selected by the usage selection of manual linear /circular interpolation signals MHUSn <Gn545.0-4>.

Usage selection of manual linear/circular interpolation signal
MHUS1 to MHUS5 <Gn545.0 to Gn545.4>

[Classification] Input signal

[Function] When a manual linear/circular interpolation signal MHLCn <Gn544.0-4> is set to 1 for the manual linear/circular interpolation function, the usage (guidance handle or approach handle) of the nth manual pulse generator is selected by the MHUSn <Gn545.0-4> signals. The number at the end of the signal name corresponds to the manual pulse generator number.

[Operation] When this signal is set to “0”

- The manual handle is used as an approach handle.

When this signal is set to “1”

- The manual handle is used as a guidance handle.
  If handle-synchronous feed signal HREV <Gn023.4> is set to “1”, this unit can be used for handle-synchronous feed.

Selection of usage of the nth manual handle

MHLCn	MHUSn	Usage
0	-	Not used for handle-synchronous feed (feed axis)
1	0	Not used for handle-synchronous feed (approach handle)
1	1	Used for handle-synchronous feed (guidance handle)

Selecting direction of manual handle rotation signal HDSR <Gn193.3>

[Classification] Input signal

[Function] Selects the effective direction of rotation of the manual pulse generator.

[Operation] When this signal is set to “0”

- Only CW (clockwise) is the effective rotation direction of the manual pulse generator.

When this signal is set to “1”

- Only CCW (counterclockwise) is the effective rotation direction of the manual pulse generator.

> **NOTE**
> This signal is available when bit 5 (HSR) of parameter No. 7106 is set to 1.

Feed zero signal FEED0 <Fn066.2>

[Classification] Output signal

[Function] Indicates that the feedrate command (F command) specifies 0.

[Output cond.] Outputting the feed zero signal FEED0 requires that bit 7 (FC0) of parameter No. 1404 be set to 1. If FC0 is set to “0”, FEED0 remains to be 0, regardless of the conditions described below.

This signal is set to “1” in the following conditions:

- The feedrate command (F command) is reset to 0 when the power switched on or a reset occurs.
- A block containing a feedrate command (F command) specifying 0 is executed during automatic operation.

This signal is set to “0” in the following conditions:

- A block containing a feedrate command (F command) specifying a value other than 0 is executed during automatic operation.
- For the machining center series, the cutting feedrate (except 0) specified in parameter No. 1411 is made valid when the power is switched on or a reset occurs.
- Bit 7 (FC0) of parameter No. 1404 is set to 0.

NOTE

The feed zero signal FEED0 is available when bit 7 (FC0) of parameter No. 1404 is set to 1.

⚠ **CAUTION**

On receiving the feed zero signal FEED0 specifying “1”, the PMC returns a dry run signal or handle-synchronous feed signal. Movement of cutting feed block will remain stopped until these signals become "1".

Signal address

	#7	#6	#5	#4	#3	#2	#1	#0
Gn019			MP2	MP1				
Gn023				HREV				
Gn046	DRN							
Gn193					HDSR

1404	FC0							

[Input type] Parameter input
[Data type] Bit path

#7 FC0 In automatic operation, when cutting feed block (G01, G02, G03, etc.) with feedrate command (F command) of 0 is commanded:
0: An alarm PS0011 “FEED ZERO (COMMAND)” occurs.
1: An alarm PS0011 does not occur, and the block is executed at a feedrate of 0.

NOTE
1 In inverse time feed (G93) mode, the alarm PS1202, "NO F COMMAND AT G93" is issued irrespective of the setting of this parameter.
2 When bit 6 (CLR) of parameter No.3402 is 1, to change this parameter FC0 from 1 to 0, reset the CNC. Or if CLR is 0, turn off and on the CNC.

	#7	#6	#5	#4	#3	#2	#1	#0
1405					HFR			

[Input type] Parameter input
[Data type] Bit path

#3 HFR Feedrate command in rapid traverse is:
0: Parameter setting value.
1: Synchronized with handle pulse by the handle-synchronous feed function.

NOTE
This parameter is available when the handle-synchronous feed function is available.

	#7	#6	#5	#4	#3	#2	#1	#0
3402		CLR						

[Input type] Parameter input
[Data type] Bit path

#6 CLR Reset key on the MDI panel, external reset signal, reset and rewind signal, and emergency stop signal
0: Cause reset state.
1: Cause clear state.
For the reset and clear states, refer to Appendix in the OPERATOR’S MANUAL.

	#7	#6	#5	#4	#3	#2	#1	#0
7106			HSR					

[Input type] Parameter input
[Data type] Bit path

#5 HSR The direction of manual pulse generator rotation in the handle-synchronous feed function is:
0: effective in both.
1: effective in one direction. The effective direction is selected by selecting direction of manual handle rotation signal HDSR <Gn193.3>.

7113	Manual handle feed magnification m

[Input type] Parameter input
[Data type] Word path
[Valid data range] 1 to 2000
This parameter sets the magnification m when manual handle feed movement selection signals MP1 and MP2 are set to “0” and “1”.

7114	Manual handle feed magnification n

[Input type] Parameter input
[Data type] Word path
[Valid data range] 1 to 2000
This parameter sets the magnification when manual handle feed movement selection signals MP1 and MP2 are set to “1”.

3.6 RIGID TAPPING BY MANUAL HANDLE

Overview

To execute rigid tapping, set rigid mode, then switch to handle mode and move the tapping axis with a manual handle.
Rigid tapping by manual handle is enabled by setting bit 0 (HRG) of parameter No. 5203 to 1.
See the section of the rigid tapping to operate the rigid tapping by manual handle.

Explanation

- Basic procedure

1 Stop the spindle and servo axes, then set MDI mode.
2 Enter and execute the following program:
Example 1)
M series/T series (G code system B, C)
M29 S100 ;
G91 G84 Z0 F1000 ;

T

Example 2)
T series (G code system A)
M29 S100 ;
G84 W0 F1000 ;

The program above is required to determine a screw lead and set rigid tapping mode. In this program, a tapping axis must always be specified. Specify a value that does not operate the tapping axis. G84 (G74) is specified for M series while G84 (G88) is specified for T series.

> ⚠ **WARNING**
> In this MDI programming, never specify commands to position the tool at a drilling position and at point R. Otherwise, the tool moves along an axis.

3 Close the position control loop of the spindle and set rigid tapping mode by executing the entered program. At this time, perform gear switching or other sequences with PMC as with memory operation.

4 After rigid mode is set upon completion of MDI program execution, switch to the handle mode.

> ⚠ **CAUTION**
> At this time, never press the reset key. Otherwise, rigid mode is canceled.

5 To perform rigid tapping, select a tapping axis, and move the tapping axis with the manual handle.

- Cancellation of rigid mode

To cancel rigid mode, specify G80 as the normal rigid tapping. When the reset key is pressed, rigid mode is canceled, but the canned cycle is not canceled.
When the rigid tapping signal RGTAP is to be set to “0” for rigid mode cancellation (when bit 2 (CRG) of parameter No. 5200 is set to 0), the G80 command ends after the rigid tapping signal RGTAP is set to “0”.

- Spindle rotation direction

The rotation direction of the spindle is determined by a specified tapping cycle G code and the setting of bit 1 (HRM) of parameter No. 5203. For example, when the parameter HRM is set to 0 in G84 mode, the spindle makes forward rotations as the tapping axis moves in the minus direction. (When the tapping axis moves in the plus direction, the spindle makes reverse rotations.)

- Arbitrary tapping axis

M

By setting bit 0 (FXY) of parameter No. 5101 to 1, an arbitrary tapping axis can be selected. In this case, specify a G code for plane selection and tapping axis address when rigid mode is set in MDI mode.

T

A tapping axis can be freely selected regardless of the setting of FXY (bit 0 of parameter No. 5101). For the program format for FANUC Series 15, however, it depends on the setting of FXY.

- Specification of G84/specification of M29 and G84 in the same block

In an MDI program for setting rigid mode, G84 can be used as a rigid tapping G code (bit 0 (G84) of parameter No. 5200 is set to 1), or M29 and G84 can be specified in the same block.
Example 1 : G91 G84 Z0 F1000 S100;
Example 2 : G91 G84 Z0 F1000 M29 S100;

- Program format for FANUC Series 15

Bit 1 (FCV) of parameter No. 0001 can be set to 1 to perform rigid tapping using program format for FANUC Series 15.

M

Example 1: G91 G84.2 (G84.3) Z0 F1000 S100; (M series)

T

Example 2: G84.2 W0 F1000 S100; (T series : G code system A)
Example 3: G91 G84.2 Z0 F1000 S100; (T series : G code system B, C)

- Acceleration or deceleration type

As the acceleration or deceleration type and acceleration or deceleration time constant used during rigid tapping by manual handle, those set in the rigid tapping parameter are enabled. These are also enabled during extraction.

- Specification of manual handle feed faster than the rapid traverse rate

Set parameter No.7117 to 0 so that when manual handle feed, which is faster than the rapid traverse rate, is specified, the handle pulses beyond the rapid traverse rate are ignored.

- Selecting a spindle from multiple spindles

When there are multiple spindles, a spindle can be selected by specifying the S command and P command at the same time.

Example :

When the second spindle is selected

```
M29 S100 P2;
G91 G84 Z0 F1000;
```

Limitation

- Excessive error check

In rigid tapping by manual handle, only an excessive error during movement is checked.

- Tool axis direction handle feed

In rigid tapping by manual handle, tool axis direction handle feed is disabled.

- Extraction override

In rigid tapping by manual handle, the extraction override function is disabled.

- Acceleration/deceleration time constant for extraction

In rigid tapping by manual handle, the use of an acceleration/deceleration time constant for extraction is disabled.

- Number of repeats

In MDI programming, never specify K0 and L0, which are used to specify that the number of repeats is 0 and to disable the execution of a G84 block. If K0 or L0 is specified, rigid mode cannot be set.

- Positioning of the tool to a drilling position

When positioning the tool to a drilling position, select the X-axis or Y-axis with the axis selection signal in handle mode. Never use the method of positioning to a drilling position in MDI mode or MEM mode because the tapping axis may operate.

- 3-dimensional rigid tapping

3-dimensional rigid tapping cannot be used for rigid tapping using a manual handle.

- Feed forward

In rigid tapping by manual handle, feed forward is disabled even if bit 2 (RFF) of parameter No. 5203 is set to 1 (feed forward is enabled in rigid tapping).

- Constant surface speed control

If rigid tapping is commanded during constant surface speed control, alarm PS0200, ”ILLEGAL S CODE COMMAND” is issued. Command rigid tapping after canceling constant surface speed control.

- Spindle control with servo motor
Rigid tapping by manual handle cannot be used against the rigid tapping with servo motor.

Parameter

	#7	#6	#5	#4	#3	#2	#1	#0
5203							HRM	HRG

[Input type] Parameter input
[Data type] Bit path

#0 HRG Rigid tapping by the manual handle is:
0: Disabled.
1: Enabled.

#1 HRM When the tapping axis moves in the negative direction during rigid tapping controlled by the manual handle, the direction in which the spindle rotates is determined as follows:
0: In G84 mode, the spindle rotates in a normal direction. In G74 mode, the spindle rotates in reverse.
1: In G84 mode, the spindle rotates in reverse. In G74 mode, the spindle rotates in a normal direction.

Alarm and message

No.	Message	Description
PS0200	ILLEGAL S CODE COMMAND	In the rigid tap, an S value was out of range or was not specified. The parameters Nos. 5241 to 5243 setting is an S value which can be specified for the rigid tap. Correct the parameters or modify the program.

Reference item

Manual name	Item name
OPERATOR'S MANUAL (B-64693EN)	Rigid tapping by manual handle
CONNECTION MANUAL (FUNCTION) (this manual)	Rigid tapping

3.7 I/O Link β*i* MANUAL HANDLE INTERFACE

Overview

This function controls manual handle feed for FANUC SERVO AMPLIFIER βi series I/O Link Option (I/O Link β*i*) by using a manual pulse generator on the host. Pulses from manual pulse generator are transferred from the host to I/O Link β*i* through I/O Link. Still further, this function can control the magnification of output signal of pulses from manual pulse generator by changing the parameter. This function is available on the peripheral control interface.

Explanation

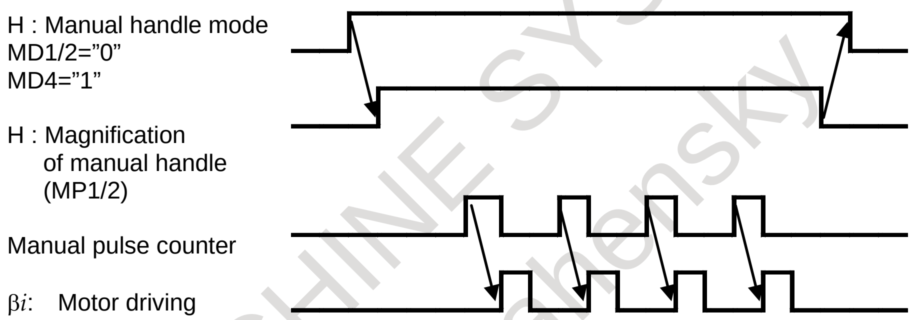
After the manual handle mode of I/O Link β*i* (MD1(Y0.0)=0), MD2(Y0.1)=0, MD4(Y0.2)=1) is selected, the host informs I/O Link β*i* of the magnification of the manual handle generator (MP1(Y7.4), MP2(Y7.5)), and changes the manual pulse counter.

After reading the varied amount of the manual pulse counter, I/O Link β*i* operates the motor.

【Timing chart】

H: The management of the host

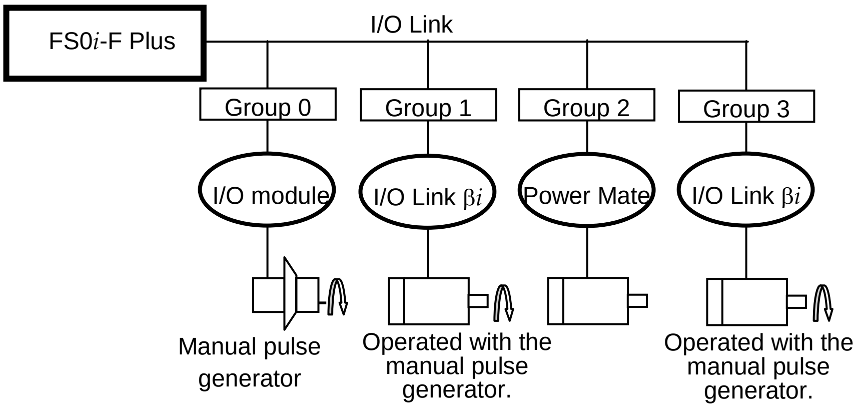
β*i*: The management of the I/O Link β*i*



> ⚠ **CAUTION**
> Be sure to assign 16 bytes signals from the host (CNC) to I/O Link β*i*.

Automatic distinction of an I/O Link β*i*

By setting bit 6 (BHS) of parameter No. 7105 to 1, it is possible to automatically distinguish between an I/O Link β*i* and a Power Mate, so that even if an I/O Link β*i* and a Power Mate are connected at the same time, the I/O Link β*i* can be operated with the manual pulse generator on the host without setting parameters Nos. 12330 to 12337.



Conceptual diagram

NOTE

1 The use of this function requires the Power Mate CNC manager.
2 Do not use direct commands with the I/O Link β*i* that uses this function. (Otherwise, movement along an axis may occur when it is switched between the a direct commands and a peripheral equipment control.)
3 Because of the execution of the automatic distinction to determine whether the slave connected with an I/O Link is an I/O Link β*i* or a Power Mate, the time required until the manual pulse generator can be used becomes longer than usual.
Time delay: (Number of Power Mate connected as slaves × 2) seconds

To execute this automatic distinction, create a ladder program that contains the sequence below.

<1> Check that the β ready signal <F531.7> is on.
<2> Enter manual handle mode.

NOTE

Do not switch to manual handle mode before the β ready signal <F531.7> is turned on.
Otherwise, unintentional movement along an axis may occur.

Signal

Mode selection signal MD1 <Yy+0.0>, MD2 <Yy+0.1>, MD4<Yy+0.2>

[Classification] CNC(host) → I/O Link β*i*

[Function] This signal selects the operation mode of I/O Link β*i*.

[Operation] This signal selects the manual handle mode of the I/O Link β*i*.

MD4	MD2	MD1
1	0	0

⚠ CAUTION

1 Rotate the manual pulse generator on the manual handle mode.
2 Don’t change the operation mode during the manual handle operation of the I/O Link β*i*.

Incremental feed signal MP1 <Yy+7.4>, MP2 <Yy+7.5>

[Classification] CNC(host) → I/O Link β*i*

[Function] This signal selects magnification of manual handle of I/O Link β*i*.

[Operation] I/O Link β*i* drives the motor by pulses multiplied by the magnification of this signal to pulses of the manual pulse generator input during manual handle mode.

MP2	MP1	Distance traveled per a pulse from the manual pulse generator
0	0	User-specified unit × 1
0	1	User-specified unit × 10
1	0	User-specified unit × 100
1	1	User-specified unit × (M/N) (M : Parameter No.0062, N : Parameter No.0063)

> ⚠ **CAUTION**
> 1 These signals are available when the bit 5 (MP) of parameter No. 0005 on the I/O Link β*i* is set to 1.
> 2 These signals are available on the manual handle mode only.
> 3 These signals are shared with the signals for rapid traverse override.
> 4 On manual handle mode, these signals mean Incremental Feed signals. On another mode, these signals mean Rapid Traverse Override signals. When you change the operation mode from the manual handle mode to another, you need to change these signals to the setting of Rapid Traverse Override.

> **NOTE**
> User-specified unit corresponds to increment system in CNC. The machine tool builder defines the weight of one user-specified unit like 0.01mm/0.01deg (IS-A), 0.001mm/0.001deg (IS-B).
> The detection unit is decided from the number of pulses and the amount of the shift per one rotation. The ratio of the user-specified unit to the detection unit is adjusted by Command multiplier (CMR).
> The number of pulses per one rotation and CMR is set to the parameters on the I/O Linkβ*i*.

Manual handle generators selection signal IOLBH1 <G199.0>, IOLBH2 <G199.1>

[Classification] Input signal (common among paths)
[Function] It selects the manual handle generator which transfers to the I/O Link β*i*.
[Operation] It selects the manual handle generator which transfers to the I/O Link β*i* by this signal.

IOLBH2	IOLBH1	Manual handle generator which transfers to I/O Link β*i*
0	0	First unit
0	1	Second unit
1	0	Third unit

> ⚠ **CAUTION**
> Don't change the manual handle generator on the manual handle mode.

β ready signal IOLBR <F531.7>

[Classification] Output signal
[Function] In connection with all I/O Link channels, this signal indicates that the detection of all I/O Link β*i*s are completed.
[Operation] This signal is set to 1 if:

- The detection of all I/O Link β*i*s from those with the same model IDs for all I/O Link channels is completed.

This signal is set to 0 if:

- The detection of all I/O Link β*i*s are not completed.
- The Power Mate CNC Manager is not available.

[Data type] Bit

> **NOTE**
> When this parameter is set, the power must be turned off before operation is continued.

G10 to G4F When the Power Mate or I/O Link β*i* is connected to the I/O Link, these bits set whether to transfer pulses from manual pulse generators connected to the I/O Link to the Power Mate or I/O Link β*i*.

The setting of each bit has the following meaning:
0: Pulses are transferred.
1: Pulses are not transferred.

The bits and the corresponding I/O Link channel numbers and group numbers are listed below:

Parameter	Channel number	Group number
G10	1	0
G11	1	1
G12	1	2
:	:	:
G1F	1	15
:	:	:
G4F	4	15

NOTE
1 When target group is neither Power Mate nor I/O Link β*i*, pulses from the manual pulse generator is not transferred to the group regardless of the parameter setting.
2 When target group is Power Mate, please set the related parameter to 1(not transferred).

FANUC SERVO AMPLIFIER β*i* series I/O Link Option MAINTENANCE MANUAL(B-65395EN)	MANUAL HANDLE INTERFACE

3.8 3-DIMENSIONAL MANUAL FEED(M SERIES)

M

Overview

This function enables the use of the following functions.

- 3-dimensional manual feed
  - Tool axis direction handle feed/tool axis direction JOG feed/tool axis direction incremental feed
  - Tool axis right-angle direction handle feed/tool axis right-angle direction JOG feed/tool axis right-angle direction incremental feed
  - Tool tip center rotation handle feed/tool tip center rotation JOG feed/tool tip center rotation incremental feed
  - Table vertical direction handle feed/table vertical direction JOG feed/table vertical direction incremental feed
  - Table horizontal direction handle feed/table horizontal direction JOG feed/table horizontal direction incremental feed

A handle interrupt can be generated for each handle feed. Handle interrupts work according to the corresponding handle feed specifications described hereinafter unless otherwise noted.

- When a second or subsequent manual handle is used

When using a second or subsequent manual handle in 3-dimensional manual feed, set the number of the handle to be used in parameter No. 12323.
At this time, use the manual handle feed axis selection signals/manual handle interrupt axis selection signals for the set handle.
In the description of this manual, the use of the first manual handle is assumed.
When using a second or subsequent manual handle, read HS1A - HS1E <Gn018.0 to 3, Gn411.0> / HS1IA - HS1IE <Gn041.0 to 3, Gn411.4> as the signals for the handle used.
Example 1:
When performing handle feed with the second manual handle
- Set 2 in parameter No. 12323.
- The manual handle feed axis selection signals to be used are HS2A to HS2E <Gn018.4 to 7, Gn411.1>.

Example 2:
When performing handle feed with the fifth manual handle
- Set 5 in parameter No. 12323.
- The manual handle feed axis selection signals to be used are HS5IA to HS5IE <Gn379.4 to 7, Gn412.4>.

- Selecting a coordinate system when calculating the tool direction

If, in 3-dimensional manual feed, a workpiece coordinate system offset is set for a rotation axis, use bit 0 (CAC) of parameter No. 12319 to select whether to use values in the workpiece or machine coordinate system when calculating the tool direction.

- When the bit 0 (CAC) of parameter No. 12319 = 0:
  Values in the machine coordinate system are used.
  For those parameters for configuring the machine, Nos. 19680 to 19714, that depend on the coordinate on a rotation axis, set the values assumed when the machine coordinate on the rotation axis is 0.

- When the bit 0 (CAC) of parameter No. 12319 = 1:
  Values in the workpiece coordinate system are used.
  For those parameters for configuring the machine, Nos. 19680 to 19714, that depend on the coordinate on a rotation axis, set the values assumed when the workpiece coordinate on the rotation axis is 0.

For the functions below, values in the workpiece coordinate system of a rotation axis are used to calculate the tool direction and, therefore, if a workpiece coordinate system offset is set for a rotation axis, and 3-dimensional manual feed is to be used together with any of the functions below, set bit 0 (CAC) of parameter No. 12319 to 1.

- Tilted working plane indexing

(Example)

Related parameters:
No.19680=2 (Tool rotation type)
No.19682=3 (the master rotation axis (C-axis) is about the Z-axis)
No.19687=2 (the slave rotation axis (B-axis) is about the Y-axis)
No.19697=3 (the reference tool axis direction is the Z-axis direction)
No.19698=0 (angle RA when the reference tool axis direction is tilted)
No.19699=0 (angle RB when the reference tool axis direction is tilted)

Workpiece coordinate system offset:
B=10.0

Example 1:
The tool is assumed to face the Z-axis direction when it is in the following states.
Position in the workpiece coordinate system B= -10.0
Position in the machine coordinate system B=0.0
In this case, values in the machine coordinate system must be used to calculate the tool direction, set bit 0 (CAC) of parameter No. 12319 to 0.

Example 2:
The tool is assumed to face the Z-axis direction when it is in the following states.
Position in the workpiece coordinate system B=0.0
Position in the machine coordinate system B=10.0
In this case, values in the workpiece coordinate system must be used to calculate the tool direction, set bit 0 (CAC) of parameter No. 12319 to 1.

- 3-Dimensional manual feed by handle in JOG mode

Even in JOG feed mode, 3-Dimensional manual feed by handle feed can be enabled using bit 0 (JHD) of parameter No.7100.

- The manual handle interruption screen in Tilted working plane indexing mode

In Tilted working plane indexing mode, when 3-dimensional handle interrupt is executed in X,Y, and Z directions of the feature coordinate system (bit 0 (TWD) of parameter No.12320 is set to 1), it can be selected whether to display the travel distance in the manual handle interruption screen in the workpiece coordinate system or the feature coordinate system, by bit 3 (DMK) of parameter No.5402 and by bit 4 (MDT) of parameter No.12319.

In the case to display the travel distance in the feature coordinate system, set bit 3 (DMK) of parameter No.5402 to 0 and bit 4 (MDT) of parameter No.12319 to 1.

3.8.1 Tool Axis Direction Handle Feed/Tool Axis Direction JOG Feed/Tool Axis Direction Incremental Feed

Overview

In the tool axis direction handle feed, tool axis direction JOG feed, and tool axis direction incremental feed, the tool or table is moved in the tool axis direction.

- Tool axis direction

The tool axis direction that is taken when all the rotation axes for controlling the tool are at an angle of 0 degree is specified in parameters Nos.19697, 19698, and 19699. As the rotation axes for controlling the tool rotate, the tool axis direction changes according to the rotation axis angle.

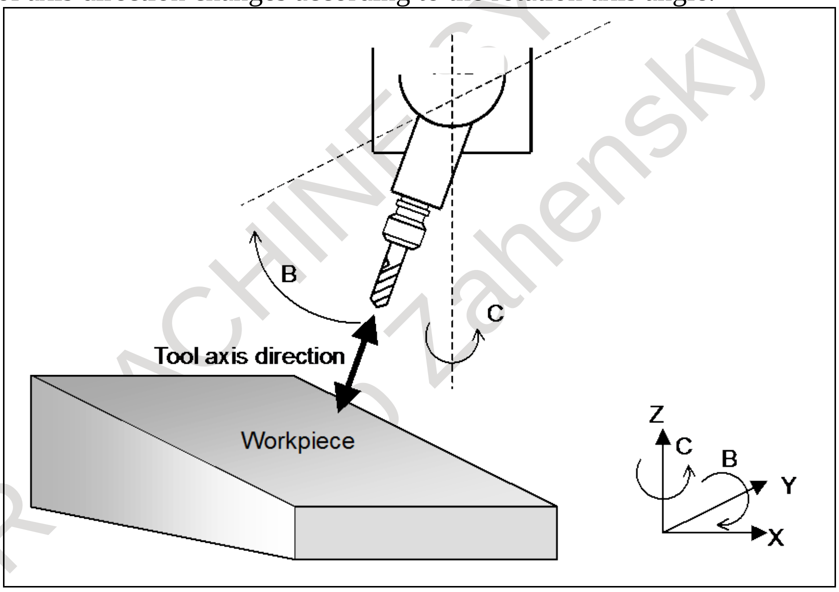

Fig. 3.9.1 Tool axis direction

- Tool axis direction feed in the tilted working plane indexing mode

If bit 0 (TWD) of parameter No. 12320 is set to 1, the feed direction of the tool axis direction feed in the tilted working plane indexing mode is assumed to be the Z direction in the feature coordinate system of the tilted working plane indexing.

3.8.1.1 Tool axis direction handle feed

The tool axis direction handle feed is enabled when the following four conditions are satisfied:

<1> Handle mode is selected.

<2> The tool axis direction feed mode signal ALNGH <Gn023.7> is set to 1 and the table base signal TB_BASE <Gn298.0> is set to 0.

<3> The state of the first manual handle feed axis selection signals (HS1A - HS1E) to make the tool axis direction handle feed mode effective is set in parameter No. 12310.

<4> The value of parameter No. 12310 matches the first manual handle feed axis selection signals (HS1A - HS1E).

- Amount of movement

When the manual pulse generator is rotated, the tool is moved in the tool axis direction by the amount of rotation.

- Feedrate clamp

The feedrate is clamped so that the speed of each moving axis dose not exceed the manual rapid traverse rate (parameter No. 1424). Handle pulses generated while the clamp feedrate is exceeded are ignored.
If Manual handle feed maximum feedrate change signal HNDLF<Gn023.3> is "1", clamping is performed by the maximum handle feedrate (parameter No. 1434).

3.8.1.2 Tool axis direction JOG feed/tool axis direction incremental feed

The tool axis direction JOG feed or tool axis direction incremental feed is enabled when the following three conditions are satisfied:

<1> JOG mode or incremental feed mode is selected.
<2> The tool axis direction feed mode signal ALNGH is set to 1 and the table base signal TB_BASE is set to 0.
<3> The feed axis direction selection signal (+Jn <Gn100>, -Jn <Gn102> (where n = 1 to the number of controlled axes)) is set to 1 for the axis corresponding to the direction specified by parameter No. 19697. (Even when the tool axis direction is slant because of the settings of parameters Nos.19698 and 19699, the signal that activates the tool axis direction JOG feed or tool axis direction incremental feed is determined by parameter No. 19697 only.)
Ex.) No.19697 = 3 (+Z-axis direction); Z-axis is the 3rd axis of control axes.
- +J3: Tool axis direction +
- -J3: Tool axis direction -

- Feedrate

The feedrate is the dry run rate (parameter No. 1410). The manual feedrate override feature is available.
If bit 2 (JFR) of parameter No. 12320 is set to 1, the feedrate is the jog feedrate (parameter No. 1423) for a driven feed axis direction selection signal. The manual feedrate override feature is available.

- Feedrate clamp

The feedrate is clamped so that the speed of each moving axis dose not exceed the manual rapid traverse rate (parameter No. 1424).

3.8.2 Tool Axis Right-Angle Direction Handle Feed/Tool Axis Right-Angle Direction JOG Feed/Tool Axis Right-Angle Direction Incremental Feed

Overview

In the tool axis right-angle direction handle feed, tool axis right-angle direction JOG feed, or tool axis right-angle direction incremental feed, the tool or table is moved in the tool axis right-angle direction.
If bit 1 (FLL) of parameter No. 12320 is set to 1, the tool or table is moved in the latitude or longitude direction determined by the tool axis direction vector.

- Tool axis right-angle direction

There are two tool axis right-angle directions, which are perpendicular to the tool axis direction (see the previous section).

Table 3.8.2 (a) Tool axis direction

Parameter No. 19697	Tool axis right-angle direction 1	Tool axis right-angle direction 2
1 (The reference tool direction is +X.)	+Y direction	+Z direction
2 (The reference tool direction is +Y.)	+Z direction	+X direction
3 (The reference tool direction is +Z.)	+X direction	+Y direction

Fig. 3.9.2 (a) shows the tool axis right-angle directions that may be taken when the angles of all the rotation axes for controlling the tool are 0 degree and when parameters Nos.19698 and 19699 are both set to 0.
When the reference tool axis direction is inclined based on the settings of parameters Nos.19698 and 19699, the tool axis right-angle direction is also inclined as much.
As the rotation axes for controlling the tool rotate, the tool axis right-angle direction changes according to the rotation axis angle.

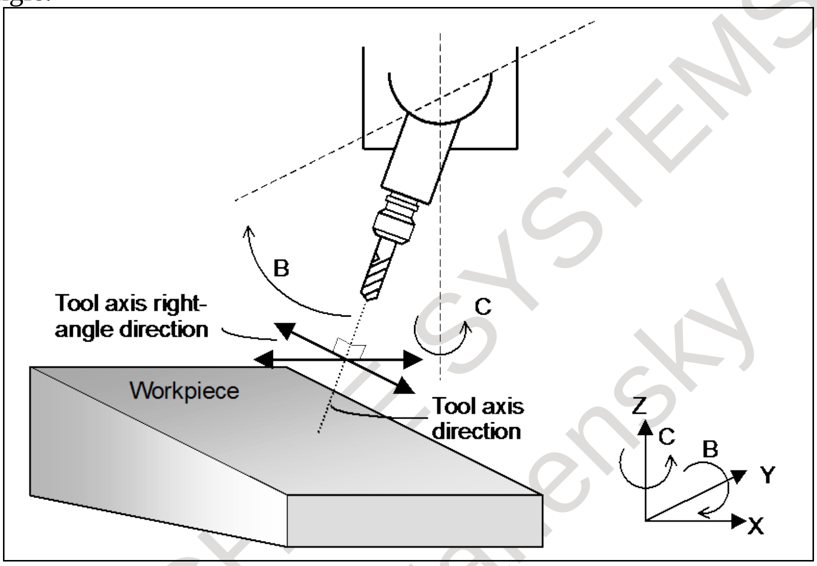

Fig. 3.8.2 (a) Tool axis direction

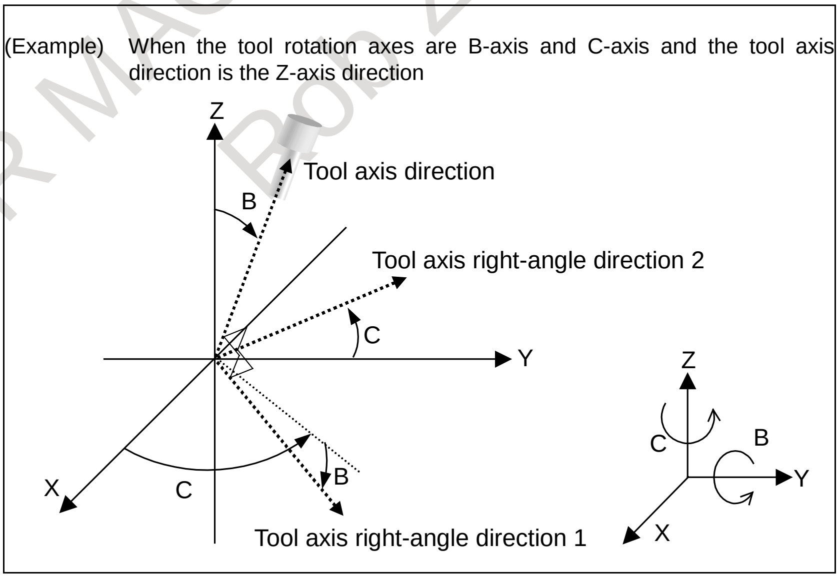

Fig. 3.8.2 (b) Example of tool axis direction

- Latitude and longitude directions

When bit 1 (FLL) of parameter No. 12320 is set to 1, the feed direction is defined as follows:

Let a vector perpendicular to a plane formed by the tool axis direction vector ($\vec{T}$) and normal axis direction vector ($\vec{P}$) (parameter No. 12321) be the tool axis right-angle direction 1 (longitude direction) vector ($\vec{R1}$). When tool axis right-angle direction 1 is selected, a movement in the positive direction means a movement in this vector direction, and a movement in the negative direction means a movement in the direction opposite to the vector direction. (Longitude direction feed)

Equation: $\vec{R1} = \vec{P} \times \vec{T}$

Let a vector perpendicular to the tool axis direction vector ($\vec{T}$) and tool axis right-angle direction 1 (longitude direction) vector ($\vec{R1}$) be the tool axis right-angle direction 2 (latitude direction) vector ($\vec{R2}$). When tool axis right-angle direction 2 is selected, a movement in the positive direction means a movement in this vector direction, and a movement in the negative direction means a movement in the direction opposite to the vector direction. (Latitude direction)

Equation: $\vec{R2} = \vec{T} \times \vec{R1}$

When the tool axis direction vector ($\vec{T}$) is parallel to the normal axis direction vector ($\vec{P}$) (parameter No. 12321) (when the angle between them is not greater than the setting of parameter No. 12322), tool axis right-angle direction 1 and tool axis right-angle direction 2 are assumed as follows:

Table 3.8.2 (b) Latitude and longitude directions

Parameter No. 12321	Normal axis direction	Tool axis right-angle direction 1	Tool axis right-angle direction 2
1	+X direction	+Y direction	+Z direction
2	+Y direction	+Z direction	+X direction
3	+Z direction	+X direction	+Y direction

If 0 is set in parameter No. 12321, the normal axis direction is set to the reference tool axis direction (parameter No. 19697).
If a value other than 0 to 3 is specified in parameter No. 12321, alarm PS5459, "MACHINE PARAMETER INCORRECT" is issued.

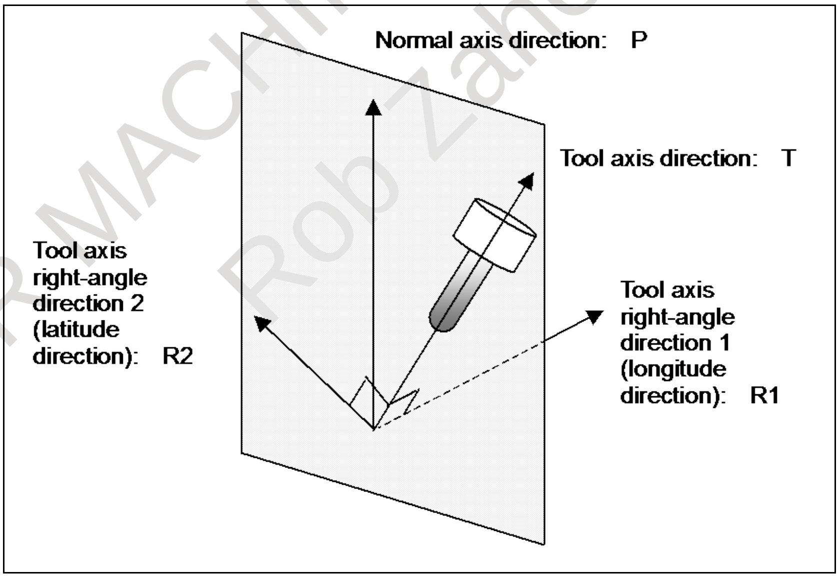

Fig. 3.8.2 (c) Latitude and longitude directions

- Tool axis right-angle direction feed in the tilted working plane indexing mode

If bit 0 (TWD) of parameter No. 12320 is set to 1, the feed direction of the tool axis right-angle direction feed in the tilted working plane indexing mode is defined as follows:
Tool axis right-angle direction 1: X direction in the feature coordinate system of the tilted working plane indexing
Tool axis right-angle direction 2: Y direction in the feature coordinate system of the tilted working plane indexing

3.8.2.1 Tool axis right-angle direction handle feed

The tool axis right-angle direction handle feed is enabled when the following four conditions are satisfied:

<1> Handle mode is selected.
<2> The tool axis right-angle direction feed mode signal RGHTH <Gn023.6> is set to 1 and the table base signal TB_BASE is set to 0.
<3> The state of the first manual handle feed axis selection signals (HS1A to HS1E) to make the tool axis right-angle direction handle feed mode effective is set in parameter No. 12311 or 12312.
<4> The value of parameter No.12311 or No.12312 matches the first manual handle feed axis selection signals (HS1A to HS1E).

- Amount of movement

When the manual pulse generator is rotated, the tool is moved in the tool axis right-angle direction by the amount of rotation.

- Feedrate clamp

The feedrate is clamped so that the speed of each moving axis dose not exceed the manual rapid traverse rate (parameter No.1424). Handle pulses generated while the clamp feedrate is exceeded are ignored.
If manual handle feed maximum feedrate change signal HNDLF<Gn023.3> is "1", clamping is performed by the maximum handle feedrate (parameter No. 1434).

3.8.2.2 Tool axis right-angle direction JOG feed/tool axis right-angle direction incremental feed

The tool axis right-angle direction JOG feed or tool axis right-angle direction incremental feed is enabled when the following three conditions are satisfied:

<1> JOG mode or incremental feed mode is selected.
<2> The tool axis right-angle direction feed mode signal RGHTH is set to 1 and the table base signal TB_BASE is set to 0.
<3> The feed axis direction selection signal (+Jn, -Jn (where n = 1 to the number of controlled axes)) is set to 1 for the axis corresponding to the direction that is perpendicular to the direction specified by parameter No. 19697. (Even when the tool axis direction is slant because of the settings of parameters Nos.19698 and 19699, the signal that activates the tool axis right-angle direction JOG feed or tool axis right-angle direction incremental feed is determined by parameter No. 19697 only.)
Ex.) Parameter No. 19697=3 (+Z-axis direction); X-, Y-, and Z-axes are the 1st, 2nd, and 3rd axes of control axes respectively.
- +J1: Tool axis right-angle direction 1 +
- -J1: Tool axis right-angle direction 1 -
- +J2: Tool axis right-angle direction 2 +
- -J2: Tool axis right-angle direction 2 -

- Feedrate

The feedrate is the dry run rate (parameter No. 1410). The manual feedrate override feature is available.
If bit 2 (JFR) of parameter No. 12320 is set to 1, the feedrate is the jog feedrate (parameter No. 1423) for a driven feed axis direction selection signal. The manual feedrate override feature is available.

- Feedrate clamp

The feedrate is clamped so that the speed of each moving axis dose not exceed the manual rapid traverse rate (parameter No. 1424).

3.8.3 Tool Tip Center Rotation Handle Feed/Tool Tip Center Rotation JOG Feed/Tool Tip Center Rotation Incremental Feed

Overview

In the tool tip center rotation handle feed, tool tip center rotation JOG feed, and tool tip center rotation incremental feed, when a rotary axis is rotated by manual feed, the linear axes (X, Y, and Z axes) are moved so that turning the rotation axis does not change the relative relationship between the tool tip position and the workpiece (table).

- The Fig. 3.8.3 (a) shows an example where the tool is rotated on the rotation axis. In this case, the linear axes are moved so that the position of the tool tip is not moved with respect to the workpiece.

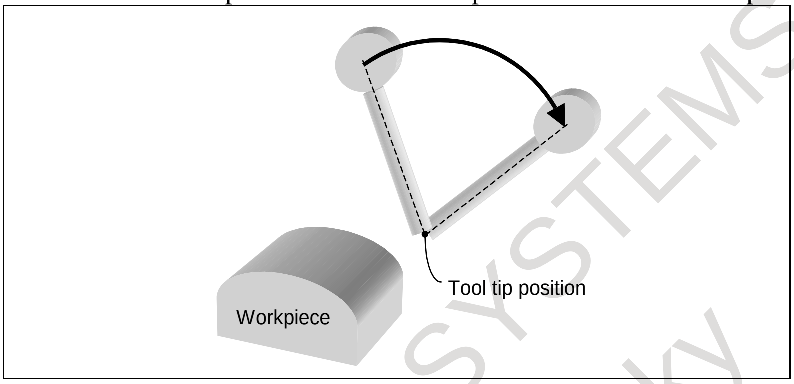

Fig. 3.8.3 (a) Example where the tool is rotated

- The Fig. 3.8.3 (b) shows an example where the table is rotated on the rotation axis. As in the previous case, the linear axes are moved so that the position of the tool tip is not moved with respect to the workpiece (table).

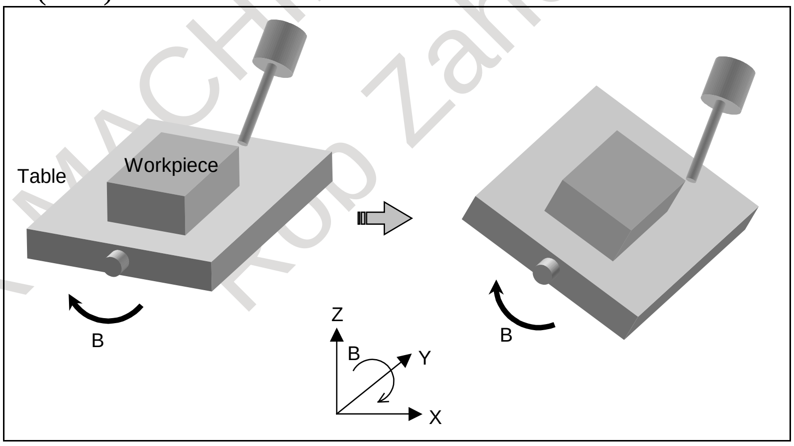

Fig. 3.8.3 (b) Example where the table is rotated

3.8.3.1 Tool tip center rotation handle feed

The tool tip center rotation handle feed is enabled when the following four conditions are satisfied:

<1> Handle mode is selected.

<2> The tool tip center rotation feed mode signal RNDH <Gn298.2> is set to 1.

<3> The state of the first manual handle feed axis selection signals (HS1A to HS1E) to make the tool tip center rotation handle feed mode effective is set in parameter No. 12313 or 12314.

<4> The value of parameter No. 12313 or 12314 matches the first manual handle feed axis selection signals (HS1A to HS1E).

- Amount of movement

When the manual pulse generator is rotated, the rotation axis is moved by the amount of rotation. The linear axes (X, Y, and Z axes) are moved so that turning the rotation axis does not change the relative relationship between the tool tip position and the workpiece.

- Feedrate clamp

The feedrate is clamped so that the synthetic speed of the linear axes (the tangential direction speed) does not exceed the manual rapid traverse rate (parameter No. 1424) (of any moving linear axis). The feedrate is also clamped so that the speed of the rotation axis does not exceed the manual rapid traverse rate (parameter No. 1424) (of that particular axis). Handle pulses generated while the clamp feedrate is exceeded are ignored.
If manual handle feed maximum feedrate change signal HNDLF<Gn023.3> is "1", clamping is performed by the maximum handle feedrate (parameter No. 1434).

3.8.3.2 Tool tip center rotation JOG feed/tool tip center rotation incremental feed

The tool tip center rotation JOG feed or tool tip center rotation incremental feed is enabled when the following three conditions are satisfied:
<1> JOG mode or incremental feed mode is selected.
<2> The tool tip center rotation feed mode signal RNDH is set to 1.
<3> The feed axis direction selection signal (+Jn, -Jn (where n = 1 to the number of controlled axes)) is set to 1 for the rotation axis to be rotated.
Ex.) When the B-axis (4th axis) is rotated
- +J4: Tool tip center rotation feed +
- -J4: Tool tip center rotation feed -

- Feedrate

Control is exerted so that the synthetic speed of the linear axes (in the tangential direction) is the dry run rate (parameter No. 1410). The manual feedrate override feature is available.
If bit 2 (JFR) of parameter No. 12320 is set to 1, the feedrate of a rotation axis is the jog feedrate (parameter No. 1423) of the axis to be rotated. The manual feedrate override feature is available.

- Feedrate clamp

The feedrate is clamped so that the synthetic speed of the linear axes (the tangential direction speed) does not exceed the manual rapid traverse rate (parameter No. 1424) (of any moving linear axis). The feedrate is also clamped so that the speed of the rotation axis does not exceed the manual rapid traverse rate (parameter No. 1424) (of that particular axis).

3.8.3.3 Selection of the tool length offset value

The tool length in 3-dimensional manual feed is determined as explained below. (Table 3.8.3.3)
If bit 2 (LOD) of parameter No. 19746 is set to 0, the value set in parameter No. 12318 is assumed to be the tool length.
If the LOD parameter is set to 1, and the tool length offset function is performed, the offset data specified for the tool length offset is assumed to be the tool length.
If the LOD parameter is set to 1, and the tool length offset function is not performed, the tool length is determined as follows. If bit 3 (LOZ) of parameter No. 19746 is set to 0, the value set in parameter No. 12318 is assumed to be the tool length in 3-dimensional manual feed; if LOZ is set to 1, the tool length is assumed to be 0.

Table 3.8.3.3 Tool length offset value in 3-dimensional manual feed

<table>
<tr><th colspan="2" rowspan="3"></th><th colspan="3">Bit 2 (LOD) of parameter No.19746</th></tr>
<tr><th rowspan="2">= 0</th><th colspan="2">= 1</th></tr>
<tr><th>Tool length offset enabled</th><th>Tool length offset canceled</th></tr>
<tr><td rowspan="2">Bit 3 (LOZ) of parameter No. 19746</td><td>= 0</td><td rowspan="2">Parameter No. 12318</td><td rowspan="2">Offset data</td><td>Parameter No. 12318</td></tr>
<tr><td>= 1</td><td>0</td></tr>
</table>

The tool length offset function is enabled when the following two conditions are both satisfied:

- The tool length offset function listed below is enabled (modal code of group 8 is except G49)
  - G43/G44 : Tool length compensation
- The H/D code is other than 0.

If bit 6 (CLR) of parameter No. 3402 is set to 0 not to clear the tool length offset vector, G codes of group 8, and H codes at the time of a reset, the tool length offset status is maintained when a reset is made in the tool length offset mode.

3.8.4 Table Vertical Direction Handle Feed/Table Vertical Direction JOG Feed/Table Vertical Direction Incremental Feed

Overview

In the table vertical direction handle feed, table vertical direction JOG feed, and table vertical direction incremental feed, the tool is moved in the table vertical direction.

- Table vertical direction

The table vertical direction is a direction vertical to the table. It is equal to the tool axis direction specified in parameter No. 19697 when all of the rotation axes for controlling the table are at a an angle of 0 degree. When the rotation axes for controlling the table rotate, the table vertical direction changes according to the rotation axis angle.

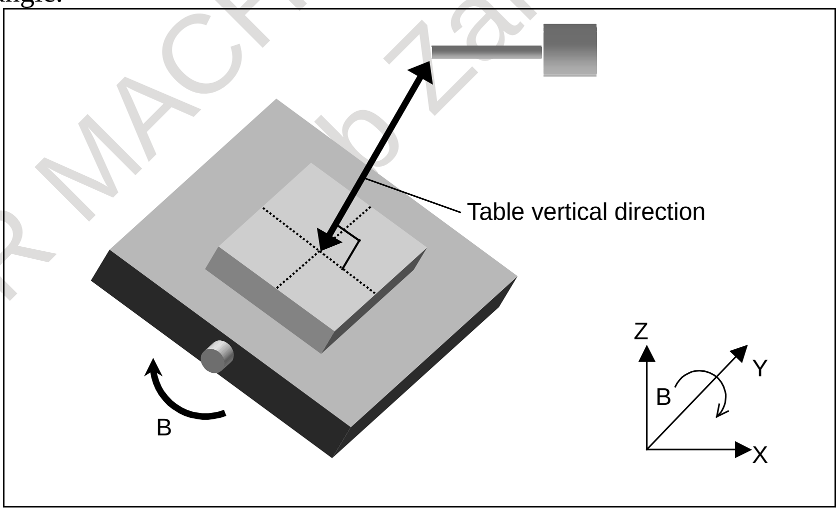

Fig. 3.8.4 Table vertical direction

- Table-based vertical direction feed in the tilted working plane indexing mode

If bit 0 (TWD) of parameter No. 12320 is set to 1, the feed direction of the table-based vertical direction feed in the tilted working plane indexing mode is assumed to be the Z direction in the feature coordinate system of the tilted working plane indexing.

3.8.4.1 Table vertical direction handle feed

The table vertical direction handle feed is enabled when the following four conditions are satisfied:

<1> Handle mode is selected.

<2> Both the tool axis direction feed mode signal ALNGH and the table base signal TB_BASE are set to 1.

<3> The state of the first manual handle feed axis selection signals (HS1A to HS1E) to make the table vertical handle feed mode effective is set in parameter No. 12310.

<4> The value of parameter No. 12310 matches the first manual handle feed axis selection signals (HS1A to HS1E).

- Amount of movement

When the manual pulse generator is rotated, the tool is moved in the table vertical direction by the amount of rotation.

- Feedrate clamp

The feedrate is clamped so that the speed of each moving axis dose not exceed the manual rapid traverse rate (parameter No. 1424). Handle pulses generated while the clamp feedrate is exceeded are ignored.
If manual handle feed maximum feedrate change signal HNDLF<Gn023.3> is "1", clamping is performed by the maximum handle feedrate (parameter No. 1434).

3.8.4.2 Table vertical direction JOG feed/table vertical direction incremental feed

The table vertical direction JOG feed or table vertical direction incremental feed is enabled when the following three conditions are satisfied:

<1> JOG mode or incremental feed mode is selected.

<2> Both the tool axis direction feed mode signal ALNGH and the table base signal TB_BASE are set to 1.

<3> The feed axis direction selection signal [+Jn,-Jn (where n = 1 to the number of controlled axes)] is set to 1 for the axis corresponding to the direction specified by parameter No. 19697.

Ex.) Parameter No. 19697 = 3 (+Z-axis direction); Z-axis is the 3rd axis of control axes.
- +J3: Table vertical direction +
- -J3: Table vertical direction -

- Feedrate

The feedrate is the dry run rate (parameter No. 1410). The manual feedrate override feature is available.
If bit 2 (JFR) of parameter No. 12320 is set to 1, the feedrate is the jog feedrate (parameter No. 1423) for a driven feed axis direction selection signal. The manual feedrate override feature is available.

- Feedrate clamp

The feedrate is clamped so that the speed of each moving axis dose not exceed the manual rapid traverse rate (parameter No. 1424).

3.8.5 Table Horizontal Direction Handle Feed/Table Horizontal Direction JOG Feed/Table Horizontal Direction Incremental Feed

Overview

In the table horizontal direction handle feed, table horizontal direction JOG feed, and table horizontal direction incremental feed, the tool is moved in the table horizontal direction.

If bit 1 (FLL) of parameter No. 12320 is set to 1, the tool or table is moved in the latitude or longitude direction determined by the table-based vertical direction vector.

- Table horizontal direction

There are two table horizontal directions, which are perpendicular to the table vertical direction (see the previous section).

Table 3.8.5 (a) Table horizontal direction

Parameter No. 19697	Table horizontal direction 1	Table horizontal direction 2
1 (The reference tool direction is +X.)	+Y direction	+Z direction
2 (The reference tool direction is +Y.)	+Z direction	+X direction
3 (The reference tool direction is +Z.)	+X direction	+Y direction

Table 3.8.5 (a) shows the table horizontal directions that may be taken when the angles of all the rotation axes for controlling the table are 0 degree.
As the rotation axes for controlling the table rotate, the table horizontal direction changes according to the rotation axis angle.

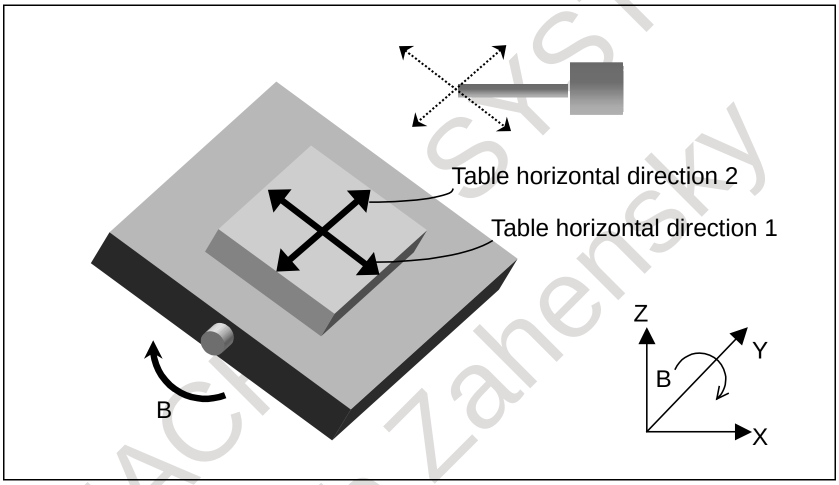

Fig. 3.8.5 (a) Table horizontal direction

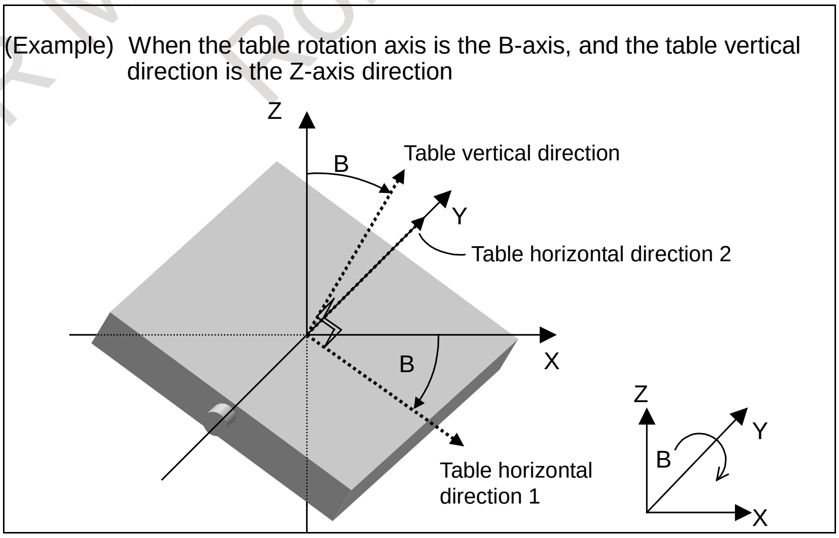

Fig. 3.8.5 (b) Example of table horizontal direction

- Latitude and longitude directions

When bit 1 (FLL) of parameter No. 12320 is set to 1, the feed direction is defined as follows:

Let a vector perpendicular to a plane formed by the table vertical direction vector ($\vec{T}$) and normal axis direction vector ($\vec{P}$) (parameter No. 12321) be the table horizontal direction 1 (longitude direction) vector ($\vec{R}1$). When table horizontal direction 1 is selected, a movement in the positive direction means a movement in this vector direction, and a movement in the negative direction means a movement in the direction opposite to the vector direction. (Longitude direction feed)

Equation: $\vec{R}1 = \vec{P} \times \vec{T}$

Let a vector perpendicular to the table vertical direction vector ($\vec{T}$) and table horizontal direction 1 (longitude direction) vector ($\vec{R}1$) be the table horizontal direction 2 (latitude direction) vector ($\vec{R}2$). When table horizontal direction 2 is selected, a movement in the positive direction means a movement in this vector direction, and a movement in the negative direction means a movement in the direction opposite to the vector direction. (Latitude direction)

Equation: $\vec{R}2 = \vec{T} \times \vec{R}1$

When table vertical direction vector ($\vec{T}$) is parallel to the normal axis direction vector ($\vec{P}$) (parameter No. 12321) (when the angle between them is not greater than the setting of parameter No. 12322), table horizontal direction 1 and table horizontal direction 2 are assumed as follows:

Table 3.8.5 (b) Latitude and longitude directions

Parameter No. 12321	Normal axis direction	Table horizontal direction 1	Table horizontal direction 2
1	+X direction	+Y direction	+Z direction
2	+Y direction	+Z direction	+X direction
3	+Z direction	+X direction	+Y direction

If 0 is set in parameter No. 12321, the normal axis direction is set to the tool axis direction.
If a value other than 0 to 3 is specified in parameter No. 12321, alarm PS5459 is issued.

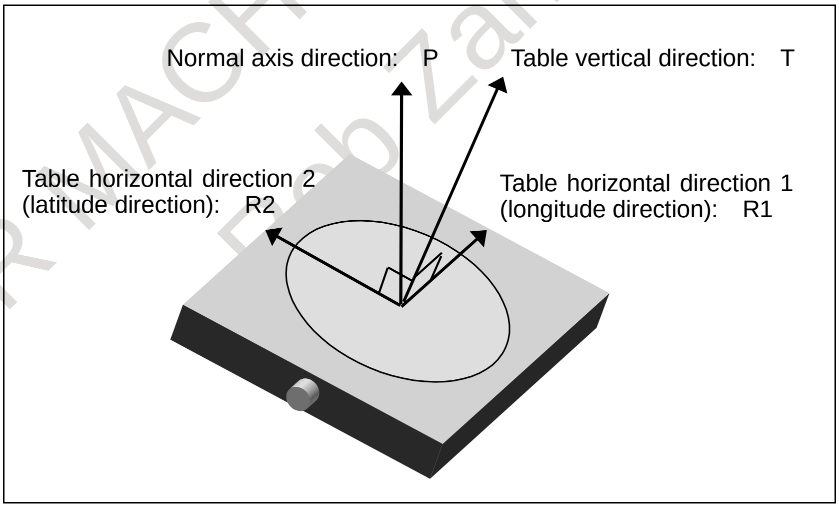

Fig. 3.8.5 (c) Latitude and longitude directions

- Table horizontal direction feed in the tilted working plane indexing mode

If bit 0 (TWD) of parameter No. 12320 is set to 1, the feed direction of the table horizontal direction feed in the tilted working plane indexing mode is defined as follows:

Table horizontal direction 1:
X direction in the feature coordinate system of the tilted working plane indexing
Table horizontal direction 2:
Y direction in the feature coordinate system of the tilted working plane indexing

3.8.5.1 Table horizontal direction handle feed

The table horizontal direction handle feed is enabled when the following four conditions are satisfied:
<1> Handle mode is selected.
<2> Both the tool axis right-angle direction feed mode signal RGHTH and the table base signal TB_BASE are set to 1.
<3> The state of the first manual handle feed axis selection signals (HS1A to HS1E) to make the table horizontal direction handle feed mode effective is set in parameter No. 12311 or 12312.
<4> The value of parameter No.12311 or 12312 matches the first manual handle feed axis selection signals (HS1A to HS1E).

- Amount of movement

When the manual pulse generator is rotated, the tool is moved in the table horizontal direction by the amount of rotation.

- Feedrate clamp

The feedrate is clamped so that the speed of each moving axis dose not exceed the manual rapid traverse rate (parameter No. 1424). Handle pulses generated while the clamp feedrate is exceeded are ignored.
If manual handle feed maximum feedrate change signal HNDLF<Gn023.3> is "1", clamping is performed by the maximum handle feedrate (parameter No. 1434).

3.8.5.2 Table horizontal direction JOG feed/table horizontal direction incremental feed

The table horizontal direction JOG feed or table horizontal direction incremental feed is enabled when the following three conditions are satisfied:
<1> JOG mode or incremental feed mode is selected.
<2> Both the tool axis right-angle direction feed mode signal RGHTH and the table base signal TB_BASE are set to 1.
<3> The feed axis direction selection signal (+Jn, -Jn (where n = 1 to the number of controlled axes)) is set to 1 for the axis corresponding to the direction that is perpendicular to the direction specified by parameter No. 19697.
Ex.) Parameter No. 19697 = 3 (+Z-axis direction); X-, Y-, and Z-axes are the 1st, 2nd, and 3rd axes of control axes respectively.
- +J1: Table horizontal direction 1 +
- -J1: Table horizontal direction 1 -
- +J2: Table horizontal direction 2 +
- -J2: Table horizontal direction 2 -

- Feedrate

The feedrate is the dry run rate (parameter No. 1410). The manual feedrate override feature is available.
If bit 2 (JFR) of parameter No. 12320 is set to 1, the feedrate is the jog feedrate (parameter No. 1423) of a driven feed axis direction selection signal. The manual feedrate override feature is available.

- Feedrate clamp

The feedrate is clamped so that the speed of each moving axis dose not exceed the manual rapid traverse rate (parameter No. 1424).

Signals

Tool axis direction feed mode signal ALNGH <Gn023.7>

[Classification] Input signal

[Function] Selects the tool axis direction handle feed mode, tool axis direction jog feed mode, tool axis direction incremental feed mode, table vertical direction handle feed mode, table vertical direction jog feed mode, or table vertical direction incremental feed mode.

[Operation]
- If this signal is set to “1” and the table base signal is set to “0”:
  In the handle mode, the tool axis direction handle feed mode is selected.
  In the jog feed mode, the tool axis direction jog feed mode is selected.
  In the incremental feed mode, the tool axis direction incremental feed mode is selected.
- If this signal is set to “1” and the table base signal is set to “1”:
  In the handle mode, the table vertical direction handle feed mode is selected.
  In the jog feed mode, the table vertical direction jog feed mode is selected.
  In the incremental feed mode, the table vertical direction incremental feed mode is selected.

Tool axis right-angle direction feed mode signal RGHTH <Gn023.6>

[Classification] Input signal

[Function] Selects the tool axis right-angle direction handle feed mode, tool axis right-angle direction jog feed mode, tool axis right-angle direction incremental feed mode, table horizontal direction handle feed mode, table horizontal direction jog feed mode, or table horizontal direction incremental feed mode.

[Operation]
- If this signal is set to “1” and the table base signal is set to “0”:
  In the handle mode, the tool axis right-angle direction handle feed mode is selected.
  In the jog feed mode, the tool axis right-angle direction jog feed mode is selected.
  In the incremental feed mode, the tool axis right-angle direction incremental feed mode is selected.
- If this signal is set to “1” and the table base signal is set to “1”:
  In the handle mode, the table horizontal direction handle feed mode is selected.
  In the jog feed mode, the table horizontal direction jog feed mode is selected.
  In the incremental feed mode, the table horizontal direction incremental feed mode is selected.

Tool tip center rotation feed mode signal RNDH <Gn298.2>

[Classification] Input signal

[Function] Selects the tool tip center rotation handle feed mode, tool tip center rotation jog feed mode, or tool tip center rotation incremental feed mode.

[Operation] If this signal is set to “1”:
In the handle mode, the tool tip center rotation handle mode is selected.
In the jog feed mode, the tool tip center rotation jog feed mode is selected.
In the incremental feed mode, the tool tip center rotation incremental feed mode is selected.

> **NOTE**
> The tool axis direction feed mode signal, the tool axis right-angle direction feed mode signal, and the tool tip center rotation feed mode signal can be set to “1” at the same time. In this case, the actually selected feed mode is determined by the manual handle feed axis selection signals for the first manual handle pulse generator (HS1A to HS1E) when the handle feed mode is set, or by the feed axis direction selection signal (+Jn, -Jn, where n is a number from 1 to the number of controlled axes) when the jog feed or incremental feed mode is set. In case of handle feed, the same value must not be set in parameters Nos. 12310 to 12314 that set the status of the manual handle feed axis selection signals for the first manual handle pulse generator to enable each feed operation. If the same value is set in these parameters, no feed mode is selected. Unless the tool axis direction feed mode signal, the tool axis right-angle direction feed mode signal, and the tool tip center rotation feed mode signal are set to “1” at the same time, the same value may be set in parameters Nos. 12310 to 12314.

Table base signal TB_BASE <Gn298.0>

[Classification] Input signal

[Function] Selects the table vertical direction mode and table horizontal direction mode.

[Operation]
- If this signal is set to “0”:
  The tool axis direction handle feed mode, tool axis direction jog feed mode, tool axis direction incremental feed mode, tool axis right-angle direction handle feed mode, tool axis right-angle direction jog feed mode, and tool axis right-angle direction incremental feed mode can be selected.
- If this signal is set to “1”:
  The table vertical direction handle feed mode, table vertical direction jog feed mode, table vertical direction incremental feed mode, table horizontal direction handle feed mode, table horizontal direction jog feed mode, and table horizontal direction incremental feed mode can be selected.

> **NOTE**
> This signal has no influence on the tool tip center rotation handle feed mode, tool tip center rotation jog feed mode, and tool tip center rotation incremental feed mode.

Parameter

	#7	#6	#5	#4	#3	#2	#1	#0
5402					DMK			

[Input type] Parameter input

[Data type] Bit path

#3 DMK The manual handle interruption screen is displayed:

0: Using the program coordinate system (post-conversion coordinate system).

1: Using the workpiece coordinate system (pre-conversion coordinate system).

This parameter is valid only in 3-dimensional coordinate conversion mode and Tilted working plane indexing mode.

> **NOTE**
> In tilted working plane indexing mode, the setting of this parameter is used only when bit 4 (MDT) of parameter No.12319 is set to 1.

	#7	#6	#5	#4	#3	#2	#1	#0
7100								JHD

[Input type] Parameter input
[Data type] Bit path

#0 JHD Manual handle feed in JOG feed mode or incremental feed in the manual handle feed is:
0: Invalid.
1: Valid.

12310	States of the manual handle feed axis selection signals when tool axis direction handle feed/interrupt and table-based vertical direction handle feed/interrupt are performed

[Input type] Parameter input
[Data type] Byte path
[Valid data range] 1 to Number of controlled axes

This parameter sets the states of the manual handle feed axis selection signal (HS1A to HS1E for the first manual handle) or the manual handle interrupt axis selection signal (HS1IA to HS1IE for the first manual handle) to perform tool axis direction handle feed/interrupt and table-based vertical direction handle feed/interrupt.
The handle for which the signal states are set is determined by parameter No. 12323.

<Table of correspondence with the manual handle feed axis selection signals>
If parameter No. 12323 is set to 1, the states of the manual handle feed axis selection signals or manual handle interrupt axis selection signals for the first manual handle in the 3-dimensional manual feed (handle feed) mode and corresponding parameter settings are listed in the table below. When the first manual handle pulse generator is turned after setting the signals corresponding to the value set in the parameter, operation is performed in the specified mode.
If the value set in the parameter is larger than number of controlled axes, the movement is not generated.

HS1E (HS1IE)	HS1D (HS1ID)	HS1C (HS1IC)	HS1B (HS1IB)	HS1A (HS1IA)	Parameter (No. 12310)
0	0	0	0	1	1
0	0	0	1	0	2
0	0	0	1	1	3
0	0	1	0	0	4
0	0	1	0	1	5
0	0	1	1	0	6
0	0	1	1	1	7
0	1	0	0	0	8
0	1	0	0	1	9
0	1	0	1	0	10
0	1	0	1	1	11
0	1	1	0	0	12
0	1	1	0	1	13
0	1	1	1	0	14
0	1	1	1	1	15
1	0	0	0	0	16
1	0	0	0	1	17
1	0	0	1	0	18

HS1E (HS1IE)	HS1D (HS1ID)	HS1C (HS1IC)	HS1B (HS1IB)	HS1A (HS1IA)	Parameter (No. 12310)
1	0	0	1	1	19
1	0	1	0	0	20
1	0	1	0	1	21
1	0	1	1	0	22
1	0	1	1	1	23
1	1	0	0	0	24

If parameter No. 12323 is set to 2 to 5, replace 1 in HS1A to HS1E and HS1IA to HS1IE above with 2 to 5.

12311	States of the manual handle feed axis selection signals when a movement is made in the first axis direction in tool axis normal direction handle feed/interrupt and table-based horizontal direction handle feed/interrupt

[Input type] Parameter input
[Data type] Byte path
[Valid data range] 1 to Number of controlled axes

This parameter sets the states of the manual handle feed axis selection signals (HS1A to HS1E for the first manual handle) or the manual handle interrupt axis selection signal (HS1IA to HS1IE for the first manual handle) when a movement is made in the first axis direction. (For settings, see "Table of correspondence with the manual handle feed axis selection signals" in the description of parameter No. 12310.)
The handle for which the signal states are set is determined by parameter No. 12323.

The table below indicates the relationships of tool axis directions, first axis directions, and second axis directions.

Parameter No. 19697	Tool axis directions	First axis directions	Second axis directions
1	X	Y	Z
2	Y	Z	X
3	Z	X	Y

Note, however, that the table above indicates the directions applicable when the angles of all rotation axes are set to 0.
In tool axis direction/tool axis normal direction feed (not table-based), the directions indicated above assume that 0 is set in parameter No. 19698 and No. 19699. When a rotation axis has made a turn or a nonzero value is set in these parameters in tool axis direction/tool axis normal direction feed, the relevant directions are inclined accordingly.

12312	States of the manual handle feed axis selection signals when a movement is made in the second axis direction in tool axis normal direction handle feed/interrupt and table-based horizontal direction handle feed/interrupt

[Input type] Parameter input
[Data type] Byte path
[Valid data range] 1 to Number of controlled axes

This parameter sets the states of the manual handle feed axis selection signals (HS1A to HS1E for the first manual handle) or the manual handle interrupt axis selection signals (HS1IA to HS1IE for the first manual handle) when a movement is made in the second axis direction. (For settings, see "Table of correspondence with the manual handle feed axis selection signals" in the description of parameter No. 12310.)
The handle for which the signal states are set is determined by parameter No. 12323.

12313	States of the manual handle feed axis selection signals when the first rotation axis is turned in tool tip center rotation handle feed/interrupt

[Input type] Parameter input
[Data type] Byte path
[Valid data range] 1 to Number of controlled axes

This parameter sets the states of the manual handle feed axis selection signals (HS1A to HS1E for the first manual handle) or the manual handle interrupt axis selection signals (HS1IA to HS1IE for the first manual handle) when the first rotation axis is turned in tool tip center rotation handle feed or interrupt. (For settings, see "Table of correspondence with the manual handle feed axis selection signals" in the description of parameter No. 12310.)
The handle for which the signal states are set is determined by parameter No. 12323.

12314	States of the manual handle feed axis selection signals when the second rotation axis is turned in tool tip center rotation handle feed/interrupt

[Input type] Parameter input
[Data type] Byte path
[Valid data range] 1 to Number of controlled axes

This parameter sets the states of the manual handle feed axis selection signals (HS1A to HS1E for the first manual handle) or the manual handle interrupt axis selection signals (HS1IA to HS1IE for the first manual handle) when the second rotation axis is turned in tool tip center rotation handle feed or interrupt. (For settings, see "Table of correspondence with the manual handle feed axis selection signals" in the description of parameter No. 12310.)
The handle for which the signal states are set is determined by parameter No. 12323.

12318	Tool length in 3-dimensional machining manual feed

[Input type] Setting input
[Data type] Real path
[Unit of data] mm, inch (machine unit)
[Min. unit of data] Depend on the increment system of the reference axis
[Valid data range] 9 digit of minimum unit of data (refer to standard parameter setting table (A))
(When the increment system is IS-B, -999999.999 to +999999.999)

This parameter sets a tool length when tool tip center rotation feed is performed with the 3-dimensional machining manual feed function and when the 3-dimensional machining manual feed screen is displayed.

> **NOTE**
> 1 Specify a radius value to set this parameter.
> 2 Do not change this parameter during 3-dimensional manual feed mode.

	#7	#6	#5	#4	#3	#2	#1	#0
12319	PRA			MDT				CAC

[Input type] Parameter input
[Data type] Bit path

#0 CAC If a workpiece coordinate system offset is set for the rotation axis, the coordinate system of the rotation axis used to calculate the 3-dimensional manual feed is:
0: Machine coordinate system.
For those parameters Nos. 19680 to 19714 used to configure the machine that depend on the coordinates of the rotation axis, set the values assumed when the machine coordinates of the rotation axis are 0.
1: Workpiece coordinate system.
For those parameters Nos. 19680 to 19714 used to configure the machine that depend on the coordinates of the rotation axis, set the values assumed when the workpiece coordinates of the rotation axis are 0.

#4 MDT In tilted working plane indexing mode, when 3-dimensional handle interrupt is executed in X,Y, and Z directions of the feature coordinate system, the travel distance displayed in the manual handle interruption screen is:
0: Displayed in the workpiece coordinate system.
1: Displayed according to the setting of bit 3 (DMK) of parameter No.5402.

This parameter is valid only when setting to execute 3-dimensional machining manual feed to X, Y, and Z directions in the feature coordinate system (bit 0 (TWD) of parameter No. 12320 is set to 1).

#7 PRA The feed direction of a 3-dimensional handle interrupt is:
0: Updated when one of the following operation is executed.
- The mode of NC (ex, MEM or HANDLE) is changed.
- Reset is executed.
- The state of manual handle interrupt axis selection signals (HS1IA to HS1ID <Gn041.0 to 3>, HS1IE<Gn411.4> in case of manual pulse generator No.1) is changed.
- 3-dimensional manual feed turns enabled or disabled.
1: Always updated.

	#7	#6	#5	#4	#3	#2	#1	#0
12320						JFR	FLL	TWD

[Input type] Setting input
[Data type] Bit path

#0 TWD The directions of 3-dimensional machining manual feed (other than tool tip center rotation feed) when the tilted working plane indexing is issued are:
0: Same as those not in the tilted working plane indexing. That is, the directions are:
Tool axis normal direction 1 (table-based horizontal direction 1)
Tool axis normal direction 2 (table-based horizontal direction 2)
Tool axis direction (table-based vertical direction)
1: X, Y, and Z directions in the feature coordinate system.

NOTE
Do not change this parameter during 3-dimensional manual feed mode.

#1 FLL The directions of tool axis normal direction feed or table-based horizontal direction feed in the 3-dimensional machining manual feed mode are:
0: Tool axis normal direction 1 (table-based horizontal direction 1) and tool axis normal direction 2 (table-based horizontal direction 2).
1: Longitude direction and latitude direction.

Bit 1 (FLL) of parameter No. 12320	Bit 0 (TWD) of parameter No. 12320	Directions of 3-dimensional machining manual feed
0	0	Conventional directions
0	1	When the tilted working plane indexing is issued: X, Y, and Z directions in the feature coordinate system When the command is not issued: Conventional directions
1	0	Longitude direction and latitude direction
1	1	When the tilted working plane indexing is issued: X, Y, and Z directions in the feature coordinate system When the command is not issued: Longitude direction and latitude direction

NOTE
Do not change this parameter during 3-dimensional manual feed mode.

#2 JFR The feedrate of 3-dimensional machining manual feed (jog feed or incremental feed) is :
0: The dry run rate (parameter No. 1410).
1: The jog feedrate (parameter No. 1423).

NOTE
Do not change this parameter during 3-dimensional manual feed mode.

12321	Normal axis direction

[Input type] Parameter input
[Data type] Byte path
[Valid data range] 0 to 3

When a tilted working plane indexing (G68.3) is issued to perform 3-dimensional machining manual feed in the latitude direction, longitude direction, and tool axis direction, this parameter sets an axis parallel to the normal direction.
1: Positive (+) X-axis direction
2: Positive (+) Y-axis direction
3: Positive (+) Z-axis direction
0: Reference tool axis direction (parameter No. 19697)

12322	Angle used to determine whether to assume the tool axis direction to be parallel to the normal direction (parameter No. 12321)

[Input type] Parameter input
[Data type] Real path
[Unit of data] deg
[Min. unit of data] Depend on the increment system of the reference axis
[Valid data range] 0 to 90

When a tilted working plane indexing (G68.3) is issued to perform 3-dimensional machining manual feed in the latitude direction, longitude direction, and tool axis direction, if the angle between the tool axis direction and normal direction (parameter No. 12321) is too small, the tool axis direction is assumed to be parallel to the normal direction (parameter No. 12321). This parameter sets the maximum angle at which the tool axis direction is assumed to be parallel to the normal direction.
When this parameter is set to 0 or a value outside the valid range, it is set to 1 degree.

12323	Number of a manual handle used for 3-dimensional machining manual feed

[Input type] Setting input
[Data type] Byte path
[Valid data range] 0 to 5

When 3-dimensional machining manual feed (handle feed) is performed, set the number of the manual handle to be used.
When the second or third manual handle is used for 3-dimensional machining manual feed, the function for manual handle feed with 2/3 handles is required.
When the fourth or fifth manual handle is used for 3-dimensional machining manual feed, the function for manual handle feed with 4/5 handles is required.
If 0 or the number of an unavailable handle is set, the first handle is assumed.

NOTE
Do not change this parameter during 3-dimensional manual feed mode.

	#7	#6	#5	#4	#3	#2	#1	#0
13112	NTD	NTA						

[Input type] Parameter input
[Data type] Bit path

#6 NTA On the 3-dimensional manual feed screen, a table-based pulse amount is:
0: Displayed.
1: Not displayed.

#7 NTD On the 3-dimensional manual feed screen, a tool axis based pulse amount is:
0: Displayed.
1: Not displayed.

	#7	#6	#5	#4	#3	#2	#1	#0
13113					CFD			CLR

[Input type] Parameter input
[Data type] Bit path

#0 CLR Upon reset, the display of a travel distance by 3-dimensional manual feed is:
0: Not cleared.
1: Cleared.

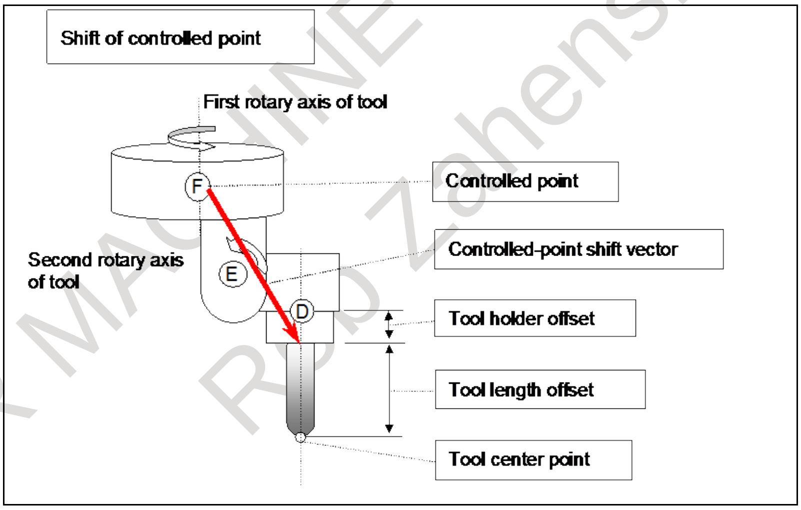
#3 CFD As feedrate F, the 3-dimensional manual feed screen displays:
0: Composite feedrate at the linear axis/rotation axis control point.
1: Feedrate at the tool tip.

	#7	#6	#5	#4	#3	#2	#1	#0
19665			SVC	SPR				

[Input type] Parameter input
[Data type] Bit path

#4 SPR The controlled point is shifted by:
0: Automatic calculation.
1: Using parameter No. 19667.

Bit 5 (SVC) of parameter No. 19665	Bit 4 (SPR) of parameter No. 19665	Shift of controlled point
0	-	Shift is not performed as not done conventionally.
1	0	The controlled point is shifted according to the result of the following automatic calculation: - (Intersection offset vector between the tool axis and the first rotation axis of the tool + intersection offset vector between the second and first rotation axes of the tool + tool holder offset (parameter No. 19666)) (See the figure below.)
1	1	The controlled point is shifted. As the shift vector, the vector set in parameter No. 19667 is used.



[Controlled-point shift vector when automatically calculated]

#5 SVC The controlled point is:
0: Not shifted.
1: Shifted.
The method of shifting is specified by bit 4 (SPR) of parameter No. 19665.

> **NOTE**
> When the machine has no rotation axis for rotating the tool (when parameter No. 19680 is set to 12 to specify the table rotation type), the controlled point is not shifted regardless of the setting of this parameter.

19666	Tool holder offset value

[Input type] Parameter input
[Data type] Real path
[Unit of data] mm, inch (machine unit)
[Min. unit of data] Depend on the increment system of the reference axis
[Valid data range] 9 digit of minimum unit of data (refer to standard parameter setting table (A))
(When the increment system is IS-B, -999999.999 to +999999.999)

Set an offset value (tool holder offset value) specific to the machine from the control point to the tool attachment position in tool length compensation (after specification of G53.1 in the tilted working plane indexing mode), tool length compensation in tool axis direction, or 3-dimensional manual feed. In tool length compensation (not in the tilted working plane indexing mode), however, tool holder offset can be enabled or disabled with bit 7 (ETH) of parameter No. 19665.

NOTE
Set a radius value.

19667	Controlled-point shift vector

[Input type] Parameter input
[Data type] Real axis
[Unit of data] mm, inch (machine unit)
[Min. unit of data] Depend on the increment system of the applied axis
[Valid data range] 9 digit of minimum unit of data (refer to standard parameter setting table (A))
(When the increment system is IS-B, -999999.999 to +999999.999)

Set the shift vector for the controlled point. This value becomes valid when bit 5 (SVC) of parameter No. 19665 is set to 1, and bit 4 (SPR) of parameter No. 19665 is set to 1.

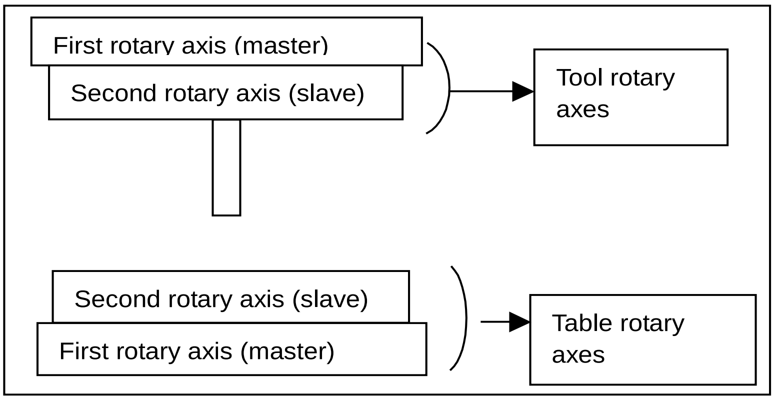
NOTE
Set a radius value.

19680	Mechanical unit type

[Input type] Parameter input
[Data type] Byte path
[Valid data range] 0 to 21

Specify the type of the mechanical unit.

Parameter No. 19680	Mechanical unit type	Controlled rotation axis	Master and slave
0		Mechanism having no rotation axis	
2	Tool rotation type	Two rotation axes of the tool	The first rotation axis is the master, and the second rotation axis is the slave.
12	Table rotation type	Two rotation axes of the table	The first rotation axis is the master, and the second rotation axis is the slave.
21	Mixed type	One rotation axis of the tool + one rotation axis of the table	The first rotation axis is the tool rotation axis, and the second rotation axis is the table rotation axis.



NOTE

A hypothetical axis is also counted as a controlled rotary axis.
<Hypothetical axis>
In some cases, it is convenient to use an imaginary rotary axis whose angle is fixed to a certain value. For example, suppose that a tool is mounted in a tilted manner through an attachment. In such a case, the rotary axis considered hypothetically is a hypothetical axis. Bits 0 (IA1) and 1 (IA2) of parameter No. 19696 determine whether each rotary axis is an ordinary rotary axis or a hypothetical axis.

19681	Controlled-axis number for the first rotation axis

[Input type] Parameter input
[Data type] Byte path
[Valid data range] 0 to Number of controlled axes

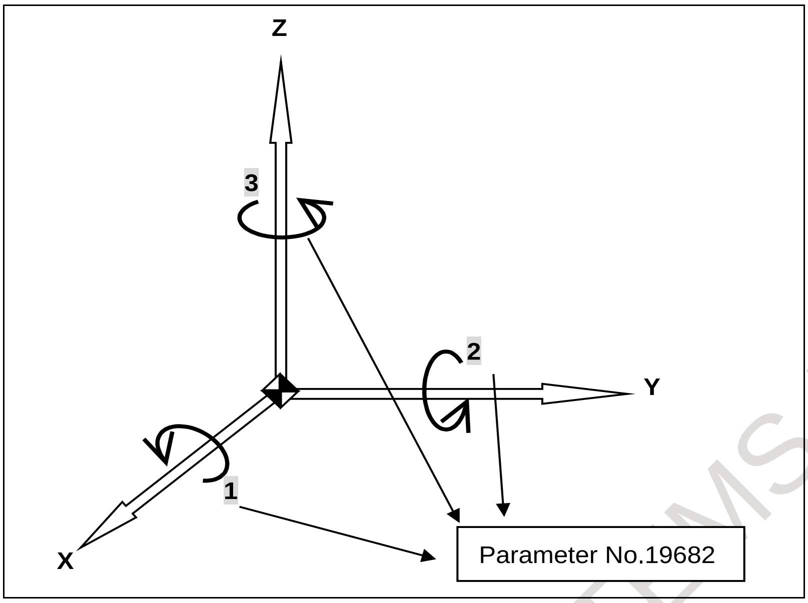
Set the controlled-axis number for the first rotation axis.
For a hypothetical axis (when bit 0 (IA1) of parameter No. 19696 is 1), set 0.

[Example] Assuming that the axis configuration in path 1 is X,Y,Z,B,C and the axis configuration in path 2 is X,Z,C,Y,B, set the parameter to 5 in path 1 and to 3 in path 2 if C is the first rotation axis in each path.

19682	Axis direction of the first rotation axis

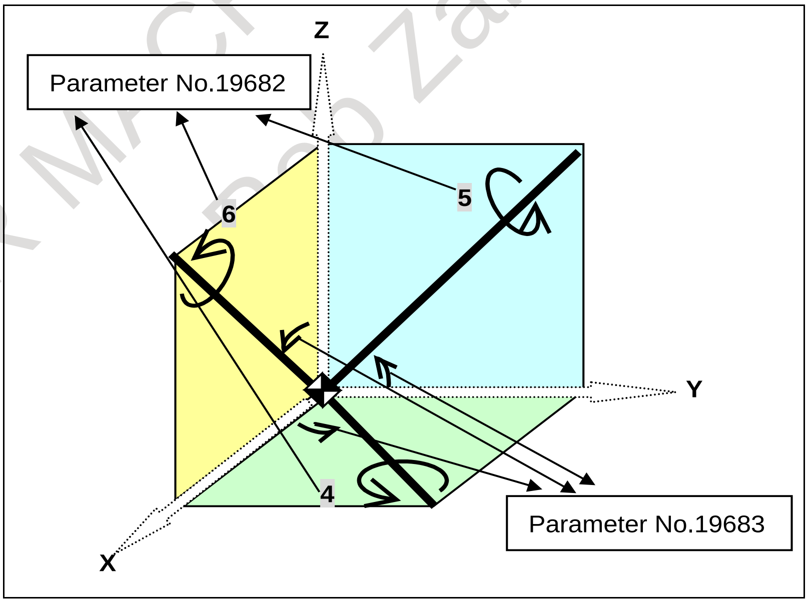
[Input type] Parameter input
[Data type] Byte path
[Valid data range] 0 to 3

Specify the axis direction of the first rotation axis.
1: On X-axis
2: On Y-axis
3: On Z-axis



19683	Inclination angle when the first rotation axis is an inclined axis

[Input type] Parameter input
[Data type] Real path
[Unit of data] Degree
[Min. unit of data] The increment system of the reference axis is to be followed.
[Valid data range] Nine digits of the least input increment (see standard parameter setting table (A).)
(-999999.999 to +999999.999 for IS-B)
When a value 1 to 3 is set in parameter No. 19682, set 0 degrees.
When a value 4 to 6 is set in parameter No. 19682, specify the inclination angle.



19684	Rotation direction of the first rotation axis

[Input type] Parameter input
[Data type] Byte path
[Valid data range] 0 to 1
Set the direction in which the first rotation axis rotates as a mechanical motion when a positive move command is issued.

0: Clockwise direction as viewed from the negative to positive direction of the axis specified in parameter No. 19682 (right-hand thread rotation)
1: Counterclockwise direction as viewed from the negative to positive direction of the axis specified in parameter No. 19682 (left-hand thread rotation)

Normally, 0 is set for a tool rotation axis, and 1 is set for a table rotation axis.

19685	Rotation angle when the first rotation axis is a hypothetical axis

[Input type] Parameter input
[Data type] Real path
[Unit of data] deg
[Min. unit of data] Depend on the increment system of the reference axis
[Valid data range] 9 digit of minimum unit of data (refer to standard parameter setting table (A))
(When the increment system is IS-B, -999999.999 to +999999.999)
When the first rotation axis is a hypothetical axis (bit 0 (IA1) of parameter No. 19696 is 1), set the rotation angle.

19686	Controlled-axis number for the second rotation axis

[Input type] Parameter input
[Data type] Byte path
[Valid data range] 0 to Number of controlled axes
Set the controlled-axis number for the second rotation axis.
For a hypothetical axis (bit 1 (IA2) of parameter No. 19696 is 1), set 0.
[Example] Assuming that the axis configuration in path 1 is X,Y,Z,B,C and the axis configuration in path 2 is X,Z,C,Y,B, set the parameter to 4 in path 1 and to 5 in path 2 if B is the second rotation axis in each path.

19687	Axis direction of the second rotation axis

[Input type] Parameter input
[Data type] Byte path
[Valid data range] 0 to 3
Specify the axis direction of the second rotation axis.
1: On X-axis
2: On Y-axis
3: On Z-axis
When the second rotation axis is the slave axis, the direction when the master axis is at 0 degrees must be set.

19688	Inclination angle when the second rotation axis is inclined

[Input type] Parameter input
[Data type] Real path
[Unit of data] Degree
[Min. unit of data] Depend on the increment system of the reference axis
[Valid data range] 9 digit of minimum unit of data (refer to standard parameter setting
(When the increment system is IS-B, -999999.999 to +999999.999)
If parameter No. 19687 is set to a value 1 to 3, set 0 degrees.
If parameter No. 19687 is set to a value 4 to 6, set the inclination angle.

19689	Rotation direction of the second rotation axis

[Input type] Parameter input
[Data type] Byte path

[Valid data range] 0 to 1
Set the direction in which the second rotation axis rotates as a mechanical motion when a positive move command is issued.
0: Clockwise direction as viewed from the negative to positive direction of the axis specified in parameter No. 19687 (right-hand thread rotation)
1: Counterclockwise direction as viewed from the negative to positive direction of the axis specified in parameter No. 19687 (left-hand thread rotation)
Normally, 0 is set for a tool rotation axis, and 1 is set for a table rotation axis.

19690	Rotation angle when the second rotation axis is a hypothetical axis

[Input type] Parameter input
[Data type] Real path
[Unit of data] Degree
[Min. unit of data] Depend on the increment system of the reference axis
[Valid data range] 9 digit of minimum unit of data (refer to standard parameter setting table (A))
(When the increment system is IS-B, -999999.999 to +999999.999)
When the second rotation axis is a hypothetical axis (bit 1 (IA2) of parameter No. 19696 is 1), set the rotation angle.

	#7	#6	#5	#4	#3	#2	#1	#0
19696							IA2	IA1

[Input type] Parameter input
[Data type] Bit path

#0 IA1 0: The first rotation axis is an ordinary rotation axis.
1: The first rotation axis is a hypothetical axis.
If IA1 is 1, set 0 as the controlled-axis number for the first rotation axis (parameter No. 19681).
Also, set parameters Nos. 19682 to 19685 on the assumption that there is a rotation axis.

#1 IA2 0: The second rotation axis is an ordinary rotation axis.
1: The second rotation axis is a hypothetical axis.
If IA2 is 1, set 0 as the controlled-axis number for the second rotation axis (parameter No. 19686).
Also, set parameters Nos. 19687 to 19690 on the assumption that there is a rotation axis.

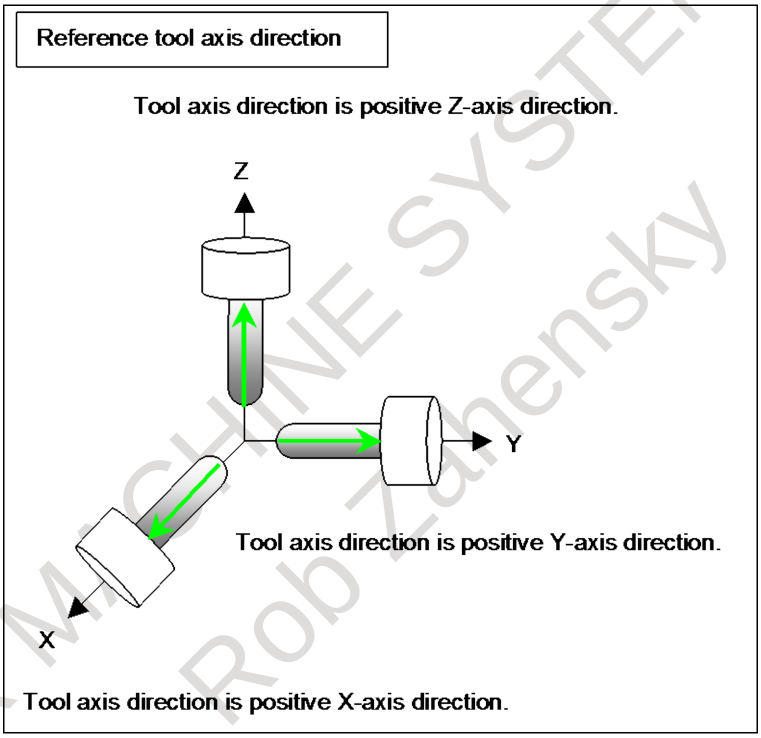
19697	Reference tool axis direction

[Input type] Parameter input
[Data type] Byte path
[Valid data range] 0 to 3

Set the tool axis direction in the machine coordinate system when the rotation axes for controlling the tool are all at 0 degrees. Also, set the tool axis direction in the machine coordinate system in a mechanism in which only the rotation axes for controlling the table are present (there is no rotation axis for controlling the tool).

1: Positive X-axis direction
2: Positive Y-axis direction
3: Positive Z-axis direction

When the reference tool axis direction is neither the X-, Y-, nor Z-axis direction, set the reference direction in this parameter, then set appropriate angles as the reference angle RA and reference angle RB (parameters Nos. 19698 and 19699).



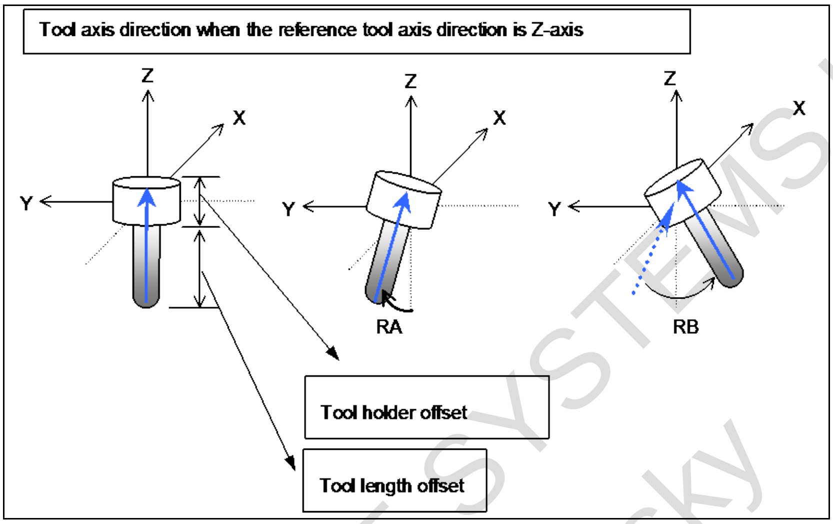
19698	Angle when the reference tool axis direction is tilted (reference angle RA)

19699	Angle when the reference tool axis direction is tilted (reference angle RB)

[Input type] Parameter input
[Data type] Real path
[Unit of data] deg
[Min. unit of data] Depend on the increment system of the reference axis
[Valid data range] 9 digit of minimum unit of data (refer to standard parameter setting
(When the increment system is IS-B, -999999.999 to +999999.999)

When the reference tool axis direction (parameter No. 19697) is set to 1, the tool axis is tilted the RA degrees on the Z-axis from the positive X-axis direction to positive Y-axis direction, then the tool axis is tilted the RB degrees on the X-axis from the positive Y-axis direction to positive Z-axis direction.

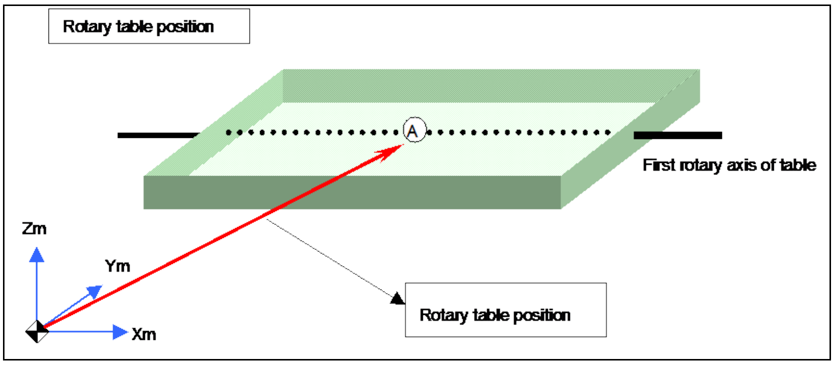
When the reference tool axis direction (parameter No. 19697) is set to 2, the tool axis is tilted the RA degrees on the X-axis from the positive Y-axis direction to positive Z-axis direction, then the tool axis is tilted the RB degrees on the Y-axis from the positive Z-axis direction to positive X-axis direction.
When the reference tool axis direction (parameter No. 19697) is set to 3, the tool axis is tilted the RA degrees on the Y-axis from the positive Z-axis direction to positive X-axis direction, then the tool axis is tilted the RB degrees on the Z-axis from the positive X-axis direction to positive Y-axis direction.



19700	Rotary table position (X-axis of the basic three axes)
19701	Rotary table position (Y-axis of the basic three axes)
19702	Rotary table position (Z-axis of the basic three axes)

[Input type] Parameter input
[Data type] Real path
[Unit of data] mm, inch (machine unit)
[Min. unit of data] Depend on the increment system of the applied axis
[Valid data range] 9 digit of minimum unit of data (refer to standard parameter setting table (A))
(When the increment system is IS-B, -999999.999 to +999999.999)

Set these parameters when parameter No. 19680 is set to 12 or 21. The vector from the origin of the machine coordinate system to point A on the first rotation axis of the table is set as the rotary table position in the machine coordinate system.



NOTE
As point A, set a position that is easy to measure on the first rotary axis of the table.
Set a radius value.
If the rotary table is moved along the X-, Y-, or Z-axis or all of these axes, set the position of the rotary table when the machine coordinates of the X-, Y-, and Z-axes are all set to 0.

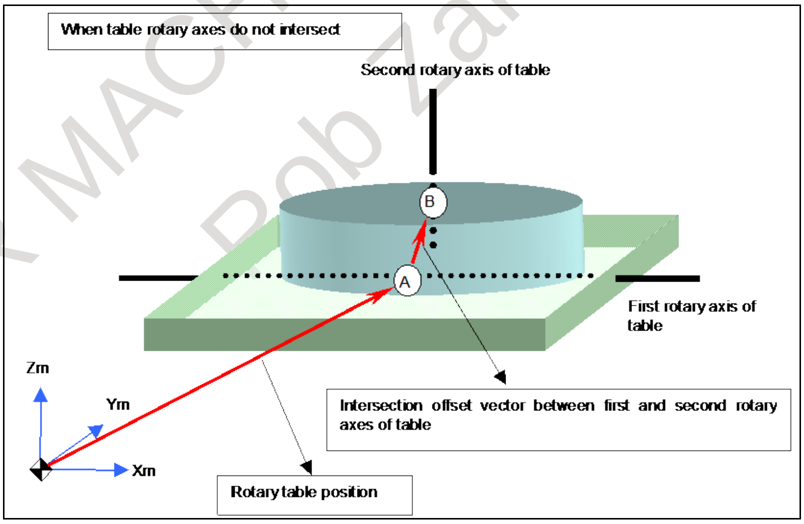
19703	Intersection offset vector between the first and second rotation axes of the table (X-axis of the basic three axes)

19704	Intersection offset vector between the first and second rotation axes of the table (Y-axis of the basic three axes)

19705	Intersection offset vector between the first and second rotation axes of the table (Z-axis of the basic three axes)

[Input type] Parameter input
[Data type] Real path
[Unit of data] mm, inch (machine unit)
[Min. unit of data] Depend on the increment system of the applied axis
[Valid data range] 9 digit of minimum unit of data (refer to standard parameter setting table (A))
(When the increment system is IS-B, -999999.999 to +999999.999)

Set these parameters when the first rotation axis and second rotation axis of the table do not intersect. These parameters are valid when parameter No. 19680 is set to 12. When the rotation axes for controlling the table are all at 0 degrees, the vector from point A to point B on the second rotation axis of the table is set as the intersection offset vector in the machine coordinate system.



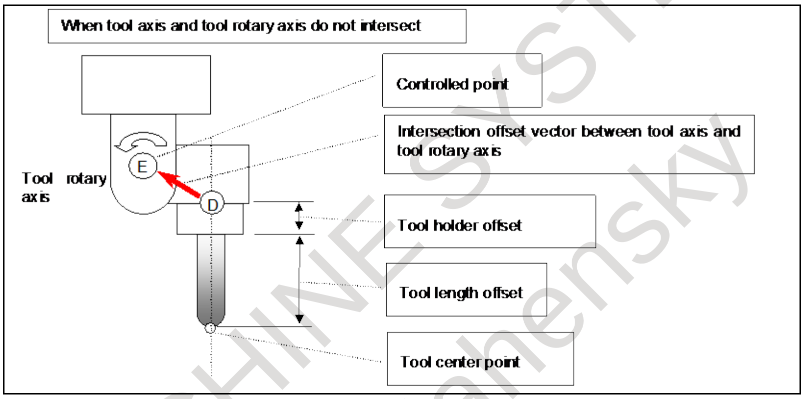
NOTE
As point B, set a position that is easy to measure on the second rotary axis of the table.
Set a radius value.

19709	Intersection offset vector between the tool axis and tool rotation axis (X-axis of the basic three axes)

19710	Intersection offset vector between the tool axis and tool rotation axis (Y-axis of the basic three axes)

19711	Intersection offset vector between the tool axis and tool rotation axis (Z-axis of the basic three axes)

[Input type] Parameter input
[Data type] Real path
[Unit of data] mm, inch (machine unit)
[Min. unit of data] Depend on the increment system of the applied axis
[Valid data range] 9 digit of minimum unit of data (refer to standard parameter setting table (A))
(When the increment system is IS-B, -999999.999 to +999999.999)
Set these parameters when the tool axis and tool rotation axis do not intersect.
These parameters are valid when parameter No. 19680 is set to 2 or 21.
If parameter No. 19680 is 21, set the vector from point D on the tool axis to point E determined on the tool rotation axis as the intersection offset vector in the machine coordinate system when the rotation axes for controlling the tool are all at 0 degrees.
If parameter No. 19680 is 2, set the vector from point D on the tool axis to point E determined on the second rotation axis of the tool as the intersection offset vector in the machine coordinate system when the rotation axes for controlling the tool are all at 0 degrees.



NOTE
Point D is determined by adding the tool length offset and tool holder offset (parameter No. 19666) to the tool tip. As point E, set a position that is easy to measure.
Set a radius value.

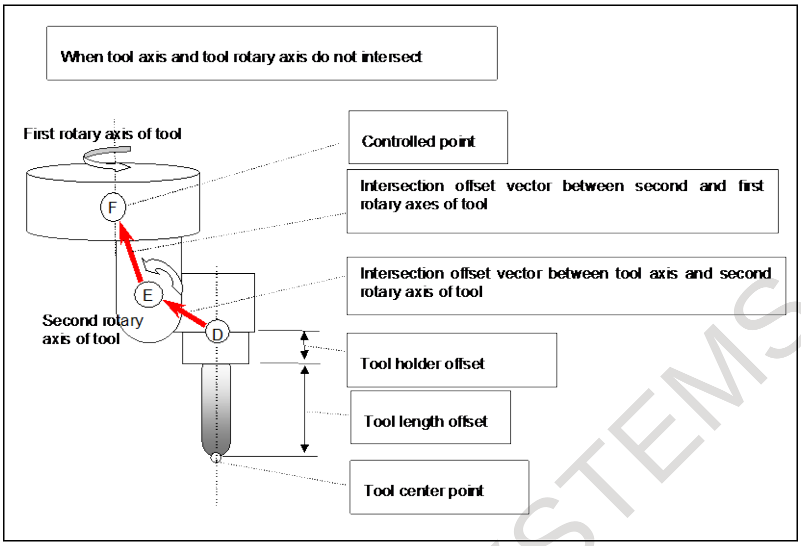
19712	Intersection offset vector between the second and first rotation axes of the tool (X-axis of the basic three axes)

19713	Intersection offset vector between the second and first rotation axes of the tool (Y-axis of the basic three axes)

19714	Intersection offset vector between the second and first rotation axes of the tool (Z-axis of the basic three axes)

[Input type] Parameter input
[Data type] Real path
[Unit of data] mm, inch (machine unit)
[Min. unit of data] Depend on the increment system of the applied axis
[Valid data range] 9 digit of minimum unit of data (refer to standard parameter setting table (A))
(When the increment system is IS-B, -999999.999 to +999999.999)
Set these parameters when the rotation axes of the tool do not intersect.
These parameters are valid when parameter No. 19680 is set to 2.

Set the vector from point E on the second rotation axis of the tool to point F on the first rotation axis of the tool as the intersection offset vector in the machine coordinate system when the rotation axes for controlling the tool are all at 0 degrees.



> **NOTE**
> As point F, set a position that is easy to measure.
> Set a radius value.

	#7	#6	#5	#4	#3	#2	#1	#0
19746					LOZ	LOD		

[Input type] Parameter input
[Data type] Bit path

#2 LOD As the tool length for 3-dimensional machining manual feed:
0: The value of parameter No. 12318 is used.
1: The tool length currently used for tool length compensation is used.

#3 LOZ When bit 2 (LOD) of parameter No. 19746 is set to 1 and tool length compensation is not applied, as the tool length for 3-dimensional machining manual feed:
0: The value of parameter No. 12318 is used.
1: 0 is used.

Note

> **NOTE**
> 1 To perform a 3-dimensional handle feed, the manual handle feed function is required. To perform a 3-dimensional handle interrupt, the manual handle interrupt function is required.
> 2 When a 3-dimensional handle interrupt is performed, rotation axis command execution must not be in progress in automatic operation.
> 3 When the manual reference position return mode is selected, 3-dimensional manual feed is not enabled.
> 4 If interlock for each axis is enabled to at least one of 3-dimensional manual feed axes, movement with manual feed is not performed.

NOTE

5 When the offset value specified for the tool length offset function is used for tool center point rotation feed (when bit 2 (LOD) of parameter No. 19746 is set to 1), the controlled point should generally be shifted. (Set bit 5 (SVC) of parameter No. 19665 to 1.)
In this case, specify the tool length with a radius value.

6 The feed direction of a 3-dimensional handle interrupt is updated as follows.
(a) When bit 7 (PRA) of parameter No. 12319 is set to 0
It is updated when one of the following operation is executed.
- The mode of NC (ex, MEM or HANDLE) is changed.
- Reset is executed.
- The state of manual handle interrupt axis selection signals (HS1IA to HS1ID <Gn041.0 to 3>, HS1IE<Gn411.4> in case of manual pulse generator No.1) is changed.
- 3-dimensional manual feed turns enabled or disabled.
(b) When bit 7 (PRA) of parameter No. 12319 is set to 1
It is always updated.

Alarm and message

No.	Message	Description
PS5459	MACHINE PARAMETER INCORRECT	A machine configuration parameters Nos.19665 to 19667 or Nos.19680 to 19744 is illegal.

Reference item

Manual name	Item name
OPERATOR'S MANUAL (B-64694EN)	3-dimensional manual feed

4 REFERENCE POSITION ESTABLISHMENT

4.1 MANUAL REFERENCE POSITION RETURN

Overview

The tool is moved in the direction specified by bit 5 (ZMI) of parameter No. 1006 setting the feed axis and direction select signal to 1 during manual reference position return mode. Movement will continue until the reference position is obtained.
Manual reference position return is performed by using a grid method. The reference position is based on an electrical grid, using on one-rotation signals received from the position detector.

The following signals relate with the manual reference position return:

	Manual reference position return
Mode selection	MD1, MD2, MD4
Selection of reference position return	ZRN, MREF
Selection of axis to be moved	+J1, -J1, +J2, -J2, +J3, -J3, ...
Selection of direction to be moved	
Selection of speed to be moved	ROV1, ROV2
Deceleration signals for reference position return	*DEC1, *DEC2, *DEC3, ...
Completion signals for reference position return	ZP1, ZP2, ZP3, ...
Reference position establishment signals	ZRF1, ZRF2, ZRF3, ...

- Workpiece coordinate system setting/automatic coordinate system setting

When the workpiece coordinate system is enable (bit 0 (NWZ) of parameter No.8136 is 0), the workpiece coordinate system is set upon the completion of manual reference position return.

When the workpiece coordinate system is disable (bit 0 (NWZ) of parameter No.8136 is 0), and bit 0 (ZPR) of parameter No. 1201 is set to 1, the coordinate system is preset automatically after the manual reference position return.
Parameter 1250 can be used to set the workpiece coordinate system, upon the completion of reference position return. The value set in the parameter sets the reference point of the tool holder or the tip position of the reference tool.
This operation is performed as if the following command were specified at the reference position:

G92X$\underline{\alpha}$Y$\underline{\beta}$Z$\underline{\gamma}$;

NOTE
Automatic coordinate system setting is not performed if the workpiece coordinate system is enable (bit 0 (NWZ) of parameter No.8136 is 0). In this case, manual reference position return always establishes a workpiece coordinate system based on the workpiece origin offsets, specified with parameters Nos. 1220 to 1226.

Explanation

- Basic procedure for manual reference position return

<1> Select manual continuous feed (JOG) mode, and the manual reference position return selection signal ZRN to 1.
<2> Feed a target axis toward the reference position by setting an appropriate feed axis and direction selection signal (+J1, -J1, +J2, -J2,…) to 1.

<3> While the feed axis and direction selection signal is 1, rapid traverse takes place along that axis. Although the rapid traverse override signals (ROV1, ROV2) are valid, the override is generally set to 100%.

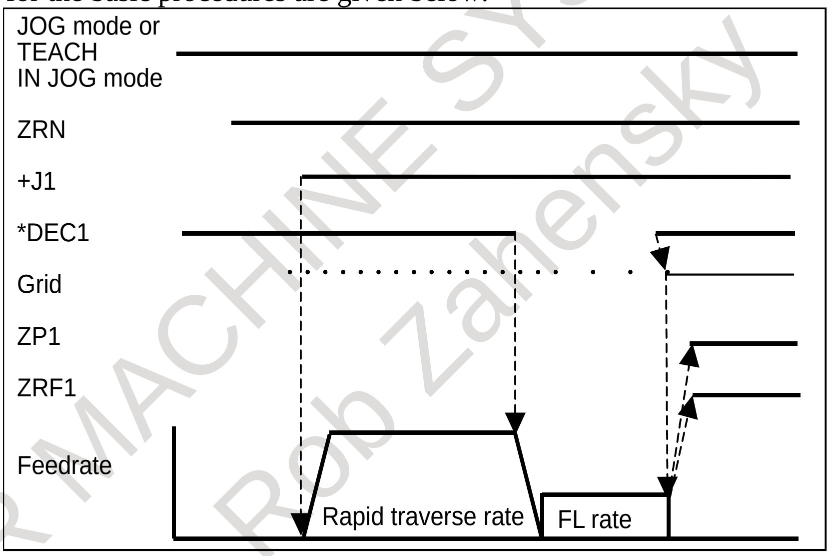
<4> When the reference position is approached, a limit switch installed on the machine is activated, making the deceleration signal for reference position (*DEC1, *DEC2, *DEC3,…) to 0. Consequently, the feedrate is decelerated to 0, then the tool is fed at a constant low speed (reference position return FL feedrate specified by parameter No. 1425 setting).

<5> When the deceleration signal returns to 1 again after the limit switch is passed, the tool is continues to feed, until the tool stops at the first grid point (electric grid point).

<6> Upon confirmation that the current position is at the in-position area, the reference position return end signal (ZP1, ZP2, ZP3,…) and the reference position establishment signal (ZRF1, ZRF2, ZRF3,…) turn to 1.

These steps are repeated for each axis.
The number of simultaneously controlled axes is usually one, but it becomes three by setting bit 0 (JAX) of parameter No. 1002.
If the feed axis direction selection signal (+J1, -J1, +J2, -J2,…) turns to 0 between step (2) and (5) , the tool is stopped at once, and reference position return is canceled. If the signal turn to 1 again, operation resumes from step (3) (rapid traverse).

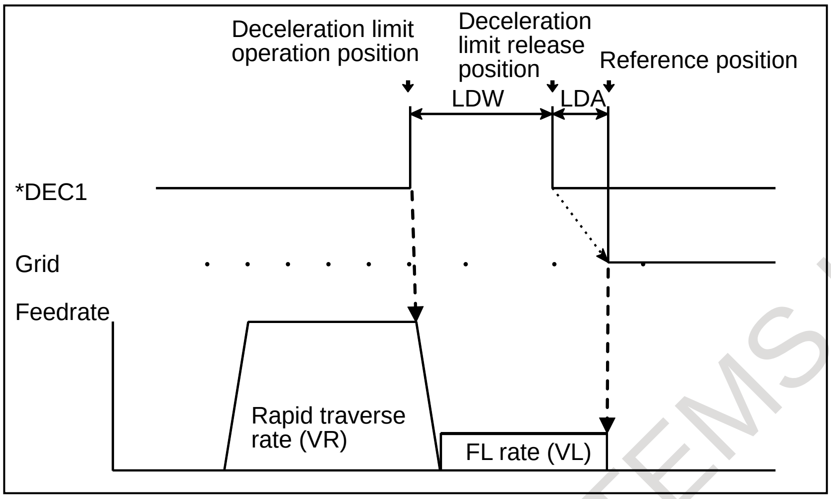
The timing charts for the basic procedures are given below.



NOTE
Grid is not a signal between PMC and CNC.

- Installation conditions for deceleration limit switch

When installing the deceleration limit switch for manual reference position return, ensure that following conditions are satisfied:



(1) LDW : Deceleration dog width [mm, inch]

$$L_{DW} > \frac{V_R\left(\frac{T_R}{2} + 30 + T_S\right) + 4V_L \times T_S}{60 \times 1000}$$

VR : Rapid traverse [mm/min, inch/min]
TR : Rapid traverse time constant [ms]
TS : Servo time constant [ms]
VL : FL speed for reference position return [mm/min, inch/min]

(2) LDA: Distance between deceleration limit switch released position and reference position
LDA = Move amount of 1/2 revolution of motor

Since the above conditions do not include the limit switch operation variations, this point must also be considered at installation.

- Servo position error and one-rotation signal

To perform the first manual reference position return after power on, the tool must be fed in manual reference position return mode, in the reference position return direction at a speed so that the servo position error exceeds the value set in parameter No. 1836. At that time, the tool must cross the grid line corresponding to a one-rotation signal from the position detector.

By the above operation, an electrical grid is established based on one-rotation signals from the position detector.

The servo position error is calculated from the following formula:

$$\text{Servo position error amount} = \frac{F \times 1000}{60} \times \frac{1}{G} \times \frac{1}{U}$$

F : Feedrate [mm/min]
G : Servo loop gain [s-1]
U : Detection unit [μm]

(Example)

When the tool is fed at a feedrate F of 6000 mm/min with a servo loop gain G of 30 [s^{-1}] and a detection unit U of 1 [μm], the servo position error is calculated as follows:

$$\text{Servo position error} = \frac{6000 \times 1000}{60} \times \frac{1}{30} \times \frac{1}{1} = 3333$$

By reversing the formula above, the following formula gives the feedrate F needed to obtain a servo position error of 128, when the servo loop gain G is 30 [s^{-1}] and the detection unit U is 1 [μm]:

$$F = \frac{128 \times 60}{1000} \times 30 = 230 \text{ [mm/min]}$$

Therefore, when the servo loop gain is 30 [s^{-1}], the detection unit is 1 [μm], and parameter No. 1836 is set to 128, the tool must be fed in the reference position return direction at a speed of at least 230 mm/min before completing manual reference position return.

When the one-rotation signal from the position detector is seized at the time of manual reference position return, bit 6 (PCR) of diagnosis data No. 201 is set to 1, and a grid for manual reference position return is established, enabling manual reference position return.

> **NOTE**
> This bit has no effect until the operation of the manual reference position return mode starts.

- Adjusting the reference position

There are the following reference position adjustment methods: Method by grid shift and method by reference position shift.
To shift the reference position within the distance to the first grid point, select the method by grid shift and set bit 4 (SFDx) of parameter No. 1008 to 0.
To shift the reference position beyond the distance to the first grid point, select the method by reference position shift and set bit 4 (SFDx) of parameter No. 1008 to 1.
Either of the methods for adjusting the reference position is available.

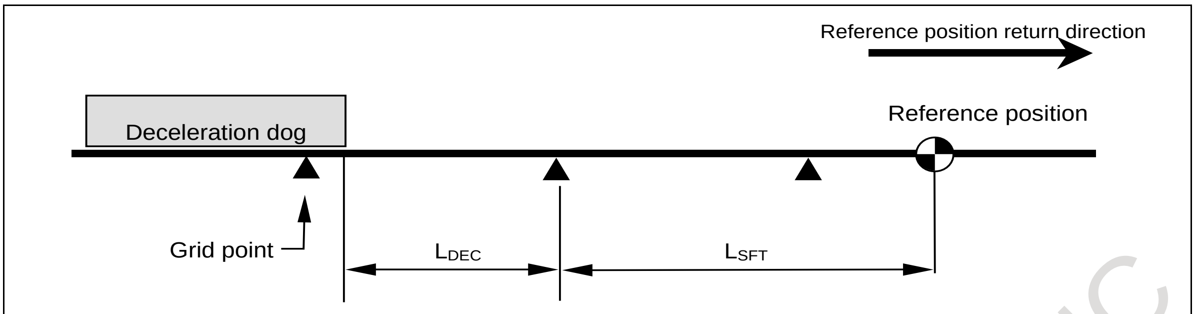
- Adjusting the reference position by grid shift

With the method for shifting the reference position by grid shift, the grid position can be shifted by the distance set in parameter No. 1850.
The distance by which the grid is to be shifted must not exceed the reference counter capacity (parameter No. 1821).
The distance between the tool and the first grid point after the tool leaves the limit switch for deceleration is indicated in diagnosis data No. 302. Furthermore, it is automatically stored in parameter No. 1844.

- Adjusting the reference position by reference position shift

With the method for shifting the reference position by reference position shift, the distance by which the reference position is to be shifted can be set in a parameter to shift it without moving the deceleration dog.

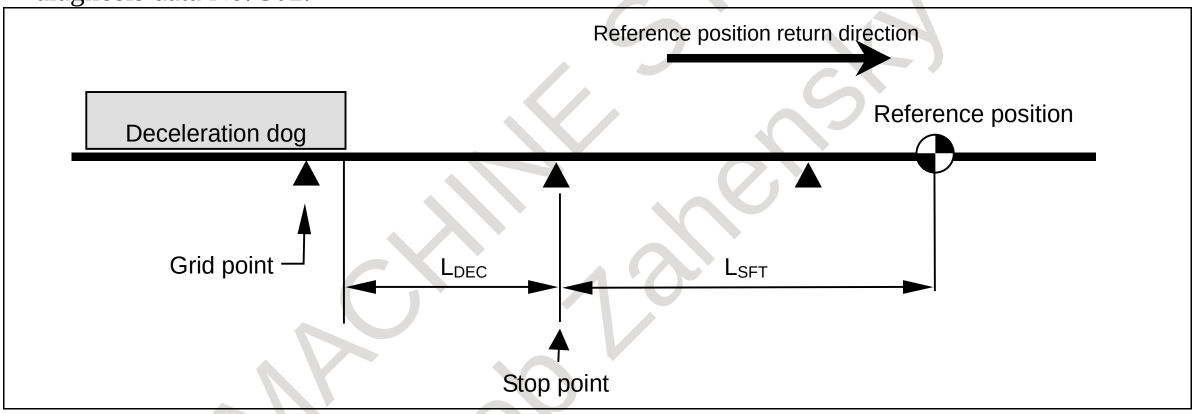
This function is enabled by setting bit 4 (SFDx) of parameter No. 1008.
The distance by which the reference position is to be shifted, shown in the figure below, can be set in parameter No. 1850 to shift the reference position.
The distance L_{DEC} for the axis along which reference position return is performed is automatically stored in parameter No. 1844. The distance L_{DEC} is indicated in diagnosis data No. 302.



L_{DEC}: Distance from the end of the deceleration dog to the first grid point after that when the distance by which the reference position is to be shifted is 0 (parameter No. 1844)
L_{SFT}: Distance by which the reference position is to be shifted (parameter No. 1850)

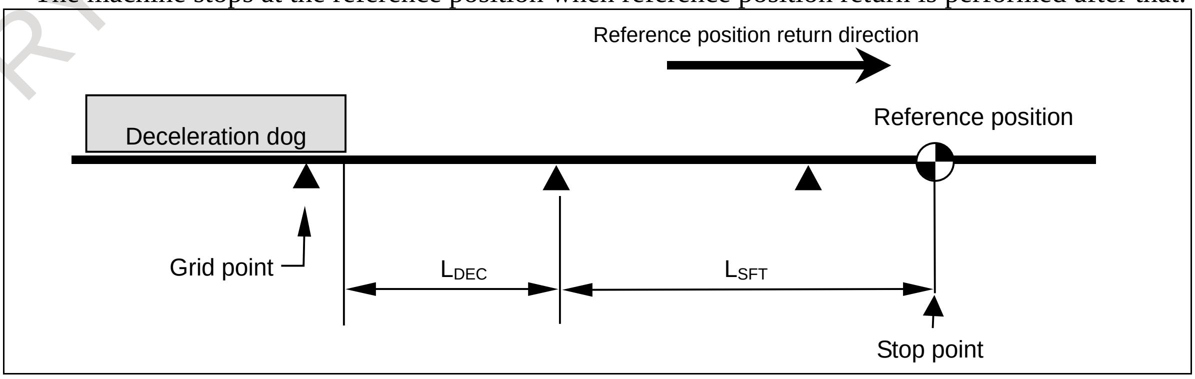
1 Set the following parameter. After setting, turn the power off, then on again.
Set bit 4 (SFDx) of parameter No. 1008 to 1.
The distance from the end of the deceleration dog to the first grid point after that (LDEC (parameter No. 1844)) is 0 when the distance by which the reference position is to be shifted is 0.
Set the distance by which the reference position is to be shifted (parameter No. 1850) to 0.

2 Perform reference position return. The machine stops at the first grid point after leaving the deceleration dog.
The distance LDEC is automatically set in parameter No. 1844. The distance LDEC is indicated in diagnosis data No. 302.



3 Obtain the distance from the stop position to the reference position (distance by which the reference position is to be shifted (LSFT)) and set it in parameter No. 1850.
Then, turn the power off.
Adjusting the reference position is now completed.

4 The machine stops at the reference position when reference position return is performed after that.



> ⚠ **CAUTION**
> 1 Reference position shift is effective only for reference position return using grid points.

> ⚠ **CAUTION**
> 2 Install a deceleration dog so that the distance between the end of the deceleration dog and the first grid point after that is at least 1/2 of the interval between grid points.
> 3 When the distance by which the reference position is to be shifted is 0, the distance between the end of the deceleration dog and the first grid point after that (LDEC (parameter No. 1844)) is automatically set. Do not change the automatically set value.
> 4 This function cannot be used together with reference position setting without dog.
> 5 This function cannot be used together with the grid compensation function in feed axis synchronous control.
> 6 This function cannot be used in case of using method of specifying the reference counter capacity with a fraction (Parameter (No.2179))

- Manual reference position return for a rotation axis about which the tool can rotate one or more turns

For a linear axis, when manual reference position return is performed, the relevant reference position return deceleration signal (*DEC1, *DEC2, *DEC3, ...) is set to 1. At this time, if an electric grid based on one-rotation signals from the position detector is not established, an alarm (PS0090) is issued.

For a rotation axis about which the tool can rotate one or more turns (type A) [bit 0 (ROTx) of parameter No. 1006 is set to 1 and bit 1 (ROSx) of parameter No. 1006 is set to 0], bit 1 (RTLx) of parameter No. 1007 can be set to 1 to specify that the alarm is not issued in this case.
With this setting, manual reference position return may be started with the relevant reference position return deceleration signal (*DEC1, *DEC2, *DEC3, ...) on the machine set to on. In this case, the machine moves not at the reference position return FL feedrate, but at the feedrate set in the relevant parameter.
Since the tool can rotate one or more turns about the rotation axis, it rotates one more turn. When the relevant reference position return deceleration signal (*DEC1, *DEC2, *DEC3, ...) on the machine is turned on, manual reference position return is performed in the same sequence as for normal manual reference position return.

> **NOTE**
> When bit 1 (RTLx) of parameter No. 1007 is set to 0, the relevant reference position return deceleration signal (*DEC1, *DEC2, *DEC3, ...) may be set to 1 before a grid is established. In this case, an alarm (PS0090) is issued.

For a rotation axis about which the tool can rotate up to one turn (type B) [bits 0 (ROTx) and 1 (ROSx) of parameter No. 1006 are set to 1], when the relevant reference position return deceleration signal (*DEC1, *DEC2, *DEC3, ...) is set to 1, a grid may not be established. In this case, an alarm (PS0090) is issued in the same manner as for a linear axis.

- High-speed manual reference position return after the reference position is established

After the reference position is established, the tool can be positioned at the feedrate set in the relevant parameter independently of the deceleration dog for manual reference position return. This operation is enabled by setting bit 7 (SJZ) of parameter No. 0002 and bit 3 (HJZx) of parameter No. 1005.
This operation is called high-speed manual reference position return.

After the reference position is established, setting a feed axis and direction selection signal to 1 in the manual reference position return mode positions the tool at the reference position. This positioning is performed irrespective of the direction specified by the feed axis and direction selection signal. After the completion of the positioning, the relevant reference position return end signal is set to 1.

> ⚠ **CAUTION**
> For high-speed manual reference position return, a feed axis and direction selection signal may be selected in the manual reference position return mode. In this case, the tool may be positioned at the reference position irrespective of the direction specified by the feed axis and direction selection signal, depending on the current position.

If the reference position is lost, manual reference position return using a deceleration dog is performed.

- Coordinate system presetting during high-speed manual reference position return

During high-speed manual reference position return, it is possible to select whether to preset the coordinate system under the conditions below.
The following applies if the workpiece coordinate system is absent and automatic coordinate system setting bit 0 (ZPR) of parameter No. 1201 is 0:
Bit 1 (HZP) of parameter No. 1206 = 0: The coordinate system is preset.
Bit 1 (HZP) of parameter No. 1206 = 1: The coordinate system is not preset.

Signal

Manual reference position return selection signal ZRN<Gn043.7>

[Classification] Input signal

[Function] This signal selects manual reference position return.
Manual reference position return is a kind of jog feed. Therefore, to select manual reference position return, it is required that the jog mode be selected and that the manual reference position return selection signal be set to 1.

[Operation] When the manual reference position return selection signal is set to 1, the control unit performs as described below.

- If jog feed mode is not selected, the control unit ignores the manual reference position return selection signal.
- If jog mode is selected, manual reference position return is enabled. In this case, the manual reference position return selection check signal MREF turns to 1.

> **NOTE**
> If the ZRN status changes state during jog feed, the feedrate is decelerated to 0. Then, to restart reference position return or jog feed, turn feed axis and direction selection signal to 0 then set it to 1.

Manual reference position return selection check signal MREF<Fn004.5>

[Classification] Output signal

[Function] This signal indicates that manual reference position return has been selected.

[Output cond.] This signal turns to 1 when:

- Manual reference position return has been selected.

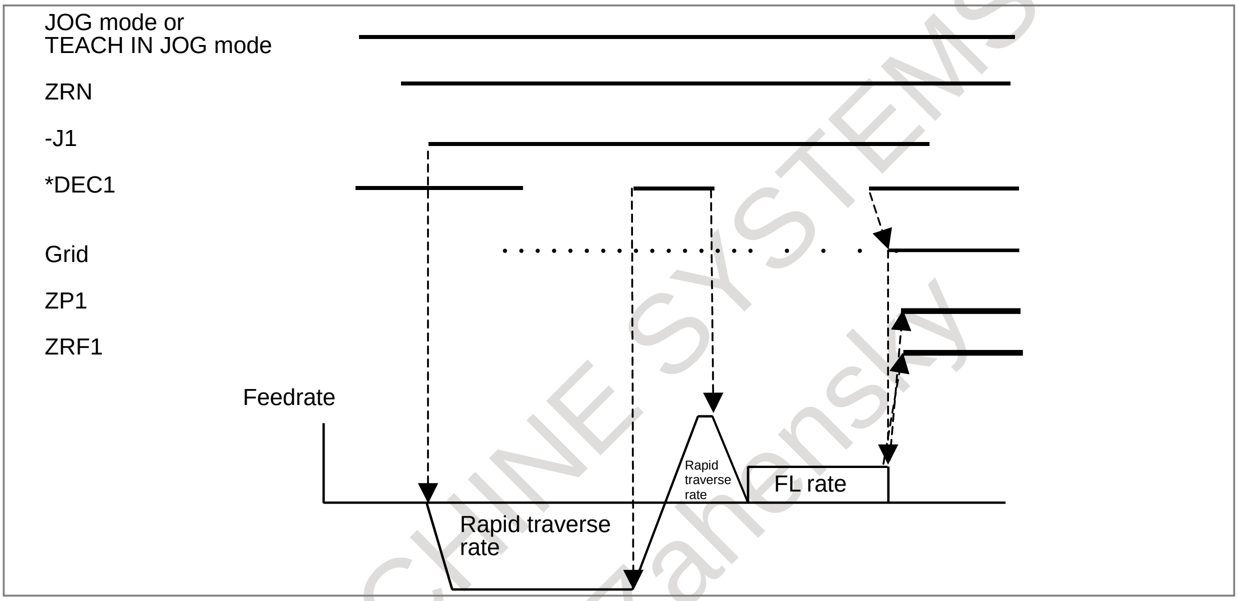
The signal turns to 0 when:

- The selection of manual reference position return has terminated.

Feed axis and direction selection signal

For details about this signal, see "Feed Axis and Direction Selection Signal". Only notes on use of reference position return are given, here.

> **NOTE**
> 1 The direction of reference position return is set for each axis by bit 5 (ZMI) of parameter No. 1006. If the tool is fed opposite to the preset direction in manual reference position return, while the deceleration signal is 0, the tool feeds until the signal returns to 1. The reference position return is then performed automatically in the predetermined direction.



> **NOTE**
> 2 When reference position return is selected, an axis who has already completed referencing movement along that axis is disabled while the reference position return selection signal (ZRN) is 1. To perform movement again, ZRN must be set 0, and the feed axis and direction selection signal must be reset to 0 and then returned to 1 again.

Reference position return deceleration signals *DEC1 to *DEC8<X009>, *DEC1#2 to *DEC8#2<X007>, *DEC1#3 to *DEC8#3<X010>

[Classification] Input signal

[Function] These signals decelerate the feedrate for manual reference position return to a low feedrate (FL).
Deceleration signals are provided for each axis. The number appended to a deceleration signal represents a controlled axis number.
*DECx
x : 1:Reference position return deceleration signal for the first axis
2:Reference position return deceleration signal for the second axis
3:Reference position return deceleration signal for the third axis
:
:

[Operation] For a description of the control unit response to the deceleration signal, see the basic procedure for manual reference position return.

The reference position return deceleration signals are assigned to path 1 to path 3.
For the axes that are assigned to path 1, *DEC1 to *DEC8 (X009) are valid.
For the axes that are assigned to path 2, *DEC1#2 to *DEC8#2 (X007) are valid.
For the axes that are assigned to path 3, *DEC1#3 to *DEC8#3 (X010) are valid.
The reference position return deceleration signals are not assigned to path 4.
(The X address and bit position for these signals for each path can be arbitrarily determined by setting bit 2 (XSG) of parameter No. 3008 to 1.)

Bit 0 (GDC) of parameter No. 3006 can be set to 1 to use input signal Gn196.

> **NOTE**
> Bit 2 (XSG) of parameter No. 3008 can be set to specify whether to fix the address of the reference position return deceleration signals to X009 (path1), X007 (path2), X010 (path3) or use a desired X address.
> When bit 2 (XSG) of parameter No. 3008 is set to 1, the X address and bit position for each reference position return deceleration signal are determined according to the setting of parameters Nos. 3013 and 3014, for each path.

Bit 5 (DEC) of parameter No. 3003 can be set to set the logic for the deceleration signals (*DEC1 to *DEC8).

Reference position return end signals ZP1 to ZP8<Fn094>

[Classification] Output signal

[Function] These signals report that the tool is at the reference position on a controlled axis.
These signals are provided for each axis. The number appended to a signal represents a controlled axis number.

ZPx

x : 1 : Reference position return end signal for the first axis
2 : Reference position return end signal for the second axis
3 : Reference position return end signal for the third axis
:
:

[Output cond.] These signals are set to 1 when:

- Manual reference position returns is completed, and the axis position is in the in-position area.
- Automatic reference position return (G28) is completed, and the axis position is in the in-position area.
- Reference position return check (G27) is completed, and the axis position is in the in-position area.

These signals turn to 0when:

- The tool has moved from the reference position.
- An emergency stop is applied.
- A servo alarm is raised.

Reference position establishment signal ZRF1 to ZRF8<Fn120>

[Classification] Output signal

[Function] Notify the system that the reference position has been established.

A reference position establishment signal is provided for each axis. The number appended to each signal indicates the number of the controlled axis.

ZRFx

x : 1 : 1st-axis reference position establishment signal
2 : 2nd-axis reference position establishment signal
3 : 3rd-axis reference position establishment signal
:
:

[Output cond.] The signals are set to 1 in the following case:

- When the reference position is established after manual reference position return
- When the reference position is established using the absolute-position detector at initial power-on

When the reference position is lost, the signals are set to 0.

Signal address

	#7	#6	#5	#4	#3	#2	#1	#0
X007	*DEC8[#2]	*DEC7[#2]	*DEC6[#2]	*DEC5[#2]	*DEC4[#2]	*DEC3[#2]	*DEC2[#2]	*DEC1[#2]
X009	*DEC8	*DEC7	*DEC6	*DEC5	*DEC4	*DEC3	*DEC2	*DEC1
X010	*DEC8[#3]	*DEC7[#3]	*DEC6[#3]	*DEC5[#3]	*DEC4[#3]	*DEC3[#3]	*DEC2[#3]	*DEC1[#3]

When the bit 0 (GDC) of parameter No. 3006 is set to 0.

Gn196	*DEC8	*DEC7	*DEC6	*DEC5	*DEC4	*DEC3	*DEC2	*DEC1

When the bit 0 (GDC) of parameter No. 3006 is set to 1.

Gn043	ZRN							

	#7	#6	#5	#4	#3	#2	#1	#0
Fn004			MREF					
Fn094	ZP8	ZP7	ZP6	ZP5	ZP4	ZP3	ZP2	ZP1
Fn120	ZRF8	ZRF7	ZRF6	ZRF5	ZRF4	ZRF3	ZRF2	ZRF1

Parameter

	#7	#6	#5	#4	#3	#2	#1	#0
0002	SJZ							

[Input type] Setting input
[Data type] Bit

#7 SJZ On an axis for which bit 3 (HJZx) of parameter No. 1005 is set:

0: If a reference position is not established yet, reference position return is performed with deceleration dogs.
If a reference position is already established, reference position return is performed at a parameter-set feedrate without using deceleration dogs.

1: Reference position return is performed with deceleration dogs at all times.

NOTE

SJZ is valid for an axis for which bit 3 (HJZx) of parameter No. 1005 is set to 1. When bit 1 (DLZx) of parameter No. 1005 is set to 1, however, manual reference position return after a reference position is set is performed at a parameter-set feedrate, regardless of the setting of SJZ.

	#7	#6	#5	#4	#3	#2	#1	#0
1002					AZR			JAX

[Input type] Parameter input
[Data type] Bit path

#0 JAX Number of axes controlled simultaneously in jog feed, manual rapid traverse and manual reference position return
0: 1 axis
1: 3 axes

#3 AZR When no reference position is set, the G28 command causes:
0: Reference position return using deceleration dogs (as during manual reference position return) to be executed.
1: Alarm PS0304, "G28 IS COMMANDED WITHOUT ZERO RETURN" to be displayed.

NOTE

When reference position return without dogs is specified, (when bit 1 (DLZ) of parameter No. 1005 is set to 1) the G28 command specified before a reference position is set causes an alarm PS0304 to be issued, regardless of the setting of AZR.

	#7	#6	#5	#4	#3	#2	#1	#0
1005					HJZx		DLZx	ZRNx

[Input type] Parameter input
[Data type] Bit axis

#0 ZRNx If a move command other than G28 is specified by automatic operation when no reference position return is performed yet after the power is turned on:
0: The alarm PS0224, "PERFORM REFERENCE POSITION RETURN." is issued.
1: Operation is performed without issuing an alarm.

NOTE

The state in which a reference position has not been established refers to the following state:
- When an absolute position detector is not used and reference position return has not been performed even once after power-up
- When an absolute position detector is used and the association of the machine position with the position detected with the absolute position detector has not been completed (See the description of bit 4 (APZx) of parameter No. 1815.)

#1 DLZx Function for setting the reference position without dogs
- 0: Disabled
- 1: Enabled

#3 HJZx When a reference position is already set:
- 0: Manual reference position return is performed with deceleration dogs.
- 1: Manual reference position return is performed using rapid traverse without deceleration dogs, or manual reference position return is performed with deceleration dogs, depending on the setting of bit 7 (SJZ) of parameter No.0002.

When the function for setting the reference position without dogs (see the description of bit 1 (DLZx) of parameter No. 1005) is used, manual reference position return after a reference position is set is always performed at a parameter-set feedrate, regardless of the setting of HJZ.

	#7	#6	#5	#4	#3	#2	#1	#0
1006			ZMIx				ROSx	ROTx

[Input type] Parameter input
[Data type] Bit axis

> **NOTE**
> When at least one of these parameters is set, the power must be turned off before operation is continued.

#0 ROTx
#1 ROSx Setting linear or rotary axis.

ROSx	ROTx	Meaning
0	0	Linear axis (1) Inch/metric conversion is done. (2) All coordinate values are linear axis type. (Is not rounded in 0 to 360°) (3) Stored pitch error compensation is linear axis type (Refer to parameter No. 3624)
0	1	Rotary axis (A type) (1) Inch/metric conversion is not done. (2) Machine coordinate values are rounded in 0 to 360°. Absolute coordinate values are rounded or not rounded by bits 0 (ROAx) and 2 (RRLx) of parameter No. 1008. (3) Stored pitch error compensation is the rotation type. (Refer to parameter No. 3624) (4) Automatic reference position return (G28, G30) is done in the reference position return direction and the move amount does not exceed one rotation.
1	1	Rotary axis (B type) (1) Inch/metric conversion is not done. (2) Machine coordinate values, absolute coordinate values and relative coordinate values are linear axis type. (Is not rounded in 0 to 360°). (3) Stored pitch error compensation is linear axis type (Refer to parameter No. 3624) (4) Cannot be used with the rotary axis roll-over function and the index table indexing function (M series)
Except for the above.		Setting is invalid (unused)

#5 ZMIx The direction of manual reference position return is:
0: + direction
1: - direction

	#7	#6	#5	#4	#3	#2	#1	#0
1007				GRDx			ALZx	RTLx

[Input type] Parameter input
[Data type] Bit axis

#0 RTLx When manual reference position return is performed on a rotary axis (A type) with the deceleration dog pressed before a reference position is established:
0: A movement is made at the reference position return feedrate FL.
1: Until a servo motor grid is established, a movement is not made at the reference position return feedrate FL even if the deceleration dog is pressed, but a movement is made at the rapid traverse rate.

If the deceleration dog is released after a movement at the rapid traverse rate and the deceleration dog is then pressed again and released after the rotary axis makes one revolution, reference position return operation is completed.
When this parameter is set to 0, the alarm PS0090, "REFERENCE POSITION RETURN FAILURE" is issued if the deceleration dog is released before a servo motor grid is established.
If this alarm is issued, start manual reference position return at a position sufficiently far away from the reference position.

#1 ALZx In automatic reference position return (G28):
0: Reference position return is performed by positioning (rapid traverse).
If no reference position return is performed after the power is turned on, however, reference position return is performed using the same sequence as for manual reference position return.
1: Reference position return is performed using the same sequence as for manual reference position return.

#4 GRDx When absolute position detection is performed for an axis and the correspondence between the machine position and the position on the absolute-position detector has not yet been established for the axis, reference position setting without digs is:
0: Not performed more than once.
1: Performed more than once.

	#7	#6	#5	#4	#3	#2	#1	#0
1008				SFDx				

[Input type] Parameter input
[Data type] Bit axis

NOTE
When this parameter is set, the power must be turned off before operation is continued.

#4 SFDx In reference position return based on the grid method, the reference position shift function is:
0: Disabled
1: Enabled

	#7	#6	#5	#4	#3	#2	#1	#0
1201						ZCL		ZPR

[Input type] Parameter input
[Data type] Bit path

#0 ZPR Automatic setting of a coordinate system when the manual reference position return is performed
0: Not set automatically
1: Set automatically

> **NOTE**
> ZPR is valid while a workpiece coordinate system function is disable (bit 0 (NWZ) of parameter No.8136 is 1). If a workpiece coordinate system function is enable (bit 0 (NWZ) of parameter No.8136 is 0), making a manual reference position return always causes the workpiece coordinate system to be established on the basis of the workpiece zero point offset (parameters Nos. 1220 to 1226), irrespective of this parameter setting.

#2 ZCL Local coordinate system when the manual reference position return is performed
0: The local coordinate system is not canceled.
1: The local coordinate system is canceled.

> **NOTE**
> ZCL is valid when the workpiece coordinate system is enable (bit 0 (NWZ) of parameter No.8136 is 0). In order to use the local coordinate system (G52), enable the workpiece coordinate system.

	#7	#6	#5	#4	#3	#2	#1	#0
1206							HZP	

[Input type] Parameter input
[Data type] Bit path

#1 HZP At high-speed manual reference position return, presetting the coordinate system is:
0: Performed.
1: Not performed.

> **NOTE**
> This parameter is valid when no workpiece coordinate system exists with bit 0 (ZPR) of parameter No. 1201 set to 0.

1240	Coordinate value of the reference position in the machine coordinate system

> **NOTE**
> When this parameter is set, the power must be turned off before operation is continued.

[Input type] Parameter input
[Data type] Real axis
[Unit of data] mm, inch, deg (machine unit)

[Min. unit of data] Depend on the increment system of the applied axis
[Valid data range] 9 digit of minimum unit of data (refer to standard parameter setting table (A))
(When the increment system is IS-B, -999999.999 to +999999.999)
Set the coordinate values of the reference position in the machine coordinate system.

1250	Coordinate system of the reference position used when automatic coordinate system setting is performed

[Input type] Parameter input
[Data type] Real axis
[Unit of data] mm, inch, deg (input unit)
[Min. unit of data] Depend on the increment system of the applied axis
[Valid data range] 9 digit of minimum unit of data (refer to standard parameter setting table (A))
(When the increment system is IS-B, -999999.999 to +999999.999)
Set the coordinate system of the reference position on each axis to be used for performing automatic coordinate system setting.

	#7	#6	#5	#4	#3	#2	#1	#0
1401						JZR		RPD

[Input type] Parameter input
[Data type] Bit path

#0 RPD Manual rapid traverse during the period from power-on time to the completion of the reference position return.
0: Disabled (Jog feed is performed.)
1: Enabled

#2 JZR The manual reference position return at jog feedrate
0: Not performed
1: Performed

	#7	#6	#5	#4	#3	#2	#1	#0
1404							DLF	

[Input type] Parameter input
[Data type] Bit path

#1 DLF After a reference position is set, manual reference position return performed at:
0: Rapid traverse rate (parameter No. 1420)
1: Manual rapid traverse rate (parameter No. 1424)

> **NOTE**
> This parameter selects a feedrate for reference position return performed without dogs. This parameter also selects a feedrate when manual reference position return is performed according to bit 7 (SJZ) of parameter No.0002 using rapid traverse without deceleration dogs after a reference position is set.

1420	Rapid traverse rate for each axis

[Input type] Parameter input
[Data type] Real axis
[Unit of data] mm/min, inch/min, deg/min (machine unit)

[Min. unit of data] Depend on the increment system of the applied axis
[Valid data range] Refer to the standard parameter setting table (C)
(When the increment system is IS-B, 0.0 to +999000.0)
Set the rapid traverse rate when the rapid traverse override is 100% for each axis.

1423	Feedrate in manual continuous feed (jog feed) for each axis

[Input type] Parameter input
[Data type] Real axis
[Unit of data] mm/min, inch/min, deg/min (machine unit)
[Min. unit of data] Depend on the increment system of the applied axis
[Valid data range] Refer to the standard parameter setting table (C)
(When the increment system is IS-B, 0.0 to +999000.0)

(1) When bit 4 (JRV) of parameter No. 1402 is set to 0 (feed per minute), specify a jog feedrate (feed per minute) under an override of 100%.
(2) When bit 4 (JRV) of parameter No. 1402 is set to 1 (feed per revolution), specify a jog feedrate (feed per revolution) under an override of 100%.

NOTE
This parameter is clamped to the axis-by-axis manual rapid traverse rate (parameter No. 1424).

1424	Manual rapid traverse rate for each axis

[Input type] Parameter input
[Data type] Real axis
[Unit of data] mm/min, inch/min, deg/min (machine unit)
[Min. unit of data] Depend on the increment system of the applied axis
[Valid data range] Refer to the standard parameter setting table (C)
(When the increment system is IS-B, 0.0 to +999000.0)
Set the rate of manual rapid traverse when the rapid traverse override is 100% for each axis.

NOTE
1 If 0 is set, the rate set in parameter No. 1420 (rapid traverse rate for each axis) is assumed.
2 When manual rapid traverse is selected (bit 0 (RPD) of parameter No. 1401 is set to 1), manual feed is performed at the feedrate set in this parameter, regardless of the setting of bit 4 (JRV) of parameter No. 1402.

1425	FL rate of the reference position return for each axis

[Input type] Parameter input
[Data type] Real axis
[Unit of data] mm/min, inch/min, deg/min (machine unit)
[Min. unit of data] Depend on the increment system of the applied axis
[Valid data range] Refer to the standard parameter setting table (C)
(When the increment system is IS-B, 0.0 to +999000.0)
Set feedrate (FL rate) after deceleration when the reference position return is performed for each axis.

1428	Reference position return feedrate for each axis

[Input type] Parameter input
[Data type] Real axis
[Unit of data] mm/min, inch/min, deg/min (machine unit)
[Min. unit of data] Depend on the increment system of the applied axis
[Valid data range] Refer to the standard parameter setting table (C)
(When the increment system is IS-B, 0.0 to +999000.0)

This parameter sets a rapid traverse rate for reference position return operation using deceleration dogs, or for reference position return operation before a reference position is set.
This parameter is also used to set a feedrate for the rapid traverse command (G00) in automatic operation before a reference position is set.

NOTE

1 To this feedrate setting 100%, a rapid traverse override (F0, 25, 50, or 100%) is applicable.
2 For automatic return after completion of reference position return and machine reference position establishment, the normal rapid traverse rate is used.
3 As a manual rapid traverse rate before machine reference position establishment by reference position return, the jog feedrate or manual rapid traverse rate can be selected with bit 0 (RPD) of parameter No. 1401.

	Before reference position establishment	After reference position establishment
Automatic reference position return (G28)	No. 1428	No. 1420
Automatic rapid traverse (G00)	No. 1428	No. 1420
Manual reference position return *1	No. 1428	No. 1428 *3
Manual rapid traverse	No. 1423 *2	No. 1424

4 When parameter No. 1428 is set to 0, the following parameter-set feedrates are applied.

	Before reference position establishment	After reference position establishment
Automatic reference position return (G28)	No. 1420	No. 1420
Automatic rapid traverse (G00)	No. 1420	No. 1420
Manual reference position return *1	No. 1424	No. 1424 *3
Manual rapid traverse	No. 1423 *2	No. 1424

No. 1420: Rapid traverse rate
No. 1423: Jog feedrate
No. 1424: Manual rapid traverse rate
*1 : By using bit 2 (JZR) of parameter No. 1401, the jog feedrate can be used for manual reference position return at all times.
*2 : When bit 0 (RPD) of parameter No. 1401 is set to 1, the setting of parameter No. 1424 is used.
*3 : When rapid traverse is used for reference position return without dogs or manual reference position return after reference position establishment, regardless of the deceleration dog, the feedrate for manual reference position return based on these functions is used (the setting of bit 1 (DLF) of parameter No. 1404 is followed).

1821	Reference counter size for each axis

> **NOTE**
> When this parameter is set, the power must be turned off before operation is continued.

[Input type] Parameter input
[Data type] 2-word axis
[Unit of data] Detection unit
[Valid data range] 0 to 999999999

Set a reference counter size.
As a reference counter size, specify a grid interval for reference position return based on the grid method.
When a value less than 0 is set, the specification of 10000 is assumed.

1836	Servo error amount where reference position return is possible

[Input type] Parameter input
[Data type] Word axis
[Unit of data] Detection unit
[Valid data range] 0 to 32767

This parameter sets a servo error used to enable reference position return.
In general, set this parameter to 0. (When 0 is set, 128 is assumed as the default.)
If, during reference position return, such a feedrate as exceeding a set value is not reached even once before the limit switch for deceleration is released (the deceleration signal (*DEC) for reference position return is set to 1 again), the alarm PS0090, "REFERENCE POSITION RETURN FAILURE" is issued.

1844	Distance to the first grid point when the reference position shift amount in the reference position shift function is 0 or when a reference position return is made by grid shift

> **NOTE**
> When this parameter is set, the power must be turned off before operation is continued.

[Input type] Parameter input
[Data type] 2-word axis
[Unit of data] Detection unit
[Valid data range] -999999999 to 999999999

(1) When the reference position shift function is enabled (when bit 4 (SFDx) of parameter No. 1008 is set to 1)
Set the distance (detection unit) to the first grid point from a point at which the deceleration dog is released when the reference position shift (parameter No. 1850) is set to 0.
(2) When a reference position return is made by grid shift with a setting not to use reference position setting without dogs (when bit 4 (SFDx) of parameter No. 1008 is set to 0, and bit 1 (DLZx) of parameter No. 1005 is set to 0)
Set the distance to the first grid point from a point at which the deceleration dog is released. (Detection unit)
(3) When a reference position return is made by grid shift with a setting to use reference position setting without dogs (when bit 4 (SFDx) of parameter No. 1008 is set to 0, and bit 1 (DLZx) of parameter No. 1005 is set to 1)
Set the distance from the start position for reference position setting without dogs to the first grid point. (Detection unit)

NOTE

1. When the reference position shift function is enabled (when bit 4 (SFDx) of parameter No. 1008 is set to 1)
   When bit 4 (SFDx) of parameter No. 1008 is set to 1, the distance from a point at which the deceleration dog is released to the first grid point (parameter No. 1844) is set to 0, and reference position shift (parameter No. 1850) is set to 0, a manual reference position return allows this parameter to be set automatically. Do not change an automatically set value.
2. When a reference position return is made by grid shift with a setting not to use reference position setting without dogs (when bit 4 (SFDx) of parameter No. 1008 is set to 0, and bit 1 (DLZx) of parameter No. 1005 is set to 0)
   When a manual reference position return using deceleration dogs is made, this parameter is set automatically.
3. When a reference position return is made by grid shift with a setting to use reference position setting without dogs (when bit 4 (SFDx) of parameter No. 1008 is set to 0, and bit 1 (DLZx) of parameter No. 1005 is set to 1)
   When a reference position setting without dogs is made, this parameter is set automatically.

1850	Grid shift and reference position shift for each axis

NOTE

When this parameter is set, the power must be turned off before operation is continued.

[Input type] Parameter input
[Data type] 2-word axis
[Unit of data] Detection unit
[Valid data range] -99999999 to 99999999

To shift the reference position, the grid can be shifted by the amount set in this parameter. Up to the maximum value counted by the reference counter can be specified as the grid shift.

In case of bit 4 (SFDx) of parameter No. 1008 is 0: Grid shift
In case of bit 4 (SFDx) of parameter No. 1008 is 1: Reference point shift

NOTE

For setting the reference position without dogs, only the grid shift function can be used.
(The reference position shift function cannot be used.)

	#7	#6	#5	#4	#3	#2	#1	#0
3003			DEC					

[Input type] Parameter input
[Data type] Bit path

#5 DEC Deceleration signal (*DEC1 to *DEC8) for reference position return
0: Deceleration is applied when the signal is 0.
1: Deceleration is applied when the signal is 1.

	#7	#6	#5	#4	#3	#2	#1	#0
3006								GDC

[Input type] Parameter input
[Data type] Bit

#0 GDC As the deceleration signal for reference position return *DEC:
0: X0009 is used.
1: Gn196 is used. (X0009 is disabled.)

> ⚠ **WARNING**
> If the signal *DEC<X0009> is used by another usage when you set 0 to this parameter, it may cause an unexpected machine behavior. Be careful enough that you must prevent the competition of the used X address.

	#7	#6	#5	#4	#3	#2	#1	#0
3008						XSG		

[Input type] Parameter input
[Data type] Bit path

> **NOTE**
> When this parameter is set, the power must be turned off before operation is continued.

#2 XSG A signal assigned to an X address is:
0: Fixed at the address.
1: Able to be reassigned to an arbitrary X address.

> **NOTE**
> When this parameter is set to 1, set parameter No. 3013, No. 3014, No. 3012, and No. 3019. If parameter No. 3013 and No. 3014 are not set, the deceleration signal for reference position return *DEC is assigned to bit 0 of <X0000>. If parameter No. 3012 and No. 3019 are not set, the skip signal, the PMC axis control skip signal, the measurement position arrival signal, the interlock signal for each axis direction, and the tool compensation value write signal are assigned to <X0000>.

> ⚠ **WARNING**
> Please set an appropriate value to parameters (Nos. 3013, 3014, 3012, 3019) beforehand when you set 1 to this parameter.
> If an input signal of the set address in parameters (Nos. 3013, 3014, 3012, 3019) is used by another usage, it may cause an unexpected machine behavior. Be careful enough that you must prevent the competition of the used X address.

3013	X address to which the deceleration signal for reference position return is assigned

> **NOTE**
> When this parameter is set, the power must be turned off before operation is continued.

[Input type] Parameter input
[Data type] Word axis
[Valid data range] 0 to 727

Set an address to which the deceleration signal *DECn for reference position return for each axis is to be assigned.

> **NOTE**
> This parameter is valid when bit 2 (XSG) of parameter No. 3008 is set to 1.
> Depending on the configuration of the I/O Link, the actually usable X addresses are:
> <X0000 to X0127>, <X0200 to X0327>, <X0400 to X0527>, <X0600 to X0727>

> ⚠ **WARNING**
> If you used the set address in this parameter by another usage, it may cause an unexpected machine behavior.
> Be careful enough that you must prevent the competition of the used X address.

3014	Bit position of an X address to which the deceleration signal for reference position return is assigned

> **NOTE**
> When this parameter is set, the power must be turned off before operation is continued.

[Input type] Parameter input
[Data type] Byte axis
[Valid data range] 0 to 7

Set a bit position to which the deceleration signal for reference position return *DECn for each axis is to be assigned.

> **NOTE**
> This parameter is valid when bit 2 (XSG) of parameter No. 3008 is set to 1.

Alarm and message

Number	Message	Description
PS0090	REFERENCE RETURN INCOMPLETE	1. The reference position return cannot be performed normally because the reference position return start point is too close to the reference position or the speed is too slow. Separate the start point far enough from the reference position, or specify a sufficiently fast speed for reference position return. 2. An attempt was made to set the zero position for the absolute position detector by return to the reference position when it was impossible to set the zero point. Rotate the motor manually at least one turn, and set the zero position of the absolute position detector after turning the CNC and servo amplifier off and then on again.
PS0091	MANUAL REFERENCE POSITION RETURN IS NOT PERFORMED IN FEED HOLD	Manual return to the reference position cannot be performed when automatic operation is halted. Perform the manual return to the reference position when automatic operation is stopped or reset.
PS0092	ZERO RETURN CHECK (G27) ERROR	The axis specified in G27 has not returned to zero. Reprogram so that the axis returns to zero.
PS0224	ZERO RETURN NOT FINISHED	Reference position return has not been performed before the automatic operation starts. Perform reference position return only when the bit 0 (ZRNx) of parameter No. 1005 is set to 0.
PS0304	G28 IS COMMANDED WITHOUT ZERO RETURN	Although a reference position was not set, an automatic return to the reference position (G28) was commanded.
PW0001	X-ADDRESS(*DEC) IS NOT ASSIGNED.	The X address of the PMC could not be assigned correctly. This alarm may occur in the following case: - During the setting of parameter No. 3013, the X address could not be assigned correctly for the deceleration dog (*DEC) for a return to the reference position. When there are four or more paths or there are nine or more axes for one path, the signals must be assigned by setting bit 2 (XSG) of parameter No. 3008, parameter No. 3013, and parameter No. 3014.

OPERATOR'S MANUAL (B-64694EN)	Manual reference position return

4.2 REFERENCE POSITION SETTING WITHOUT DOG

Overview

This function moves each axis in the manual continuous feed mode near the reference position. It then sets the reference position in the reference position return mode without the deceleration signal for reference position return. This is done by setting the feed axis and direction select signal to 1. With this function, the machine reference position can be set at a given position without installing the limit switches for reference position return.

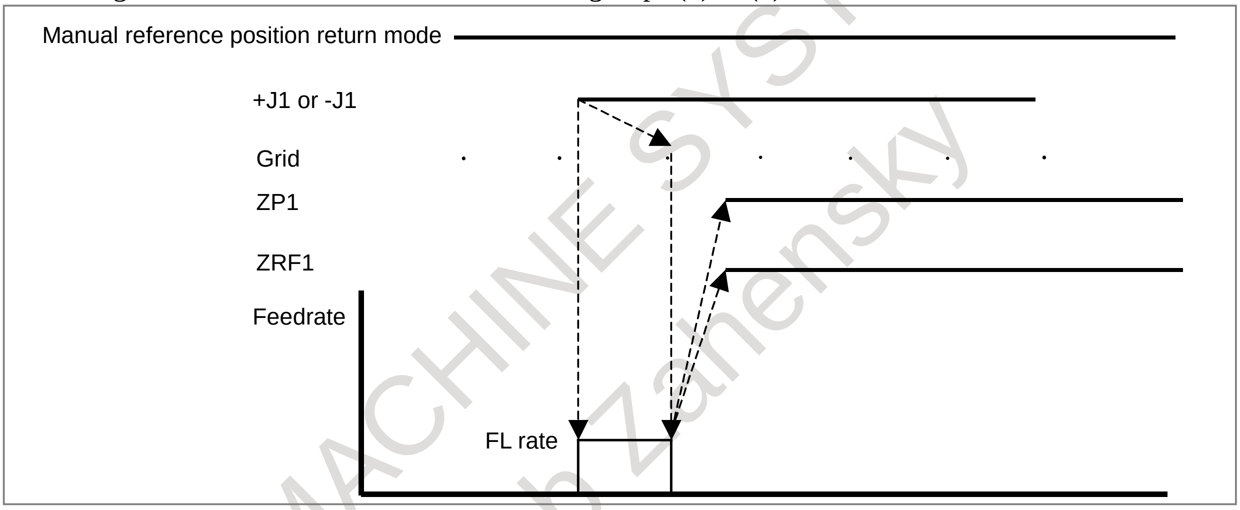
If the absolute-position detector is provided, the set reference position is retained after the power is turned off. In this case, when the power is turned on again, there is no need for setting the reference position again.

Explanation

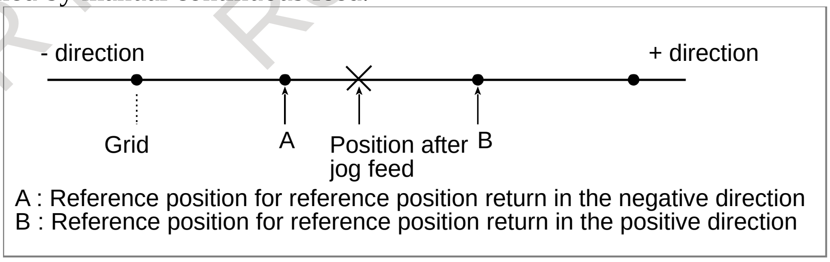
- Basic Procedure for Setting the Reference Position Without DOG

(1) Feed the tool, along the axis for which the reference position is to be set, by manual continuous feed in the reference position return direction. Stop the tool near the reference position, but do not exceed the reference position.
(2) Enter manual reference position return mode, then set 1 for the feed axis direction selection signal (for the positive or negative direction) for the axis.
(3) The CNC positions the tool to the nearest grid point (based on one-rotation signals from the position detector) in the reference position return direction specified with bit 5 (ZMIx) of parameter No.1006. The point at which the tool is positioned becomes the reference position.
(4) The CNC checks that the tool is positioned to within the in-position area, then sets the completion signal (ZPx) for reference position return and the reference position establishment signal (ZRFx) to 1.

The timing chart for the basic elements constituting steps (2) to (4) is shown below.



The following figure shows the positional relation between the reference position and the point to which the tool is positioned by manual continuous feed.



- Servo position error and one-rotation signal

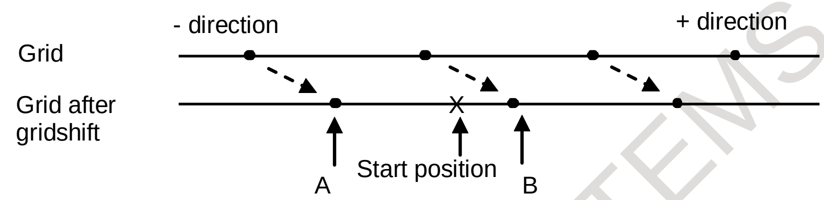
To set the reference position without DOG, when the reference position has not yet been established. The tool must be fed, in manual continuous feed mode, in the reference position return direction at such a speed that the servo position error exceeds the value set in parameter No. 1836. The tool must cross the grid line corresponding to a one-rotation signal from the position detector.
Section "MANUAL REFERENCE POSITION RETUNR" explains how to calculate the servo position error.
When the one-rotation signal from the position detector is seized at the time of reference position setting without DOG, bit 6 (PCR) of diagnosis data No. 201 is set to 1, and a grid for manual reference position return is established, enabling setting of the reference position without DOG.

> **NOTE**
> This bit has no effect until operation in the jog mode starts during setting of the reference position without DOG.

- Grid shift

To shift the reference position, the grid can be shifted by the distance set in parameter No. 1850. The grid shift to be set in the parameter must not exceed the reference counter capacity (parameter No. 1821). Reference position shift function can not be used.

When the grid has been shifted, the relationship between the start position for the reference point return operation and the reference point to be set is shown below.



A : Reference position for reference position return in the negative direction
B : Reference position for reference position return in the positive direction

- Manual reference position return

When the feed axis and direction selection signal is set to 1 in manual reference position return mode after the reference position has been established, the tool is positioned to the reference position regardless of the direction specified by the feed axis and direction selection signal. The completion signal for reference position return is then set to 1.

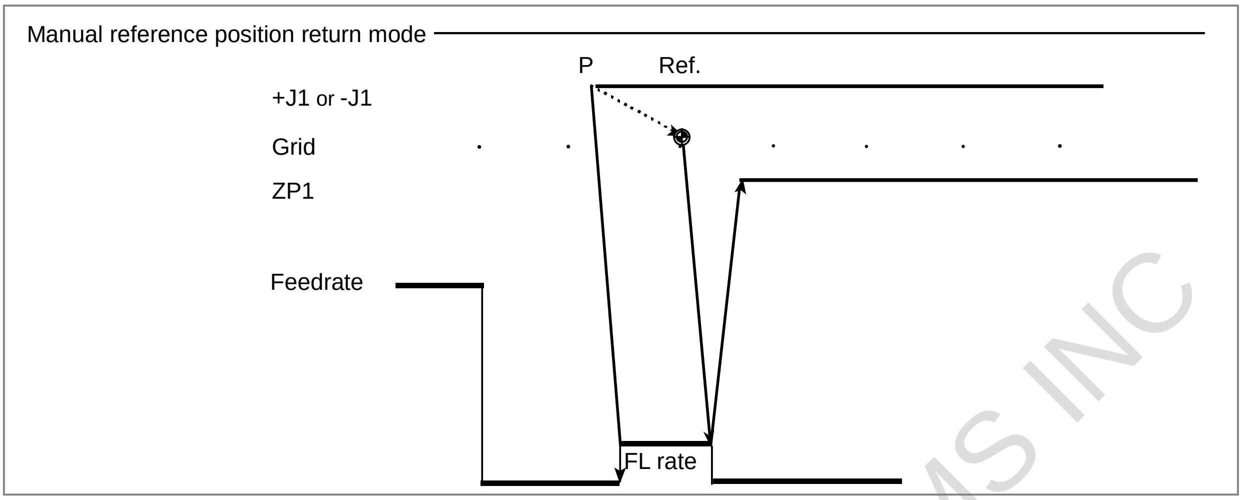
Caution

> **⚠ CAUTION**
> When a feed axis and direction selection signal is selected in the manual reference position mode, the tool may be positioned at the reference position irrespective of the direction specified by the feed axis and direction selection signal, depending on the current position.

- Setting the reference position without dog when the absolute-position detector loses the reference position

When an absolute-position detector is provided [bit 5 (APCx) of parameter No. 1815 is set to 1] and the reference position is lost [bit 4 (APZx) of parameter No. 1815 is set to 0], an alarm (DS0300) is issued.

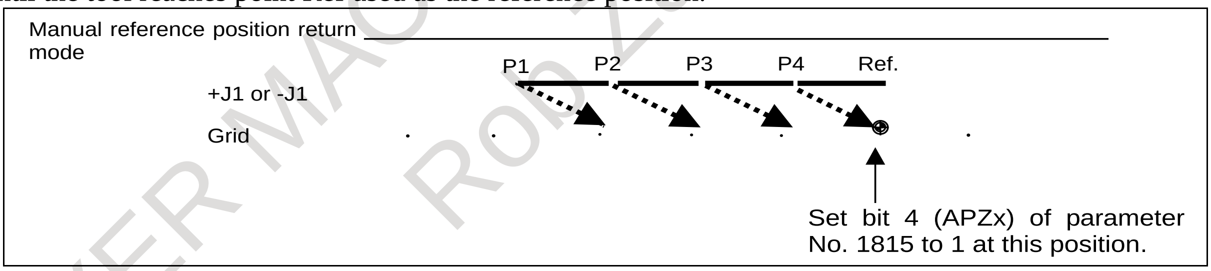
As described in "Basic Procedure for Setting the Reference Position Without DOG," feed the tool to point P in the figure below in the jog feed mode.
Then, put the machine into the manual reference position return mode and set the reference position without dog.



Upon the completion of setting the reference position without dog, the tool is positioned at a grid point and point Ref. in the figure is used as the reference position.
The correspondence between the machine position and reference position for the absolute-position detector has been established, and the reference position is also established. [Bit 4 (APZx) of parameter No. 1815 is set to 1.]
Then, reset the system to release the alarm DS0300.
With the first reference position return without dog, the correspondence between the machine position and position in the absolute-position detector has been established.

Bit 4 (GRDx) of parameter No. 1007 can be set to 1 to set the reference position without dog twice or more when an alarm DS0300 is issued due to absolute-position detection.
Bit 4 (APZx) of parameter No. 1815 remains set to 0 after the reference position is set without dog and the tool reaches the reference position.

As shown in the figure below, reference position return without dog is repeated from P2 to P3 and P4 until the tool reaches point Ref used as the reference position.



Put the system in the MDI mode at point Ref used as the reference position and set bit 4 (APZx) of parameter No. 1815 to 1.
Then, turn the power off, then on again. The correspondence between the machine position and position in the absolute-position detector has been established.

Parameter

	#7	#6	#5	#4	#3	#2	#1	#0
1002	**IDG**							

[Input type] Parameter input
[Data type] Bit path

#7 IDG When the reference position is set without dogs, automatic setting of the bit 0 (IDGx) of parameter No. 1012 to prevent the reference position from being set again is:
0: Not performed.
1: Performed.

> **NOTE**
> When this parameter is set to 0, bit 0 (IDGx) of parameter No. 1012 is invalid.

	#7	#6	#5	#4	#3	#2	#1	#0
1005							DLZx	

[Input type] Parameter input
[Data type] Bit axis

#1 DLZx Function for setting the reference position without dogs
0: Disabled
1: Enabled

	#7	#6	#5	#4	#3	#2	#1	#0
1006			ZMIx					

[Input type] Parameter input
[Data type] Bit axis

> **NOTE**
> When this parameter is set, the power must be turned off before operation is continued.

#5 ZMIx The direction of manual reference position return is:
0: + direction
1: - direction

	#7	#6	#5	#4	#3	#2	#1	#0
1007				GRDx				

[Input type] Parameter input
[Data type] Bit axis

#4 GRDx When absolute position detection is performed for an axis and the correspondence between the machine position and the position on the absolute-position detector has not yet been established for the axis, reference position setting without digs is:
0: Not performed more than once.
1: Performed more than once.

	#7	#6	#5	#4	#3	#2	#1	#0
1012								IDGx

[Input type] Parameter input
[Data type] Bit axis

#0 IDGx The function for setting the reference position again, without dogs, is:
0: Not inhibited.
1: Inhibited. (The alarm PS0301 is issued.)

> **NOTE**
>
> IDGx is enabled when the bit 7 (IDG) of parameter No. 1002 is 1.
> If the function for setting the reference position without dogs is used, and the reference position is lost in absolute position detection for a cause, the alarm DS0300 is issued when the power is turned on again.
> If the operator performs reference position return, as a result of mistakenly identifying the alarm as that requesting the operator to perform a normal reference position return, an invalid reference position may be set. To prevent such an operator error, the IDGx parameter is provided to prevent the reference position from being set again without dogs.
>
> (1) If the bit 7 (IDG) of parameter No. 1002 is set to 1, the bit 0 (IDGx) of parameter No. 1012 is automatically set to 1 when the reference position is set using the function for setting the reference position without dogs. This prevents the reference position from being set again without dogs.
>
> (2) Once the reference position is prevented from being set for an axis again, without dogs, any attempt to set the reference position for the axis without dogs results in the output of an alarm PS0301.
>
> (3) When the reference position must be set again without dogs, bit 0 (IDGx) of parameter No. is set to 1012 to 0 before setting the reference position.

1250	**Coordinate system of the reference position used when automatic coordinate system setting is performed**

[Input type] Parameter input
[Data type] Real axis
[Unit of data] mm, inch, deg (input unit)
[Min. unit of data] Depend on the increment system of the applied axis
[Valid data range] 9 digit of minimum unit of data (refer to standard parameter setting table (A))
(When the increment system is IS-B, -999999.999 to +999999.999)

Set the coordinate system of the reference position on each axis to be used for performing automatic coordinate system setting.

1425	**FL rate of the reference position return for each axis**

[Input type] Parameter input
[Data type] Real axis
[Unit of data] mm/min, inch/min, deg/min (machine unit)
[Min. unit of data] Depend on the increment system of the applied axis
[Valid data range] Refer to the standard parameter setting table (C)
(When the increment system is IS-B, 0.0 to +999000.0)

Set feedrate (FL rate) after deceleration when the reference position return is performed for each axis.

1821	Reference counter size for each axis

> **NOTE**
> When this parameter is set, the power must be turned off before operation is continued.

[Input type] Parameter input
[Data type] 2-word axis
[Unit of data] Detection unit
[Valid data range] 0 to 999999999

Set a reference counter size.
As a reference counter size, specify a grid interval for reference position return based on the grid method.
When a value less than 0 is set, the specification of 10000 is assumed.

1836	Servo error amount where reference position return is possible

[Input type] Parameter input
[Data type] Word axis
[Unit of data] Detection unit
[Valid data range] 0 to 32767

This parameter sets a servo error used to enable reference position return.
In general, set this parameter to 0. (When 0 is set, 128 is assumed as the default.)
If, during reference position return, such a feedrate as exceeding a set value is not reached even once before the limit switch for deceleration is released (the deceleration signal (*DEC) for reference position return is set to 1 again), the alarm PS0090, "REFERENCE POSITION RETURN FAILURE" is issued.

1850	Grid shift and reference position shift for each axis

> **NOTE**
> When this parameter is set, the power must be turned off before operation is continued.

[Input type] Parameter input
[Data type] 2-word axis
[Unit of data] Detection unit
[Valid data range] -99999999 to 99999999

To shift the reference position, the grid can be shifted by the amount set in this parameter.
Up to the maximum value counted by the reference counter can be specified as the grid shift.
In case of bit 4 (SFDx) of parameter No. 1008 is 0: Grid shift
In case of bit 4 (SFDx) of parameter No. 1008 is 1: Reference point shift

> **NOTE**
> For setting the reference position without dogs, only the grid shift function can be used.
> (The reference position shift function cannot be used.)

Alarm and message

Number	Message	Description
PS0090	REFERENCE RETURN INCOMPLETE	1. The reference position return cannot be performed normally because the reference position return start point is too close to the reference position or the speed is too slow. Separate the start point far enough from the reference position, or specify a sufficiently fast speed for reference position return. 2. An attempt was made to set the zero position for the absolute position detector by return to the reference position when it was impossible to set the zero point. Rotate the motor manually at least one turn, and set the zero position of the absolute position detector after turning the CNC and servo amplifier off and then on again.
PS0091	MANUAL REFERENCE POSITION RETURN IS NOT PERFORMED IN FEED HOLD	Manual return to the reference position cannot be performed when automatic operation is halted. Perform the manual return to the reference position when automatic operation is stopped or reset.
PS0224	ZERO RETURN NOT FINISHED	Reference position return has not been performed before the automatic operation starts. Perform reference position return only when the bit 0 (ZRNx) of parameter No. 1005 is set to 0.
PS0301	RESETTING OF REFERENCE RETURN IS INHIBITED	Although bit 0 (IDGx) of parameter No. 1012 was set to 1 to inhibit the reference position from being set again for a return to the reference position without a dog, an attempt was made to perform a manual return to the reference position.
PS0302	SETTING THE REFERENCE POSITION WITHOUT DOG IS NOT PERFORMED	The reference position could not be set for a return to the reference position without a dog. Possible causes are: - The axis was not moved in the direction of a return to the reference position for jog feeding. - The axis was moved in the direction opposite to the direction of a manual return to the reference position. - Since the one-rotation signal sent from the position detector is not detected, the grid for manual reference position return is not established. (Bit 6 of diagnostic data No. 0201 must be 1.)
PS0304	G28 IS COMMANDED WITHOUT ZERO RETURN	Although a reference position was not set, an automatic return to the reference position (G28) was commanded.
DS0300	APC ALARM: NEED REF RETURN	A setting to zero position for the absolute position detector (association with reference position and the counter value of the absolute position detector) is required. Perform the return to the reference position. This alarm may occur with other alarms simultaneously. In this case, other alarms must be handled first.
DS0405	ZERO RETURN END NOT ON REF	The axis specified in automatic zero return was not at the correct zero point when positioning was completed. The position control system is in error. A return to the reference position might not be performed correctly because of an abnormality inside the CNC or servo system. Restart from a manual return to the reference position.

NOTE

For reference position setting without dog, if G28 is specified before the reference position is established, an alarm PS0304 is issued.

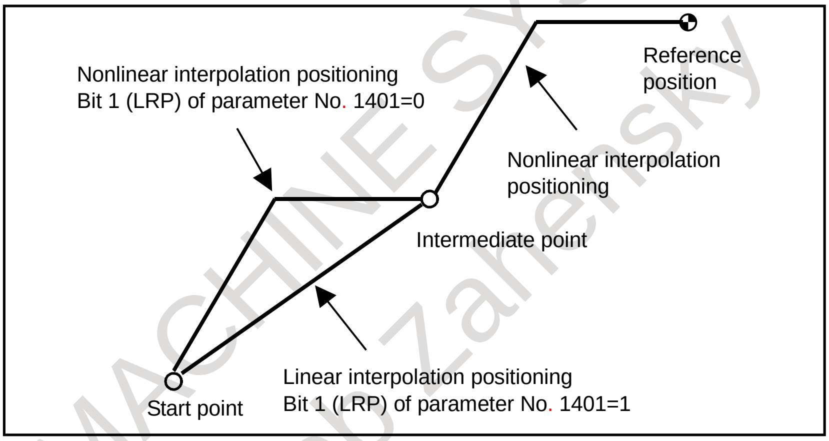
4.3 AUTOMATIC REFERENCE POSITION RETURN AND RETURN FROM THE REFERENCE POSITION

Explanation

- Automatic reference position return (G28)

The G28 command positions the tool to the reference position, via the specified intermediate point, then sets the completion signal for reference position return (see Section "Manual Reference Position Return") to 1.
The reference position must be set in parameter No. 1240 (with the coordinates specified in the machine coordinate system,).
The tool moves to the intermediate point or reference position at the rapid traverse rate.
One of the following can be selected by bit 1 (LRP) of parameter No. 1401 for the tool path to the intermediate point in automatic reference position return (G28), as with the positioning command (G00).

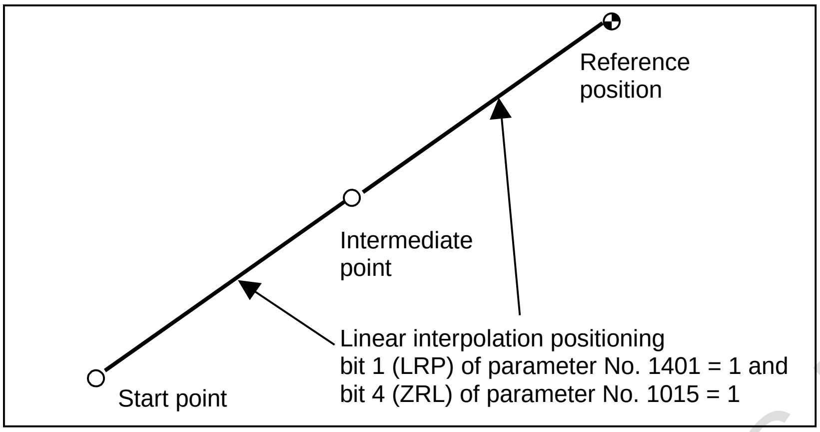
- Nonlinear interpolation positioning
  The tool is positioned with the rapid traverse rate for each axis separately. The tool path is normally straight.
- Linear interpolation positioning
  The tool is positioned within the shortest possible time at a speed that is not more than the rapid traverse rate for each axis.



In this case, nonlinear interpolation positioning is used for the tool path from the intermediate point to the reference position.

Positioning in the machine coordinate system is used for traversing from the intermediate point to the reference position by the automatic reference position return (G28) or positioning in the machine coordinate system (G53).
Generally, nonlinear interpolation positioning is used for positioning in the machine coordinate system.

When linear interpolation positioning has been selected by setting bit 1 (LRP) of parameter No. 1401 to 1, linear interpolation positioning can be used for the tool path from the intermediate point to the reference position in automatic reference position return (G28) by setting bit 4 (ZRL) of parameter No. 1015.



> ⚠ **CAUTION**
> If G28 is specified when the reference point is not established, nonlinear interpolation positioning is used for the tool path from the intermediate point to the reference position and the same sequence as manual reference position return is used.

- Automatic reference position return (G28) if roll over is used on a rotation axis (type A)

If, in an absolute command for automatic reference position return (G28) on a rotation axis, the rotation axis is of type A (bit 0 (ROT) of parameter No. 1006 is set to 1 and bit 1 (ROS) of parameter No. 1006 is set to 0) and roll over is used (bit 0 (ROA) of parameter No. 1008 is set to 1), movement to the midpoint follows the setting of bit 1 (RAB) of parameter No. 1008, and movement from the midpoint to the reference position follows the setting of bit 5 (ZMI) of parameter No. 1006.
If, however, bit 6 (RRF) of parameter No. 1008 is set to 1, movement from the midpoint to the reference position also follows the setting of bit 1 (RAB) of parameter No. 1008.

- Restriction on automatic reference position return (G28)

There are restrictions when the following functions are used. Please refer to each function for detail.

- Mirror image
- Plane conversion
- Machine lock
- Extension of the manual handle retrace function
- Improvement of tool compensation for tool retract and recover
- Retrace
- Positioning by optimum accelerations
- In-position check disable signal
- Axis switching
- Spindle electronic gear box
- Superimposed control
- Simple spindle electronic gear box
- Electronic gear box
- Figure copying
- Programmable mirror image
- Flexible synchronization control
- Inter-path flexible synchronous control
- High precision oscillation function
- High-speed program check function
- Synchronous control
- Composite control
- Tool functions of lathe system

- Normal direction control
- Compensation function
- Coordinate system rotation
- Cutter compensation and tool nose radius compensation
- Tool length compensation

M

- Scaling

- Return from reference position (G29)

Before specifying return from the reference position (G29), return to the reference position by specifying G28 or G30.
For incremental programming, the command value specifies the incremental value from the intermediate point.
Traverse from the intermediate point and specified position is performed at the speed specified by the parameter.
When the workpiece coordinate system is changed after the tool reaches the reference position through the intermediate point by the G28 command, the intermediate point also shifts to a new coordinate system. If G29 is then commanded, the tool moves to the commanded position through the intermediate point which has been shifted to the new coordinate system. The same operations are performed also for G30 commands.

After power-up, if G29 (return from the reference position) is executed even though G28 (automatic reference position return) or G30 (2nd, 3rd or 4th reference position return) has not been executed, alarm PS0305, "INTERMEDIATE POSITION IS NOT ASSIGNED", is issued.

For the tool path in return from the reference position (G29), axis-by-axis rapid traverse rate is used for positioning to the intermediate point or the specified position. bit 1 (LRP) of parameter No. 1401 can be used to specify whether nonlinear interpolation positioning or linear interpolation positioning is used for the tool path from the reference position to the intermediate point and the tool path from the intermediate point to the specified position.

NOTE

As with the positioning command (G00), positioning in the absolute coordinate system is used for traversing from the reference position to the intermediate point or traversing from the intermediate point to the specified point. Therefore, the tool path is specified by bit 1 (LRP) of parameter No. 1401.

Parameter

	#7	#6	#5	#4	#3	#2	#1	#0
1002					AZR			

[Input type] Parameter input
[Data type] Bit path

#3 AZR When no reference position is set, the G28 command causes:
0: Reference position return using deceleration dogs (as during manual reference position return) to be executed.
1: Alarm PS0304, "G28 IS COMMANDED WITHOUT ZERO RETURN" to be displayed.

> **NOTE**
> When reference position return without dogs is specified, (refer to bit 1 (DLZx) of parameter No. 1005) the G28 command specified before a reference position is set causes an alarm PS0304, regardless of the setting of AZR.

	#7	#6	#5	#4	#3	#2	#1	#0
1006			ZMIx				ROSx	ROTx

[Input type] Parameter input
[Data type] Bit axis

> **NOTE**
> When at least one of these parameters is set, the power must be turned off before operation is continued.

#0 ROTx
#1 ROSx Setting linear or rotary axis.

ROSx	ROTx	Meaning
0	0	Linear axis (1) Inch/metric conversion is done. (2) All coordinate values are linear axis type. (Is not rounded in 0 to 360°) (3) Stored pitch error compensation is linear axis type (Refer to parameter No. 3624)
0	1	Rotary axis (A type) (1) Inch/metric conversion is not done. (2) Machine coordinate values are rounded in 0 to 360°. Absolute coordinate values are rounded or not rounded by bits 0 (ROAx) and 2 (RRLx) of parameter No. 1008. (3) Stored pitch error compensation is the rotation type. (Refer to parameter No. 3624) (4) Automatic reference position return (G28, G30) is done in the reference position return direction and the move amount does not exceed one rotation.

ROSx	ROTx	Meaning
1	1	Rotary axis (B type) (1) Inch/metric conversion is not done. (2) Machine coordinate values, absolute coordinate values and relative coordinate values are linear axis type. (Is not rounded in 0 to 360°). (3) Stored pitch error compensation is linear axis type (Refer to parameter No. 3624) (4) Cannot be used with the rotary axis roll-over function and the index table indexing function (M series)
Except for the above.		Setting is invalid (unused)

#5 ZMIx The direction of manual reference position return is:
0: + direction
1: - direction

	#7	#6	#5	#4	#3	#2	#1	#0
1007							ALZx	

[Input type] Parameter input
[Data type] Bit axis

#1 ALZx In automatic reference position return (G28):
0: Reference position return is performed by positioning (rapid traverse).
If no reference position return is performed after the power is turned on, however, reference position return is performed using the same sequence as for manual reference position return.
1: Reference position return is performed using the same sequence as for manual reference position return.

	#7	#6	#5	#4	#3	#2	#1	#0
1008		RRFx					RABx	ROAx

[Input type] Parameter input
[Data type] Bit axis

NOTE
When at least one of these parameters is set, the power must be turned off before operation is continued.

#0 ROAx The rotary axis roll-over is
0: Invalid
1: Valid

NOTE
ROAx specifies the function only for a rotary axis (for which bit 0 (ROTx) of parameter No. 1006 is set to 1)

#1 RABx In the absolute programming, the axis rotates in the direction
0: In which the distance to the target is shorter.
1: Specified by the sign of command value.

NOTE
RABx is valid only when ROAx is 1.

#6 RRFx When a reference position return command (G28) is specified, the rotation direction of an absolute command for the rotary axis roll-over function follows:

0: Up to the middle point, it depends on the setting of bit 1 (RAB) of parameter No. 1008. From the middle point to the origin, it depends on the setting of bit 5 (ZMI) of parameter No. 1006.

1: It depends on the setting of bit 1 (RAB) of parameter No. 1008.

When bit 1 (ALZ) of parameter No. 1007 is 1, reference position return is performed using the same sequence as for manual reference position return.

> **NOTE**
> The setting of bit 6 (RRF) of parameter No. 1008 to 1 is valid when all of the following conditions are met:
> - Rotary axis (A type) (Bit 0 (ROT) of parameter No. 1006 is set to 1, bit 1 (ROS) of parameter No. 1006 is set to 0)
> - Roll-over is enabled (Bit 0 (ROA) of parameter No. 1008 is set to 1)
> - The reference position has been established.

#0 RNO When Automatic reference position return include the Cs axis for which no reference position is established is specified,:

0: Nano interpolation of all axes is invalid.

1: Nano interpolation of all axes other than the Cs is valid.

Alarm and message

Number	Message	Description
PS0304	G28 IS COMMANDED WITHOUT ZERO RETURN	Although a reference position was not set, an automatic return to the reference position (G28) was commanded.
PS0305	INTERMEDIATE POSITION IS NOT ASSIGNED	Although a G28 (automatic return to the reference position) or G30 (return to the second, third, or fourth reference position) command was not issued after power-up, G29 (return from the reference position) was commanded.
DS0405	ZERO RETURN END NOT ON REF	The axis specified in automatic zero return was not at the correct zero point when positioning was completed. The position control system is in error. A return to the reference position might not be performed correctly because of an abnormality inside the CNC or servo system. Restart from a manual return to the reference position.

Caution

⚠ **CAUTION**

1 If G28 is specified when the reference point is not established, traversing from the intermediate point is performed in the same sequence as with manual reference position return. In this case, the direction in which the tool moves from the intermediate point is determine by the direction of reference position return set by bit 5 (ZMIx) of parameter No. 1006, so the intermediate point must be a position from which reference position return can be performed.

2 If G28 is specified when the machine is locked, the reference position return complete signal is not set to 1.

3 When data is input in millimeters for an inch machine, the reference position return complete signal may be set to 1 even when there is a difference from the reference position by the minimum setting unit programmatically. This error occurs because the least input increment is smaller than the least command increment of the machine system.

CONNECTION MANUAL (FUNCTION) (This manual)	Linear interpolation type G28,G30,G53

4.4 2ND REFERENCE POSITION RETURN / 3RD, 4TH REFERENCE POSITION RETURN

Overview

The G30 command positions the tool to the 2nd, 3rd, or 4th reference position, via the specified intermediate point. It then sets the completion signal for 2nd, 3rd, or 4th reference position return to 1.

The 2nd, 3rd, or 4th reference position must be set in parameter No. 1241, 1242, or 1243 with coordinates in the machine coordinate system.

On the tool path for return to the 2nd, 3rd, or 4th reference position (G30), the tool is moved to the intermediate point or reference position at the rapid traverse rate for each axis.
Bit 1 (LRP) of parameter No. 1401 can be set to specify whether to use nonlinear interpolation positioning or linear interpolation positioning for the tool path to the intermediate point during return to the 2nd, 3rd, or 4th reference position (G30) in the same way as for automatic reference position return (G28).
When bit 1 (LRP) of parameter No. 1401 is set to 1 to use linear interpolation positioning, bit 4 (ZRL) of parameter No. 1015 can be set to use linear interpolation positioning for the tool path from the intermediate point to the reference position during return to the 2nd, 3rd, or 4th reference position (G30).

Return to the 2nd, 3rd, or 4th reference position can be performed only after the reference position has been established.

Signal

Second reference position return end signals ZP21 to ZP28<Fn096>
Third reference position return end signals ZP31 to ZP38<Fn098>
Fourth reference position return end signals ZP41 to ZP48<Fn100>

[Classification] Output signal

[Function] The second, third, and fourth reference position end signals report the tool is at the second, third, and fourth reference positions on a controlled axis.
A numeric character appended to the end of a signal represents a controlled axis number, and a numeric character immediately following ZP represents a reference position number.

Z P x y

x : 2 ..... Second reference position return
3 ..... Third reference position return
4 ..... Fourth reference position return

y : 1 ..... Return end signal for the first axis
2 ..... Return end signal for the second axis
3 ..... Return end signal for the third axis
: :

[Output cond.] These signals turn to 1 when:

- The second, third, or fourth reference position return (G30) is completed, and the current position is in the in-position area.

These signals turn to 0 when:

- The tool moved from the reference position.
- An emergency stop is applied.
- A servo alarm is raised.

4.5 IN-POSITION CHECK DISABLE REFERENCE POSITION RETURN

Overview

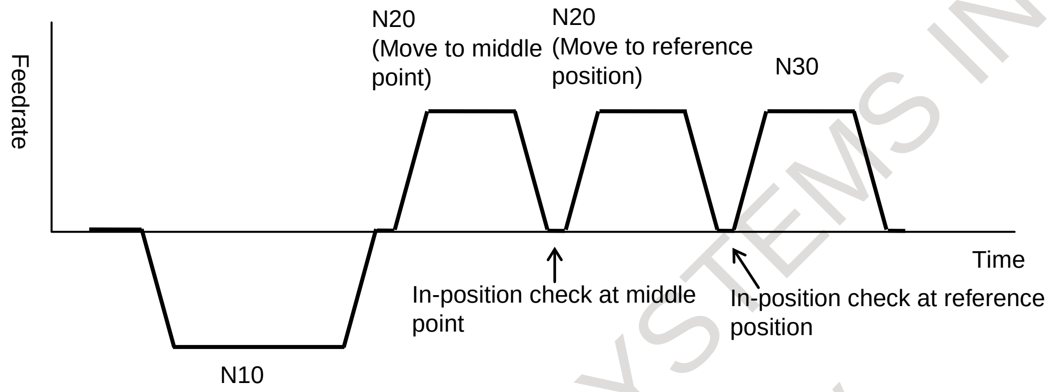
You can disable in-position check at a middle point and reference position by specifying G28.2 or G30.2 as a reference point return command.
Disabling the in-position check at the middle point and reference position reduces the cycle time.
Note that, if the G28.2 command causes reference position return at low speed, the in-position check is disabled at the middle point but enabled at the reference position.
In the operations of and restrictions on reference position return, G28.2 and G30.2 are the same as G28 and G30, except for in-position check.

Example

(1) Reference position return by G28

```
O0002;
N10 G00 X-100.0;
N20 G28 X-50.0;
N30 G00 X50.0;
N40 M30;
```

NOTE)- The program is started at coordinate X = 0.0.
- The X-coordinate of the first reference position is 0.0.



(2) Reference position return by G28.2

```
O0003;
N10 G00 X-100.0;
N20 G28.2 X-50.0;
N30 G00 X50.0;
N40 M30;
```

NOTE)- The program is started at coordinate X = 0.0.
- The X-coordinate of the first reference position is 0.0.

4.6 REFERENCE POINT SETTING WITH MECHANICAL STOPPER

Overview

This function automates the procedure of butting the tool against a mechanical stopper on an axis to set a reference position. The purpose of this function is to eliminate the variations in reference position setting that arise depending on the operator, and to minimize work required to make fine adjustments after reference position setting.

Select the axis for which the reference position is to be set, then perform cycle start. Then, the following operations are performed automatically:

1. The torque (force) of the selected axis is reduced to make the butting feedrate constant, and the tool is butted against the mechanical stopper. Then, the tool is withdrawn a parameter-set distance from the mechanical stopper.
2. Again, the torque (force) of the selected axis is reduced, and the tool is butted against the mechanical stopper. Then, the tool is withdrawn a parameter-set distance from the mechanical stopper.
3. The withdrawal point on the axis is set as the reference position.

Explanation

- Basic procedure for reference point setting with mechanical stopper

(1) First, set the parameters required for reference point setting with mechanical stopper.

Bit 5 (ZMIx) of parameter No.1006...... Direction of reference position setting
Parameter No.7181................................ Withdrawal distance
Parameter No.7182................................ Reference position setting distance
Parameter No.7183................................ Butting feedrate 1
Parameter No.7184................................ Butting feedrate 2
Parameter No.7185................................ Withdrawal feedrate in reference position setting
Parameter No.7186................................ Torque limit (for 0% to 39%)
Parameter No.7187................................ Torque limit (for 0% to 100%)

(2) Select manual reference position return mode.

(3) By using a manual handle feed axis select signal (HS1A to HS1E), select the axis on which the reference position is to be set.

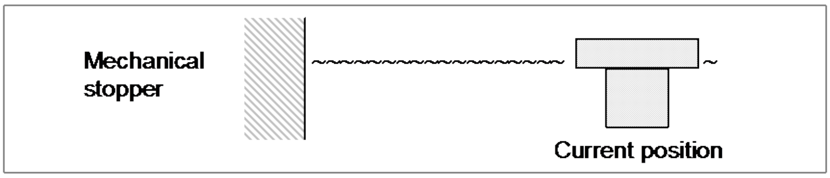
(4) Perform cycle start.

This starts the cycle operation for reference position setting.

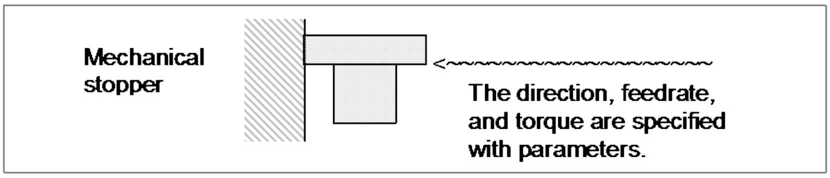
> **NOTE**
> To set the torque limit to more than 39%, set parameter No.7187.

- Cycle operation

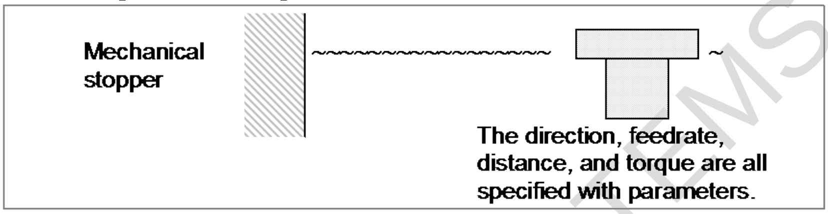
When no reference position has been set, operations (A) to (E), below, are performed automatically to set a reference position.



(A) The tool is moved along a specified axis with a limited torque until it butts against the mechanical stopper.
- The tool is moved in the direction specified with bit 5 (ZMIx) of parameter No.1006,
- At the feedrate specified with parameter No.7183,
- At the torque specified with parameter No.7186 or No.7187 (until the tool strikes the mechanical stopper).

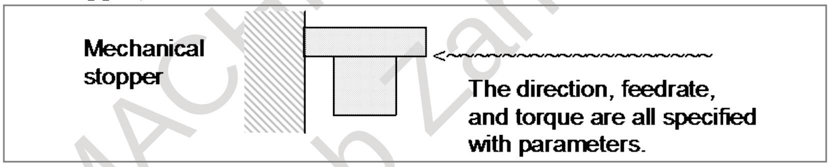


(B) After the tool strikes the mechanical stopper, the tool is withdrawn in the direction opposite to the butting direction, along the axis for a parameter-set distance.
- The tool is moved in the direction opposite to that specified with bit 5 (ZMIx) of parameter No.1006,
- At the feedrate specified with parameter No.7185,
- For the distance specified with parameter No.7181.

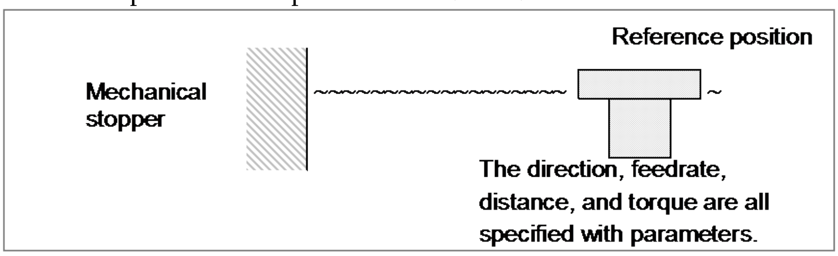


(C) Operations (D) and (E) are performed from the withdrawal point, such that the tool is butted against the mechanical stopper at a constant feedrate in reference position setting.

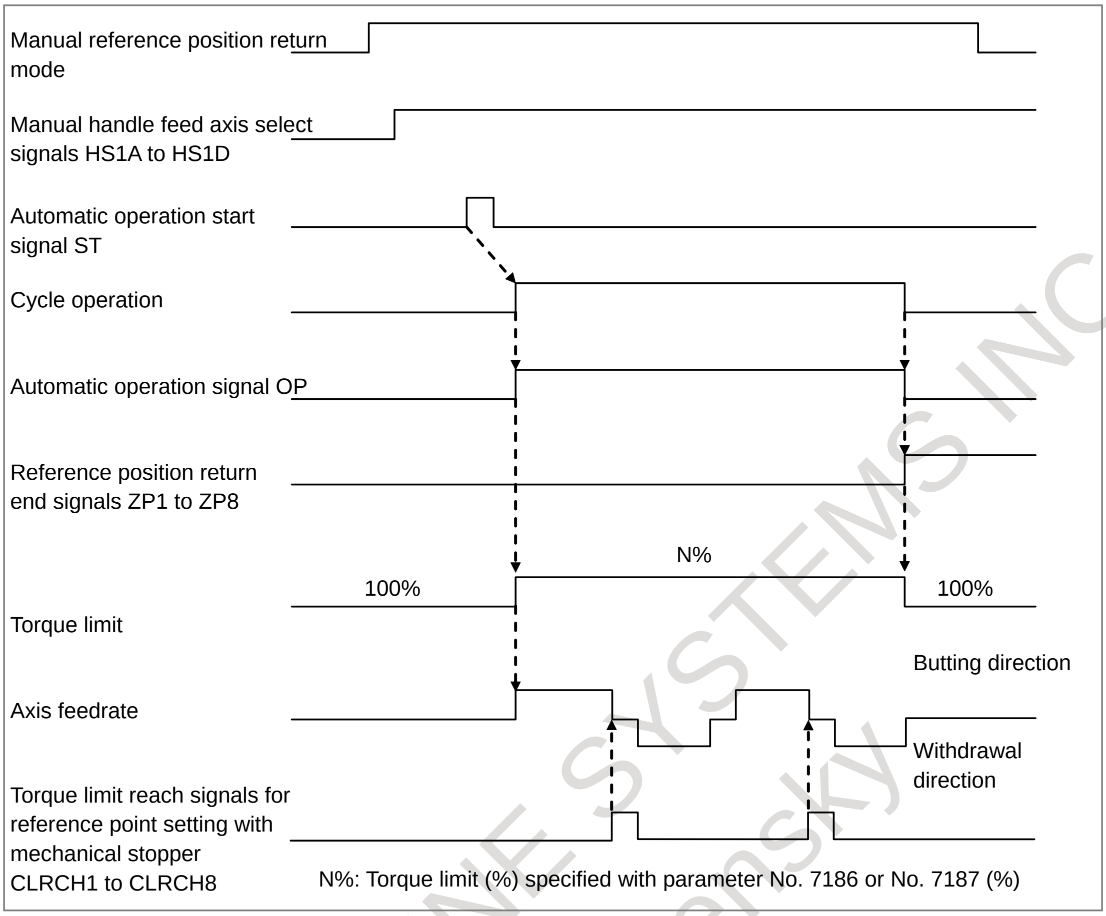
(D) The tool moves along the specified axis at a specified torque until it butts against the mechanical stopper.
- The tool moves in the direction specified with bit 5 (ZMIx) of parameter No.1006,
- At the feedrate specified with parameter No.7184,
- At the torque specified with parameter No.7186 or No.7187 (until the tool strikes the mechanical stopper).



(E) After the tool strikes the mechanical stopper end on the axis, the tool is withdrawn in the direction opposite to the butting direction, along the axis for a parameter-set distance.
- The tool is moved in the direction opposite to that specified with bit 5 (ZMIx) of parameter No.1006,
- At the feedrate specified with parameter No. 7185,
- For the distance specified with parameter No.7182.



For parameter No.7183 and No.7184, set the feedrates at which the tool is moved toward the mechanical stopper with a limited torque, considering the machine accuracy.
After the tool strikes the mechanical stopper, and the tool is withdrawn the distance specified with parameter No.7182, the withdrawal point is set as the reference position on the specified axis. Then, the reference position return end signal and reference position establishment signal are set to 1.
The timing chart for the cycle operation is shown below.



- Cycle operation after the reference position has been established

When the reference position has been established, cycle operation is not performed by operations for reference position setting with a mechanical stopper. In this case, the tool is positioned to the reference position in the rapid traverse mode. After the completion of the positioning, the relevant reference position return end signal is set to 1.
This signal is not set to 1 during automatic operation.

Signal

Cycle start signal ST<Gn007.2>

[Classification] Input signal
[Function] Starts automatic operation.
[Operation] When signal ST is set to 1 then 0 in memory (MEM) mode, DNC operation mode (RMT) or manual data input (MDI) mode, the CNC enters the cycle start state and starts operation.

MEM, RMT, or MDI mode

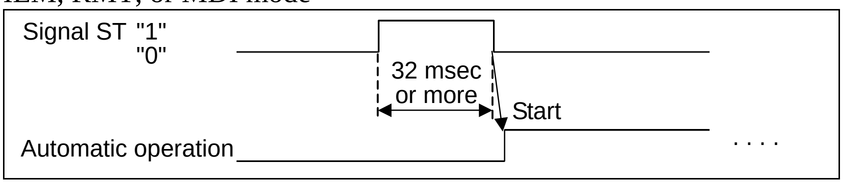


Fig.4.6 (a)

Torque limit reach signals for reference point setting with mechanical stopper

CLRCH1 to CLRCH8 <Fn180>

[Classification] Output signal

[Function] These signals are used to post notification of the torque limit having been reached for each corresponding axis during cycle operation for reference point setting with mechanical stopper.

[Output cond.] Each signal is set to 1 when:

- The torque limit is reached for the corresponding axis during cycle operation for reference point setting with mechanical stopper.

Each signal is set to 0 when:

- The torque limit is not reached for the corresponding axis during cycle operation for reference point setting with mechanical stopper.

[Data type] Bit axis

> **NOTE**
> When this parameter is set, the power must be turned off before operation is continued.

#5 ZMIx The direction of manual reference position return is:
0: + direction
1: - direction

7181	First withdrawal distance in reference point setting with mechanical stopper
7182	Second withdrawal distance in reference point setting with mechanical stopper

[Input type] Parameter input
[Data type] Real axis
[Unit of data] mm, inch, deg (machine unit)
[Min. unit of data] Depend on the increment system of the applied axis
[Valid data range] 9 digit of minimum unit of data (refer to standard parameter setting table (A))
(When the increment system is IS-B, -999999.999 to +999999.999)
This parameter sets the distance, by which an axis is withdrawn after the axis butts against the mechanical stopper in each cycle operation, (the distance from the mechanical stopper to the withdrawal point).

> **NOTE**
> Set the same direction as that set in bit 5 (ZMIx) of parameter No.1006. Cycle operation cannot be started if the opposite direction is set.

7183	First butting feedrate in reference point setting with mechanical stopper
7184	Second butting feedrate in reference point setting with mechanical stopper or butting feedrate in reference point setting with mechanical stopper by Grid Method
7185	Withdrawal feedrate (common to the first and second butting operations) in reference point setting with mechanical stopper

[Input type] Parameter input
[Data type] Real axis
[Unit of data] mm/min, inch/min, deg/min (machine unit)
[Min. unit of data] Depend on the increment system of the applied axis
[Valid data range] Refer to the standard parameter setting table (C)
(When the increment system is IS-B, 0.0 to +999000.0)

This parameter sets a feedrate used to butt against the stopper along an axis in each cycle.

7186	Torque limit value in reference point setting with mechanical stopper

[Input type] Parameter input
[Data type] Byte axis
[Valid data range] 0 to 100

This parameter sets a torque limit value. A value from 0 to 100 corresponds to 0% to 39%. The torque limit value is obtained by multiplying the setting by 1/255. If more than 39% is to be set, use parameter No. 7187.

NOTE
When 0 is set in this parameter, 100% is assumed.

7187	Torque limit value in reference point setting with mechanical stopper or reference point setting with mechanical stopper by Grid Method

[Input type] Parameter input
[Data type] Word axis
[Valid data range] 0 to 255

This parameter sets a torque limit value. As for the setting value, 0-255 corresponds to 0% to 100%.

When this parameter is set for reference point setting with mechanical stopper, parameter No.7186 is ignored. When this parameter is set to 0, the setting of parameter No.7186 is used.

However, in case of reference point setting with mechanical stopper by Grid Method, only this parameter is valid. If this parameter is set to 0, 100% of the rated torque is assumed even if parameter No.7186 is set up.

Alarm and message

Number	Message	Description
PS0307	CAN NOT START REFERENCE RETURN WITH MECHANICAL STOPPER SETTING	An attempt was made to set a butt-type reference position for an axis for which to use the function to set a reference position without a dog.
SV0047	REFERENCE POINT SETTING WITH MECHANICAL STOPPER IS BROKEN OFF	Reference point setting with mechanical stopper is broken off. Reference point setting again after reset.

Warning

⚠ **WARNING**

When cycle operation of Reference point setting with mechanical stopper is completed, Reference position return end signals ZPx <Fn094> turns to "1". Before completing the cycle operation, namely, when the RESET is executed or operation mode is changed to a mode other than REF mode in the state of ZPx signal is "0", the cycle operation is broken off. In such a case, take the action along the following procedure.
The situations that require interruption, it is assumed that the following situations: When the cycle operation is started the axis is stopped or is not moved while ZPx signal is "0" for the torque limit value is too low.

The countermeasure differs as follows in the case with and without an alarm SV0047, "REFERENCE POINT SETTING WITH MECHANICAL STOPPER IS BROKEN OFF" occurs during the interruption.

<u>Without alarm SV0047</u>

1 Enter state emergency stop.
2 In the case of axis that uses the absolute position detector (bit 5 (APC) of parameter No.1815 is 1), bit 4 (APZ) of parameter No.1815 is set to 0.
3 If there is a factor in stopping axis, remove it. In addition, change the parameters such as the torque limit value as needed.
4 Turn the power off, then on again.
5 Start over Reference point setting with mechanical stopper again from beginning.

<u>With alarm SV0047</u>

1 If there is a factor in stopping axis, remove it. In addition, change the parameters such as the torque limit value as needed.
2 Release alarm by reset operation.
3 Start over Reference point setting with mechanical stopper again from beginning.

Note

NOTE

1 Multiple axes cannot be selected simultaneously.
2 This cycle is not executed if either of the following conditions is satisfied:
 (A) Automatic operation signal OP <Fn000.7> is set to 1.
 (B) The direction of reference position return (bit 5 (ZMIx) of parameter No. 1006) does not agree with the sign of a reference position setting distance (parameter No. 7181 or 7182).
3 During cycle operation, excess error and feed hold in the moving and stopped states are not checked.
4 During withdrawal operation, the torque limit is effective, but the tool is not butted when the limit is reached. The torque limit is released after the reference position is established.
5 When the RESET signal is input during cycle operation, operation stops, but the torque limit is not released.

NOTE

6 This function cannot be used together with the grid shift function or reference position shift function.
7 This function cannot be used for angular, synchronous, Cs, spindle positioning, or index table indexing axis.
8 Acceleration/deceleration is applied for this function in the same way as for manual reference position return.
9 When this function is used and the manual reference position return mode is selected, feed axis and direction selection signals (such as +J1 and -J1) must be disabled.

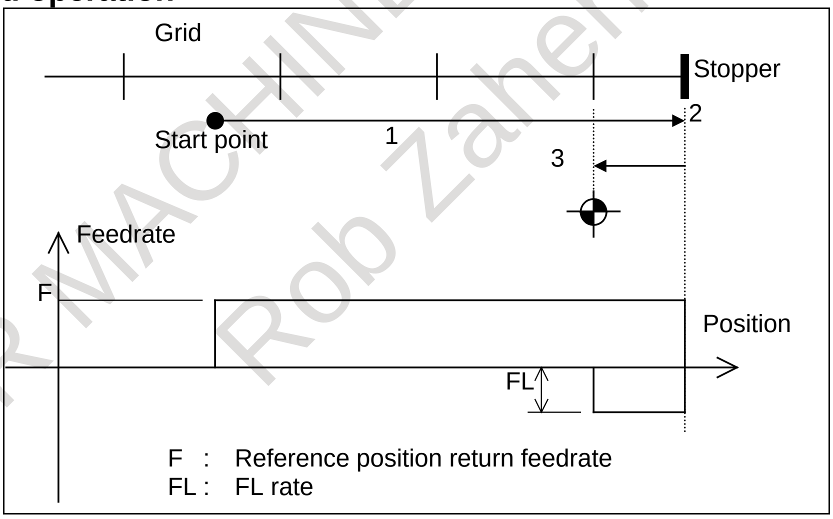
4.7 REFERENCE POINT SETTING WITH MECHANICAL STOPPER BY GRID METHOD

Overview

A reference position return for an axis can be made by pushing the axis against the mechanical stopper without using a limit switch or deceleration dog. As this reference position setting uses a grid method, its precision is on the same level as for a manual reference position return. Unlike the deceleration dog, however, the mechanical stopper cannot be shifted for reference position setting. It requires using also the "reference position shift function" or "grid shift function."

Explanation

- Setting and operation



- Setting

(1) Set a mechanical stopper near the reference position.
(2) Specify the direction of a reference position return as toward the stopper (using bit 5 (ZMIx) of parameter No. 1006).
(3) Set parameter No.7187 with the motor torque limit override value when the axis is pushed against the stopper.
(4) Set parameter No.7184 with the feedrate (reference position return feedrate) at which the axis is pushed against the stopper.
(5) Set parameter No.1425 with the feedrate (reference position return FL rate) at which the axis moves to the reference position from the stopper.

- Operation

(1) The machine is placed in the reference position return mode, and the feed axis direction select signal is issued to feed the axis toward the stopper. At this time, torque limit override is put in effect.
(2) When the axis hits the stopper, it stops because of a torque limit. When it is detected that the axis has stopped because of a torque limit, the axis starts moving back.
(3) When the axis stops at the first grid, its reference position return is completed. However, grids are ignored if a parameter specifies so, until the amount of servo position deviation changes from positive to negative or vice versa.

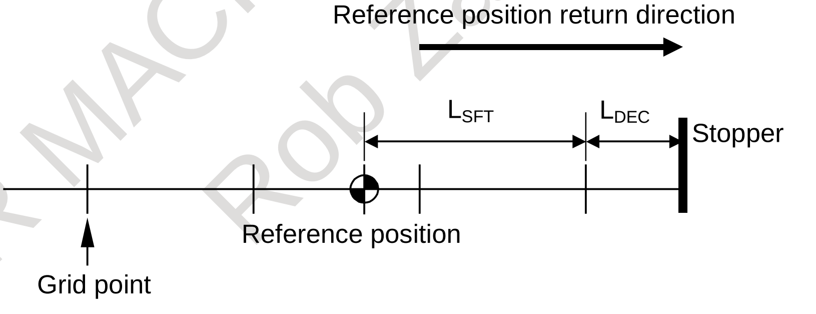
> **NOTE**
> An alarm (PS0090), "REFERENCE RETURN INCOMPLETE", is raised if an attempt is made to perform reference point setting with mechanical stopper by Grid Method without establishing electrical grids based on the one-rotation signal from the position detector.

Reference position adjustment by grid shifting

The reference position can be shifted by as much as an amount of grid position shift specified in parameter No.1850.
A maximum grid shift amount that can be specified is below a reference counter capacity specified in parameter No.1821 (grid interval).

Reference position adjustment by reference position shifting

The reference position can be shifted by specifying an amount of reference position shift in parameter No.1850.
This function is enabled by setting the bit 4 (SFDx) of parameter No. 1008 to 1.
The reference position can be shifted by specifying the reference position shift amount shown below in parameter No.1850.
The distance L_{DEC} the axis moved for a reference position return is automatically saved to parameter No.1844.



L_{DEC} : Distance the axis moves to get to the first grid point from the stopper if the reference position shift amount is 0 (parameter No.1844).
L_{SFT} : Reference position shift amount (parameter No.1850)

- Procedure

(1) Set up the following parameters. Then, turn the power off.
Bit 4 (SFDx) of parameter No. 1008 is set to 1.
Parameter No.1844 is set to 0.
Parameter No.1850 is set to 0.
(2) Make a reference position return. The machine first hits the stopper and then stops at the first grid point. The distance L_{DEC} is automatically saved to parameter No.1844. Do not change the automatically set value.
(3) Obtain the distance (reference position shift amount L_{SFT}) from the stop position to the reference position, and set it in parameter No.1850. Then, turn the power off.

This is the end of reference position adjustment.

(4) The machine will stop at the reference position from now on whenever a reference position return is made.

> **NOTE**
> 1 When reference position return with mechanical stopper by grid method is performed while reference position is established, reference position return with mechanical stopper by grid method is performed again.
> 2 When the relation of the sign of parameters Nos.1844 and 1850 is contradicted, the amount of the grid shift becomes effective only below the capacity of the Reference counter.

Parameter

	#7	#6	#5	#4	#3	#2	#1	#0
1006			ZMIx					

[Input type] Parameter input
[Data type] Bit axis

> **NOTE**
> When this parameter is set, the power must be turned off before operation is continued.

#5 ZMIx The direction of manual reference position return is:
0: + direction
1: - direction

	#7	#6	#5	#4	#3	#2	#1	#0
1008				SFDx				

[Input type] Parameter input
[Data type] Bit axis

> **NOTE**
> When this parameter is set, the power must be turned off before operation is continued.

#4 SFDx In reference position return based on the grid method, the reference position shift function is:
0: Disabled
1: Enabled

1425	FL rate of the reference position return for each axis

[Input type] Parameter input
[Data type] Real axis
[Unit of data] mm/min, inch/min, deg/min (machine unit)
[Min. unit of data] Depend on the increment system of the applied axis
[Valid data range] Refer to the standard parameter setting table (C)
(When the increment system is IS-B, 0.0 to +999000.0)
Set feedrate (FL rate) after deceleration when the reference position return is performed for each axis.

1821	Reference counter size for each axis

> **NOTE**
> When this parameter is set, the power must be turned off before operation is continued.

[Input type] Parameter input
[Data type] 2-word axis
[Unit of data] Detection unit
[Valid data range] 0 to 999999999

Set a reference counter size.
As a reference counter size, specify a grid interval for reference position return based on the grid method.
When a value less than 0 is set, the specification of 10000 is assumed.
When a linear scale with absolute address reference marks is used, set the interval of mark 1.

1844	Distance to the first grid point when the reference position shift amount in the reference position shift function is 0 or when a reference position return is made by grid shift

> **NOTE**
> When this parameter is set, the power must be turned off before operation is continued.

[Input type] Parameter input
[Data type] 2-word axis
[Unit of data] Detection unit
[Valid data range] -999999999 to 999999999

(1) When the reference position shift function is enabled (when bit 4 (SFDx) of parameter No. 1008 is set to 1)
Set the distance (detection unit) to the first grid point from a point at which the deceleration dog is released when the reference position shift (parameter No. 1850) is set to 0.
(2) When a reference position return is made by grid shift with a setting not to use reference position setting without dogs (when bit 4 (SFDx) of parameter No. 1008 is set to 0, and bit 1 (DLZx) of parameter No. 1005 is set to 0)
Set the distance to the first grid point from a point at which the deceleration dog is released. (Detection unit)
(3) When a reference position return is made by grid shift with a setting to use reference position setting without dogs (when bit 4 (SFDx) of parameter No. 1008 is set to 0, and bit 1 (DLZx) of parameter No. 1005 is set to 1)
Set the distance from the start position for reference position setting without dogs to the first grid point. (Detection unit)

> **NOTE**
> 1 When the reference position shift function is enabled (when bit 4 (SFDx) of parameter No. 1008 is set to 1)
> When bit 4 (SFDx) of parameter No. 1008 is set to 1, the distance from a point at which the deceleration dog is released to the first grid point (parameter No. 1844) is set to 0, and reference position shift (parameter No. 1850) is set to 0, a manual reference position return allows this parameter to be set automatically. Do not change an automatically set value.

> **NOTE**
> 2 When a reference position return is made by grid shift with a setting not to use reference position setting without dogs (when bit 4 (SFDx) of parameter No. 1008 is set to 0, and bit 1 (DLZx) of parameter No. 1005 is set to 0)
> When a manual reference position return using deceleration dogs is made, this parameter is set automatically.
> 3 When a reference position return is made by grid shift with a setting to use reference position setting without dogs (when bit 4 (SFDx) of parameter No. 1008 is set to 0, and bit 1 (DLZx) of parameter No. 1005 is set to 1)
> When a reference position setting without dogs is made, this parameter is set automatically.

1850	Grid shift and reference position shift for each axis

> **NOTE**
> When this parameter is set, the power must be turned off before operation is continued.

[Input type] Parameter input
[Data type] 2-word axis
[Unit of data] Detection unit
[Valid data range] -99999999 to 99999999

To shift the reference position, the grid can be shifted by the amount set in this parameter. Grid shift amount that can be set is a value less than reference counter size.
When bit 4 (SFDx) of parameter No.1008 is 0, it is grid shift, and when bit 4 (SFDx) of parameter No.1008 is 1, it is reference point shift.

> **NOTE**
> For setting the reference position without dogs, only the grid shift function can be used. (The reference position shift function cannot be used.)

7184	Second butting feedrate in reference point setting with mechanical stopper or butting feedrate in reference point setting with mechanical stopper by Grid Method

[Input type] Parameter input
[Data type] Real axis
[Unit of data] mm/min, inch/min, deg/min (machine unit)
[Min. unit of data] Depend on the increment system of the applied axis
[Valid data range] Refer to the standard parameter setting table (C)
(When the increment system is IS-B, 0.0 to +999000.0)

This parameter sets a feedrate used to butt against the stopper along an axis.

7186	Torque limit value in reference point setting with mechanical stopper

[Input type] Parameter input
[Data type] Byte axis
[Valid data range] 0 to 100

This parameter sets a torque limit value. A value from 0 to 100 corresponds to 0% to 39%. The torque limit value is obtained by multiplying the setting by 1/255. If more than 39% is to be set, use parameter No. 7187.

> **NOTE**
> When 0 is set in this parameter, 100% is assumed.

7187	Torque limit value in reference point setting with mechanical stopper or reference point setting with mechanical stopper by Grid Method

[Input type] Parameter input
[Data type] Word axis
[Valid data range] 0 to 255

This parameter sets a torque limit value. As for the setting value, 0-255 corresponds to 0% to 100%.
When this parameter is set for reference point setting with mechanical stopper, parameter No.7186 is ignored. When this parameter is set to 0, the setting of parameter No.7186 is used.
However, in case of reference point setting with mechanical stopper by Grid Method, only this parameter is valid. If this parameter is set to 0, 100% of the rated torque is assumed even if parameter No.7186 is set up.

	#7	#6	#5	#4	#3	#2	#1	#0
7188	RNWx							GRSx

[Input type] Parameter input
[Data type] Bit axis

#0 GRSx Reference point setting with mechanical stopper by Grid Method is:
0: Not performed.
1: Performed.

#7 RNWx During reference point setting with mechanical stopper by Grid Method, until the sign of servo position deviation is inverted, the grid is
0: Not ignored.
1: Ignored.

Warning

> ⚠ **WARNING**
> When cycle operation of Reference point setting with mechanical stopper by grid method is completed, Reference position return end signals ZPx <Fn094> turns to "1".
> Before completing the cycle operation, namely, when the RESET is executed or operation mode is changed to a mode other than REF mode in the state of ZPx signal is "0", the cycle operation is broken off. In such a case, emergency stop is applied. And, start over Reference point setting with mechanical stopper by grid method after emergency stop cancellation.

4.8 DISTANCE CODED LINEAR SCALE INTERFACE

Overview

The interval of each reference marks (one-rotation signal) of distance coded linear scale are variable. Accordingly, if the interval is determined, the absolute position can be determined. The CNC measures the interval of reference marks by axis moving of short distance and determines the absolute position. Consequently the reference position can be established without moving to reference position.

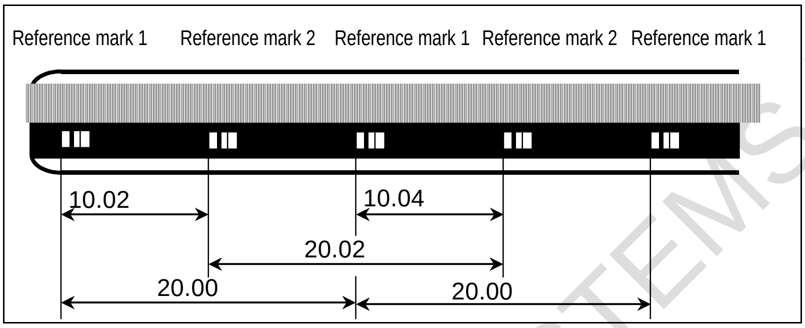


Fig. 4.8 (a) Example of distance coded linear scale

Procedure for reference position establishment

- Procedure

(1) Select the JOG mode, and set the manual reference position return selection signal ZRN to 1.
(2) Set the feed axis and direction selection signal(+J1, -J1, +J2, -J2, …) to "1" and feed the axis for which you want to establish a reference point.
(3) The axis is fed at a constant low speed (reference position return FL feedrate specified by parameter No. 1425 setting).
(4) When a reference mark is detected, the axis stops, then the axis is fed at a constant low speed again.
(5) Above (4) is executed repeatedly until two, three or four reference marks are detected. And absolute position is determined and the reference position establishment signal (ZRF1, ZRF2, ZRF3, …) turns to 1.
(A number of reference marks is determined by the bits 2 (DC2) and 1 (DC4x) of parameter No. 1802.)

> ⚠ **CAUTION**
> When the scale correctly detects the mark, the reference position is correctly established regardless of the number of detected reference marks. When the scale misreads the mark position, the alarm DS1449 "REFERENCE MARK ARE DIFFERENT FROM PARAMETER" is usually issued. However, if the interval of the detected mark is same as the parameters, the alarm might not be issued and the reference position might be established with the wrong position.
> It is reliable to avoid misreading the reference marks by using more number of detecting reference marks. It is recommended that the reference position is established by detecting four reference marks though the number of detecting reference marks can be selected from two to four reference marks number.

The timing chart for this procedure is given below.

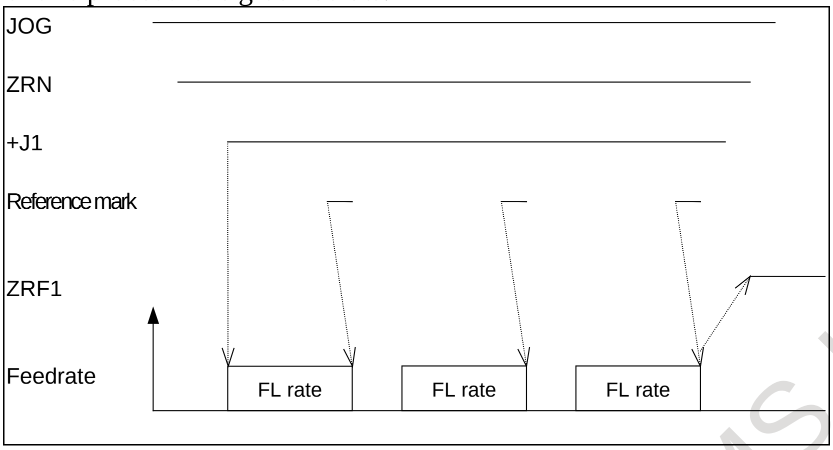

Fig. 4.8 (b) Timing chart for reference position establishment

- Procedure for establishing a reference position through automatic operation

If an automatic reference position returns (G28) is specified before a reference position is not established, steps (3) to (5) above are performed automatically.
After the reference position is established, the automatic reference position return is performed.

- Stopping the operation for establishing a reference position

The operation for establishing a reference position is stopped if any of the following operations is performed in steps (3) to (5), described above.

- Reset
- Setting the feed axis and direction selection signal (+J1, -J1, +J2, -J2, etc.) to 0

If any of the following operations is performed during the operation of automatic reference position return (G28) before a reference position is not established, the operation for establishing a reference position stops:

- Reset
- Performing feed hold during movement from an intermediate position

If the operation for establishing a reference position is stopped by an operation other than a reset, the operation for establishing a reference position must be reset and resumed.

Explanation

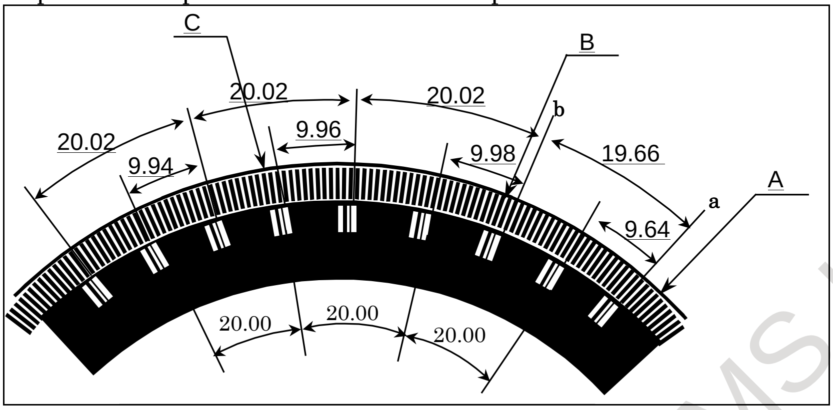
- Reference Position Return

(1) When axis is moved in REF mode while reference position is not established, reference position establishment procedure is executed.
(2) When axis is moved in REF mode while reference position is established, reference position establishment procedure is not executed and axis is moved to reference position.
(3) When the reference position is not established and the reference position return command (G28) is executed, the reference position establishment procedure is executed. The next movement the axis depends on the setting of bit 0 (RFS) of parameter No. 1818.
(4) When the reference position is already established and the reference position command (G28) is executed, the movement of the axis depends on the setting of bit 1 (RF2) of parameter No. 1818.

- Distance coded rotary encoder

In case of setting a rotary axis, if bit 3 (DCRx) of parameter No. 1815 is set, the setting axis is regarded as being equipped with a distance coded rotary encoder.
In case of distance coded rotary encoder, the marker interval may be different from parameter setting value at the joint of the encircled circle (a-b section of the following figure). When the reference point return is executed through this section, it is not able to establish the reference point. Therefore, in case of

distance coded rotary encoder, if the reference point return is started for B point from A point of below figure, the reference point is not established yet at B point. The reference point return is re-started for C point. The reference point return procedure is finished at C point.



- In case of distance coded rotary encoder, only the measurement by three points or four points is possible. (Bit 2 (DC2) of parameter No. 1802 is disregarded as 0.)

- Rotary axis (B type)

The distance coded rotary encoder does not have the rotary data. For example, 30.000 degree and 390.000 degree have completely same scale data though their position is different from each other by just one rotation. When distance coded rotary encoder is used and rotary axis is B type (bit 0 of parameter No.1006 is 1 and bit 1 of parameter No.1006 is 1 (machine coordinate system of rotary axis is linear axis type)), reference position established by this function is rounded by the amount of movement per a rotation of rotary axis even if the axis is rotated more than one rotation.
For this case, when the Reference point is established, correct machine coordinates can be established even the turn of the machine more than one revolution by setting the bit 0 (RVSx) of parameter No.1815 to "1".
Moreover, the present machine coordinates are stored immediately before the power is turned off when the parameter RSVx is set to 1. Therefore, immediately after the power is turned on again, this function can restore the approximate machine coordinates and enables the function for checking the stored stroke during the time from power-on to the reference position establishment. Even before the reference position is established by reference position return, the stored stroke check can be performed using approximate machine coordinates. Absolute coordinates are set based on the machine coordinates. Data such as workpiece offsets specified by G92, G52, and so on before the power is turned off, however, is not set. If bit 3 (PPD) of parameter No. 3104 is set to 1, the relative position indication is preset.

Axis synchronous control

In case of the synchronization establishment of the axis synchronous control, when the position is set immediately after turning on of the power, the synchronization establishment is executed.

Parameter setting procedure

1 The bit 0 (RVSx) of parameter No.1815 is set to 0, the power supply of CNC is turned off once, and it turns on again.
2 The reference position is established by manual reference position return.
3 The reference position returns, and it moves to the reference position.
4 The bit 0 (RVSx) of parameter No.1815 is set to 1, the power supply of CNC is turned off once, and it turns on again.

NOTE

1. a machine coordinate value may get out over a rotation, in the case of moving over 180 degree during turning off, because CNC saves a machine coordinate value just before CNC turns off and in following turning on get from the value.
2. Temporary absolute coordinate setting and this function cannot be used together within same axis.
3. This function can be used only when the amount of one rotation of rotary axis is 360 degree. Set 0 to the parameter No.1869.
   If the values other than 0 are set, an alarm DS1448, "ILLEGAL PARAMETER (D.C.S.)", is issued.
4. Set the parameter No.1240 to 0 because the reference position must be 0 degree.
5. If the tool is already beyond a stored stroke immediately after the power is turned on, an overtravel alarm (OT alarm) is issued.
   In this case, release the alarm by moving the tool along the axis in the direction that does not cause overtravel.
   If bit 6 (LZR) of parameter No. 1300 is set to 1, the function for checking the stored stroke during the time from power–on to the reference position establishment is disabled.
6. When the power is turned on while the CAN key and the <P> address key are held down, the stored stroke check immediately after power-on is disabled.
   (When the MDI keys are provided as standard keys)
   (When performing this operation, exercise special care.)
   In this case, machine coordinates and absolute coordinates are set.
   When the compact type MDI keys are used, the stored stroke immediately after power-on is disabled by holding down the CAN key and <O> address key at power-on.

- Requirements when this function is used with axis synchronous control axes

When this function is used with axis synchronous control axes, the distance coded linear scale used for the master axis and that used for the slave axis must have reference marks placed at identical intervals.
(Set identical values in parameters Nos. 1821 and 1882 for both the master and slave axes.)
A distance coded linear scale can be installed on the master and slave axes either in the same or opposite direction.
This function does not work unless the use of this function is specified for both the master and slave axes (bit 2 (DCL) of parameter No. 1815 is 1).
Also, in all parameters related to this function, except parameters Nos. 1883 and 1884 (distance from the scale zero point to reference position 1, 2), set identical values for both the master and slave axes.
If a parameter value for the master axis differs from the corresponding parameter value for the slave axis, alarm SV1051 "ILLEGAL SYNCHRONOUS AXIS" is issued.

NOTE

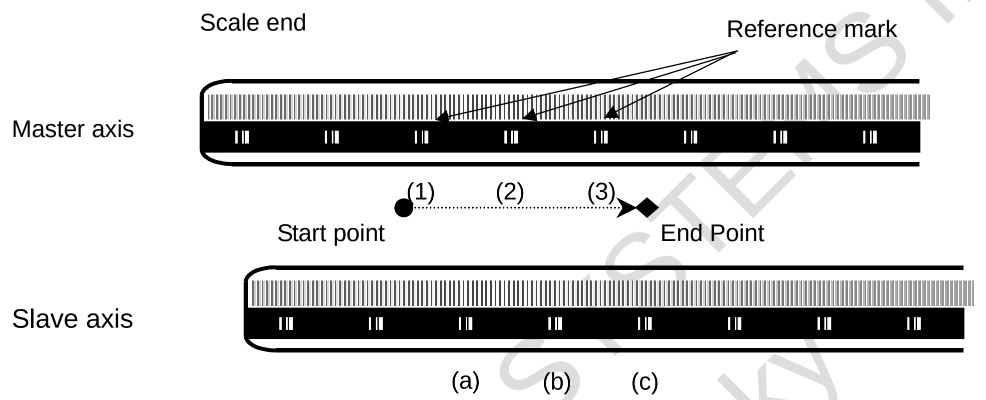
1. When this function is used with axis synchronous control axes for which the operation mode is switched between synchronization operation and normal operation, this function is enabled only if the synchronization select signal (SYNC1, SYNC2, ...) is 1. (During establishment of a reference position, the synchronization select signal status must be maintained.)
2. When this function is used by the axis synchronous control, only one axis is available for the slave axis. When the slave axis of the axis synchronous control is two or more settings, the alarm DS0027 "MISMATCH OF SYNCHRONOUS AXIS(D.C.S)" is issued.

- Reference position establishment with axis synchronous control axes

With axis synchronous control axes, a reference position is established as follows. When a reference mark for the master or slave axis is detected, a stop takes place temporarily. Then, a feed operation is performed again at the reference position return FL feedrate. This sequence is repeated until a reference mark is detected for both the master and slave axes. Then the absolute position is calculated for both the master and slave axes, and the reference position establishment signal (ZRF1, ZRF2, ...) are set to 1.

After the reference position has been established by the above operation, a synchronization error is corrected. (Checking for excessive synchronization error alarm 2 is made even during reference position establishment.)

(Example of 3 points measurement system)



In the above example, the following sequence is executed.

a. When the reference mark (1) of the master axis is detected, both master axis and slave axis stop.
b. Both the axes begin to move again at a reference position return FL feedrate.
c. When the reference mark (a) of the slave axis is detected, both axes stop again.
d. Both the axes begin to move again at FL feedrate.
e. Both axes repeat the operation until all point ((2) -> (b) ->(3)) are detected.
f. When the slave axis detects the third reference mark (c), both the axes end the reference position establishment.

> **NOTE**
> In case of this function is used with axis synchronous control axes, if the value of parameters Nos. 1883 and 1884 (Distance 1, 2 from the scale zero point to reference position) for both the master and slave axes is 0, the reference position is not established. Also, the reference position establishment signals (ZRF1, ZRF2, ...) are not set to "1".

- PMC control axis

In PMC axis control, if the reference position return command (axis control command code 05H) is issued for an axis having a distance coded linear scale, reference position return is performed according to the reference position return sequence for the distance coded linear scale.

Specifically, the following operations take place:

Before reference position establishment	The reference position is established by detecting two, three or four reference marks. Movement to the reference position is not performed.
After reference position establishment	Positioning at the reference position is performed.

- Arbitrary angular axis control

There are the following limitations when the angular axis control is used.

(a) It is necessary to use the linear scale with the distance coded reference mark for both the perpendicular axis and the angular axis.

(b) When the reference point of the perpendicular axis is established, it is necessary to establish the reference point of the angular axis previously. When perpendicular axis is commanded first or perpendicular axis and angular axis are commanded simultaneously, the alarm DS0020, "REFERENCE RETURN INCOMPLETE", is generated.

(c) During the reference position establishment operation of the angular axis, the command in the perpendicular axis is invalid in the manual reference point return.

Note

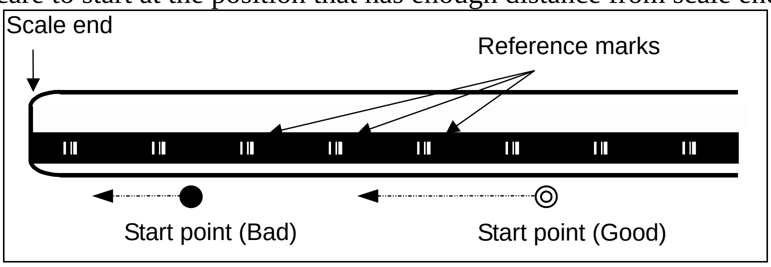
(1) In the case of the actual interval of reference marks is different from parameter setting value, the alarm DS1449, "REFERENCE MARK ARE DIFFERENT FROM PARAMETER", occurs.

(2) This function is disabled if any of the following conditions is satisfied:
- Either parameter 1821 (mark-1 interval) or parameter 1882 (mark-2 interval) is set to 0.
- Parameters Nos. 1821 and 1882 have identical settings.
- The difference between the settings made for parameters Nos. 1821 and 1882 is greater than or equal to twice either setting.
- The absolute-position detection function is enabled (bit 5 (APCx) of parameter No.1815 is 1).

(3) A difference of parameter No.1821 (mark-1 interval) and No.1882 (mark-2 interval) must be more than 4.
Example)
When the scale, which is that mark1 interval is 20.000mm and mark2 interval is 20.004mm, is used on IS-B machine:
When the detection unit of 0.001mm is selected, parameter No.1821 and No.1882 must be set 20000 and 20004, and the difference of them is 4.
To use such a scale, please adjust the detection unit by modification of parameter No. 1820 (CMR) and No.2084/2085 (flexible feed gear) to make the difference of No.1821 and 1882 more than 4 as following examples.
(a) Set the detection unit=0.0001mm, and parameter No.1821 is set to 200000, parameter No.1882 is set to 200040
(b) Set the detection unit=0.0005mm, and parameter No.1821 is set to 40000, parameter No.1882 is set to 40008

NOTE
When the detection unit is changed, parameters relating to the detection unit (such as the effective area and positional deviation limit) must also be changed accordingly.

(4) In this procedure, the axis does not stop until two, three or four reference marks are detected. If this procedure is started at the position near the scale end, the axis does not stop until over travel alarm occurs. Please care to start at the position that has enough distance from scale end.



(5) When the axis used this function, the following function can not be used.
- Absolute position detection

(6) If axial movement is made in the direction opposite to that of reference position return, the movement is reversed to the direction of reference position return after three or four reference marks

have been detected. Steps 3 to 5 of the basic procedure for establishing a reference position are carried out to establish the reference position.

(7) Straightness compensation function
When the reference position establishment of moving axis is executed after the establishment of compensation axis, the compensation axis is moved by straightness compensation amount when the reference point of moving axis is established.

(8) The reference position establishment is not performed during synchronous control is activated.

(9) The reference position establishment is not performed during composite control is activated.

(10) The reference position establishment is not performed during superimposed control is activated.

(11) No reference position can be established during flexible synchronization control.

Parameter

	#7	#6	#5	#4	#3	#2	#1	#0
1802						DC2x	DC4x	

[Input type] Parameter input
[Data type] Bit axis

#1 DC4x When the reference position is established on the linear scale with reference marks:
0: An absolute position is established by detecting three reference marks.
1: An absolute position is established by detecting four reference marks.

#2 DC2x Reference position establishment operation for a linear scale with reference marks is performed as follows:
0: The setting of bit 1 (DC4) of parameter No. 1802 is followed.
1: An absolute position is established by detecting two reference marks.

NOTE
1 When this parameter is set to 1, specify the direction of the scale zero point by setting bit 4 (SCP) of parameter No. 1817.
2 When a rotary encoder with absolute address reference marks is used, this parameter is invalid. Even when this parameter is set to 1, the setting of bit 1 (DC4) of parameter No. 1802 is followed.

	#7	#6	#5	#4	#3	#2	#1	#0
1815					DCRx	DCLx	OPTx	RVSx

[Input type] Parameter input
[Data type] Bit axis

NOTE
When at least one of these parameters is set, the power must be turned off before operation is continued.

#0 RVSx When the scale without rotary data is used:
0: The CNC does not maintain the rotary data.
1: The CNC maintains the rotary data.
This parameter is effective in the axis that satisfies either of the following conditions.
- The axis is rotary axis B type and the movable range is more than one rotation.
- Bit 6 (RVLx) of parameter No.11802 is 1.

NOTE

1 In the case of a rotary axis B type whose movable range is over one rotation, a rotary scale with rotary data had better be used. Otherwise, a machine coordinate value may get out over a rotation, in the case of moving over 180 degree during turning off.

2 This parameter is available for the axis that is rotary axis B type or the axis whose bit 6 (RVLx) of parameter No.11802 is 1. This parameter is available for the axis with an absolute position detector (absolute Pulsecoder), a distance coded rotary scale interface (phase A/B) or a rotary scale with distance-coded reference marks (serial).

3 If this parameter is available, the machine coordinate value just before CNC turns off is saved. In the case of moving over the following amounts during turning off or before reference position return, a machine coordinate value may get out over a rotation because CNC saves a machine coordinate value just before CNC turns off and in following turning on get from the value.
In case of the rotary axis B type :
    Over 180 degree
In case of the linear axis type :
    Over 1/4 of values set to parameter No.11810.

4 If this parameter is changed, the correspondence between the machine position and the absolute position detector is lost. So, establish the reference position again. (Bit 4 (APZx) of parameter No.1815 is set to 0, and an alarm DS0300, “APC ALARM: NEED REF RETURN” is issued. The cause that sets bit 4 (APZx) of parameter No.1815 to 0 is indicated in bit 0 of diagnosis data No.310).

5 Absolute coordinate value is set by machine coordinate value. However, after CNC turns on, the workpiece offset such as G92 and G52 executed before CNC turns off is not set.

6 This function cannot be used together with the bit 3 (SCRx) of parameter No. 1817 that convert scale data.

7 In case of the rotary axis B type and the amount of one rotation of rotary axis is 360, set the parameter No.1869 to 0. Moreover, set the parameter No.1240 to 0 because the reference position must be 0 degree.

8 In case of the rotary axis B type and the amount of one rotation of rotary axis is not 360, set the parameter No.1869 to the amount of one rotation. Moreover, set the parameter No.1240 to 0 because the reference position must be 0 degree.

9 In case of the linear axis type, set the amount of the movement per one motor rotation to the parameter No.11810.

10 This parameter cannot be used together with the stored stroke limit check immediately after power-on (bit 0 (DOTx) of parameter No.1311 is 1).

#1 OPTx The separate position detector is:

0: Not to be used (semi-closed system)

1: To be used (full-closed system)

> **NOTE**
> Set 1 when this function is used.

#2 DCLx As a separate position detector, a linear scale with reference marks or a linear scale with an absolute address zero point is:
0: Not used.
1: Used.

> **NOTE**
> Set 1 when this function is used.

#3 DCRx As a scale with absolute address reference marks:
0: A rotary encoder with absolute address reference marks is not used.
1: A rotary encoder with absolute address reference marks is used.

> **NOTE**
> When using a rotary encoder with absolute address reference marks, bit 2 (DCLx) of parameter No. 1815 set also to 1.

	#7	#6	#5	#4	#3	#2	#1	#0
1817				SCPx				

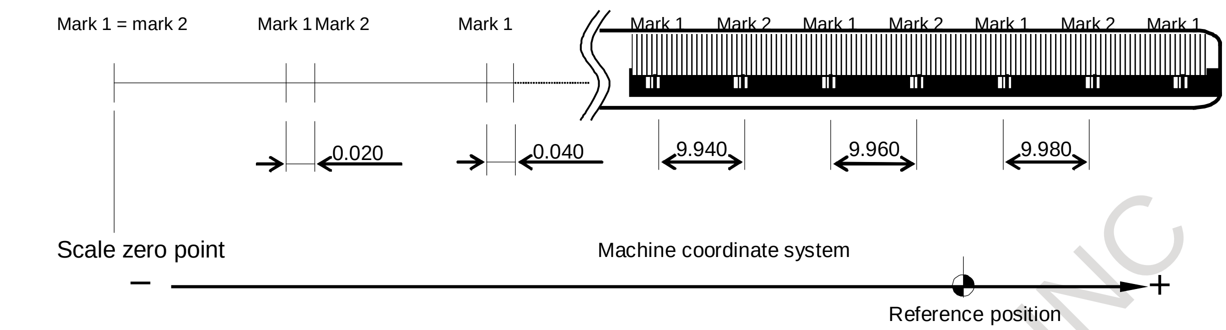
[Input type] Parameter input
[Data type] Bit axis

> **NOTE**
> When this parameter is set, the power must be turned off before operation is continued.

#4 SCPx For two-point measurement (when bit 2 (DC2) of parameter No. 1802 is set to 1), the scale zero point direction is:
0: On the minus side. (The reference position is located in the plus direction when viewed from the scale zero point.)
1: On the plus side. (The reference position is located in the minus direction when viewed from the scale zero point.)

> **NOTE**
> 1 This parameter is valid when bit 2 (DC2) of parameter No. 1802 is set to 1.
> 2 If this parameter is set to an incorrect value, an incorrect coordinate system is established. In such a case, reverse the setting then perform reference position establishment operation again.

- When parameter SCP = 0



- When parameter SCP = 1

	#7	#6	#5	#4	#3	#2	#1	#0
1818							**RF2x**	**RFSx**

[Input type] Parameter input
[Data type] Bit axis

#0 RFSx If G28 is specified for an axis for which a reference position is not established (ZRF = 0) when a linear scale with an absolute address zero point or a linear scale with absolute address reference marks is used:
0: A movement is made to the reference position after reference position establishment operation.
1: No movement is made after reference position establishment operation, but the operation is completed.

> **NOTE**
> This parameter disables movement based on the G28 command to a reference position. So, use this parameter only in special cases.

#1 RF2x If G28 is specified for an axis for which a reference position is already established (ZRF = 1) when a linear scale with an absolute address zero point or a linear scale with absolute address reference marks is used:
0: A movement is made to the reference position.
1: No movement is made to the intermediate position and reference position, but the operation is completed.

> **NOTE**
> This parameter disables movement based on the G28 command to a reference position. So, use this parameter only in special cases.

	#7	#6	#5	#4	#3	#2	#1	#0
1819						DATx		

[Input type] Parameter input
[Data type] Bit axis

#2 DATx When a linear scale with an absolute address zero point or a linear scale with absolute address reference marks is used, the automatic setting of parameters Nos. 1883 and 1884 at manual reference position return time is:
0: Not performed.
1: Performed.
The automatic setting procedure is as follows:
<1> Set an appropriate value in parameters Nos. 1815, 1821, and 1882.
<2> Position the machine at the reference position by manual operation.
<3> Set this parameter to 1.
Alarm PS5220, "REFERENCE POINT ADJUSTMENT MODE", occurs.
<4> Perform a manual reference position return operation. Upon completion of manual reference position return operation, parameters Nos. 1883 and 1884 are set, and this parameter is automatically set to 0.
Make a reset to release alarm PS5220.

1869	The amount of one rotation of rotary axis B type (each axis)

NOTE
When this parameter is set, the power must be turned off before operation is continued.

[Input type] Parameter input
[Data type] Real axis
[Unit of data] deg
[Min. unit of data] Depend on the increment system of the applied axis
[Valid data range] 0 or positive 9 digit of minimum unit of data (Refer to the standard parameter setting table (B))
(When the increment system is IS-B, 0.0 to +999999.999)
Normally, the amount of one rotation of rotary axis is 360, and the machine position 0 is the reference position.
In this case, this parameter is set to 0.

For instance, when this parameter is set to 523.000, the amount of one rotation become 523.000 (in the case of IS-B), if it is necessary to set it arbitrarily.

NOTE
1 This parameter is available for only the rotary axis B type with an absolute position detector (absolute Pulsecoder) or a rotary scale with distance-coded reference marks (serial), as for the bit 3 (SCRx) of parameter No. 1817 is set to 1 or the bit 0 (RVSx) of parameter No. 1815 is set to 1.
2 In the case that the amount of one rotation of rotary axis is 360, this parameter is set to 0.If it is necessary to set an amount of one rotation of rotary axis arbitrarily, this parameter is set to the amount of one rotation.

> **NOTE**
> 3 When this parameter is set, machine position and position on absolute position detector become uncorresponding. So, establish the reference position again. (Consequently, the bit 4 (APZx) of parameter No. 1815 (indicating that the correspondence is established) is set to 0, and an alarm DS0300, “APC ALARM: NEED REF RETURN”, occurs. Why the bit 4 (APZx) of parameter No. 1815 is set to 0 can be checked using bit 0 of diagnosis data No.310).
> 4 This parameter No. 1869 is common in movable range that is under one rotation (the bit 3 (SCRx) of parameter No. 1817 is set to 1) and movable range that is over one rotation (the bit 0 (RVSx) of parameter No. 1815 is set to 1).
> 5 Please set 0 to this parameter if the distance coded rotary scale interface (phase A/B) is used.

1821	Reference counter size for each axis

> **NOTE**
> When this parameter is set, the power must be turned off before operation is continued.

[Input type] Parameter input
[Data type] 2-word axis
[Unit of data] Detection unit
[Valid data range] 0 to 999999999

Set the interval of reference mark 1 of distance coded linear scale.

1882	Interval of reference mark 2

> **NOTE**
> When this parameter is set, the power must be turned off before operation is continued.

[Input type] Parameter input
[Data type] 2-word axis
[Unit of data] Detection unit
[Valid data range] 0 to 999999999

Set the interval of reference mark 2 of distance coded linear scale.

1883	Distance 1 from the scale zero point to reference position

> **NOTE**
> When this parameter is set, the power must be turned off before operation is continued.

[Input type] Parameter input
[Data type] 2-word axis
[Unit of data] Detection unit
[Valid data range] -999999999 to 999999999

1884	Distance 2 from the scale zero point to reference position

> **NOTE**
> When this parameter is set, the power must be turned off before operation is continued.

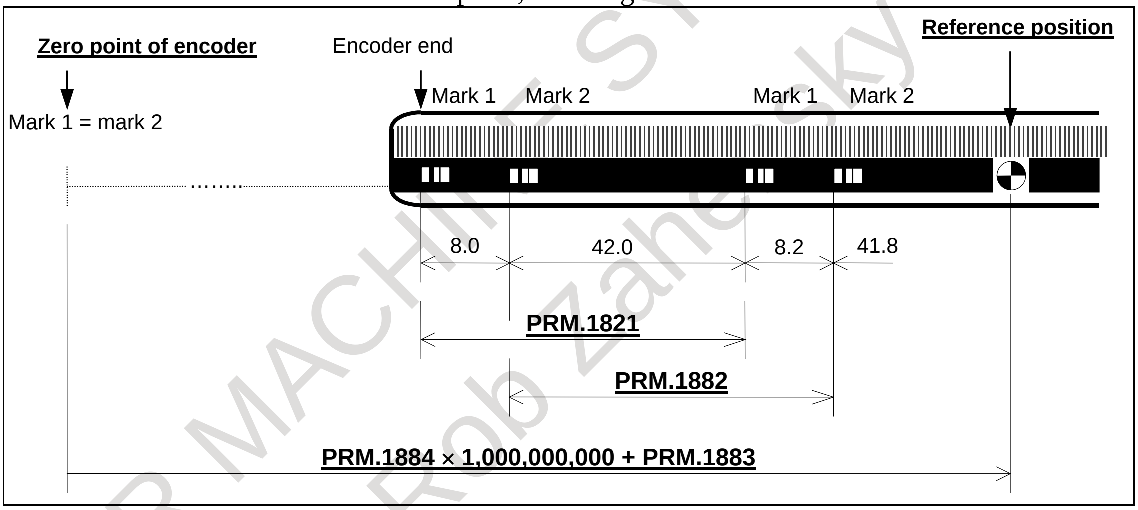
[Input type] Parameter input
[Data type] 2-word axis
[Unit of data] Detection unit
[Valid data range] -999 to 999

When a linear scale with absolute address reference marks is used, set the distance from the scale zero point to reference position in parameter Nos. 1883 and 1884).

Distance from the zero point to the reference position of a linear scale
= No. 1884 × 1,000,000,000 + No. 1883

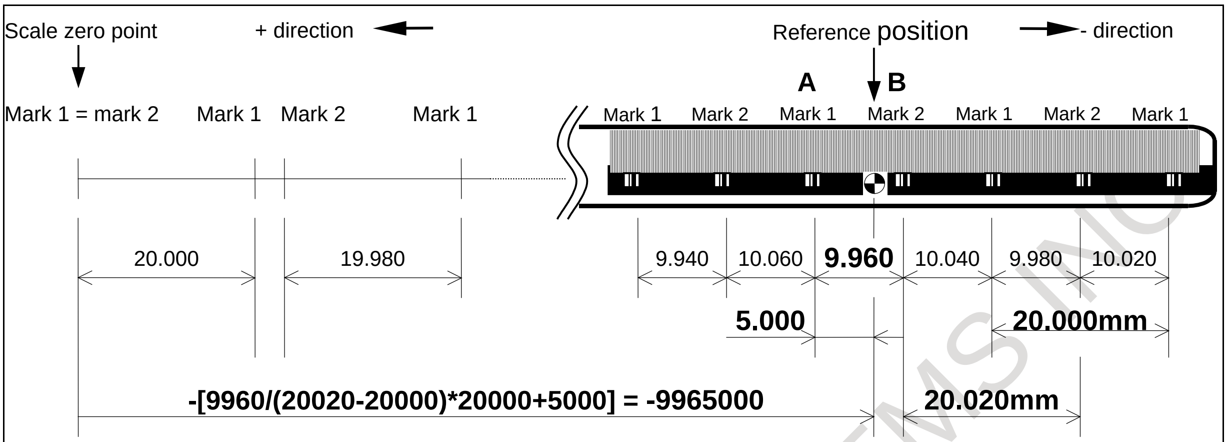
The scale zero point represents a point where mark 1 and mark 2 match. Usually, this point is a virtual point that does not physically exist on the scale. (See the following figure.)

If the reference position is placed in the + direction when viewed from the scale zero point, set a positive value. If the reference position is placed in the - direction when viewed from the scale zero point, set a negative value.



[Example of parameter settings]

When an encoder as shown the following figure is used with an IS-B, millimeter machine:



Parameters

No.1821 (interval of mark 1) = 20000
No.1882 (interval of mark 2) = 20020
No.1883 (reference position) = position of point A + 5.000
= distance between A and B/(mark 2 – mark 1) × mark 1 + 5000
= 9960/(20020-20000) × 20000 + 5000
= 9965000
= -9965000 (the reference position is on the negative side)

[Setting parameter No. 1883]

When it is difficult to measure the distance from the scale zero point to the reference position (parameter No. 1883), the method described below can be used to find the distance.

<1> Set parameter No. 1815 to enable this function.
Set an appropriate value in parameter No. 1821 and No. 1882.
Parameter No. 1240 is set to 0.
Parameters Nos. 1883 and 1884 are set to 0.
<2> At an appropriate position, establish a reference position.
(As a result, the machine coordinate represents the distance from the scale zero point to the current position.)
<3> By jog feed or handle feed, place the machine at the accurate reference position.
<4> In parameter No. 1883, set the machine coordinate of that time converted to the detection unit (machine coordinate × CMR).
<5> If necessary, set parameter No. 1240.

NOTE

1 Set parameter Nos. 1883 and 1884 so that the distance from the scale zero point to the reference position is within the range from -999,999,999,999 to +999,999,999,999. If a value beyond this range is set, an alarm DS1448, "ILLEGAL PARAMETER (D.C.S.)", is issued.
2 The scale area on the scale cannot be extended across the scale zero point. Make parameter settings not to cause the scale area to extend beyond the scale zero point.

Alarm and message

Number	Message	Description
PS5220	REFERENCE POINT ADJUSTMENT MODE	In case of distance coded linear scale I/F, the reference point auto setting bit 2 (DATx) of parameter No. 1819 is set to 1. Move the machine to reference position by manual operation and execute manual reference return.
SV1051	ILLEGAL SYNCHRONOUS AXIS	In axis synchronous control, the parameter setting for the axis for which distance coded linear scale I/F is used, is incorrect. Set the following parameters to the same values for the master axis and slave axis. - Parameter No. 1821 (mark-1 interval) - Parameter No. 1882 (mark-2 interval) - Bit 2 (DC2x) and Bit 1 (DC4x) of parameter No.1802 (the number of marks)
DS0020	REFERENCE RETURN INCOMPLETE	An attempt was made to perform an automatic return to the reference position on the perpendicular axis before the completion of a return to the reference position on the angular axis. However, this attempt failed because a manual return to the reference position during angular axis control or an automatic return to the reference position after power-up was not commanded. First, return to the reference position on the angular axis, then return to the reference position on the perpendicular axis.
DS0026	MISMATCH OF ANGULAR AXIS(D.C.S)	On angular axis control, one of the angular/perpendicular axes is the scale with ref-pos, and the other of them is not the scale with ref-pos. Such system is not admired.
DS0027	MISMATCH OF SYNCHRONOUS AXIS(D.C.S)	- Master/slave axes of axis synchronous control, one of them is the linear scale with distance-coded reference marks, and the other of them is not the linear scale with distance-coded reference marks. Please establish reference position with the input signal SYNCn<Gn138>, SYNCJn<Gn140> or parameter setting to 0. - The slave axis of the axis synchronous control is two or more settings. Such system is not admired.
DS1448	ILLEGAL PARAMETER (D.C.S.)	The setting value of parameter for distance coded linear scale I/F is satisfied the following any conditions. - The absolute-position detection function is enabled. - Either parameter No. 1821 (mark-1 interval) or parameter 1882 (mark-2 interval) is set to 0. - Parameters Nos. 1821 and 1882 have identical settings. - The difference between the settings made for parameters Nos. 1821 and 1882 is greater than or equal to twice either setting. - The setting value of parameters 1883 and 1884 are over the valid data range. - In case of Rotary axis (B type), the values other than 0 are set to the parameter No.1868 and No.1869 or bit 0 (RVSx) of parameter No.1815 is set to 1.
DS1449	REFERENCE MARK ARE DIFFERENT FROM PARAMETER	In case of distance coded linear scale I/F, the actual interval of reference marks is different from setting value in parameters Nos. 1821 and 1882.

Diagnosis data

[Data type] 2-word axis
[Unit of data] Detection unit
[Valid data range] -999 to 999

Scale counter value of the reference marks of distance coded linear scale = diagnosis data No.3551 × 1,000,000,000 + diagnosis data No.3550

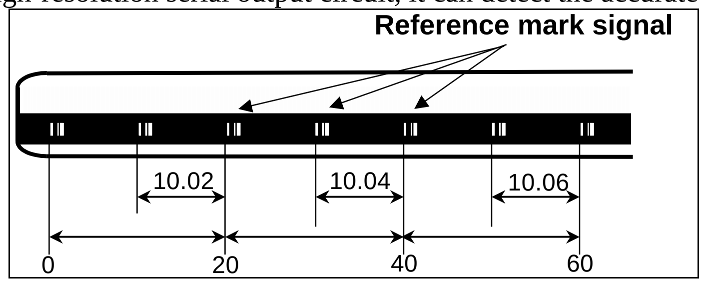
4.9 LINEAR SCALE WITH DISTANCE-CODED REFERENCE MARKS (SERIAL)

Overview

By using High-resolution serial output circuit for the linear scale with distance-coded reference marks (serial), the CNC measures the interval of referenced mark by axis moving of short distance and determines the absolute position.
This function enables high-speed high-precision detection by using High-resolution serial output circuit.
It is available that using maximum stroke 30 meters length.

Explanation

The linear scale with distance-coded reference marks (serial) is combined the irregular reference marked linear scale with the High-resolution serial output circuit, it can detect the accurate position.



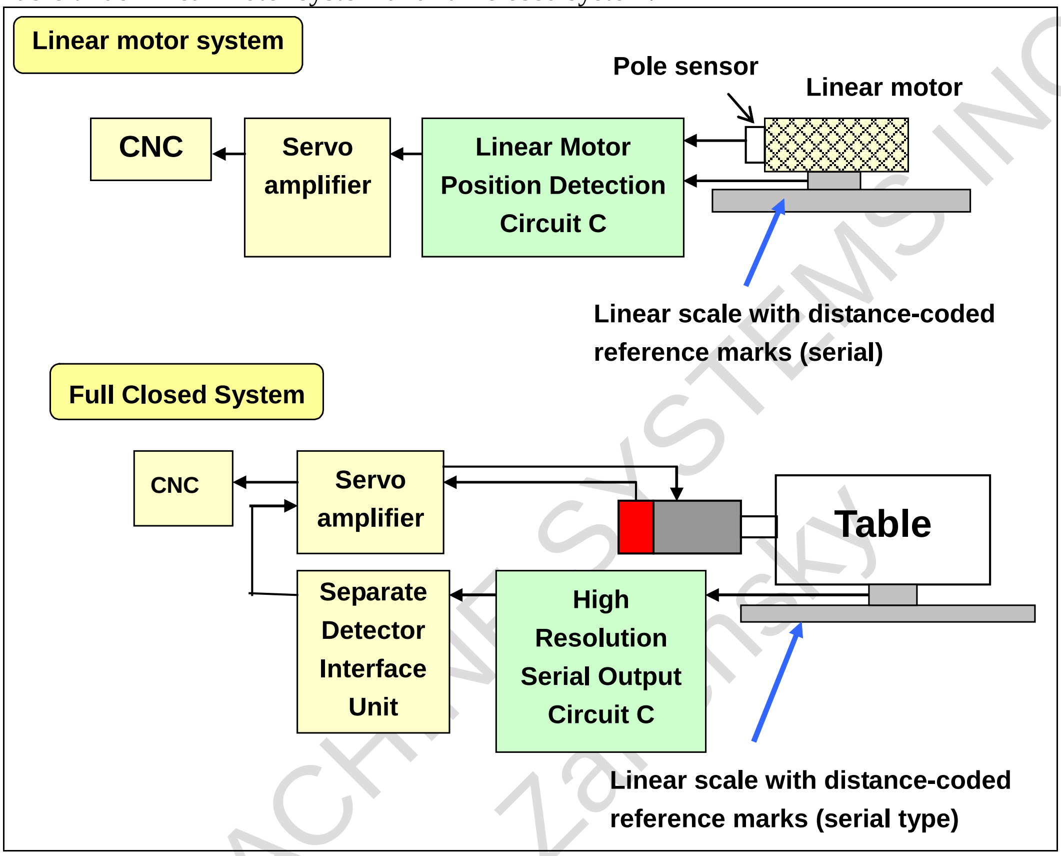
The CNC measures the interval of referenced mark by axis moving of short distance and determines the absolute position, because of the interval of each reference mark is different with regular interval.

It is not necessary that the axis is moved to the reference position for establishment of reference position.

This function enables high-speed high-precision detection by using High-resolution serial output circuit. It is available that using maximum stroke 30 meters length.

- Connection

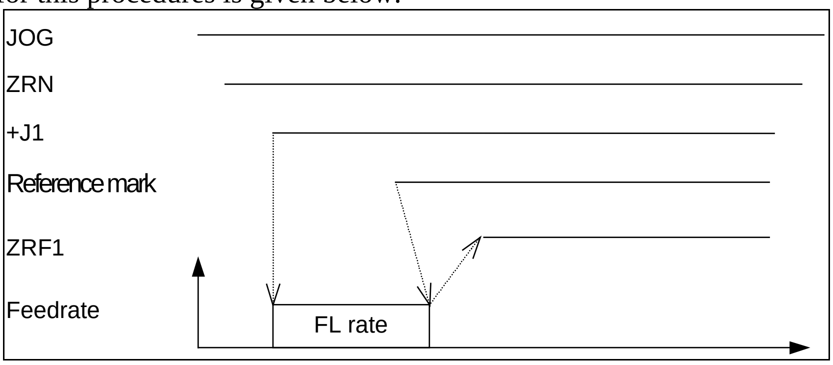
It is available under linear motor system and full closed system.



- Procedure for reference position establishment through manual operation

(1) Select the JOG mode, and set the manual reference position return selection signal ZRN to "1".
(2) Set the feed axis and direction selection signal (+J1, -J1, +J2, -J2, …) of a target axis to "1" and feed toward the reference position.
(3) The axis is fed at a constant low speed (reference position return FL feedrate specified by parameter No.1425 setting).
(4) When the absolute position of linear scale with distance-coded reference marks (serial) is detected, the axis stops. Then the absolute position of CNC is calculated and the reference position establishment signal (ZRF1, ZRF2, ZRF3, …) turns to "1".

The timing chart for this procedures is given below.



- Procedure for reference position establishment through automatic operation

If an automatic reference position return (G28) is specified before a reference position is not established, steps (3) to (4) above are performed automatically.
After the reference position is established, the automatic reference position return is performed by setting of bit 0 (RFS) of parameter No. 1818.

- Stopping the operation for establishing a reference position

The operation for establishing a reference position is stopped if any of the following operations is performed in steps (3) to (4), described above.

- Reset
- Setting the feed axis and direction selection signal (+J1, -J1, +J2, -J2, etc.) to "0"
- Setting the Servo off signals (SVF1, SVF2, etc.) to "1"

If any of the following operations is performed during the operation of automatic reference position return (G28) before a reference position is not established, the operation for establishing a reference position stops:

- Reset
- Performing feed hold during movement from an intermediate position to the reference position
- Setting the Servo off signals (SVF1, SVF2, etc.) to "1"

If the operation for establishing a reference position is stopped by an operation other than a reset, the operation for establishing a reference position must be reset and resumed.

- Establishing a reference position and moving to the reference position

By following operation, establishing a reference position and moving to the reference position is performed.

	Moving through manual operation in REF mode	Moving through automatic operation by automatic reference position return (G28)
The reference position is not established.	Establishing the reference position	Firstly, moving to the intermediate position, and establishing the reference position. Secondly, whether moving to the reference position or not is performed by setting bit 0 (RFS) of parameter No.1818.
The reference position is established.	Moving to the reference position	Whether moving to the intermediate position and the reference position or not is performed by setting bit 1 (RF2) of parameter No.1818.

- Axis synchronous control

In case of using the axis synchronous control, please confirm the following items.

- When this function is used with axis synchronous control axes, the linear scale with distance-coded reference marks (serial) used for the master axis and that used for the slave axis must have reference marks placed at identical intervals.
- The linear scale with distance-coded reference marks (serial) can be installed on the master and slave axes either in the same or opposite direction.
- To the axis parameters, which relate to this function (except No.1883, No.1884) (distance from the scale zero point to reference position), the same value must be set for the master axis and for the slave axis.
- The linear scale with distance-coded reference marks (serial) should be applied for the master axis and the slave axis.
  If either of the master axis or the slave axis is not the linear scale with distance-coded reference marks (serial), alarm DS0018, "SERIAL DCL:MISMATCH (SSYNC CTRL)", occurs when reference position establishment is tried by the axis synchronous control.
- During operating the establishment of reference position, the state of synchronous control axis selection signals (SYNCn<Gn138> or SYNCJn<Gn140>) should be kept.

Both of synchronous axes (master axis and slave axis) are fed on the reference position return FL feedrate until distance coded scales of both axes detect the absolute position.
Then absolute position of both axes are calculated and the reference position establishment signal (ZRF1, ZRF2, ...) turn to "1".

> **NOTE**
> When this function is used by the axis synchronous control, only one axis is available for the slave axis.

- Angular axis control

In case of using the angular axis control, please confirm the following items.

- It is necessary to use the linear scale with distance-coded reference marks (serial) for both the perpendicular axis and the angular axis.
  If not, the alarm DS0019, "2SERIAL DCL:MISMATCH(ANGL-AXIS)", occurs when reference position establishment is commanded.
- Please set so that whenever the reference position establishment of angular axes is tried, perpendicular axes are fed (bit 2 (AZR) of parameter No. 8200 to 0 and input signal NOZAGC <G063.5> to "0").
  If not, the alarm DS0019 occurs when reference position establishment is commanded.
- When the reference point of the perpendicular axis is established, it is necessary to establish the reference point of the angular axis previously. When the perpendicular axis is commanded previously or the perpendicular axis and the angular axis are commanded simultaneously, the alarm DS0020, "REFERENCE RETURN INCOMPLETE", occurs.
- On angular axis control, if you use automatic setting of parameter Nos.1883 and 1884 on reference position establishment (bit 2 (DATx) of parameter No.1819=1) for both the perpendicular axis and the angular axis, please establish reference point of perpendicular axis after reference position auto establishment and return of angular axis.

In manual reference position return, the perpendicular axis cannot be specified while the angular axis reference point is being established. The perpendicular axis, if specified, is ignored.

Parameters

	#7	#6	#5	#4	#3	#2	#1	#0
1815						DCLx	OPTx	

[Input type] Parameter input
[Data type] Bit axis

> **NOTE**
> When at least one of these parameters is set, the power must be turned off before operation is continued.

#1 OPTx The separate position detector is:
0: Not to be used (semi-closed system)
1: To be used (full-closed system)

> **NOTE**
> Set this parameter to 1 when using a linear scale with distance-coded reference marks (serial) (full-closed system).

#2 DCLx As a separate position detector, a linear scale with reference marks or a linear scale with an absolute address zero point is:
0: Not used.

1: Used.

	#7	#6	#5	#4	#3	#2	#1	#0
1818					SDCx		RF2x	RFSx

[Input type] Parameter input
[Data type] Bit axis

#0 RFSx If G28 is specified for an axis for which a reference position is not established (ZRF = 0) when a linear scale with an absolute address zero point is used:
0: A movement is made to the reference position after reference position establishment operation.
1: No movement is made after reference position establishment operation, but the operation is completed.

> **NOTE**
> This parameter disables movement based on the G28 command to a reference position. So, use this parameter only in special cases.

#1 RF2x If G28 is specified for an axis for which a reference position is already established (ZRF = 1) when a linear scale with an absolute address zero point is used:
0: A movement is made to the reference position.
1: No movement is made to the intermediate position and reference position, but the operation is completed.

> **NOTE**
> This parameter disables movement based on the G28 command to a reference position. So, use this parameter only in special cases.

#3 SDCx A linear scale with an absolute address zero point is:
0: Not used.
1: Used.

> **NOTE**
> 1 When the parameter SDCx is set, the power must be turned off before operation is continued. Alarm PW0000, “POWER MUST BE OFF ” does not occur.
> 2 Please set bit 1 (SDC) of parameter No. 1815 to 1 when the full closed system. But please set this parameter to 0 when the Linear motor system.

	#7	#6	#5	#4	#3	#2	#1	#0
1819						DATx		

[Input type] Parameter input
[Data type] Bit axis

#2 DATx The automatic setting of parameters Nos. 1883 and 1884 at manual reference position return time is:
0: Not performed.
1: Performed.

The automatic setting procedure is as follows:
<1> Set an appropriate value in parameters Nos. 1815, 1821, and 1882.
(In case of the linear scale with distance-coded reference marks (serial), it is not necessary to set the parameter No.1882.)
<2> Position the machine at the reference position by manual operation.
<3> Set this parameter to 1.
Alarm PS5220, "REFERENCE POINT ADJUSTMENT MODE", occurs.
<4> Perform a manual reference position return operation. Upon completion of manual reference position return operation, parameters Nos. 1883 and 1884 are set, and this parameter is automatically set to 0.
Make a reset to release alarm PS5220.

1883	Distance 1 from the base point to reference position

NOTE
When this parameter is set, the power must be turned off before operation is continued.

[Input type] Parameter input
[Data type] 2-word axis
[Unit of data] Detection unit
[Valid data range] -999999999 to 999999999

1884	Distance 2 from the base point to reference position

NOTE
When this parameter is set, the power must be turned off before operation is continued.

[Input type] Parameter input
[Data type] 2-word axis
[Unit of data] Detection unit
[Valid data range] -999 to 999
Set the distance from the base point to the reference position in parameter Nos. 1883 and 1884. The base point is a point at a scale end as shown Fig. 4.9 (a).

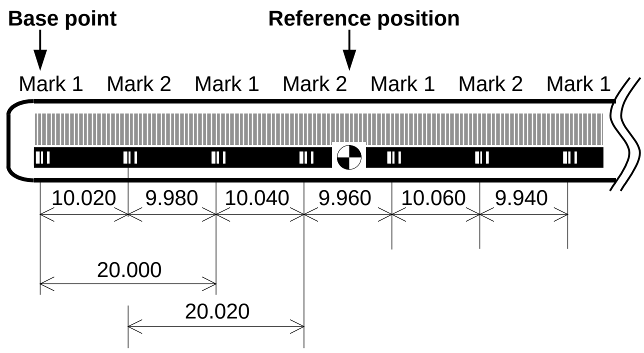


Fig. 4.9 (a)

If the reference position is located in the positive direction when viewed from the base point, set a positive value; if the reference position is located in the negative direction, set a negative value. Set the value by following the steps explained below.

<1> Set bit 1 (OPT) of parameter No. 1815 , bit 2 (DCL) of parameter No. 1815, and bit 3 (SDC) of parameter No. 1818 to enable this function.
Set 0 in parameter No. 1240.
Set 0 in parameter Nos. 1883 and 1884.
<2> At an appropriate position, establish a reference position.
(Consequently, the machine coordinate value indicates the distance from the base point to current position.)
<3> By jog feed or handle feed, place the machine at the accurate reference position.
<4> In parameters Nos. 1883 and 1884, set the machine coordinate of that time converted to the detection unit (machine coordinate × CMR).

If necessary, set parameter No. 1240.

NOTE
1. Set parameter Nos. 1883 and 1884 so that the distance from the base point to the reference position is within the range from -999,999,999,999 to +999,999,999,999. If a value beyond this range is set, an alarm DS0016, "SERIAL DCL:FOLLOW-UP ERROR", is issued.
2. The scale area on the scale cannot be extended across the base point. Make parameter settings not to cause the scale area to extend beyond the base point.

14010	Maximum allowable travel distance when the reference position is established for a linear scale with an absolute address reference position

[Input type] Parameter input
[Data type] 2-word axis
[Unit of data] Detection unit
[Valid data range] 0 to 99999999

This parameter sets the maximum allowable travel distance at the FL rate when the reference position is established for a linear scale with an absolute address reference position. When the travel distance exceeds the setting of this parameter, the alarm DS0017, “SERIAL DCL:REF-POS ESTABLISH ERR” is issued. When this parameter is set to 0, the maximum allowable travel distance is not checked.

NOTE
1. To establish the reference position with axis synchronous control, set the parameter for both master and slave axes.
2. In angular axis control, the setting of this parameter is invalid to the orthogonal axis where the reference position on the angular axis is being established.

Alarm and message

No.	Message	Description
PS0372	REFERENCE RETURN INCOMPLETE	An attempt was made to perform an automatic return to the reference position on the orthogonal axis before the completion of a return to the reference position on the angular axis. However, this attempt failed because a manual return to the reference position during angular axis control or an automatic return to the reference position after power-up was not commanded. First, return to the reference position on the angular axis, then return to the reference position on the orthogonal axis.

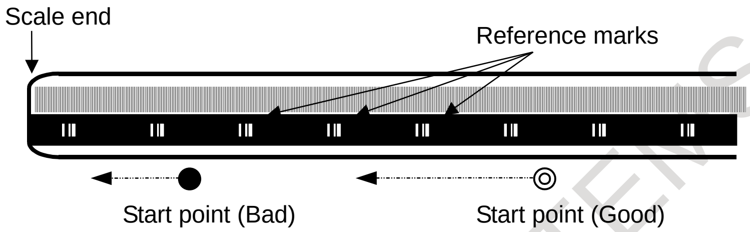
No.	Message	Description
PS0376	SERIAL DCL: ILLEGAL PARAMETER	1. When bit 1 (OPTx) of parameter No. 1815 is set to 1, bit 3 (PFSE) of parameter No. 2002 is set to 0 2. The absolute-position detection function is enabled. (Bit 5 (APCx) of parameter No. 1815 is set to 1.)
PS5220	REFERENCE POINT ADJUSTMENT MODE	In case of distance coded linear scale I/F, the reference point auto setting bit 2 (DATx) of parameter No. 1819 is set to 1. Move the machine to reference position by manual operation and execute manual reference return.
DS0016	SERIAL DCL:FOLLOW-UP ERROR	1. The specification of parameter No. 1883 or 1884 is out of range. 2. During the establishment of an origin, the distance between the current position and the reference position (detection unit) exceeded ±2147483647. To avoid this situation, modify either the current position or the reference position.
DS0017	SERIAL DCL:REF-POS ESTABLISH ERR	During the establishment of an origin, the amount of travel at the FL feedrate exceeded the setting of parameter No. 14010.
DS0018	SERIAL DCL:MISMATCH (SSYNC CTRL)	Master/slave axes of axis synchronous control, one of them is the linear scale with distance-coded reference marks (serial) and the other of them is not the linear scale with distance-coded reference marks (serial). Please establish reference position with the input signal SYNCn<G138>, SYNCJn<G140> or bit 5 (SCA) of parameter No. 8304 setting to 0.
DS0019	SERIAL DCL:MISMATCH(ANGL-AXIS)	On angular axis control, one of the angular/perpendicular axes is the scale with ref-pos, and the other of them is not the scale with ref-pos. Such system is not admired.
DS0020	REFERENCE RETURN INCOMPLETE	An attempt was made to perform an automatic return to the reference position on the orthogonal axis before the completion of a return to the reference position on the angular axis. However, this attempt failed because a manual return to the reference position during angular axis control or an automatic return to the reference position after power-up was not commanded. First, return to the reference position on the angular axis, then return to the reference position on the orthogonal axis.
SV0366	PULSE MISS(INT)	A pulse error occurred on the built-in Pulsecoder.
SV0367	COUNT MISS(INT)	A count error occurred on the built-in Pulsecoder.
SV0382	COUNT MISS(EXT)	A count error occurred on the separate detector.
SV0383	PULSE MISS(EXT)	A pulse error occurred on the separate detector.

Caution

> ⚠ **CAUTION**
> 1 When the Linear scale with distance-coded reference marks (serial) is used, set bit 3 (SDCx) of parameter No. 1818 of the corresponding axis to 1.

⚠ CAUTION

2. On the Linear scale with distance-coded reference marks (serial), the axis does not stop until three reference marks are detected. If this procedure is started at the position near the scale end, CNC can not detect three reference marks and the axis does not stop until over travel alarm occurs. Please care to start at the position that has enough distance from scale end.
   And if establishment of reference position is failed, the establishment is retried. Then axis does not stop until still more three reference marks are detected. So set the maximum move amount (detection unit: parameter No.14010) not to reach the scale end.



3. On flexible synchronization mode, reference position can't be established.
4. In case that straightness compensation function is used, the movement is explained below.
   When the reference position establishment of moving axis is executed after the establishment of compensation axis after power on, the compensation axis is moved by straightness compensation amount when the reference point of moving axis is established.
5. It is not available to use this function and the temporary absolute coordinate setting together.
6. This function cannot be used together with synchronous control, composite control, and superimposed control.
7. When the axis used this function, the following function can not be used.
   - Absolute position detection

4.10 EXTENDED FUNCTION OF THE DISTANCE CODED LINEAR SCALE INTERFACE

Overview

The distance coded linear scale interface has reference marks at intervals that change at a constant rate. By determining the reference mark interval, the corresponding absolute position can be deduced. When a G00 command or a move command in jog feed is specified for an axis for which the distance coded linear scale interface is used, this function establishes the reference position by measuring the reference mark intervals automatically. Therefore, after CNC power-up, the reference position can be established without performing reference position return operation.

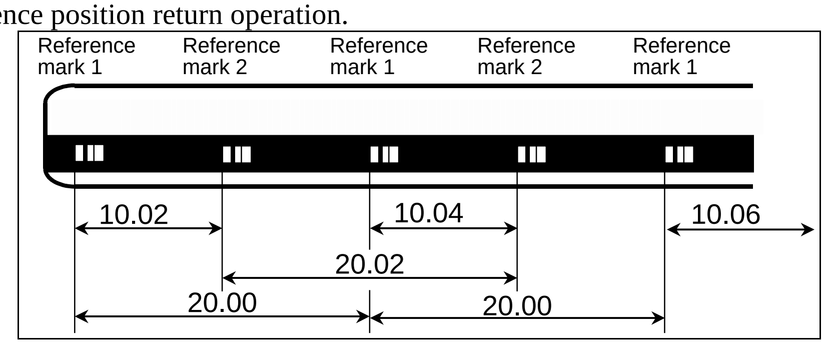


Fig. 4.10 (a) Sample distance coded linear scale interface

To use this function, the distance coded linear scale interface is also required.

4.10.1 Reference Position Established by the G00 Command

Explanation

- Activation conditions

When the following conditions are satisfied, reference position establishment operation is performed automatically:

<1> A G00 command is specified to cause a movement along an axis for which no reference position has been established.

<2> The movement direction in <1> above matches the reference position return direction set by bit 5 (ZMI) of parameter No. 1006.

<3> The specified axis is not in the following modes:

- 3-dimensional coordinate conversion
- Coordinate system rotation
- Mirror image (mirror image by signal or setting)
- Programmable mirror image
- Scaling (M series)
- AI contour control mode
- Mirror image of facing tool posts

> **NOTE**
> If all the above conditions are not satisfied, the reference position establishment operation is not performed, and normal G00 command operation is performed.

- Operation

The reference position establishment procedure is explained below.

<1> The tool is fed along a specified axis at the reference position return FL feedrate (parameter No. 1425).

<2> Upon detection of a reference mark on the scale, the tool is stopped briefly then fed at the reference position return FL feedrate.

<3> Step <2> above is repeated until two, three, or four reference marks are detected on the scale. Then, the reference position is established, and the reference position establishment signal (ZRF1, ZRF2, ZRF3, etc.) is set to "1".

<4> The tool is fed to a specified end point at a rapid traverse rate.

A time chart for the above procedure is shown below.

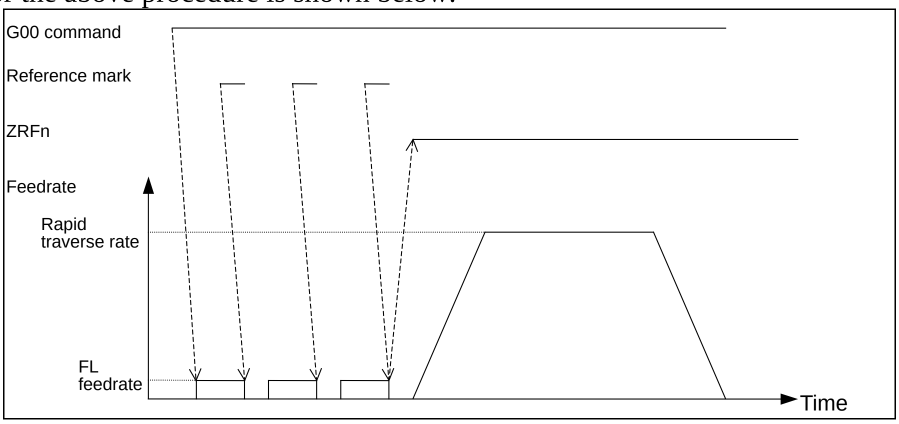

Fig. 4.10.1 (a) Time chart for reference position establishment (G00)

The specifications for the steps of detecting reference marks and establishing the reference position (steps <1> to <3> above) are the same as for the conventional distance coded linear scale interface. The restrictions are also the same.
For details, refer to " Linear scale with distance-coded reference marks (serial)."

- Tool path

The tool path in the G00 command is explained below.

(1) When no axis requires the reference position establishment When the reference position has already been established for all specified axes, the reference position establishment operation is not performed.
For example, suppose that the reference position is already established for the X-, Y-, and Z-axes, and that G00 Xxx Yyy Zzz; is specified. Then, normal rapid traverse operation takes place. The tool path follows the setting in bit 1 (LRP) of parameter No. 1401.

(2) When all axes require the reference position establishment operation
Suppose that the reference position is not established for the X-, Y-, and Z-axes and that G00 Xxx Yyy Zzz; is specified. The operation in this case is shown in the Fig. 4.10.1 (b).
Operation 1 in the figure establishes the reference position. During the establishment operation, the tool path is always of the non-linear interpolation type regardless of the setting in bit 1 (LRP) of parameter No. 1401.
Operation 2 performs positioning to a specified end point. During this operation, the tool path follows the setting in bit 1 (LRP) of parameter No. 1401.
After operation 1 is completed for all axes, operation 2 starts.

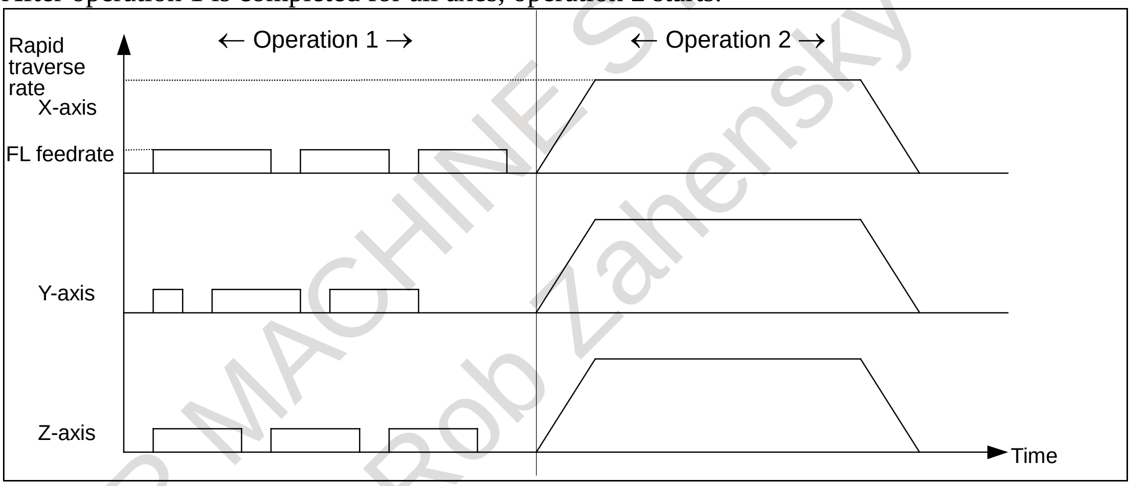

Fig. 4.10.1 (b) When the reference position is established for all axes

(3) When some axes require the reference position establishment operation and others do not require the establishment operation
For example, suppose that the reference position is already established for the X-axis and that the reference position is not yet established for the Y- and Z-axes. Also suppose that G00 Xxx Yyy Zzz; is specified. The operation in this case is shown in the Fig. 4.10.1 (c).
In operation 1 in the figure, movement to a specified position is made along the X-axis for which the reference position is already established. For the Y- and Z-axes for which no reference position is established, the reference position is established. During the establishment operation, the tool path is always of the non-linear interpolation type regardless of the setting in bit 1 (LRP) of parameter No. 1401.
In operation 2, positioning to a specified end point is performed along the Y- and Z-axes. The tool path along the Y- and Z-axes then follows the setting in bit 1 (LRP) of parameter No. 1401. Because positioning to the specified position is already made along the X-axis, no movement is made along the X-axis.
After operation 1 is completed for all axes, operation 2 starts.

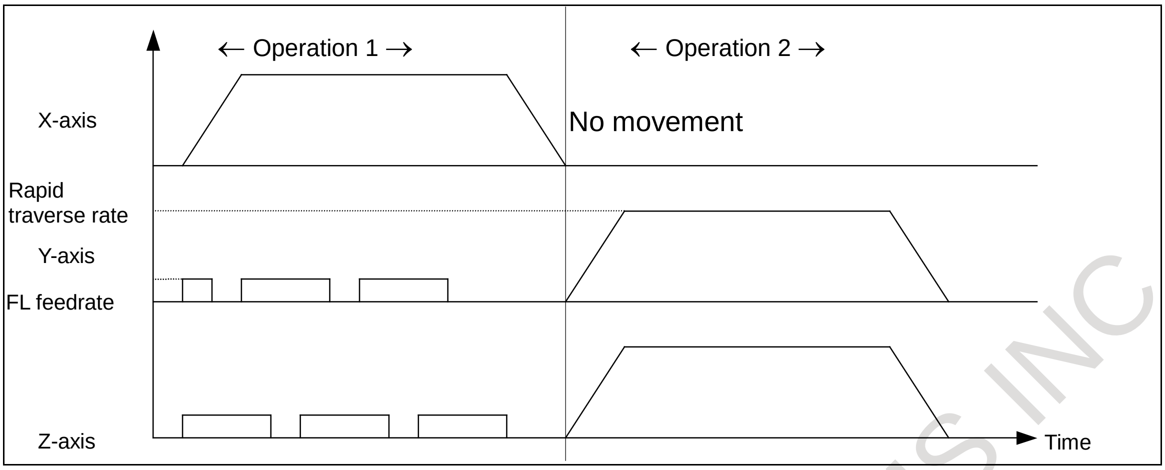

Fig. 4.10.1 (c) When an axis does not require the reference position establishment operation and others require the establishment operation

- Absolute command and incremental command

After the reference position has been established, positioning to a specified end point is performed. This operation is explained below.

(1) When an absolute command is specified
Movement to the end point in the new coordinate system that has been established in step <3> is made. For example, when G90 G00 Xxx.Yyy.; is specified, the tool moves as indicated with the bold line in the Fig. 4.10.1 (d). Note that, however, the figure shows the positional relationship among points and that the intermediate tool path is not always of the linear interpolation type.

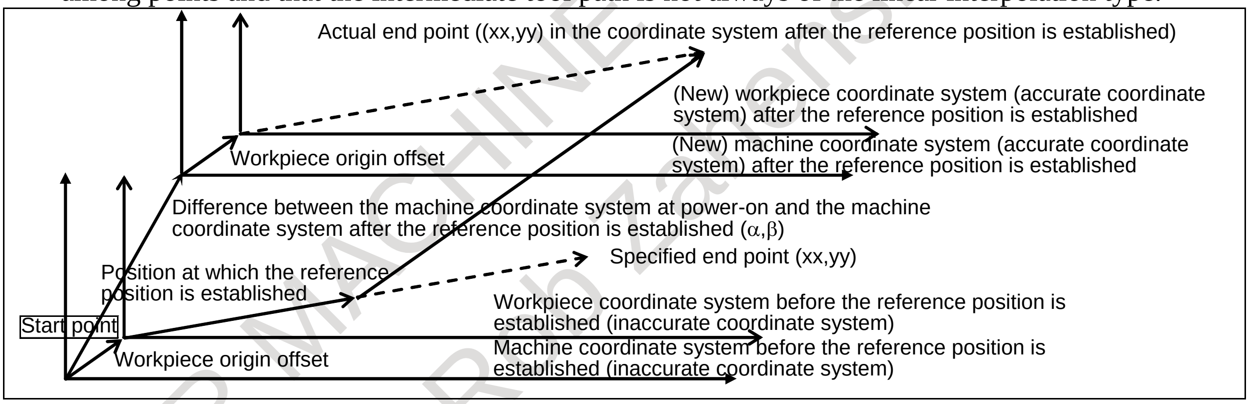

Fig. 4.10.1 (d) Operation when an absolute command is specified

(2) When an incremental command is specified
Movement is made along each axis by a specified distance. (The movement is indicated with the bold line in the Fig. 4.10.1 (e). Note that the intermediate tool path is not always of the linear interpolation type.) The coordinates at the end point are those in a newly established coordinate system. When there is a difference (α, β) between the newly established coordinate system and the old coordinate system, the coordinates at the end point are shifted by (α, β). For example, when G91 G00 X100.0Y30.0; is specified from the position of which absolute coordinates are (0,0), the distance of movement along each axis is (100,30), and the coordinates of the end point are (100-α, 30-β).

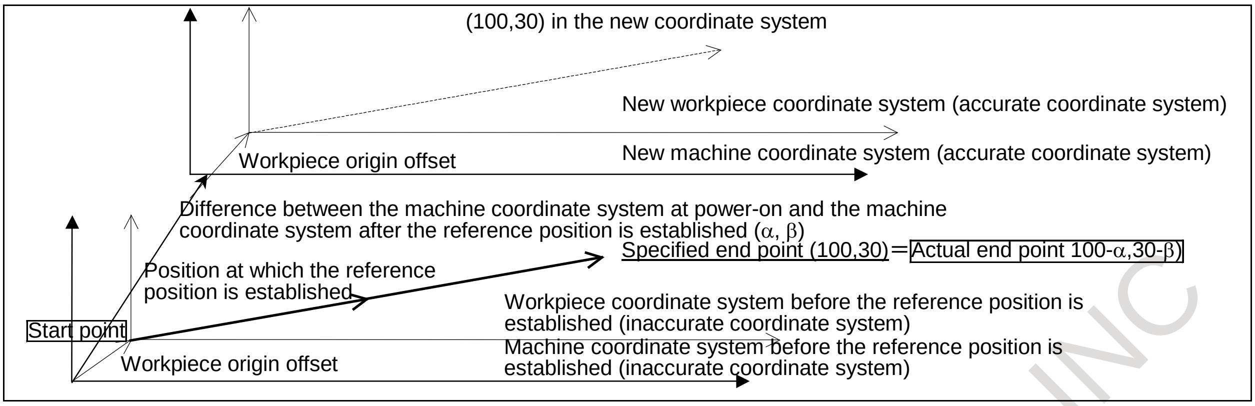

Fig. 4.10.1 (e) Operation when an incremental command is specified

- When a short distance is specified

When a short distance is specified, the end point can be reached before two, three, or four reference marks are passed. Even in such a case, the CNC makes a movement at the FL feedrate while detecting reference marks, but the CNC does not establish the reference position even when the end point is reached.
If the reference position is not established, the next G00 command causes the reference position establishment operation again. The CNC does not use data on the reference marks detected through the previous movement and detects three or four reference marks again to establish the reference position.

- Interruption by feed hold

When a feed hold has been applied during reference position establishment operation, the reference position establishment operation is not performed after execution is restarted. After the restart, non-linear interpolation type positioning is performed. In this block, the reference position is not established, so reference position establishment operation is performed again when the next G00 command is specified.

- Interruption by reset or emergency stop

When a reset or emergency stop is applied during reference position establishment operation, the reference position establishment operation is interrupted. Since the reference position is not established, reference position establishment operation is performed again when the next G00 command is specified.

- When an illegal reference mark interval is detected

If a correct reference mark interval cannot be detected for a cause, the tool is positioned to the end point without establishing the reference position. Therefore, the machine position, absolute coordinates, and machine coordinates of the end point are set as if a G00 command without reference position establishment operation were executed. However, the intermediate tool path is different from the tool path obtained by executing the G00 command.
Since the reference position is not established, reference position establishment operation is performed again when the next G00 command is specified.
Even when the CNC detects an illegal reference mark interval, it does not issue the alarm DS1449 "REFERENCE MARK ARE DIFFERENT FROM PARAMETER".

4.10.2 Reference Position Establishment by Jog Feed

Explanation

- Activation condition

If the following conditions are satisfied, reference position establishment operation is performed automatically:

<1> For an axis for which no reference position has been established, feed axis and direction selection signal +Jn or -Jn <G100, G102> is input in jog mode.

<2> The move direction in <1> above matches the reference position return direction set by bit 5 (ZMI) of parameter No. 1006.

<3> The specified axis is not in the following modes:
- 3-dimensional coordinate conversion
- Mirror image (mirror image by signal or setting)

> **NOTE**
> If all the above conditions are not satisfied, reference position establishment operation is not performed, and the same operation as normal jog feed is performed.

- Operation

The reference position establishment procedure is explained below.

<1> A movement on the specified axis starts at the FL feedrate of reference position return (parameter No.1425).

<2> Upon detection of a reference mark on the scale, the tool is stopped briefly then fed at the reference position return FL feedrate.

<3> Step <2> above is repeated until two, three, or four reference marks are detected on the scale. Then, the reference position is established, and the reference position established establishment signal (ZRF1, ZRF2, ZRF3, etc.) is set to "1".

<4> The tool is fed in the direction selected by the feed axis direction selection signal at the jog feedrate.

When the feed axis and direction selection signal is set to "0" during steps <2> to <4>, feed operation stops. When the feed axis direction selection signal is set to "1" again, the reference position is established. A time chart for the above procedure is shown below.

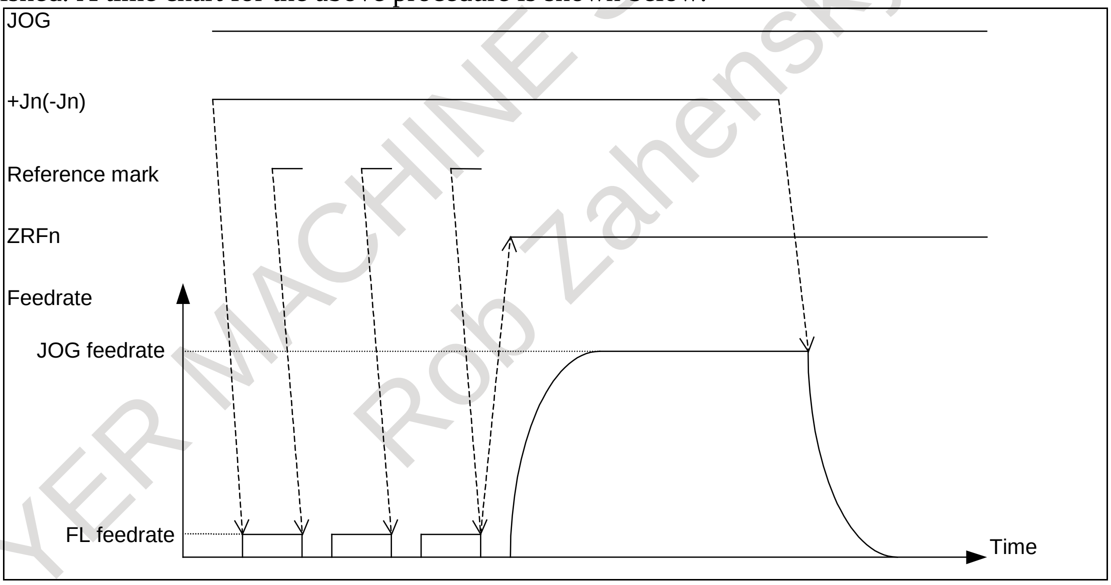

Fig. 4.10.2 (a) Time chart for reference position establishment (jog feed)

- Interruption by the feed axis and direction selection signal

If the feed axis and direction selection signal +Jn (-Jn) is set to "0" during reference position establishment, the reference position establishment operation is interrupted. In this case, data on the reference marks detected through the previous movement is not used for the next reference establishment operation. When the feed axis and direction selection signal +Jn (-Jn) is set to "1" again, the reference position establishment operation is resumed, and the reference position is established after two, three, or four reference marks are detected.

- Interruption by reset or emergency stop

When a reset or emergency stop is applied during reference position establishment operation, axis movement stops, and the reference position establishment operation is interrupted. In this case, data on the reference marks detected through the previous movement is not used for the next reference establishment operation. When the feed axis and direction selection signal +Jn (-Jn) is set to "1" again, the reference position is established after two, three, or four reference marks are detected.

Caution

- PMC axis control

The reference position establishment operation is not performed in rapid traverse (axis control command 00h) or continuous feed (axis control command 06h) under PMC axis control.

- Rapid traverse operation other than G00

In a rapid traverse operation automatically generated by a command such as canned cycle, no reference position establishment operation is carried out.

- Reference position establishment operation

This function has the same specifications as the conventional function of the distance coded linear scale interface, with regard to the operation to detect a reference mark and establish a reference position. The parameter setting, limitation, and the like are also the same.
For details, refer to " Linear scale with distance-coded reference marks (serial)."

Parameter

	#7	#6	#5	#4	#3	#2	#1	#0
1802						DC2x	DC4x	

[Input type] Parameter input
[Data type] Bit axis

#1 DC4x When the reference position is established on the linear scale with reference marks:
0: An absolute position is established by detecting three reference marks.
1: An absolute position is established by detecting four reference marks.

#2 DC2x Reference position establishment operation for a linear scale with reference marks is performed as follows:
0: The setting of bit 1 (DC4) of parameter No. 1802 is followed.
1: An absolute position is established by detecting two reference marks.

> **NOTE**
> 1 When this parameter is set to 1, specify the direction of the scale zero point by setting bit 4 (SCP) of parameter No. 1817.
> 2 When a rotary encoder with absolute address reference marks is used, this parameter is invalid. Even when this parameter is set to 1, the setting of bit 1 (DC4) of parameter No. 1802 is followed.

	#7	#6	#5	#4	#3	#2	#1	#0
1815						DCLx	OPTx	

[Input type] Parameter input
[Data type] Bit axis

> **NOTE**
> When at least one of these parameters is set, the power must be turned off before operation is continued.

#1 OPTx The separate position detector is:
0: Not to be used (semi-closed system)
1: To be used (full-closed system)

> **NOTE**
> Set 1 when this function is used.

#2 DCLx As a separate position detector, a linear scale with reference marks or a linear scale with an absolute address zero point is:
0: Not used.
1: Used.

> **NOTE**
> Set 1 when this function is used.

	#7	#6	#5	#4	#3	#2	#1	#0
1818						DG0		

[Input type] Parameter input
[Data type] Bit axis

#2 DG0 When the linear scale function with absolute address reference marks is used, reference position establishment operation based on the G00 command and jog feed is:
0: Disabled.
1: Enabled.

4.11 REFERENCE POSITION SIGNAL OUTPUT FUNCTION

Overview

If, after the establishment of the reference position on each axis, the coordinates in the machine coordinate system match the reference position, this function outputs a signal as the DO signal <Fn517> of the PMC.
Also, if the coordinates in the machine coordinate system match the second reference position, the function outputs a signal as the DO signal <Fn518> of the PMC.

Signal

Reference position match signals RP11 to RP18<Fn517>

[Classification] Output signal
[Function] Reports that the coordinates in the machine coordinate system match the reference position.
There is an independent one for each axis, with the last digit indicating the number of the corresponding controlled axis.
RP1x
x : 1 The machine coordinates on the first axis match the reference position.
2 The machine coordinates on the second axis match the reference position.
3 The machine coordinates on the third axis match the reference position.
: :
: :

[Output cond.] This signal becomes "1" only when, after the establishment of the reference position on each axis, the coordinates in the machine coordinate system match the reference position.

> **NOTE**
> This signal does not take the delay due to acceleration/deceleration into consideration.
> No in-position check is performed.

Second reference position match signals RP21 to RP28<Fn518>

[Classification] Output signal

[Function] Reports that the coordinates in the machine coordinate system match the second reference position.
There is an independent one for each axis, with the last digit indicating the number of the corresponding controlled axis.

RP2x

x : 1 The machine coordinates on the first axis match the second reference position.
2 The machine coordinates on the second axis match the second reference position.
3 The machine coordinates on the third axis match the second reference position.
: :
: :

[Output cond.] This signal becomes "1" only when, after the establishment of the reference position on each axis, the coordinates in the machine coordinate system match the second reference position.

> **NOTE**
> This signal does not take the delay due to acceleration/deceleration into consideration.
> No in-position check is performed.

Signal address

	#7	#6	#5	#4	#3	#2	#1	#0
Fn517	RP18	RP17	RP16	RP15	RP14	RP13	RP12	RP11
Fn518	RP28	RP27	RP26	RP25	RP24	RP23	RP22	RP21

Parameter

	#7	#6	#5	#4	#3	#2	#1	#0
1205			R2O	R1O				

[Input type] Parameter input
[Data type] Bit path

#4 R1O The output of the signal for the reference position is:
0: Disabled.
1: Enabled.

#5 R2O The output of the signal for the second reference position is:
0: Disabled.
1: Enabled.

NOTE

NOTE
1 For an axis subject to angular axis control, a signal is output in the angular coordinate system.
2 For the third/fourth reference positions and floating reference positions, no signals are output.

4.12 CORRESPONDENCE OF ROTARY SCALE WITHOUT ROTARY DATA

Overview

This manual describes how to deal with an absolute position detector (absolute pulse coder) or a scale with distance-coded reference marks (serial), when the rotary scale without rotary data is used, such as Heidenhain rotary scale RCN723 or Futaba rotary scale FRR902L3DB.
And it is required to set some servo parameters in order to use Heidenhain rotary scale RCN223, 723 and 220. In the case of using such a scale, please set servo parameters with referring to Subsection 4.14.5 “Method of using Heidenhain rotary scale RCN223, 723 and 220”.

⚠ **WARNING**
Please set the parameters that correspond to the absolute position detector which is actually used. If the parameter is not set correctly, the machine coordinates are not correctly established at power-on.

4.12.1 Setting Method by Rotary Axis Type and Movable Range

Rotary axis type	Movable range	Parameters required setting		Reference item
Rotary axis B type	Under one rotation	No.1817#3	No.1868	Subsec. 4.14.2
Rotary axis B type	Over one rotation	No.1815#0		Subsec. 4.14.3
Rotary axis A type	-	No.1815#6		Subsec. 4.14.4

See the following description for the rotary axial type.

Parameter

	#7	#6	#5	#4	#3	#2	#1	#0
1006							ROSx	ROTx

[Input type] Parameter input
[Data type] Bit axis

NOTE
When at least one of these parameters is set, the power must be turned off before operation is continued.

#0 ROTx
#1 ROSx Setting linear or rotary axis.

ROSx	ROTx	Meaning
0	0	Linear axis (1) Inch/metric conversion is done. (2) All coordinate values are linear axis type. (Is not rounded in 0 to 360°) (3) Stored pitch error compensation is linear axis type (Refer to parameter No. 3624)
0	1	Rotary axis (A type) (1) Inch/metric conversion is not done. (2) Machine coordinate values are rounded in 0 to 360°. Absolute coordinate values are rounded or not rounded by bits 0 (ROAx) and 2 (RRLx) of parameter No. 1008. (3) Stored pitch error compensation is the rotation type. (Refer to parameter No. 3624) (4) Automatic reference position return (G28, G30) is done in the reference position return direction and the move amount does not exceed one rotation.
1	1	Rotary axis (B type) (1) Inch/metric conversion is not done. (2) Machine coordinate values, absolute coordinate values and relative coordinate values are linear axis type. (Is not rounded in 0 to 360°). (3) Stored pitch error compensation is linear axis type (Refer to parameter No. 3624) (4) Cannot be used with the rotary axis roll-over function and the index table indexing function (M series)
Except for the above.		Setting is invalid (unused)

4.12.2 In the Case of a Rotary Axis B Type whose Movable Range is under One Rotation

In the case of a rotary axis B type whose movable range is under one rotation with an absolute position detector (absolute pulse coder) or a scale with distance-coded reference marks (serial), there is an uncontinuous point of scale data which is under one rotation, if a rotary scale without data (the number of rotation) is used. Then, if the scale data within the movable range of the rotary axis is continuous, it is possible to acquire the correct machine coordinate value of NC. On the other hand, if an uncontinuous point of scale data is in movable range, the machine coordinate value of NC is different from correct position.
In this function, by the bit 3 (SCRx) of parameter No.1817 and parameter No.1868, the machine coordinate value of NC become correct even if an uncontinuous point of scale data is in movable range. Therefore, it is possible to set a rotary axis B type even if there is no rotation speed data on the rotary scale on the rotary axis whose movable range is under one rotation.

Example 1

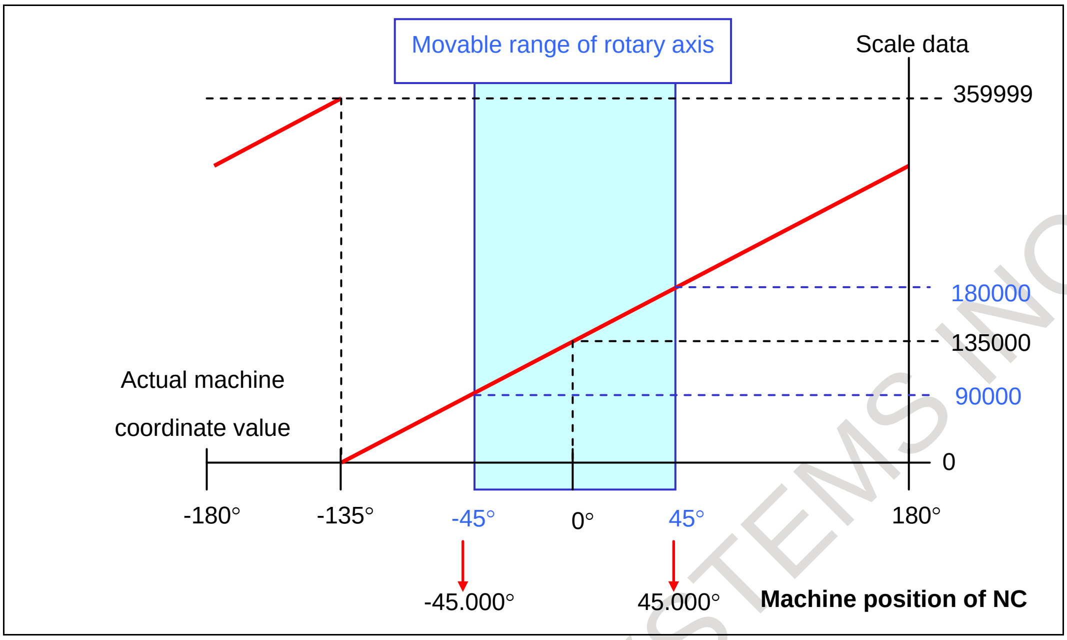

Fig. 4.12.2 (a) The case that the scale data is continuous in movable range of rotary axis

In the case of Fig. 4.12.2 (a), the scale data is continuous from 90000 to 18000.
Because the machine coordinate value of NC is shown by the following equation, (scale data when the power is turned on) - (scale data on the machine coordinate value equals 0), the machine coordinate value of NC becomes correct ones from -45.000 to 45.000.

Example 2

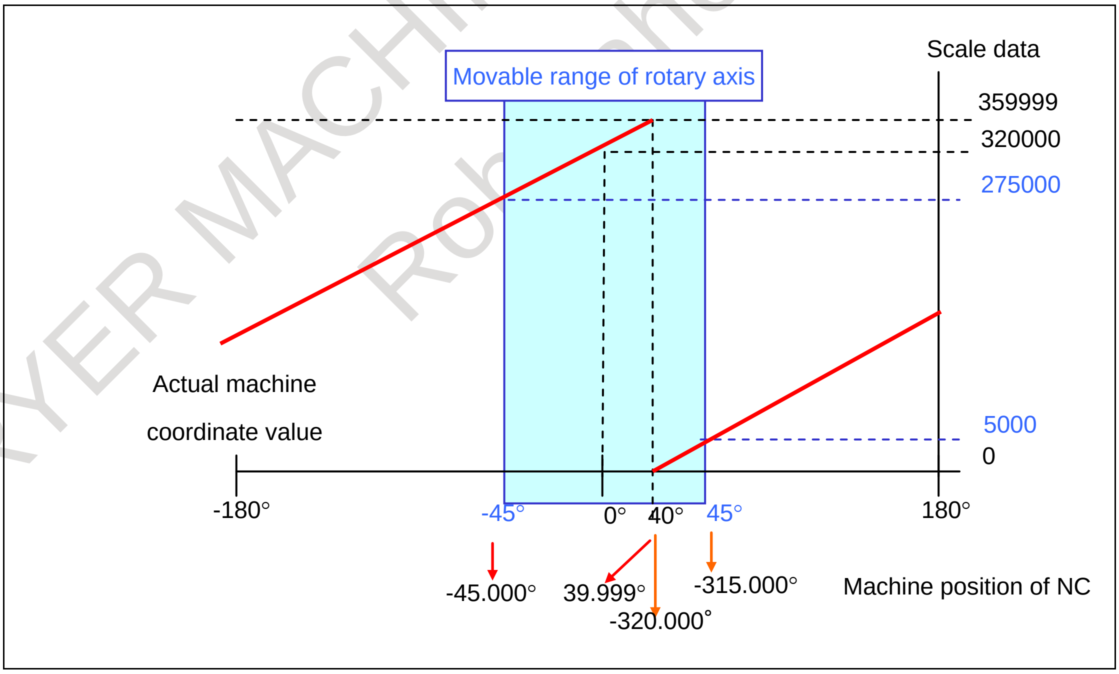

Fig. 4.12.2 (b) The case that the scale data is uncontinuous in movable range of rotary axis.

In the case of Fig. 4.12.2 (b), the scale data of movable range is uncontinuous, 275000 to 359999 and 0 to 5000, because the uncontinuous point whose machine coordinate value 40.000 exists.

Because the machine coordinate value of NC is shown by the following equation, (scale data when the power is turned on) - (scale data on the machine coordinate value equals 0),
NC shows two position ranges. One is correct ones from -45.000 to 0.000 to 39.999. And another is wrong ones from -320.000 to -315.000, which is different from correct position by 360 degree.

Example 3

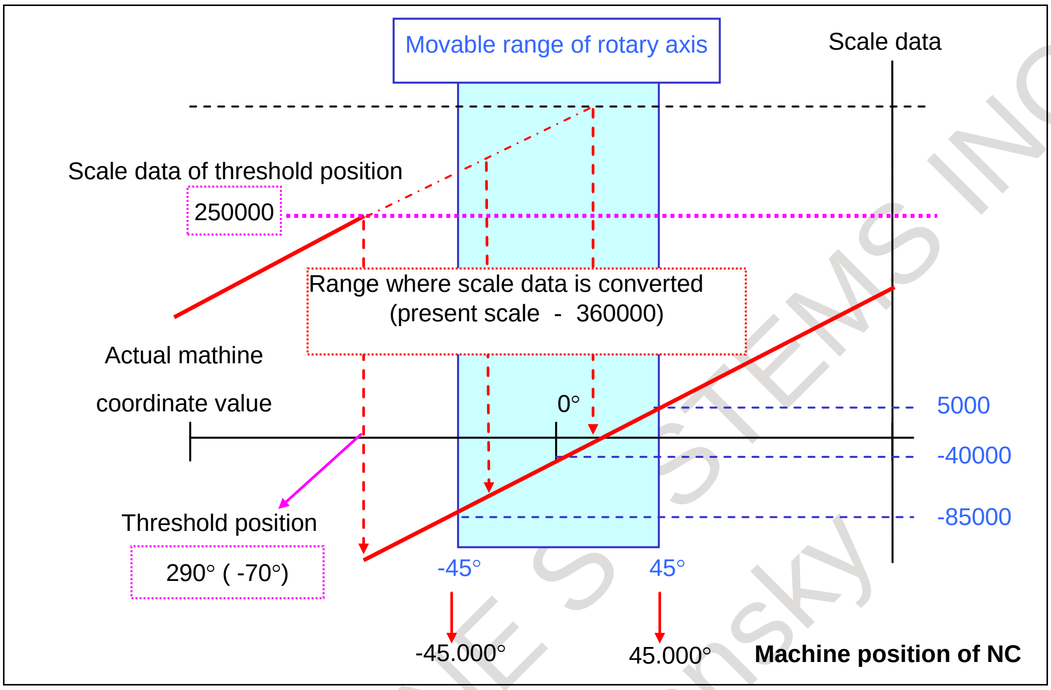

Fig. 4.12.2 (c) The case that parameter No.1817#3 is set to 1 and No.1868 (the threshold position) is set to 290.0.

In the case of Fig. 4.12.2 (b), if the bit 3 (SCRx) of parameter No. 1817 is set to 1 and No.1868 (threshold position) is set to 290.0, the scale data of the threshold position (parameter No.1868) or more (250000 to 359999) is converted to the data which is subtracted by the amount of one rotation (360000 in this case), as shown in Fig. 4.12.2 (c). Therefore, the scale data is continuous as -85000 to 5000 in movable range of the rotary axis. The machine coordinate value of NC can become correct value as -45.000 to 45.000 because the scale data is continuous in movable range of the rotary axis like Example 1.
The parameter No.1868 (the threshold position) is required to be set the position out of movable range and positive value. (0.0 to 360.0: Set to 290.0 instead of –70.0, in this case.)

An uncontinuous point of scale data

Before using this function, it is necessary to know the position of the uncontinuous point. By the following process, the position of the uncontinuous point can be found in the case of an absolute position detector (absolute pulse coder) (bit 5 (APC) of parameter No.1815=1).

1. Perform a reference position return of the rotary axis with the parameter No.1817#3=0.

→ The correspondence between the reference position and position in the absolute-position detector has been established. (parameter No.1815#4=1)

2. Record machine coordinate value after moving the axis to one side of end of movable range.

3. Turn the CNC off and on.

4. The machine coordinate value before and after the power supply turning on are compared.
- In the case that the machine coordinate value misses by the amount of one rotation :
  →Go to the process 7 because an uncontinuous point of scale data exists within movable range.
- In the case that the machine coordinate value does not miss and CNC starts normally :
  →Record the machine coordinate value after moving to the other side of end of movable range.

5. Turn the CNC off and on.

6. The machine coordinate value before and after the power supply turning on are compared.
- In the case that the machine coordinate value misses by the amount of one rotation :
  →Go to the process 7 because an uncontinuous point of scale data exists within movable range.
- In the case that the machine coordinate value does not miss and CNC starts normally :
  →There is not an uncontinuous point within movable range.

It is unnecessary to use this function.
(No.1817#3=0)

7. Record the machine coordinate value after moving by a constant interval (10 degree, for example) from present position for an inside of movable range.

8. Turn the CNC off and on.
- Until exceeding an uncontinuous point, the machine coordinate position is still different by 360 degree.
  → Until exceeding an uncontinuous point, repeat process 7 and 8.
- After exceeding an uncontinuous point, the CNC starts on correct position.
  →By the above process it is possible to know the approximate position of the uncontinuous point.

In the case of the Fig. 4.12.2 (b) :

1. A reference position return finishing.
2. Moving the axis to one side of movable range (the machine coordinate value -45.000).
3. Turnning the CNC off and on.
4. Moving to the other side of movable range (the machine coordinate value is 45.000) because the machine coordinate value at power on is correct.
5. Turnning the CNC off and on.
6. Starting on -315.000 with the machine coordinate missing by 360 degree.
7. Shifting to the inside direction by 10 degree and moving to the machine coordinate -325.000.
8. Turnning the CNC off and on.

9. Starting correctly on the machine coordinate 35.000.

Thus an uncontinuous point of scale data is found between 35.000 and 45.000.

Parameter

	#7	#6	#5	#4	#3	#2	#1	#0
1815			APCx	APZx				

[Input type] Parameter input
[Data type] Bit axis

> **NOTE**
> When at least one of these parameters is set, the power must be turned off before operation is continued.

#4 APZx Machine position and position on absolute position detector when the absolute position detector is used
0: Not corresponding
1: Corresponding
When an absolute position detector is used, after primary adjustment is performed or after the absolute position detector is replaced, this parameter must be set to 0, power must be turned off and on, then manual reference position return must be performed. This completes the positional correspondence between the machine position and the position on the absolute position detector, and sets this parameter to 1 automatically.

#5 APCx Position detector
0: Other than absolute position detector
1: Absolute position detector (absolute Pulsecoder)

> **NOTE**
> 1 In case of using FANUC absolute pulsecoder as absolute position detector for the rotary axis A type that machine coordinate values are rounded in 0 to 360°, set the parameter RON (No.1815#6) to 0. If the parameter is not set correctly, the machine coordinates are not correctly established at power-on.
> 2 In case of using a rotary scale without rotary data made by another company as absolute position detector, please refer to "CORRESPONDENCE OF ROTARY SCALE WITHOUT ROTARY DATA" in the “CONNECTION MANUAL (FUNCTION)” (B-64693EN-1) and set an appropriate value corresponding to the detector. If the parameter is not set correctly, the machine coordinates are not correctly established at power-on.
> 3 When the servo axis is disabled (bit 4 (KSVx) of parameter No. 11802 is set to 1), an absolute position detector cannot be used (bit 5 (APCx) of parameter No. 1815 cannot be set to 1). If an absolute position detector is used, alarm SV0301, "APC ALARM; COMMUNICATION ERROR" is issued.

	#7	#6	#5	#4	#3	#2	#1	#0
1817					SCRx			

[Input type] Parameter input
[Data type] Bit axis

> **NOTE**
> When this parameter is set, the power must be turned off before operation is continued.

#3 SCRx Specifies whether to convert scale data by using threshold position (parameter No. 1868) so that rotary axis B type is available, in the case of the axis B type that use a rotary scale without data (the number of rotation), whose movable range is under one rotation:
0 : Not to convert.
1 : To convert.

> **NOTE**
> 1 This parameter is available for only the rotary axis B type with an absolute position detector (absolute Pulsecoder) or a rotary scale with distance-coded reference marks (serial). This function cannot be used for distance coded rotary scale interface (phase A/B).
> 2 Don't set this parameter in the case of no uncontinuous point within movable range of rotary axis even if the rotary axis B type.
> 3 When this parameter is set, machine position and position on absolute position detector become uncorresponding. So, establish the reference position again. (Consequently, the bit 4 (APZ) of parameter No. 1815 (indicating that the correspondence is established) is set to 0, and an alarm DS0300, "APC ALARM: NEED REF RETURN", occurs. Why the bit 4 (APZ) of parameter No. 1815 is set to 0 can be checked using diagnosis data No. 310#0).
> 4 This function cannot be used together with the bit 0 (RVSx) of parameter No. 1815 that save rotary data by CNC.
> 5 In this function, the amount of one rotation of rotary axis assumes 360, and the machine position 0 assumes the reference position. It is not possible to apply to a rotary axis other than the above-mentioned setting.
> 6 Set the parameter No. 1240 to 0.

1868	Threshold position for converting scale data (each axis)

> **NOTE**
> When this parameter is set, the power must be turned off before operation is continued.

[Input type] Parameter input
[Data type] Real axis
[Unit of data] deg (machine unit)
[Min. unit of data] Depend on the increment system of the applied axis
[Valid data range] 0 or positive 9 digit of minimum unit of data (Refer to the standard parameter setting table (B))
(When the increment system is IS-B, 0.0 to ++999999.999)

In the case that scale data of a rotary scale without rotary data is larger than the scale data of the threshold position (this parameter value), it is converted to be continuous data in movable range by subtracting data of one rotation. The machine coordinate value out of movable range (angle from an uncontinuous point) must be set as threshold position. As for the axis for which this parameter is set to 0, conversion of scale data is not performed.

> **NOTE**
> 1 This parameter is available for only the rotary axis B type with an absolute position detector (absolute Pulsecoder) or a rotary scale with distance-coded reference marks (serial), for which the bit 3 (SCRx) of parameter No. 1817 is set to 1.
> 2 This function cannot be used for distance coded rotary scale interface (phase A/B).
> 3 Don't set this parameter in the case of no uncontinuous point within movable range of rotary axis even if the rotary axis B type.
> 4 When this parameter is set, machine position and position on absolute position detector become uncorresponding. So, establish the reference position again. (Consequently, the bit 4 (APZ) of parameter No. 1815 (indicating that the correspondence is established) is set to 0, and an alarm DS0300, "APC ALARM: NEED REF RETURN", occurs. Why the bit 4 (APZ) of parameter No. 1815 is set to 0 can be checked using diagnosis data No. 0310#0).

1869	The amount of one rotation of rotary axis B type (each axis)

> **NOTE**
> When this parameter is set, the power must be turned off before operation is continued.

[Input type] Parameter input
[Data type] Real axis
[Unit of data] deg (machine unit)
[Min. unit of data] Depend on the increment system of the applied axis
[Valid data range] 0 or positive 9 digit of minimum unit of data (Refer to the standard parameter setting table (B))
(When the increment system is IS-B, 0.0 to ++999999.999)
Normally, the amount of one rotation of rotary axis is 360, and the machine position 0 is the reference position.
In this case, this parameter is set to 0.

For instance, when this parameter is set to 523.000, the amount of one rotation become 523.000 (in the case of IS-B), if it is necessary to set it arbitrarily.

> **NOTE**
> 1 This parameter is available for only the rotary axis B type with an absolute position detector (absolute Pulsecoder) or a rotary scale with distance-coded reference marks (serial), as for the bit 3 (SCRx) of parameter No. 1817 is set to 1 or the bit 0 (RVS) of parameter No. 1815 is set to 1.

> **NOTE**
> 2 In the case that the amount of one rotation of rotary axis is 360, this parameter is set to 0.If it is necessary to set an amount of one rotation of rotary axis arbitrarily, this parameter is set to the amount of one rotation.
> 3 When this parameter is set, machine position and position on absolute position detector become uncorresponding. So, establish the reference position again. (Consequently, the bit 4 (APZ) of parameter No. 1815 (indicating that the correspondence is established) is set to 0, and an alarm DS0300, “APC ALARM: NEED REF RETURN”, occurs. Why the bit 4 (APZ) of parameter No. 1815 is set to 0 can be checked using diagnosis data No. 0310#0).
> 4 This parameter No. 1869 is common in movable range that is under one rotation (the bit 3 (SCRx) of parameter No. 1817 is set to 1) and movable range that is over one rotation (the bit 0 (RVS) of parameter No. 1815 is set to 1).
> 5 Please set 0 to this parameter if the distance coded rotary scale interface (phase A/B) is used.

4.12.3 In the Case of a Rotary Axis B Type whose Movable Range is over One Rotation

As for an axis whose movable range is over one rotation and its rotary scale which has no rotary data , for example, 30.000 degree and 390.000 degree have completely same scale data though their position is different from each other by just one rotation. It is possible to set rotary axis B type because CNC saves the rotary data by the following parameter even if in this case.
As attention, a machine coordinate value may get out over a rotation, in the case of moving over 180 degree during turning off, because CNC saves a machine coordinate value just before CNC turns off and in following turning on get from the value.

Parameter

	#7	#6	#5	#4	#3	#2	#1	#0
1815								RVSx

[Input type] Parameter input
[Data type] Bit axis

> **NOTE**
> When this parameter is set, the power must be turned off before operation is continued.

#0 RVSx When the scale without rotary data is used:
0: The CNC does not maintain the rotary data.
1: The CNC maintains the rotary data.
This parameter is effective in the axis that satisfies either of the following conditions.
- The axis is rotary axis B type and the movable range is more than one rotation.
- The parameter RVL(No.11802#6)=1.

NOTE

1. In the case of a rotary axis B type whose movable range is over one rotation, a rotary scale with rotary data had better be used. Otherwise, a machine coordinate value may get out over a rotation, in the case of moving over 180 degree during turning off.
2. This parameter is available for the axis that is rotary axis B type or the axis whose bit 6 (RVLx) of parameter No.11802 is 1. This parameter is available for the axis with an absolute position detector (absolute Pulsecoder), a distance coded rotary scale interface (phase A/B) or a rotary scale with distance-coded reference marks (serial).
3. If this parameter is available, the machine coordinate value just before CNC turns off is saved. In the case of moving over the following amounts during turning off or before reference position return, a machine coordinate value may get out over a rotation because CNC saves a machine coordinate value just before CNC turns off and in following turning on get from the value.
   In case of the rotary axis B type :
   Over 180 degree
   In case of the linear axis type :
   Over 1/4 of values set to parameter No.11810.
4. If this parameter is changed, the correspondence between the machine position and the absolute position detector is lost. So, establish the reference position again. (Bit 4 (APZ) of parameter No.1815 is set to 0, and an alarm DS0300, “APC ALARM: NEED REF RETURN” is issued. The cause that sets bit 4 (APZ) of parameter No.1815 to 0 is indicated in diagnosis data No.310#0).
5. Absolute coordinate value is set by machine coordinate value. However, after CNC turns on, the workpiece offset such as G92 and G52 executed before CNC turns off is not set.
6. This function cannot be used together with the bit 3 (SCRx) of parameter No. 1817 that convert scale data.
7. In case of the rotary axis B type and the amount of one rotation of rotary axis is 360, set the parameter No.1869 to 0. Moreover, set the parameter No.1240 to 0 because the reference position must be 0 degree.
8. In case of the rotary axis B type and the amount of one rotation of rotary axis is not 360, set the parameter No.1869 to the amount of one rotation. Moreover, set the parameter No.1240 to 0 because the reference position must be 0 degree.
9. In case of the linear axis type, set the amount of the movement per one motor rotation to the parameter No.11810.
10. This parameter cannot be used together with the stored stroke limit check immediately after power-on (parameter DOT(No.1311#0)).

1869	**The amount of one rotation of rotary axis B type (each axis)**

> **NOTE**
> When this parameter is set, the power must be turned off before operation is continued.

[Input type] Parameter input
[Data type] Real axis
[Unit of data] deg (machine unit)
[Min. unit of data] Depend on the increment system of the applied axis
[Valid data range] 0 or positive 9 digit of minimum unit of data (Refer to the standard parameter setting table (B))
(When the increment system is IS-B, 0.0 to ++999999.999)
Normally, the amount of one rotation of rotary axis is 360, and the machine position 0 is the reference position.
In this case, this parameter is set to 0.

For instance, when this parameter is set to 523.000, the amount of one rotation become 523.000 (in the case of IS-B), if it is necessary to set it arbitrarily.

> **NOTE**
> 1 This parameter is available for only the rotary axis B type with an absolute position detector (absolute Pulsecoder) or a rotary scale with distance-coded reference marks (serial), as for the bit 3 (SCRx) of parameter No. 1817 is set to 1 or the bit 0 (RVS) of parameter No. 1815 is set to 1.
> 2 In the case that the amount of one rotation of rotary axis is 360, this parameter is set to 0.If it is necessary to set an amount of one rotation of rotary axis arbitrarily, this parameter is set to the amount of one rotation.
> 3 When this parameter is set, machine position and position on absolute position detector become uncorresponding. So, establish the reference position again. (Consequently, the bit 4 (APZ) of parameter No. 1815 (indicating that the correspondence is established) is set to 0, and an alarm DS0300, “APC ALARM: NEED REF RETURN”, occurs. Why the bit 4 (APZ) of parameter No. 1815 is set to 0 can be checked using diagnosis data No. 0310#0).
> 4 This parameter No. 1869 is common in movable range that is under one rotation (the bit 3 (SCRx) of parameter No. 1817 is set to 1) and movable range that is over one rotation (the bit 0 (RVS) of parameter No. 1815 is set to 1).
> 5 Please set 0 to this parameter if the distance coded rotary scale interface (phase A/B) is used.

4.12.4 In the Case of a Rotary Axis A Type

In the case of a rotary axis A type with an absolute position detector (absolute pulse coder), when the machine coordinate passes 0 degree or the shift value per one rotation (360 degree or the value of parameter No.1260), the data for the reference position (parameters Nos.1860 to 1862) is renewed so that following up at power on is within one rotation. But as for the absolute position detector (absolute pulse

coder) using a scale without rotary data, the data for the reference position (parameters Nos.1860 to 1862) need not be renewed because scale data without rotary data is always read at turning on.
In this case, be sure to set the following parameters.

Parameter

1260	The shift amount per one rotation of a rotary axis

> **NOTE**
> When this parameter is set, the power must be turned off before operation is continued.

[Input type] Parameter input
[Data type] Real axis
[Unit of data] deg
[Min. unit of data] Depend on the increment system of the applied axis
[Valid data range] 0 or positive 9 digit of minimum unit of data (refer to the standard parameter setting table (B))
(When the increment system is IS-B, 0.0 to +999999.999)
Set the shift amount per one rotation of a rotary axis.
For the rotary axis used for cylindrical interpolation, set the standard value.

	#7	#6	#5	#4	#3	#2	#1	#0
1815		RONx						

[Input type] Parameter input
[Data type] Bit axis

> **NOTE**
> When this parameter is set, the power must be turned off before operation is continued.

#6 RONx With a rotary axis A type, an absolute position detector (absolute Pulsecoder) using a scale without rotary data is:
0: Not used.
1: Used.

> **NOTE**
> 1 This parameter is available for only the rotary axis A type with an absolute position detector (absolute Pulsecoder). This function cannot be used for a rotary scale with distance-coded reference marks (serial) or for a distance coded rotary scale interface (phase A/B).
> 2 Set this parameter to 1 for the rotary axis A type using a rotary scale without rotary data such as HEIDENHAIN rotary scale RCN 223F, 727F, etc.
> Set this parameter to 0 in any other case. If the parameter is not set correctly, the machine coordinates are not correctly established at power-on.

NOTE

3 When this parameter is set, machine position and position on absolute position detector become uncorresponding. So, establish the reference position again. (Consequently, the bit 4 (APZ) of parameter No. 1815 (indicating that the correspondence is established) is set to 0, and an alarm DS0300, “APC ALARM: NEED REF RETURN”, occurs. Why the bit 4 (APZ) of parameter No. 1815 is set to 0 can be checked using diagnosis data No. 0310#0).

1860	**Value 1 for the zero point of the absolute position detector**
1861	**Value 2 for the zero point of the absolute position detector**
1862	**Value 3 for the zero point of the absolute position detector**

NOTE

When this parameter is set, the power must be turned off before operation is continued.

[Input type] Locked parameter
[Data type] 2-word axis

Parameters Nos.1860 to 1862 are values for the zero point of the absolute position detector (association with reference position and the counter value of the absolute position detector).
The CNC automatically sets parameters Nos.1860 to 1862 when correspondence between the reference position and the absolute position detector is performed.
It is not available to set parameters Nos.1860 to 1862 by using inputting of MDI operation, FOCAS2, PMC window or programmable parameter input(G10).

The zero point data of the absolute position detection can be restored and parameters Nos.1860 to 1862 can be set, by the parameter input from connected I/O unit or by restoring the SRAM area of boot system.
When the zero point data of the absolute position detection are restored, be careful about the following.

- When the zero point data of absolute position detection are restored, back up them right before the restoring and use backup data.
- When the motor or the detector is exchanged, the zero point data of absolute position detection cannot be restored. After exchange, set the zero point of the absolute position detector again.
- When the zero point data of the absolute position detection are restored by them of the other machine, the zero point of the absolute position detector is set to wrong position. Don't restore the zero point data of absolute position detection by them of the other machine.
- When the zero point data of absolute position detection are backed up with reference position not established and restored by backup data, setting of the zero point of the absolute position detector is required after restoring.

⚠ **WARNING**

If the zero point of the absolute position detector is not set properly, the machine coordinate system is not established correctly.

4.12.5 Method of Using Heidenhain Rotary Scale RCN223, 723 and 220

Heidenhain rotary scale RCN223, 723 and 220 are the detectors which save absolute position only within one rotation.

- In the case of RCN223, 723 and 220, there is the case that wrong positional data (rotary data) is read on absolute positional communication because it is not saved (it is undefined).

And the former two detectors (RCN223 and 723) are the detectors which have eight million pulses every one rotation.

- In the case of RCN223 and 723, if it is used as usual, eight grids are made every one rotation.

The following parameters in addition to "setting method by rotary axis type and movable range" (Subsection 4.14.1 - 4.14.4) are necessary to resolve these problems.

Parameter

	#7	#6	#5	#4	#3	#2	#1	#0
2275							RCNCLR	800PLS

[Input type] Parameter input
[Data type] Bit axis

#0 800PLS A rotary encoder (RCN223, 723 or etc.) with eight million pulses per revolution is:
0: Not to be used. (To use the RCN220, leave this bit set to 0.)
1: To be used. (1 grid point occur per revolution.)

#1 RCNCLR The number of revolution is:
0: Not to be cleared.
1: To be cleared. (To use the RCN220, RCN223, or RCN723, set the bit to 1.)
This function bit is to be set in combination with the number of data mask digits, described in parameter (No.2394).

2394	Number of data mask digits

[Input type] Parameter input
[Data type]
[Setting value] 5 or 8
The value to be set in this parameter depends on the detector. At present, only the following detectors require clearing the speed data. Set 5 to use the RCN220, and set 8 to use the RCN223, or RCN723. This parameter is to be set in combination with RCNCLR(No.2275#1).

NOTE
The rotary data of the RCN220, RCN223, or RCN723 is maintained while the power to the separate detector interface unit is on. The data, however, is cleared when the unit is turned off.
Since the rotary data becomes undetermined depending on where the power is turned off, it is necessary to make a setting to clear the rotary data. In addition, for this reason, the RCN220,RCN223, and RCN723 cannot be used with a linear axis.
However, the detectors are available with a linear axis even if the rotary data is cleared by setting the parameters RVL(No.11802 #6)=1 and RVS(No.1815#0)=1.

- Other parameters that must be set

When using RCN220, the other settings are the same as normal α/αi pulse coders. The setting method for RCN223 and RCN723 are as follows.

[Flexible feed gear]
Parameters Nos.2084, 2085
In the case of RCN223, 723, amount of pulses per every one rotation are regarded as eight million pulses.

$$\text{<flexible feed gear (N/M)>} = \frac{\dfrac{\text{Amount of table moving every one rotation of a detector [deg]}}{\text{Increment of detection [deg]}}}{8{,}000{,}000}$$

[Amount of positional pulse]
Parameter No.2024
amount of positional pulse = 100,000 * (deceleration ratio from a motor to a table)

* As a result of this equation when amount of pulses exceeds input range (0 to 32767), set the positional pulse in following process with using ”positional feed back pulse conversion coefficient”
Amount of positional pulse = A × B
In this case, select B in which A is within 32767. And A, B are set as following.
A : A parameter, amount of positional pulse (within 32767)
No.2024
B : A parameter, positional feed back pulse conversion coefficient
No.2185

[Reference counter capacity]
Parameter No.1821
Set amount of feed back pulses (detection unit) per a table rotation.

* Set amount of (pulses per one table rotation / 8) as reference counter capacity in the case of bit 0 (800PLS) of parameter No. 2275=0. But in this case eight grids are made every one table rotation.

- Example of parameters setting

[System construction]
- Heidenhain rotary encorder RCN223
- The least input increment is 1/10,000 degree
- In the case that moving distance is 180 degree every one motor rotation (deceleration ratio is 1/2)
- Deceleration ratio between a rotary table and a separate encorder = 1/1

[Setting parameters]
- Set bit 1 (OPTx) of parameter No. 1815=1 so that separate detector is available.
- Set bit 0 (800PLS) of parameter No. 2275=1, bit 1 (RCNCLR) of parameter No. 2275=1, No.2394=8 so that RCN223 is used.
- Parameters for flexible feed gear are calculated.
  Flexible feed gear (N/M) = (360 degree / 0.0001 degree) / 8,000,000 =9 / 20
  So, No.2084=9, No.2085=20
- Amount of positional pulses is calculated.
  Amount of positional pulses = 100,000 × (1 / 2) = 50,000
  Because this value exceeds input range (0 to 32767), following is considered
  50,000 = 12,500 × 4 → A = 12,500, B=4
  A is set for “amount of positional pulse” and B is set for “positional pulse conversion coefficient”
  No.2024＝12,500, No.2185=4
- Reference counter capacity is calculated.
  Reference counter capacity = 360 degree / 0.0001 degree = 3,600,000

Parameter

	#7	#6	#5	#4	#3	#2	#1	#0
1815							OPTx	

[Input type] Parameter input
[Data type] Bit axis

> **NOTE**
> When at least one of these parameters is set, the power must be turned off before operation is continued.

#1 OPTx The separate position detector is:
0: Not to be used (semi-closed system)
1: To be used (full-closed system)

> **NOTE**
> 1 In case of using the absolute position detector (bit 5 (APCx) of parameter No.1815 is set to 1), please set the following parameters that correspond to the absolute position detector which is actually used.
> - parameter No.1815#6, No.1815#0, No.1817#3, No.1868, No.2275#1, No.2394
>
> If these parameters are not set correctly, the machine coordinates are not correctly established at power-on.
> 2 Set this parameter to 1 when using a linear scale with reference marks or a linear scale with distance-coded reference marks (serial) (full-closed system).

1821	Reference counter size for each axis

> **NOTE**
> When this parameter is set, the power must be turned off before operation is continued.

[Input type] Parameter input
[Data type] 2-word axis
[Unit of data] Detection unit
[Valid data range] 0 to 999999999

Set a reference counter size.
As a reference counter size, specify a grid interval for reference position return based on the grid method.
When a value less than 0 is set, the specification of 10000 is assumed.
When a linear scale with absolute address reference marks is used, set the interval of mark 1.

2024	Amount of positional pulse

[Input type] Parameter input
Set an amount of positional pulse.
amount of positional pulse = 100,000 * (deceleration ratio from a motor to a table)

As a result of this equation when amount of pulses exceeds input range (0 to 32767), set the positional pulse in following process with using "positional feed back pulse conversion coefficient"

Amount of positional pulse = A × B

In this case, select B in which A is within 32767. And A, B are set as following.

A : A parameter, amount of positional pulse (within 32767)
No.2024

B : A parameter, positional feed back pulse conversion coefficient
No.2185

2084	Flexible feed gear (numerator)

2085	Flexible feed gear (denominator)

[Input type] Parameter input

Set a flexible feed gear.

In the case of RCN223, 723, amount of pulses per every one rotation are regarded as eight million pulses.

<flexible feed gear (N/M)> =

$$\frac{\dfrac{\text{Amount of table moving every one rotation of a detector [deg]}}{\text{Increment of detection [deg]}}}{8{,}000{,}000}$$

2185	Positional feed back pulse conversion coefficient

[Input type] Parameter input

Set a positional feed back pulse conversion coefficient.

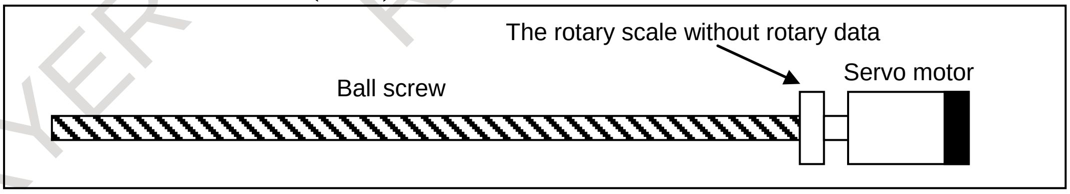
Use this parameter when amount of positional pulses (the parameter No.2024) exceeds input range (0 to 32767).

Refer to the parameter No.2024 for the setting method.

4.12.6 In Case of a Linear Axis

Explanation

An absolute position detection using a rotary scale without rotary data or a linear scale with distance-coded reference marks (serial) is available.



This parameter is effective in the axis that satisfies all the following conditions.

- Parameter ROT(No.1006#0)=0
- Parameter ROS(No.1006#1)=0
- Parameter RVS(No.1815#0)=1
- Parameter RVL(No.11802#6)=1
- The amount of the movement per rotation is set to parameter No.11810.

NOTE

1 To use this function, please set the parameters that relate to the rotary scale without rotary data correctly : 800PLS, RCNCLR(No.2275#0 and #1), and parameter No.2394. About details, please refer to the "4.14.5 Method of Using Heidenhain Rotary Scale RCN223, 723 and 220".

> **NOTE**
> 2 To change this function from effective to ineffective, set the related parameters again correctly.
> 3 Please refer also to notes that described in parameters RVS(No.1815#0) and No.11810.

Parameter

	#7	#6	#5	#4	#3	#2	#1	#0
1006							**ROSx**	**ROTx**

[Input type] Parameter input
[Data type] Bit axis

> **NOTE**
> When at least one of these parameters is set, the power must be turned off before operation is continued.

#0 ROTx
#1 ROSx Setting linear or rotary axis.

ROSx	ROTx	Meaning
0	0	Linear axis (1) Inch/metric conversion is done. (2) All coordinate values are linear axis type. (Is not rounded in 0 to 360°) (3) Stored pitch error compensation is linear axis type (Refer to parameter No. 3624)
0	1	Rotary axis (A type) (1) Inch/metric conversion is not done. (2) Machine coordinate values are rounded in 0 to 360°. Absolute coordinate values are rounded or not rounded by bits 0 (ROAx) and 2 (RRLx) of parameter No. 1008. (3) Stored pitch error compensation is the rotation type. (Refer to parameter No. 3624) (4) Automatic reference position return (G28, G30) is done in the reference position return direction and the move amount does not exceed one rotation.
1	1	Rotary axis (B type) (1) Inch/metric conversion is not done. (2) Machine coordinate values, absolute coordinate values and relative coordinate values are linear axis type. (Is not rounded in 0 to 360°). (3) Stored pitch error compensation is linear axis type (Refer to parameter No. 3624) (4) Cannot be used with the rotary axis roll-over function and the index table indexing function (M series)
Except for the above.		Setting is invalid (unused)

	#7	#6	#5	#4	#3	#2	#1	#0
1815								**RVSx**

[Input type] Parameter input
[Data type] Bit axis

> **NOTE**
> When this parameter is set, the power must be turned off before operation is continued.

#0 RVSx When the scale without rotary data is used:

0: The CNC does not maintain the rotary data.

1: The CNC maintains the rotary data.

This parameter is effective in the axis that satisfies either of the following conditions.

- The axis is rotary axis B type and the movable range is more than one rotation.
- The parameter RVL(No.11802#6)=1.

> **NOTE**
> 1 In the case of a rotary axis B type whose movable range is over one rotation, a rotary scale with rotary data had better be used.
> 2 This parameter is available for the axis that is rotary axis B type or the axis whose bit 6 (RVLx) of parameter No.11802 is 1. This parameter is available for the axis with an absolute position detector (absolute Pulsecoder), a distance coded rotary scale interface (phase A/B) or a rotary scale with distance-coded reference marks (serial).
> 3 If this parameter is available, the machine coordinate value just before CNC turns off is saved. In the case of moving over the following amounts during turning off or before reference position return, a machine coordinate value may get out over a rotation because CNC saves a machine coordinate value just before CNC turns off and in following turning on get from the value.
> In case of the rotary axis B type :
> Over 180 degree
> In case of the linear axis type :
> Over 1/4 of values set to parameter No.11810.
> 4 If this parameter is changed, the correspondence between the machine position and the absolute position detector is lost. So, establish the reference position again. (Bit 4 (APZ) of parameter No.1815 is set to 0, and an alarm DS0300, “APC ALARM: NEED REF RETURN” is issued. The cause that sets bit 4 (APZ) of parameter No.1815 to 0 is indicated in diagnosis data No.310#0).
> 5 Absolute coordinate value is set by machine coordinate value. However, after CNC turns on, the workpiece offset such as G92 and G52 executed before CNC turns off is not set.
> 6 This function cannot be used together with the bit 3 (SCRx) of parameter No. 1817 that convert scale data.
> 7 In case of the rotary axis B type and the amount of one rotation of rotary axis is 360, set the parameter No.1869 to 0. Moreover, set the parameter No.1240 to 0 because the reference position must be 0 degree.
> 8 In case of the rotary axis B type and the amount of one rotation of rotary axis is not 360, set the parameter No.1869 to the amount of one rotation. Moreover, set the parameter No.1240 to 0 because the reference position must be 0 degree.
> 9 In case of the linear axis type, set the amount of the movement per one motor rotation to the parameter No.11810.

> **NOTE**
> 10 This parameter cannot be used together with the stored stroke limit check immediately after power-on (parameter DOT(No.1311#0)).

	#7	#6	#5	#4	#3	#2	#1	#0
2275							RCNCLR	800PLS

[Input type] Parameter input
[Data type] Bit axis

#0 800PLS A rotary encoder (RCN223, 723 or etc.) with eight million pulses per revolution is:
0: Not to be used. (To use the RCN220, leave this bit set to 0.)
1: To be used. (1 grid point occur per revolution.)

#1 RCNCLR The number of revolution is:
0: Not to be cleared.
1: To be cleared. (To use the RCN220, RCN223, or RCN723, set the bit to 1.)
This function bit is to be set in combination with the number of data mask digits, described in parameter (No.2394).

2394	Number of data mask digits

[Input type] Parameter input
[Data type]
[Setting value] 5 or 8
The value to be set in this parameter depends on the detector. At present, only the following detectors require clearing the speed data. Set 5 to use the RCN220, and set 8 to use the RCN223, or RCN723. This parameter is to be set in combination with RCNCLR(No.2275#1).

> **NOTE**
> The rotary data of the RCN220, RCN223, or RCN723 is maintained while the power to the separate detector interface unit is on. The data, however, is cleared when the unit is turned off.
> Since the rotary data becomes undetermined depending on where the power is turned off, it is necessary to make a setting to clear the rotary data. In addition, for this reason, the RCN220,RCN223, and RCN723 cannot be used with a linear axis.
> However, the detectors are available with a linear axis even if the rotary data is cleared by setting the parameters RVL(No.11802 #6)=1 and RVS(No.1815#0)=1.

[Data type] Bit axis

> **NOTE**
> When this parameter is set, the power must be turned off before operation is continued.

#6 RVL In case of using the rotary scale without rotary data to the linear axis type, an absolute position detector or a rotary scale with distance-coded reference marks (serial) is:
0: Not available.
1: Available.

> **NOTE**
> 1 Please use this parameter with a linear axis.
> 2 This parameter is effective when the parameter RVS(No.1815#0) is 1.
> 3 Set the parameter No.11810 to the amount of one rotation.

11810	The amount of the movement per one motor rotation of linear axis type (each axis)

> **NOTE**
> When this parameter is set, the power must be turned off before operation is continued.

[Input type] Parameter input
[Data type] Real axis
[Unit of data] mm, inch (machine unit)
[Min. unit of data] Depend on the increment system of the applied axis
[Valid data range] 0 or positive 9 digit of minimum unit of data (refer to the standard parameter setting table (B))
(When the increment system is IS-B, 0.0 to +999999.999)
In case of using the rotary scale without rotary data to the linear axis type, set the amount of the movement per one motor rotation. When 0 is set in this parameter, 360. is assumed.

> **NOTE**
> 1 This parameter is effective in the axis that satisfies all the following conditions.
> - Linear axis
> - Parameter RVS(No.1815#0)=1
> - Parameter RVL(No.11802#6)=1
> 2 This parameter is available for the axis with an absolute position detector (absolute Pulsecoder) or a rotary scale with distance-coded reference marks (serial).
> 3 If this parameter is changed, the correspondence between the machine position and the absolute position detector is lost. So, establish the reference position again. (Bit 4 (APZ) of parameter No.1815 is set to 0, and an alarm DS0300, "APC ALARM: NEED REF RETURN" is issued. The cause that sets bit 4 (APZ) of parameter No.1815 to 0 is indicated in diagnosis data No.310#0).

4.12.7 Diagnosis Data

This diagnosis data shows the reason that the parameter APZ is set to 0.

#0 PR1 One of the following parameters was changed:
No.1815#0, No.1815#1, No.1815#6, No.1817#3, No.1820, No.1821, No.1822, No.1823, No.1850, No.1868, No.1869, No.1874, No.1875, No.1876, No.1878, No.1883, No.1884, No.2022, No.2084, No.2085, No.2179, increment system for a rotary axis A type, No.11802#6, No.11810

4.13 MANUAL 2ND/3RD/4TH REFERENCE POSITION RETURN FUNCTION

Overview

This function enables positioning to the 2nd/3rd/4th reference position by JOG feed operation in manual reference position return mode.

Use the manual 2nd/3rd/4th reference position return select 1 signal SLREF <Gn340.5> and the manual 2nd/3rd/4th reference position return select 2 signal SLRER <Gn340.6> to select the reference position to which to return, then set the feed axis direction selection signal +/-Jx to 1 in manual reference position return mode to enable 2nd/3rd/4th reference position return.

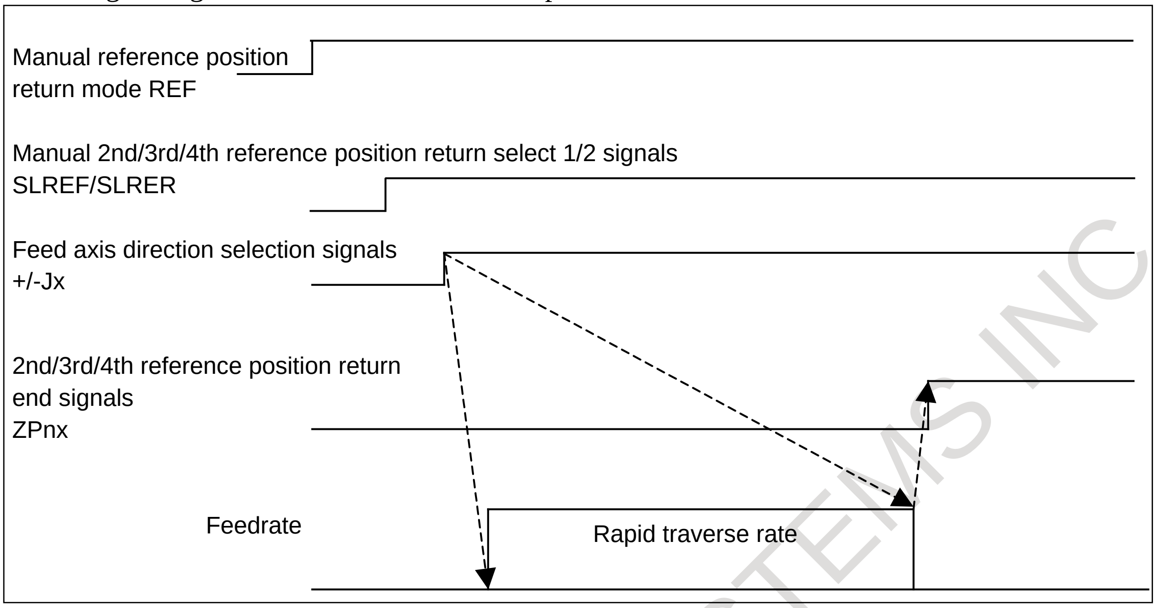
The feedrate is set by rapid traverse rate parameter No. 1420 for each axis. (Rapid traverse override is effective.)
By using bit 2 (JZR) of parameter No. 1401, the jog feedfrate can be used for manual reference position return at all time.
Bit 1 (DLF) of parameter No. 1404 can be used to select rapid traverse rate parameter No. 1420 for each axis or manual rapid traverse rate parameter No. 1424. This parameter selects a feedrate for reference position return performed without dogs. This parameter also selects a feedrate when manual reference position return is performed according to bit 7 (SJZ) of parameter No.0002 using rapid traverse without deceleration dogs after a reference position is set.

When the tool returns to the reference position of a controlled axis, the following reference position return end signal is set to 1.

(ZP2x <Fn096> for return to the 2nd reference position, ZP3x <Fn098> for return to the 3rd reference position, or ZP4x <Fn100> for return to the 4th reference position)

Although one axis can be moved at the same time, using bit 0 (JAX) of parameter No. 1002 allows up to three axes to move at the same time.
The 2nd, 3rd, and 4th reference positions must be set in advance in parameters Nos. 1241 to 1243 with coordinates in the machine coordinate system.
2nd/3rd/4th reference position return can be used only after the relevant reference position has been established.

The following timing chart summarizes the above procedure:



Caution

⚠ CAUTION

1 When high-speed manual reference position return is used, selecting a feed axis direction selection signal in manual reference position return mode may position the tool at the reference position irrespective of the direction specified by the feed axis direction selection signal, depending on the current position.

2 For manual 1st reference position return, be sure to set the manual 2nd/3rd/4th reference position return select 1/2 signals SLREF <Gn340.5> and SLRER <Gn340.6> to 0.

Note

NOTE

1 Manually returning to the 2nd reference position requires for manual 2nd/3rd/4th reference position return.
Also, manually returning to the 3rd or 4th reference position requires for manual 2nd/3rd/4th reference position return and 3rd/4th reference position return.

2 Once the reference position return end signal has been set to 1, the machine cannot run again in JOG mode until it is released from the reference position return mode.

3 The reference position return end signal will be set to 0 in the following cases:
- The tool moved from the reference position.
- Emergency stop is applied.
- A servo alarm is raised.
- The servo is turned off.

4 Do not change the manual 2nd/3rd/4th reference position return select 1/2 signal during moving for reference position return. Even if the signal is changed, the tool returns to the reference position selected at the start.

NOTE

5 When 1st reference position return has never be performed (the 1st reference position has not been established), returning to the 2nd/3rd/4th reference position is not executed.
6 This function cannot be used in composite control or superimposed control mode.
7 This function cannot be used for the Cs contour control axis.
8 For details of the mode change to the manual reference position return mode, refer to the “MODE SELECTION” in this manual.
9 For details of the high-speed manual reference position return, refer to the “MANUAL REFERENCE POSITION RETURN” in this manual.

Signal

Manual 2nd/3rd/4th reference position return select 1 signal SLREF <Gn340.5>
Manual 2nd/3rd/4th reference position return select 2 signal SLRER <Gn340.6>

[Classification] Input signal

[Function] These signals select the 1st, 2nd, 3rd, or 4th reference position to which to return the tool using the manual reference position return function.

SLRER <Gn340.6>	SLREF <Gn340.5>	
0	0	1st reference position return
0	1	2nd reference position return
1	0	3rd reference position return
1	1	4th reference position return

2nd reference position return end signals ZP21 to ZP28 <Fn096>
3rd reference position return end signals ZP31 to ZP38 <Fn098>
4th reference position return end signals ZP41 to ZP48 <Fn100>

[Classification] Output signal

[Function] These signals indicate that the tool currently exists at the 2nd, 3rd, or 4th reference position on a controlled axis.
The signals are available to each axis; the numeric character at the end of each signal name represents the number of a controlled axis and the one immediately following ZP represents the number of a reference position.

ZP x y

x : 2 ..... 2nd reference position return
3 ..... 3rd reference position return
4 ..... 4th reference position return

y : 1 ..... Return end signal for the 1st axis
2 ..... Return end signal for the 2nd axis
3 ..... Return end signal for the 3rd axis
: :

[Output cond.] The output is 1 when:

- The tool has returned to the 2nd, 3rd, or 4th reference position and is in the in-position state.

The output is 0 when:

- The tool moved from the reference position.
- Emergency stop is applied.
- A servo alarm is raised.
- The servo is turned off.

Signal address

	#7	#6	#5	#4	#3	#2	#1	#0

Parameter

	#7	#6	#5	#4	#3	#2	#1	#0
0002	SJZ							

[Input type] Setting input
[Data type] Bit

#7 SJZ On an axis for which bit 3 (HJZx) of parameter No. 1005 is set:
- 0: If a reference position is not established yet, reference position return is performed with deceleration dogs.
  If a reference position is already established, reference position return is performed at a parameter-set feedrate without using deceleration dogs.
- 1: Reference position return is performed with deceleration dogs at all times.

> **NOTE**
> SJZ is valid for an axis for which bit 3 (HJZx) of parameter No. 1005 is set to 1. When bit 1 (DLZx) of parameter No. 1005 is set to 1, however, manual reference position return after a reference position is set is performed at a parameter-set feedrate, regardless of the setting of SJZ.

	#7	#6	#5	#4	#3	#2	#1	#0
1002								JAX

[Input type] Parameter input
[Data type] Bit path

#0 JAX Number of axes controlled simultaneously in jog feed, manual rapid traverse and manual reference position return
- 0: 1 axis
- 1: 3 axes

1241	Coordinate value of the second reference position in the machine coordinate system
1242	Coordinate value of the third reference position in the machine coordinate system
1243	Coordinate value of the fourth reference position in the machine coordinate system

[Input type] Parameter input
[Data type] Real axis
[Unit of data] mm, inch, deg(machine unit)
[Min. unit of data] Depend on the increment system of the applied axis
[Valid data range] 9 digit of minimum unit of data (refer to standard parameter setting table (A))
(When the increment system is IS-B, -999999.999 to +999999.999)

Set the coordinate values of the second to fourth reference positions in the machine coordinate system.

	#7	#6	#5	#4	#3	#2	#1	#0
1401						JZR		

[Input type] Parameter input
[Data type] Bit path

#2 JZR The manual reference position return at jog feedrate
0: Not performed
1: Performed

	#7	#6	#5	#4	#3	#2	#1	#0
1404							DLF	

[Input type] Parameter input
[Data type] Bit path

#1 DLF After a reference position is set, manual reference position return performed at:
0: Rapid traverse rate (parameter No.1420)
1: Manual rapid traverse rate (parameter No.1424)

NOTE
This parameter selects a feedrate for reference position return performed without dogs. This parameter also selects a feedrate when manual reference position return is performed according to bit 7 (SJZ) of parameter No.0002 using rapid traverse without deceleration dogs after a reference position is set.

1420	Rapid traverse rate for each axis

[Input type] Parameter input
[Data type] Real axis
[Unit of data] mm/min, inch/min, deg/min (machine unit)
[Min. unit of data] Depend on the increment system of the applied axis
[Valid data range] Refer to the standard parameter setting table (C)
(When the increment system is IS-B, 0.0 to +999000.0)
Set the rapid traverse rate when the rapid traverse override is 100% for each axis.

1424	Manual rapid traverse rate for each axis

[Input type] Parameter input
[Data type] Real axis
[Unit of data] mm/min, inch/min, deg/min (machine unit)
[Min. unit of data] Depend on the increment system of the applied axis
[Valid data range] Refer to the standard parameter setting table (C)
(When the increment system is IS-B, 0.0 to +999000.0)
Set the rate of manual rapid traverse when the rapid traverse override is 100% for each axis.

NOTE

1. If 0 is set, the rate set in parameter No. 1420 (rapid traverse rate for each axis) is assumed.
2. When manual rapid traverse is selected (bit 0 (RPD) of parameter No. 1401 is set to 1), manual feed is performed at the feedrate set in this parameter, regardless of the setting of bit 4 (JRV) of parameter No. 1402.

5 AUTOMATIC OPERATION

5.1 CYCLE START/FEED HOLD

Overview

- Start of automatic operation (cycle start)

When automatic operation start signal ST is set to 1 then 0 while the CNC is in memory (MEM) mode, DNC operation mode (RMT), or manual data input (MDI) mode, the CNC enters the automatic operation start state then starts operating.

Signal ST, however, is ignored in the following cases:

1. When the mode is other than MEM, RMT, or MDI
2. When the feed hold signal (*SP) is set to 0
3. When the emergency stop signal (*ESP) is set to 0
4. When the external reset signal (ERS) is set to 1
5. When the reset and rewind signal (RRW) is set to 1
6. When MDI RESET key is pressed
7. When the CNC is in the alarm state
8. When the CNC is in the NOT READY state
9. When automatic operation is executing
10. When the program restart signal (SRN) is 1
11. When the CNC is searching for a sequence number.

The CNC enters the feed hold state and stops operation in the following cases during automatic operation:

1. When the feed hold signal (*SP) is set to 0
2. When the mode is changed to manual operation mode (JOG, INC, HND, REF, TJOG, or THND).
3. When an alarm occurs in the CNC (However, in the case that PS, SR, IO, and a part of other alarm occurs, the CNC enters the automatic operation stop state)

The CNC enters the automatic operation stop state and stops operating in the following cases during automatic operation:

1. When a single command block is completed during a single block operation
2. When operation in manual data input (MDI) mode has been completed
3. When a PS, SR, IO alarm and etc. occurs in the CNC
4. When a single command block is completed after the mode is changed to other automatic operation mode or memory edit (EDIT)

The CNC enters the reset state and stops operating in the following cases during automatic operation:

1. When the emergency stop signal (*ESP) is set to 0
2. When the external reset signal (ERS) is set to 1
3. When the reset and rewind signal (RRW) is set to 1
4. When MDI RESET key is pressed

The state of the CNC (automatic operation start, feed hold, automatic operation stop, or reset) is posted to the PMC with status output signals OP, SPL, and STL. See the table in the "Signal" section for details.

- Halt of automatic operation (feed hold)

When the feed hold signal *SP is set to 0 during automatic operation, the CNC enters the feed hold state and stops operation. At the same time, cycle start lamp signal STL is set to 0 and feed hold lamp signal SPL is set to 1. Re-setting signal *SP to 1 in itself will not restart automatic operation. To restart automatic operation, first set signal *SP to 1, then set signal ST to 1 and then to 0.

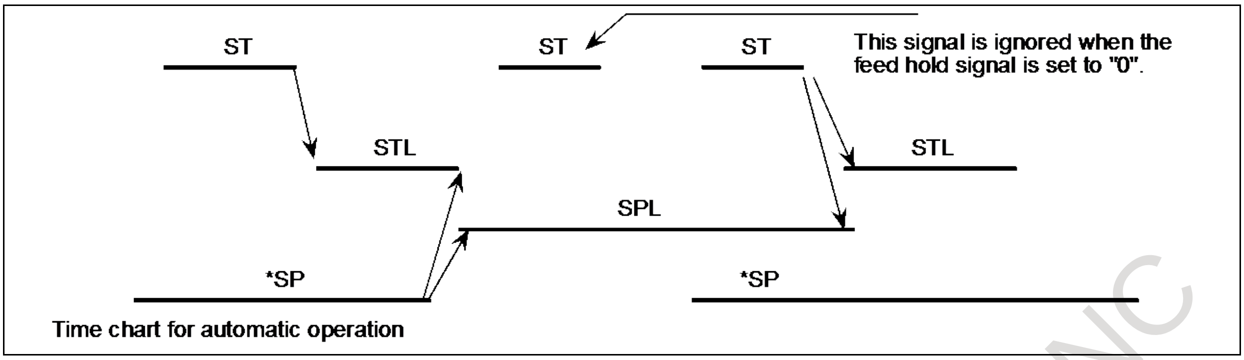

Fig. 5.1 (a)

When signal *SP is set to 0 during the execution of a block containing only the M, S, T, or B function, signal STL is immediately set to 0, signal SPL is set to 1, and the CNC enters the feed hold state. If the FIN signal is subsequently sent from the PMC, the CNC executes processing up until the end of the block that has been halted. Upon the completion of that block, signal SPL is set to 0 (signal STL remains set to 0) and the CNC enters the automatic operation stop state.

(a) During threading
When signal *SP is set to 0 during threading, the CNC enters the feed hold state after executing a non-threading block after the threading blocks.
In lathe system, when signal *SP is set to 0 during threading with the G92 command (threading cycle), signal SPL is immediately set to 1 but operation continues up until the end of the retraction block following threading. When signal *SP is set to 0 during threading with the G32 (M series: G33) command, signal SPL is immediately set to 1 but operation continues until the end of a non-threading block following the threading blocks. (Stopping feeding during threading is dangerous because the amount of cutting will increase.)

(b) During tapping in a canned cycle
When signal *SP is set to 0 during tapping in a canned cycle (G84), signal SPL is immediately set to 1 but operation continues until the tool returns to the initial level or R point level after the completion of tapping.

(c) When a macro instruction is being executed
Operation stops after the currently executing macro instruction has been completed.

Signal

Cycle start signal ST<Gn007.2>

[Classification] Input signal
[Function] Starts automatic operation.
[Operation] When signal ST is set to 1 then 0 in memory (MEM) mode, DNC operation mode (RMT) or manual data input (MDI) mode, the CNC enters the cycle start state and starts operation.
MEM, RMT, or MDI mode

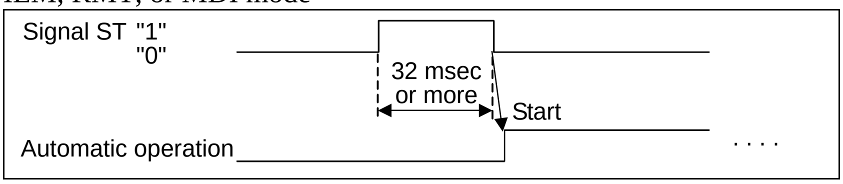

Fig. 5.1 (b)

Feed hold signal *SP<Gn008.5>

[Classification] Input signal
[Function] Halts automatic operation.
[Operation] When signal *SP is set to 0 during automatic operation, the CNC enters the feed hold state and stops operation. Automatic operation cannot be started when signal *SP is set to 0.
MEM, RMT, or MDI mode

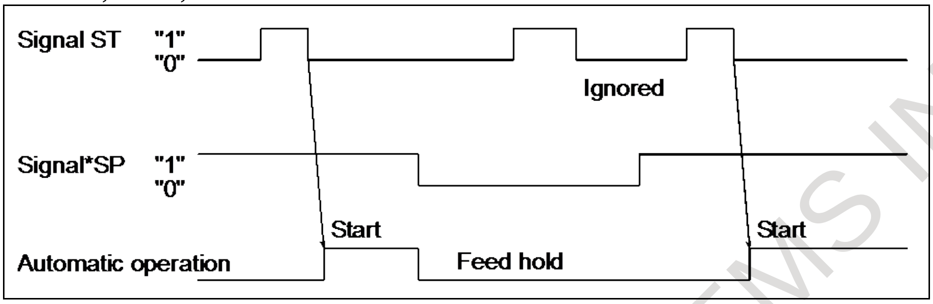

Fig. 5.1 (c)

Automatic operation signal OP<Fn000.7>

[Classification] Output signal
[Function] Notifies the PMC that automatic operation is in progress.
[Output cond.] This signal is set to 1 or 0, according to the state of the CNC, as listed in Table 5.1 (a).

Cycle start lamp signal STL<Fn000.5>

[Classification] Output signal
[Function] Notifies the PMC that automatic operation start is entered.
[Output cond.] This signal is set to 1 or 0, according to the state of the CNC, as listed in Table 5.1 (a).

Feed hold lamp signal SPL<Fn000.4>

[Classification] Output signal
[Function] Notifies the PMC that feed hold state is entered.
[Output cond.] This signal is set to 1 or 0, according to the state of the CNC, as listed in Table 5.1 (a).
Signals OP, STL, and SPL are the signals to inform PMC of the operation condition of CNC.

Table 5.1 (a) Status of operation

Signal name / State of the operation	Cycle start lamp STL	Feed hold lamp SPL	Automatic operation lamp OP
Cycle start state	1	0	1
Feed hold state	0	1	1
Automatic operation stop state	0	0	1
Reset state	0	0	0

(a) Cycle start state
The CNC is executing memory operation or manual data input operation commands.
(b) Feed hold state
The CNC is not executing memory operation nor manual data input operation commands while the commands to be executed remain.
(c) Automatic operation stop state
Memory operation or manual data input operation has been completed and stopped.
(d) Reset state
The automatic operation has been forcibly terminated.

> **NOTE**
> If bit 2 (OPS) of parameter No. 11223 is set to 1, signal OP is set to 1 when a sequence number is searched for by operating keys on the MDI unit in the automatic operation mode (MEM).

Signal address

	#7	#6	#5	#4	#3	#2	#1	#0

[Input type] Parameter input
[Data type] Bit path

#2 OPS In the MEM mode, when a sequence number search operation ([N SEARCH]) is performed, automatic operation signal OP <Fn000.7> is:
0: Kept 0.
1: Set to 1.

Alarm and message

- Self-diagnosis information

During automatic operation, the machine may sometimes show no movement while no alarm is detected. In that case, the CNC may be performing processing or waiting for the occurrence of an event. The state of the CNC can be obtained using the CNC self-diagnosis function (diagnosis data 1000 to 1015).

	MDI operation
	DNC operation
	Checking by self-diagnosis screen

5.2 RESET AND REWIND

Overview

The CNC is reset and enters the reset state in the following cases:

1. When the emergency stop signal (*ESP) is set to 0
2. When the external reset signal (ERS) is set to 1
3. When the reset and rewind signal (RRW) is set to 1
4. When MDI  key is pressed

When the CNC is reset, the resetting signal (RST) is output to the PMC. The resetting signal (RST) is set to 0 when the resetting signal output time, set with parameter No. 3017, has elapsed after the above conditions have been released.

RST signal output time = Treset (Reset processing time) + (parameter setting value) × 16 msec.

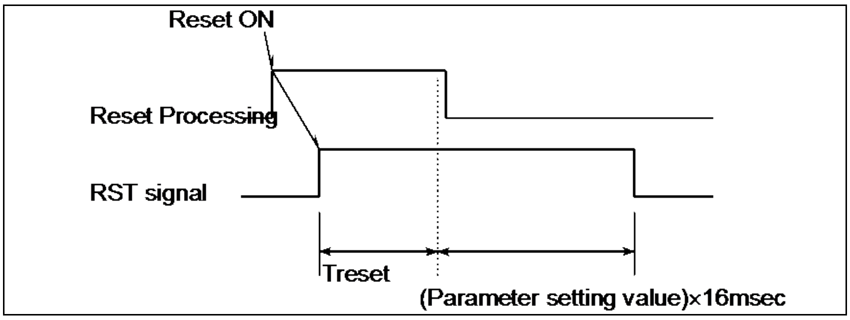

Fig. 5.2 (a)

> ⚠ **CAUTION**
> Treset requires at least 16 msec. This time will be longer on optional configurations.

When the CNC is reset during automatic operation, automatic operation is stopped and tool movement along the controlled axis is decelerated and stopped(CAUTION 1). When the CNC is reset during the execution of the M, S, T, or B function, signal MF, SF, TF, or BF is set to 0 within 100 ms.
Tool movement along the controlled axis is also decelerated and stopped(CAUTION 1) in manual operation (jog feed, manual handle feed, incremental feed, or etc).

> ⚠ **CAUTION**
> When the emergency stop signal (*ESP) is set to 0, the tool is stopped by an emergency stop.

Bit 6 (CLR) of parameter No. 3402 is used to select whether the CNC internal data (such as modal G codes) is cleared or reset when the CNC is reset. Refer to the Appendix F, "Status when turning on power, when cleared, and when reset" in the Operator's Manual for the state of the internal data when cleared or reset.
The following parameters are also used to select how to handle processing for CNC data when the CNC is reset.

- Bit 7 (MCL) of parameter No. 3203
  Whether programs created in MDI mode are erased or stored
- Bit 6 (CCV) of parameter No. 6001
  Whether custom macro variables #100 to #149 (or to #199) are cleared or stored

- Warning indication during a reset in program operation

On the reset state setting for address G, F, H, D, T, S, M, or B (second auxiliary function) when reset occurs, if a reset occurs during block execution in program operation, modal information returns to the state before block execution. Therefore, the warning "MODAL DATA IS CHANGED BY BLOCK STOP" can be displayed so that the operator may notice the modal information is not updated by information of the interrupted block.
To enable or disable the warning, set bit 1 (WMD) of parameter No. 10334.
However, the warning is not displayed if a reset occurs by the reset of the reset & rewind signal RRW.

- Reset & Rewind

When the reset & rewind signal RRW becomes 1, a reset and rewinding are performed.
Rewinding is described below.

1. When automatic operation (DNC operation (RMT)) mode is selected, if a portable tape reader is connected to the selected input/output equipment, the portable tape reader is rewound.
   The rewinding signal RWD is output while the portable tape reader is being rewound. This signal becomes 0 when rewinding is completed.
2. When automatic operation (Memory operation (MEM)) mode or Memory edit (EDIT) mode is selected, the beginning of the selected program is found. When automatic operation (Manual data

input (MDI)) mode is selected, if reset is performed, motion is different according to the state of the program execution and the parameter setting. For details, refer to III-4.2, “MDI OPERATION” in the OPERATOR’S MANUAL (Common to Lathe System / Machining Center System) (B-64694EN). Bit 2 (RWM) of parameter No. 3001 can be used to specify whether the rewinding signal RWD is output.
When RWM is 1, the rewinding signal RWD is kept 1 for 100 ms and then becomes 0. Since the time required for finding the beginning of the program in memory is almost zero, the beginning is already found by the time the rewinding signal RWD becomes 0.

- Reset & Rewind in manual mode

When bit 0 (MRW) of parameter No.10337 is set to 1, the rewind of a program by reset & rewind RRW <Gn008.6> has been possible in manual mode.

Signal

External reset signal ERS<Gn008.7>

[Classification] Input signal
[Function] Reset the CNC.
[Operation] Turning the signal ERS to 1 resets the CNC and enters the reset state. While the CNC is reset, the resetting signal RST turns to 1.

Reset & rewind signal RRW<Gn008.6>

[Classification] Input signal
[Function] CNC is reset and a program under an automatic operation is rewound.
[Operation] As described in the item "Reset & Rewind".

Resetting signal RST<Fn001.1>

[Classification] Output signal
[Function] Notifies the PMC that the CNC is being reset. This signal is used for reset processing on the PMC.
[Output cond.] This signal is set to 1 in the following cases:
1. When the emergency stop signal (*ESP) is set to 0
2. When the external reset signal (ERS) is set to 1
3. When the reset & rewind signal (RRW) is set to 1
4. When MDI RESET key is pressed

This signal is set to 0 in the following case:
- When the resetting signal output time, set with parameter No. 3017, has elapsed after the above conditions have been released and the CNC is reset

Rewinding signal RWD<Fn000.0>

[Classification] Output signal
[Function] Notifies the PMC that the CNC is being rewound.
[Output cond.] As described in the item "Reset and Rewind".

MDI reset confirmation signal MDIRST<Fn006.1>

[Classification] Output signal
[Function] Notifies the PMC that the MDI RESET key has been pressed.
[Output cond.] This signal is set to 1 when:
- The RESET key is pressed when a path for which MDI reset is enabled is selected.

This signal is set to 0 when:

- The MDI RESET key is not pressed.
- A path for which MDI reset is not enabled is selected.

5.2.1 MDI reset key invalidation function

Overview

It is possible to select whether to make effective the MDI reset key in the automatic operation by parameter settings. As a result, the stop of the automatic operation can be disabled even if the MDI reset key is pressed by mistake in the automatic operation. However, when the automatic operation is not executed or the alarm is generated, the MDI reset key is effective.

Explanation

When the following two conditions are satisfied, this function is effective.
- bit 2 (NRP) of parameter No.13450 is 1.
- Reset key input invalid signal IRTKY<Gn299.7> is 1.

When this function is effective, Table 5.2.1 (a) indicates the relation between the CNC state and the MDI reset key valid (the CNC is reset.) / invalid (the CNC is not reset.).
Even if MDI reset key is pressed, CNC is not reset if MDI reset key is invalid. The program being executed is not interrupted.
However, when the MDI reset key is pushed in the following cases, the CNC is reset regardless of the CNC state shown in Table 5.2.1 (a).
- The alarm is generated.
- The cancel key is pushed at the same time.

Table 5.2.1 (a) The relation between the CNC state and the MDI reset key valid / invalid

Signal name / CNC state	Cycle start lamp STL	Feed hold lamp SPL	Automatic operation OP	MDI reset key valid / invalid
Cycle start state	1	0	1	invalid
Feed hold state	0	1	1	invalid
Automatic operation stop state	0	0	1	invalid / valid (NOTE *)
Reset state	0	0	0	valid

(NOTE *) When bit 3 (NRP) of parameter No.13450 is 1, the MDI reset key is valid in the automatic operation stop state.

Signal

Reset key input invalid signal IRTKY <Gn299.7>

[Classification] Input signal
[Function] The MDI reset key valid / invalid is switched in the automatic operation.
[Operation] 0 : The MDI reset key is valid.
1 : The MDI reset key is invalid.

> **NOTE**
> When bit 2 (NRP) of parameter No.13450 is 1, this signal is effective.

Signal address

	#7	#6	#5	#4	#3	#2	#1	#0
Gn299	IRTKY							

Parameter

	#7	#6	#5	#4	#3	#2	#1	#0
13450					NRC	NRP		

[Input type] Parameter input
[Data type] Bit path

#2 NRP When the MDI reset key is pushed in the automatic operation
0: the CNC is reset.
1: the CNC is not reset.

> **NOTE**
> Bit 2 (NRP) of parameter No.13450 and Reset key input invalid signal IRTKY <Gn299.7> must be set “1” for each path to enable this function.

#3 NRC When bit 2 (NRP) of parameter No.13450 is 1, and the MDI reset key is pushed in the automatic operation stop state,
0: the CNC is not reset.
1: the CNC is reset.

When bit 2 (NRP) of parameter No.13450 is 1, the table below indicates the relation between the CNC state and the MDI reset key valid / invalid.

Signal name / CNC state	Cycle start lamp STL	Feed hold lamp SPL	Automatic operation OP	MDI reset key valid / invalid
Cycle start state	1	0	1	invalid
Feed hold state	0	1	1	invalid
Automatic operation stop state	0	0	1	invalid / valid (NOTE *)
Reset state	0	0	0	valid

(NOTE *) When bit 3 (NRP) of parameter No.13450 is 1, the MDI reset key is valid in the automatic operation stop state.

5.3 TESTING A PROGRAM

Overview

Before machining is started, the automatic running check can be executed. It checks whether the created program can operate the machine as desired. This check can be accomplished by running the machine or viewing the position display change without running the machine.

5.3.1 Machine Lock

Overview

The change of the position display can be monitored without moving the machine. When all-axis machine lock signal MLK, or each-axis machine lock signals MLK1 to MLK8 are set to 1, output pulses (move commands) to the servo motors are stopped and the machine coordinates are not updated in manual and automatic operation. The commands are distributed, however, updating the absolute and relative coordinates. The operator can therefore check if the commands are correct by monitoring the position display.

Explanation

- Automatic operation in the machine lock state (M, S, T, and B commands)

Machine lock applies only to move commands along controlled axes. Updating modal G codes or setting a coordinate system is performed normally. M, S, T, and B (2nd auxiliary function) commands are also performed normally.

- Turning on/off the machine lock signal during movement along an axis

When the machine lock signal for an axis is set to 1 during movement along the axis that is not in the machine lock state, the axis is immediately placed in the machine lock state and output pulses (move commands) to the servo motor are stopped. The tool is decelerated and stopped with the automatic acceleration/deceleration function.
On the other hand, when the machine lock signal for an axis is set to 0 during distribution of the move command along the axis in the machine lock state, pulse (move command) output for the axis is immediately restarted. The tool is accelerated with the automatic acceleration/deceleration function.

- Machine lock shift value

When a move command is executed in the machine lock state after once the workpiece coordinate system is fixed, the workpiece coordinate system is shifted from the machine coordinate system because machine coordinates are not updated. This shift amount is called a machine lock shift value. Diagnosis data No.4104 indicates the machine lock shift value.
The machine lock shift value is cancelled by the manual reference position return or the workpiece coordinate system preset operation.

- Machine lock shift value check in automatic operation

If bit 2 (MSC) of parameter No.11501 is 1, when the workpiece coordinate system is shifted by the axis movement in the machine lock state, the alarm PS5559"ILL. AXIS OPERATION (COORD SYS)" is issued. This can prevent forgetting to cancel the shift value by the manual reference position return and the workpiece coordinate system preset operation after the machine lock is released.

- Coordinate position display screen

When a machine lock is being applied to an axis, “L” appears on the left side of the axis address of the axis on the coordinate position display screen.

Limitation

- Outputting the movement state of ax axis

Axis moving signals MV1 to MV8 <Fn102> are useful in the machine lock state.
Axis moving direction signals MVD1 to MVD8 <Fb106> are useless in the machine lock state. These signals maintain their condition before the machine lock.

- Reference position return (G27, G28, and G30)

When the reference position return command (G28), or 2nd to 4th reference position return command (G30), is executed for an axis in the machine lock state, in motion to middle point, distribution and position updating are performed. The tool, however, is not returned to the reference position. The reference position return completion signals (ZP1 to ZP4) are not output.
The reference position return check command (G27) is ignored in the machine lock state.

- Selecting a machine coordinate system (G53)

When a positioning of machine coordinate system (G53) is specified in the machine lock state, move commands are invalid and absolute coordinates and relative coordinates are not updated.
When machine lock is applied during G53 movement, output pulses (move commands) to the servo motors are stopped and machine coordinates are not updated. The absolute and relative coordinates are updated.

- High precision oscillation function

Do not switch machine lock signal to the oscillation axis during oscillation motion, otherwise an alarm PS5050 "ILL-COMMAND IN G81.1 MODE" is issued.

- Manual intervention and return

Do not perform manual intervention in the machine lock state, otherwise the tool might move to wrong position in return operation.

- Tool retract and recover

Do not perform manual retraction in the machine lock state, otherwise the tool might move to wrong position in recovery.

- Program restart / Quick program restart

The tool cannot be returned to a correct position under the following conditions.
- Manual operation is performed in the machine lock state.
- When program restart is specified in the machine lock state, then the machine lock is canceled.

- Type for counting time of tool management function

The count-up operation is not performed in the machine lock state.

- High-speed program check function

During the high-speed program check mode, all-axis machine lock signal MLK and each-axis machine lock signals MLK1 to MLK8 are invalid except for PMC control axis.

- PMC axis control

When bit 0 (MLE) of parameter No.8001 is 1, all-axis machine lock signal MLK and each-axis machine lock signals MLK1 to MLK8 are invalid for PMC-controlled axes. However, each-axis machine lock signals MLK1 to MLK8 become valid by setting bit 1 (MLS) of parameter No.8006 to "1".
All-axis machine lock signal and each-axis machine lock signals are invalid in the following command irrespective of setting parameter MLE and MLS.
- Speed command
- Torque control command

T

- Balance cutting

Balance cutting is not performed in the machine lock state.

- Each-axis machine lock

In some functions (e.g., synchronous control, coordinate system rotation), axes which are not specified move. And relationships between each-axis machine lock signals and effecting axis are various ways.

1 In the following functions, each-axis machine lock signals effect to output pulses (move commands) after conversion.
   - Coordinate system rotation
   - 3-dimentional coordinate conversion
   - Tilted working plane indexing

2 In arbitrary angular axis control, each-axis machine signals are applied to move commands specified in the Cartesian coordinate system (the program coordinate system).
   When each-axis machine lock signal is applied to the perpendicular axis, machine lock is valid to a movement of the perpendicular axis by specifying the perpendicular axis, but invalid to a movement of the perpendicular axis by specifying the angular axis.
   When each-axis machine lock signal is apply to the angular axis, machine lock is valid to the movement of the perpendicular axis and the angular axis by specifying the angular axis.

3 Table 5.3.1 (a) and Table 5.3.1 (b) list about the relational functions to synchronous control.

Table 5.3.1 (a)

Function	Moving axis	MLKx to master axis	MLKx to slave axis
Axis synchronous control	Master axis	Valid	Invalid
	Slave axis	Valid	Invalid
Tandem control	Master axis	Valid	Invalid
	Slave axis	Valid	Invalid
Flexible synchronization control	Master axis	Valid	Invalid
	Slave axis (By specifying master axis)	Valid	Invalid
	Slave axis (By specifying slave axis)	Invalid	Valid
Synchronous control	Master axis	Valid	Invalid
	Slave axis	Invalid	Valid
Superimposed control	Master axis	Valid	Invalid
	Slave axis (By specifying master axis)	Valid	Invalid
	Slave axis (By specifying slave axis)	Invalid	Valid

Table 5.3.1 (b)

Function	Moving axis	MLKx to composite axis 1	MLKx to composite axis 2
Composite control	Composite axis 1	Invalid	Valid
	Composite axis 2	Valid	Invalid

- Functions that cannot be used simultaneously

The following functions are not useful in the machine lock state because they depend on machine coordinates.

- Stored stroke check 1
- Stored stroke check 2, 3
- Stored stroke check before movement
- Position switch
- High-speed position switch

Signal

All-axis machine lock signal MLK<Gn044.1>

[Classification] Input signal

[Function] Places all controlled axes in the machine lock state.

[Operation] When this signal is set to 1, pulses (move commands) are not output to the servo motors for all axes in manual or automatic operation.

Each-axis machine lock signals MLK1 to MLK8<Gn108>

[Classification] Input signal

[Function] Place the corresponding controlled axes in the machine lock state.
These signals are provided for each controlled axis. The signal number corresponds to the number of the controlled axis.

MLK 1

1 . . . Machine lock for the 1st axis
2 . . . Machine lock for the 2nd axis
3 . . . Machine lock for the 3rd axis
:

[Operation] When these signals are set to 1, pulses (move commands) are not output to the servo motors for the corresponding axes (1st to 8th) in manual or automatic operation.

All-axis machine lock check signal MMLK<Fn004.1>

[Classification] Output signal

[Function] Notifies the PMC of the state of the all-axis machine lock signal.

[Output cond.] This signal is set to 1 in the following case:

- When all-axis machine lock signal MLK is set to 1

This signal is set to 0 in the following case:

- When all-axis machine lock signal MLK is set to 0

Signal address

11501						MSC		

[Input type] Parameter input

[Data type] Bit path

#2 MSC The machine lock shift value check in automatic operation is:

0: Not applied.

1: Applied.

NOTE
1. This function is invalid for the axis in the machine lock state.
2. The followings can be commanded with the machine lock shift value remained.
   - Automatic reference position return (The middle point is not specified)
   - Workpiece coordinate system preset
   - Local coordinate system setting
   - Machine coordinate system setting
   - Coordinate system setting
   - Workpiece coordinate system setting (Axis movement is not specified)
3. In other automatic operation, if there is no movement in the machine coordinate system, the alarm is not issued.
4. This function is invalid for the dummy axis. (Bit 4(KSV) of parameter No.11802 is set to 1 or bit 0(DMY) of parameter No.2009 is set to 1.)

Alarm and message

Number	Message	Description
PS5559	ILL. AXIS OPERATION (COORD SYS)	When the bit 2(MSC) of parameter No.11501 is set to 1, and the workpiece coordinate system is shifted from the machine coordinate system by the movement command in the machine lock state, the axis movement was commanded. Please operate "reference position return" or "workpiece coordinate system preset" etc.

5.3.2 Dry Run

Overview

Dry run is valid only for automatic operation.
The tool is moved at a constant feedrate regardless of the feedrate specified in the program. This function is used, for example, to check the movement of the tool without a workpiece.

⚠ **CAUTION**
This feedrate depends on the specified parameters, the manual rapid traverse switching signal (RT), manual feedrate override signals (*JV0 to *JV15), and whether the command block specifies rapid traverse or cutting feed, as listed in the table below.

Table 5.3.2 (a)

Manual rapid traverse switching signal (RT)	Program command	
	Rapid traverse	Cutting feed
1	Rapid traverse rate	Dry run feedrate × Jvmax (*2)
0	Dry run speed × JV, or rapid traverse rate (*1)	Dry run feedrate × JV (*2)

Max. cutting feedrate : Setting by parameter No.1430
Rapid traverse rate : Setting by parameter No.1420

Dry run feedrate : Setting by parameter No.1410
JV : Manual feedrate override
Jvmax : Maximum value of manual feedrate override

*1 Dry run feedrate × JV when bit 6 (RDR) of parameter No. 1401 is 1. Rapid traverse rate when parameter RDR is 0.
*2 Clamped by maximum cutting feedrate.

The acceleration/deceleration type and the time constant for this feedrate are listed in the table below.

Table 5.3.2 (b)

Manual rapid traverse switching signal (RT)	Program command	
	Rapid traverse	Cutting feed
1	Rapid traverse type	Cutting feed type
0	Jog feed type, or Rapid traverse type(*3)	Cutting feed type

Time constant for Rapid traverse type : Setting by parameter No.1620
Time constant for Jog feed type : Setting by parameter No.1624
Time constant for Cutting feed type : Setting by parameter No.1622

*3 Jog feed type when bit 6 (RDR) of parameter No. 1401 is 1. Rapid traverse type when parameter RDR is 0.

Signal

Dry run signal DRN<Gn046.7>

[Classification] Input signal
[Function] Enables dry run.
[Operation] When this signal is set to 1, the tool is moved at the feedrate specified for dry run.
When this signal is set to 0, the tool is moved normally.

> ⚠ **CAUTION**
> When the dry run signal is changed from 0 to 1 or 1 to 0 during the movement of the tool, the feedrate of the tool is first decelerated to 0 before being accelerated to the specified feedrate.

Dry run check signal MDRN<Fn002.7>

[Classification] Output signal
[Function] Notifies the PMC of the state of the dry run signal.
[Output cond.] This signal is set to 1 in the following case:
- When dry run signal DRN is set to 1

This signal is set to 0 in the following case:
- When dry run signal DRN is set to 0

Signal address

	#7	#6	#5	#4	#3	#2	#1	#0
Gn046	DRN							

	#7	#6	#5	#4	#3	#2	#1	#0
Fn002	MDRN							

Parameter

	#7	#6	#5	#4	#3	#2	#1	#0
1401		RDR	TDR					

[Input type] Parameter input
[Data type] Bit path

#5 TDR Dry run during threading or tapping (tapping cycle G74 or G84, rigid tapping)
0: Enabled
1: Disabled

#6 RDR Dry run for rapid traverse command
0: Disabled
1: Enabled

1410	**Dry run rate**

[Input type] Parameter input
[Data type] Real path
[Unit of data] mm/min, inch/min, deg/min (machine unit)
[Min. unit of data] Depend on the increment system of the reference axis
[Valid data range] Refer to the standard parameter setting table (C)
(When the increment system is IS-B, 0.0 to +999000.0)
Set the dry run rate at the 100% position on the jog feedrate specification dial. The unit of data depends on the increment system of the reference axis. Setting this parameter to 0 results in alarm PS5009, "PARAMETER ZERO (DRY RUN)", being issued.

1420	**Rapid traverse rate for each axis**

[Input type] Parameter input
[Data type] Real axis
[Unit of data] mm/min, inch/min, deg/min (machine unit)
[Min. unit of data] Depend on the increment system of the applied axis
[Valid data range] Refer to the standard parameter setting table (C)
(When the increment system is IS-B, 0.0 to +999000.0)
Set the rapid traverse rate when the rapid traverse override is 100% for each axis.

Manual name	Item name
OPERATOR'S MANUAL (B-64694EN)	Dry run

5.3.3 Single Block

Overview

Single block operation is valid only for automatic operation.
When the single block signal (SBK) is set to 1 during automatic operation, the CNC enters the automatic operation stop state after executing the current block. In subsequent automatic operation, the CNC enters the automatic operation stop state after executing each block in the program. When the single block signal (SBK) is set to 0, normal automatic operation is restored.
Single block operation during the execution of custom macro statements depends on the setting of bits 5 (SBM) and 7 (SBV) of parameter No. 6000, as follows:

SBM=0, SBV=0 : Operation does not stop in the custom macro statements but stops once the next NC command has been executed.

SBM=1 : Operation stops after each block in the custom macro statements.

SBV=1 : Single block operation in custom macro statements is suppressed using macro system variable #3003. Execution of custom macro statements is stopped after each block execution.

> **NOTE**
> 1 In the cutter or tool nose radius compensation mode, the block look-ahead operation is performed even in single-block operation to calculate a path intersection after offsetting. So, a macro statement is also executed when read in advance. Therefore, turn off the cutter or tool nose radius compensation mode, when the single block operation is enabled for custom macro statements by SBM=1 or SBV=1.
> 2 When the single block operation is enabled for custom macro statements by SBM=1 or SBV=1, a custom macro statement block is assumed to be an NC statement block that does not involve movement. Therefore, the motion may differ between the normal operation and the single block operation.

When M99 is executed by the single block operation, operation stops after executing the next block of M99. However, when the single block stop is invalidated by the system variable #3003, and the single block stop is validated again by the system variable #3003, the single block stop is done with the first M99. However, when bit 0 (M99) of parameter No.11648 is set to 1, operation can be stopped with M99.
When the CNC is in the automatic operation stop state during single block operation, the mode can be changed to manual data input (MDI), manual handle feed (HNDL), incremental feed (INC), or jog feed (JOG), by using the mode select signals (MD1, MD2, and MD4).

Signal

Single block signal SBK<Gn046.1>

[Classification] Input signal
[Function] Enables single block operation.
[Operation] When this signal is set to 1, single block operation is performed.
When this signal is set to 0, normal operation is performed.

Single block check signal MSBK<Fn004.3>

[Classification] Output signal
[Function] Notifies the PMC of the state of the single block signal.
[Output cond.] This signal is set to 1 in the following case:
- When single block signal SBK is set to 1

This signal is set to 0 in the following case:
- When single block signal SBK is set to 0

Signal address

	#7	#6	#5	#4	#3	#2	#1	#0
Gn046							SBK	

	#7	#6	#5	#4	#3	#2	#1	#0
Fn004					MSBK			

Parameter

	#7	#6	#5	#4	#3	#2	#1	#0
6000	SBV		SBM					

[Input type] Parameter input
[Data type] Bit path

#5 SBM Custom macro statement

0: Not stop the single block

1: Stops the single block

If you want to disable the single blocks in custom macro statements using system variable #3003, set this parameter to 0. If this parameter is set to 1, the single blocks in custom macro statements cannot be disabled using system variable #3003. To control single blocks in custom macro statements using system variable #3003, use bit 7 (SBV) of parameter No. 6000.

#7 SBV Custom macro statement

0: Not stop the single block

1: Enable/disable single block stop with system variable #3003

		Bit 5 (SBM) of parameter No. 6000	
		0	1
Bit 7 (SBV) of parameter No. 6000	0	Disables single block stop.	Enables single block stop. (With variable #3003, single block stop cannot be enabled/disabled. Single block stop is enabled at all times.)
	1	Enables single block stop. (With variable #3003, single block stop can be enabled/disabled.)	

NOTE

1. In the cutter or tool nose radius compensation mode, the block look-ahead operation is performed even in single-block operation to calculate a path intersection after offsetting. So, a macro statement is also executed when read in advance. Therefore, turn off the cutter or tool nose radius compensation mode, when the single block operation is enabled for custom macro statements by SBM=1 or SBV=1.
2. When the single block operation is enabled for custom macro statements by SBM=1 or SBV=1, a custom macro statement block is assumed to be an NC statement block that does not involve movement. Therefore, the motion may differ between the normal operation and the single block operation.

	#7	#6	#5	#4	#3	#2	#1	#0
11648								M99

[Input type] Parameter input

[Data type] Bit

#0 M99 When the M99 is executed in the single block operation:

0: Operating stops after executing the previous return block.

1: Operating stops before executing the previous return block.

This function is effective only for M99 commanded in the following programs.

- Execution macro of macro executor
- Programs in "//CNC_MEM/SYSTEM" folder (*1)
- Programs in "//CNC_MEM/MTB1" folder (Embedded macro) (*1)
- Programs in "//CNC_MEM/MTB2" folder(*1)
- Programs of O number within the range specified by parameter 11656 and 11658.

(*1) It is effective only to the program put on the right under of each folder. When the subfolder is made and the program is put, parameter M99 is invalid to such a program.

11656	The first O number of the program for parameter M99(No.11648#0) make effective

[Input type] Parameter input
[Data type] 2-word path
[Valid data range] 1 to 99999999

Specify the first O number for parameter M99(No.11648#0) make effective.
When this parameter is 0, the specification of O number in which parameter M99 is made effective is invalid.

11657	The number of programs for parameter M99(No.11648#0) make effective

[Input type] Parameter input
[Data type] 2-word path
[Valid data range] 1 to 99999999

Specify the number of programs for parameter M99(No.11648#0) make effective.
When this parameter is 0, the specification of O number in which parameter M99 is made effective is invalid.

CAUTION

⚠ CAUTION

1. Operation in thread cutting
   When the SBK signal turns to 1 during thread cutting, operation stops after execution of the first non-thread cutting block after the thread cutting command.
2. Operation in canned cycle
   When the SBK signal turns to 1 during canned cycle operation, the operation stops at each positioning, approach, drilling and retreat instead of the end of the block. The SPL signal turns to 1 while the STL signal turns to 0, showing that the end of the block has not been reached. When the execution of one block is completed, the STL and SPL signals turn to 0 and the operation is stopped.
3. When a parameter M99(No.11648#0) is set to 1, the tool path might be different because of a single block operation and a continuous operation, when the block where the movements do not exist is commanded just before or just behind M99 in the cutter compensation and tool nose radius compensation mode.

5.3.4 High-speed Program Check Function

Overview

High-speed program check function has following features.

- The program format check and the stroke limit check are available without axes movements.
- The program check is executed with the maximum feedrate of CNC system and without the acceleration/deceleration regardless of the specified data.
- After the program check is completed, the reference position return is not necessary because the workpiece coordinate system preset is executed automatically at the end of the high-speed program check mode.
- In case that the bit 3 (PGR) of parameter No. 3454 is set to 1, the data, which are changed during the high-speed program check mode, are restored to the data at the start of the high-speed program check mode when ending the high-speed program check mode.

By this, after ending the high-speed program check mode, the automatic operation can be executed with the data before the start of the high-speed program check mode.

Explanation

- Basic operation procedure of the high-speed program check

(1) Set the high-speed program check mode.
(2) Perform a cycle start operation. The high-speed program check is then performed.
(3) After program execution is completed and the check ends, the high-speed program check mode ends.

- Start of High-speed program check mode

The high-speed program check mode is started under both of the following conditions.

- The signal PGCK <Gn290.5> for high-speed program check is 1.
- MEM or DNC mode is selected.

When the mode is except MEM or DNC mode, the high-speed program check mode is not started even if the signal PGCK <Gn290.5> is 1.

- End of High-speed program check mode

The high-speed program check mode is ended under one of the following conditions.

- The signal PGCK <Gn290.5> is changed from 1 to 0.
- A mode except MEM or DNC is selected during the high-speed program check mode.

> **NOTE**
> The alarm PS5365 occurs when the signal PGCK <Gn290.5> is changed while a program is executing.

- Program Check Start

The program check is started when the signal ST <Gn007.2> for cycle start signal is changed from 1 to 0 at the high-speed program check mode.
Then, the program execution is started without axes movements.

- Stroke Limit Check

Following the stroke limit check is executed without axes movements during the high-speed program check mode.

- Stored stroke check 1
- Stored stroke check 2, 3
- Stroke limit check before move

> **NOTE**
> The stroke limit check during the high-speed program check mode is similar to the normal stored stroke limit check. (The alarm 500 etc. occurs at exceeding the stroke limit.)
> As for the details of occurrence alarms, refer to chapter of stored stroke check in Operator's Manual.

- Program Check Feedrate

During the high-speed program check mode, the feedrate of program execution becomes the maximum feedrate of CNC system regardless of the specified feedrate.
The feedrate clamp, override and dry run are not effective.

Table 5.3.4 (a)

Increment system	Program check execution feedrate		
	IS-A	IS-B	IS-C
Millimeter machine (unit: mm/min)	999000	999000	999000
Inch machine (unit: inch/min)	96000	9600	9600
Rotary axis (unit: deg/min)	999000	999000	999000

> ⚠ **CAUTION**
> The program check execution feedrate at circle interpolation is according to the bit 7 (PGF) of parameter No. 1490 setting.

> **NOTE**
> 1 The execution time of dwell is the same as a normal operation.
> 2 The PS011 alarm occurs when there is no F command in a normal operation. However, it is executed at maximum speed without the alarm in the high-speed program check mode even if there is no F command.

- Acceleration / deceleration

During the high-speed program check mode, the acceleration/deceleration after interpolation and before interpolation is not executed regardless of the acceleration/deceleration setting value. (Acceleration/deceleration time constant becomes to 0.)

- Workpiece Coordinate System Preset

When the high-speed program check mode is ended, the workpiece coordinate system preset is executed automatically.
Therefore, the program execution can be done without doing the reference position return after the program check.

> ⚠ **WARNING**
> When the coordinate system is set before the high-speed program check mode is turned on by the work coordinate system setting G92 (machining center system and G code system B or C of the lathe system), G50 (G code system A of the lathe system) and the local coordinate system setting G52, their setting values are deleted by the execution of the work coordinate system preset.

> **NOTE**
> 1 When the bit 3 (PGR) of parameter No. 3454 is set to 0, set the bit 6 (WPS) of parameter No. 3006 to 1 to do workpiece coordinate system preset at the end of the high-speed program check mode. When the bit 3 (PGR) of parameter No. 3454 is set to 1, workpiece coordinate system preset is executed at the end of the high-speed program check mode regardless of the bit 6 (WPS) of parameter No. 3006 setting.
> 2 When the bit 3 (PGR) of parameter No. 3454 is set to 1 in multi-path system, all paths must be in the high-speed program check mode simultaneously. If some paths are in the high-speed program check mode, the automatic operation can not be executed in other paths.

- Machine Coordinate Display For Program Check

During the high-speed program check mode, it is possible to change the display of machine coordinates from the actual machine coordinates to the machine coordinates for the program check by setting bit 7 (PGM) of parameter No.11320.

And it is possible to change the display of machine coordinate for each axis from the actual machine coordinate to the machine coordinate for the program check by setting bit 4 (PGA) of parameter No.3115.

NOTE

1. When the signal EAX* <Gn136> for control axis select (PMC axis control) is set to 1, the machine coordinate of the axis shows the actual machine coordinate regardless of the parameter PGM and PGA setting.
2. The diagnosis data No. 301 (machine position) always shows the actual machine coordinate (the machine position from the reference position) regardless of the parameter PGM and PGA setting.

- Display during High-speed program check mode

During the high-speed program check mode, "PRG-CHK" blinks on the lower right of the CNC display.

- Tool life

If tool life management command or tool management command is specified during the high-speed program check mode, tool life is not counted.

- Auxiliary function

When the bit 6 (PGS) of parameter No. 3001 is set to 0, the auxiliary function is not executed during the high-speed program check mode. This is same as when the signal AFL <Gn005.6> for auxiliary function lock is 1. That is, M, S, T, and B function code signals and strobe signals are not output.
When the bit 6 (PGS) of parameter No. 3001 is set to 1, the M, S, T, and B function code signals and strobe signals are output during the high-speed program check mode. This is same as the normal operation.

⚠ WARNING

Please note that the spindle rotates by S command under the either of following conditions during the high-speed program check mode. To prohibit the rotation of the spindle in the high-speed program check mode, take countermeasure in PMC ladder using the signal PRGMD<Fn290.5>.

- Lathe system
- Constant surface speed control is effective
- T type gear selection method (bit 4 (GTT) of parameter No. 3706 =1)

⚠ CAUTION

1. When the bit 6 (PGS) of parameter No. 3001 is set to 1, the M, S, T, and B codes are output to the PMC. Therefore, if it is not necessary to execute the M, S, T, and B command during high-speed program check mode, please modify ladder sequence not to execute M, S, T, and B code by referring to the signal <Fn290.5> for the high-speed program check mode.
2. If M code (Parameter No.11275), which turns on each axis workpiece coordinate system preset signal, is commanded in the high-speed program check mode with bit 6 (PGS) of parameter No. 3001=0, the alarm PS5364 occurs. In the machine that uses such a program, set bit 6 (PGS) of parameter No. 3001 to 1.
3. In case of using the tool management function, set bit 6 (PGS) of parameter No. 3001 to 1 and execute the window function (code 329) by T code and M code as well as usually operation in order to execute the tool compensation correctly with D99 and H99.

- Data save at start of high-speed program check mode

When the bit 3 (PGR) of parameter No. 3454 is set to 1, the following data are saved at the start of the high-speed program check mode.

- Modal G-code
- F, S, T, M, B, H, D-code
- Tool life management data
- Tool management data
- Variable data changed by programmable data entry (G10)
  - Tool offset values
  - External workpiece origin offset values
  - Workpiece origin offset values (1 to 6)
  - Workpiece origin offset values of additional workpiece coordinate systems (1 to 48 or 1 to 300)
  - Rotary table dynamic fixture offset values (Machining center system)
  - Parameters
  - Tool data of the path interference check function (Lathe system and multi path system)
  - Workpiece coordinate system shift values (Lathe system)
  - Graphic parameters
- Macro variables
  - Local variables #1 to #33
  - Common variables #100 to #149 (#199), #500 to #531 (#999)

NOTE

1. The data of the periodic maintenance screen are not saved.
2. When the bit 6 (PGS) of parameter No. 3001 is set to 1, the M, S, T, and B codes are not saved.
3. In multi path system, the data in all paths is saved when one path becomes the high-speed program check mode.

- Data restore at end of high-speed program check mode

In case that the bit 3 (PGR) of parameter No. 3454 is set to 1, the data, which are changed during the high-speed program check mode, are restored to the data at the start of the high-speed program check mode when ending the high-speed program check mode.
By this, after ending the high-speed program check mode, the automatic operation can be executed with the data before the start of the high-speed program check mode.
The data to be restored are the same as those of described on "Data save at start of high-speed program check mode".

⚠ **WARNING**

1. In multi path system, the data in all paths is saved when one path becomes the high-speed program check mode, and the data in all paths is restored when all paths get out of the high-speed program check mode. That is, when there is different timing of changing the high-speed program check signal PGCK<Gn290.5> in each path, the completion of the high-speed program check mode in a path might influence the operation of other paths. For instance, if the high-speed program check mode of a path is turned off when machining is in progress on another path, it might face dangerous situation because the data of other paths during machining also changes. Therefore, in multi path system, please keep the timing of the state of the high-speed program check mode simultaneously in all paths when you set bit 3 (PGR) of parameter No. 3454 to 1. Please do not have both paths of the high-speed program check mode and paths of normal mode in a multi path system.

> ⚠ **WARNING**
>
> 2 The coordinate value set by the work coordinate system setting G92 (machining center system and G code system B or C of the lathe system), G50 (G code system A of the lathe system) and the local coordinate system setting G52 is not restored.

> ⚠ **CAUTION**
>
> 1 After restoring the data, the absolute coordinate is calculated from machine coordinate by using the restored data.
> 2 In case that the relative position display is preset (the bit 3 (PPD) of parameter No. 3104 is set to 1) in the coordinate system setting, the relative coordinate is not restored and presets same value as the absolute coordinate.
> 3 The data of the periodic maintenance screen are not restored.
> 4 When the bit 6 (PGS) of parameter No. 3001 is set to 1, the M, S, T, and B codes are not restored.
> 5 The save/restore of the data before/after the program check of the high-speed program check function is realized by saving all data before the program check and restoring all data after the program check. Therefore, even when the data is changed without the program command such as the PMC window during the program check, the changed data returns to the value before the program check.

Limitation

- High-speed program check signal

The alarm PS5365 occurs when the signal PGCK <Gn290.5> is changed from 0 to 1 or from 1 to 0 while a program is executing.

- Stroke limit check

When a command that exceeds a stroke limit is specified in the high speed program check mode, an overtravel alarm occurs after the stroke limit is exceeded regardless of the bit 7 (BFA) of parameter No. 1300 setting.
The process of the overtravel alarm cancellation is as follows.
(1) Change to the mode except MEM or DNC.
(2) Push RESET key or input reset signal.

The alarm cancellation of stroke limit check 1 is based on the bit 4 (OF1) of parameter No. 1301. Therefore, when the parameter OF1 is set to 0, the alarm is cancelled by the above process and when this parameter is set to 1, the alarm is cancelled automatically when the high-speed program check mode is ended.

Bit 4 (OF1) of parameter No. 1301:
If the axis is moved into the allowable range after an OT alarm is generated by stored stroke check 1,
0: The alarm is not canceled before a reset is made.
1: The alarm is immediately canceled.

- Stroke limit check before move

When there is a movement command that exceeds the stroke limit in the high-speed program check mode, an alarm of the stroke limit check before move and a usual overtravel alarm might occur at the same time.

- Stored stroke check 2, 3

In case that there is narrow forbidden area, the alarm might not be able to be detected in the block which crosses the forbidden area in the high-speed program check mode.

- Machine coordinate display

As for the axis whose the signal EAX* <Gn136> for control axis select (PMC axis control) is 1, the machine coordinate shows the actual machine coordinate (the machine position from the reference position) regardless of the bit 7 (PGM) of parameter No. 11320 and bit 4 (PGA) of parameter No. 3115 setting.

- Workpiece coordinate system preset

Please set the bit 6 (WPS) of parameter No. 3006 to 1 to do workpiece coordinate system preset automatically at the end of the high-speed program check mode.
When the workpiece coordinate system preset is commanded by the soft key operation or input signal during the high-speed program check mode, the workpiece coordinate system is established based on the actual machine coordinate.

> ⚠ **WARNING**
> When the coordinate system is set before the high-speed program check mode is turned on by the work coordinate system setting G92 (machining center system and G code system B or C of the lathe system), G50 (G code system A of the lathe system) and the local coordinate system setting G52, their setting values are deleted by the execution of the work coordinate system preset.

- Reference Position Return (G28)

The alarm PS5364 occurs when the reference position is not established and G28 is specified during the high-speed program check mode.

- Machine Lock Signal

During the high-speed program check mode, all-axis machine lock signal MLK <Gn044.1> and each-axis machine lock signals MLK1 to MLK8 <Gn108> are invalid except for PMC control axis.

- Control axis select signal (PMC axis control)

In case that the bit 3 (PGR) of parameter No. 3454 is set to 1, the alarm PS5364 occurs when the signal EAX* <Gn136> for control axis select (PMC axis control) is changed from 0 to 1 or from 1 to 0 during the high-speed program check mode.

- Save / restore of data

The save/restore of the data before/after the program check of the high-speed program check function is realized by saving all data before the program check and restoring all data after the program check.
Therefore, even when the data is changed without the program command such as the PMC window during the program check, the changed data returns to the value before the program check.

- Restore of data

When the power off request alarm is generated during the high-speed program check mode and the CNC power is turned off immediately, the changed data still remain. Therefore, if a restore of data is necessary, turn off the CNC power after ending the high-speed program check mode and restoring the saved data.

- Programmable parameter input (G10)

The bit 3 (PGR) of parameter No. 3454 and the bit 6 (PGS) of parameter No. 3001 can not be changed by programmable parameter input (G10). When G10 L52 is commanded to these parameter bits, the alarm PS5364 occurs.

- Cycle start

In case that the bit 3 (PGR) of parameter No. 3454 is set to 1, the signal ST <Gn007.2> for cycle start are invalid during the data saving and restoring.

- Unusable functions

The high-speed program check function can not be used in combination with the following functions.

- Angular axis control
- Flexible synchronization control

If some of above functions are effective, the alarm PS5364 occurs at the start of the high-speed program check mode.

- Unavailable command

Following functions can not be specified during the high-speed program check mode. If the following functions are specified, the alarm PS5364 occurs.

- Electronic gear box

- Restriction of commands

During the high-speed program check mode, the axes movements of the following functions can not be checked with this function.

- PMC axis control

  The axis whose the signal EAX* <Gn136> for control axis select (PMC axis control) is 1 is not checked in the high speed program check mode. The stroke limit check of the PMC axis is done by the actual machine coordinate.

- Auxiliary function

When the bit 6 (PGS) of parameter No. 3001 is set to 1, the M, S, T, and B codes are not saved/restored at the start/end of the high-speed program check mode.
Therefore, the M, S, T, and B codes, which are output during the high-speed program check mode, are effective after the end of the high-speed program check mode.
When the bit 6 (PGS) of parameter No. 3001 is set to 1, the M, S, T, and B codes are output to the PMC.
Therefore, if it is not necessary to execute the M, S, T, and B command during high-speed program check mode, please modify ladder sequence not to execute M, S, T, and B code by referring to the signal <Fn290.5> for the high-speed program check mode.

- Tool management function

When instructing in D99 and H99 by the tool management function, the window function notifies CNC side of the tool at the spindle position and the tool compensation is executed by using the tool offset amount of the tool. Therefore, in order to execute the tool compensation correctly with D99 and H99 in the tool management function, please set bit 6 (PGS) of parameter No. 3001 to 1 and execute the window function (code 329) by T code and M code in PMC ladder as well as usually operation.

- Multi path system

In case that save/restore of data is effective (bit 1 (PGR) of parameter No. 3454 is set to 1)
please make the state of the high-speed program check mode the same in all paths in the multi path system.

- Synchronous / Composite control

In case that you execute the high-speed program check for program that uses the synchronous/composite control, please set paths related to synchronous/composite control into high-speed program check mode. When all of them are not under high-speed program check mode, the cycle start is disregarded and the program cannot be started.

- Superimposed control

> ⚠ **WARNING**
> When the Superimposed control is executed in the high-speed program check mode, the stroke limit is not checked correctly.

Signal

High-speed program check signal PGCK<Gn290.5>

[Classification] Input signal

[Function] Specify the high-speed program check mode.

[Operation] When this signal is 1, the high-speed program check mode is effective.
When this signal is 0, the high-speed program check mode is not effective.

> **NOTE**
> The alarm PS5365 occurs when the signal PGCK <Gn290.5> is changed while a program is executing.

High-speed program check mode signal PRGMD<Fn290.5>

[Classification] Output signal

[Function] Notify that the high-speed program check mode is active.

[Operation] This signal turns to 1 under both of the following conditions.

- The signal PGCK <Gn290.5> is 1.
- MEM or DNC mode is selected.

In case that the bit 3 (PGR) of parameter No. 3454 is set to 1, the data are saved under both of the above conditions. This signal turns to 1 when the save of data is completed.
This signal turns to 0 under one of the following conditions.

- The signal PGCK <Gn290.5> is 0.
- A mode except MEM or DNC is selected.

In case that the bit 3 (PGR) of parameter No. 3454 is set to 1, the data are restored under one of the above conditions. This signal turns to 0 when the restore of data is completed.

High-speed program check saving data signal PCKSV<Fn290.4>

[Classification] Output signal

[Function] Notify that the data which are changed by automatic operation during the high-speed program check mode are saved.

[Operation] This signal turns to 1 under the following conditions.

- The save of the data, which are changed by automatic operation, is complete at the start of the high-speed program check mode.

This signal turns to 0 under the following conditions.

- The restore of the data, which are changed by automatic operation, is complete at the end of the high-speed program check mode.

Signal address

	#7	#6	#5	#4	#3	#2	#1	#0
Gn290			PGCK					

	#7	#6	#5	#4	#3	#2	#1	#0
Fn290			PRGMD	PCKSV				

Parameter

	#7	#6	#5	#4	#3	#2	#1	#0
1490	PGF							

[Input type] Parameter input

[Data type] Bit path

#7 PGF The feedrate specified for circular interpolation in the high-speed program check mode is:

0: The dry run feedrate.
At this time, manual feedrate override signals *JV0 to *JV15 <Gn010 to Gn011> can be used.

1: The maximum feedrate specified by the CNC.

> ⚠ **CAUTION**
> If this parameter is set to 1, feedrate clamp, override, and dry run for circular interpolation is disabled. If a movement around a stroke limit is specified, therefore, a stroke limit check cannot sometimes be made correctly.

	#7	#6	#5	#4	#3	#2	#1	#0
3001		PGS						

[Input type] Parameter input
[Data type] Bit path

#6 PGS In the high speed program check mode, M, S, T, and B codes are:
0: Not output.
1: Output.

> ⚠ **CAUTION**
> 1 If this parameter is set to 1, M, S, T, and B codes are neither saved nor restored at the start and end of the high speed program check mode.
> Accordingly, M, S, T, and B codes output in the high speed program check mode remain valid even after the high speed program check mode ends.
> 2 If this parameter is set to 1, M, S, T, and B codes are output to the PMC in the high speed program check mode.
> Therefore, when M, S, T, and B commands need not be executed in the high speed program check mode, create a ladder sequence that references the high speed program check mode signal <Fn290.5> and suppresses the execution of any of the M, S, T, and B codes.
> 3 If this parameter is set to 1, the operation of the M, S, T, and B codes depends on the status of auxiliary function lock signal AFL <Gn005.6>.
> 4 In the high speed program check mode, an attempt to rewrite this bit parameter by using G10 results in an alarm PS5364, “ILLEGAL COMMAND IN PROGRAM CHECK”.

	#7	#6	#5	#4	#3	#2	#1	#0
3006		WPS						

[Input type] Parameter input
[Data type] Bit

#6 WPS Each axis workpiece coordinate system preset signal:
0: Disabled.
1: Enabled.
When this parameter is set to 1, a workpiece coordinate system is preset after the end of the high speed program check mode.

	#7	#6	#5	#4	#3	#2	#1	#0
3454					**PGR**			

[Input type] Parameter input
[Data type] Bit path

#3 PGR In the high speed program check mode, data modified during automatic operation is:
0: Neither stored nor restored.
1: Stored and restored.

If this parameter is set to 1, when the high speed program check mode ends, data modified during automatic operation in the high speed program check mode can be restored to the state present before the start of the high speed program check mode.
After the high speed program check mode ends, therefore, it is possible to perform automatic operation in the state present before the start of the high speed program check mode.

> ⚠ **WARNING**
> In a multi-path system, when one of the paths enters the high-speed program check mode, data of all paths is stored. After there is no path left in the high-speed program check mode, the data of all paths is restored at a time. This means that when the time to change the status of the high-speed program check input signal PGCK<Gn290.5> differs among the paths, the end of the high-speed program check mode in a path may affect the operation of other paths. For example, if the high-speed program check mode of a path is turned off when machining is in progress on another path, data of the path on which machining is in progress is also restored, which poses serious danger. Therefore, when bit 3 (PGR) of parameter No. 3454 is set to 1 in a multi-path system, the status of the high-speed program check mode must be made consistent throughout the paths. Make sure that paths placed in the high-speed program check mode and paths placed in the normal mode are not present at the same time.

> ⚠ **CAUTION**
> 1 When this parameter is set to 1, the workpiece coordinate system preset is executed at the end of high-speed program check mode regardless of the setting of the bit 6 (WPS) of parameter No. 3006.
> 2 The absolute coordinate and relative coordinate of the axis, whose the signal EAX* <Gn136> for control axis select (PMC axis control) is 1 at the start/end of high-speed program check mode are not saved/restored.
> 3 The data of the periodic maintenance screen are not saved/restored.
> 4 During the high-speed program check mode, if G10 command is specified to this parameter bit, the alarm PS5364 occurs.
> 5 During the high-speed program check mode, if the EAX* <Gn136> is changed from 0 to 1 or from 1 to 0, the alarm PS5364 occurs.

	#7	#6	#5	#4	#3	#2	#1	#0
11320	PGM							

[Input type] Parameter input
[Data type] Bit path

#7 PGM In the high speed program check mode, the machine position is displayed with:
0: Actual machine coordinates. (Machine position relative to the reference position)
1: Machine coordinates for the program check.

	#7	#6	#5	#4	#3	#2	#1	#0
3115				PGAx				

[Input type] Parameter input
[Data type] Bit axis

#4 PGAx In the high speed program check mode, the machine position on each axis is:
0: Displayed according to the setting of bit 7 (PGM) of parameter No. 11320.
1: Displayed with machine coordinates used for program checking.

NOTE
1 When PMC axis select signal EAX*<Gn136> is set to 1 for an axis, the actual machine coordinate value on the axis is indicated regardless of the settings of bit 7 (PGM) of parameter No. 11320 and bit 4 (PGA) of parameter No. 3115.
2 In diagnosis data No. 301 (machine position), actual machine coordinates are always displayed regardless of the settings of bit 7 (PGM) of parameter No. 11320 and bit 4 (PGA) of parameter No. 3115.

Alarm and message

Number	Message	Description
PS5364	ILLEGAL COMMAND IN PROGRAM CHECK	(1) An invalid G code is specified in high-speed program check mode. (2) Angular axis control is available. (3) Following operation is done. - During the high-speed program check mode, an axis, which is never established the reference position, is returned to the reference position. (4) During the high-speed program check mode, the signal EAX* <Gn136> is changed. (5) During the high-speed program check mode, G10 is commanded to the bit 3 (PGR) of parameter No. 3454. (6) During the high-speed program check mode, G10 is commanded to the bit 6 (PGS) of parameter No. 3001.
PS5365	NOT CHANGE OF PROGRAM CHECK MODE	Switching of high-speed program check input signal PGCK<Gn290.5> was performed during execution of the program.

5.3.5 Manual Handle Retrace

Overview

In this function, the program can be executed both forward and backward with a manual handle (manual pulse generator) under automatic operation.

Therefore, errors of a program, interference, and so on can be checked easily by working a machine actually.

- Checking mode

In this mode, the program can be executed forward and backward and the program can be checked.
To change to the checking mode, it is necessary to change the mode to the MEM mode, and the checking mode signal MMOD<Gn067.2> is set to 1. This function makes the data to execute the program backward when the program is executed forward in the checking mode.
To work a machine synchronizing with a pulse generated by a manual handle in the checking mode, the manual handle check signal MCHK <Gn067.3> is set to 1 in addition to the above-mentioned. As a result, it becomes possible to check the program with a manual handle.

> **NOTE**
> During the checking mode, it is not possible to change the parameter and offset.

- Forward movement with a manual handle

The "forward movement" is that the program is executed forward by turning a manual handle in the positive direction (when the manual handle check signal is set to 1.) or in no relation to rotation of a manual handle (when the manual handle check signal is set to 0.).
When the manual handle check signal is set to 1, the execution speed of the program is proportional to the number of rotations of a manual handle. The program is executed forward rapidly when a manual handle is turned to the positive direction rapidly. And, the program is executed forward slowly when a manual handle is turned to the positive direction slowly. The distance magnification traveled per pulse from manual handle can be switched as same as a usual manual handle feed function.
When the manual handle check signal is set to 0, the execution of the program is controlled as same as an automatic operation.

- Backward movement

The "backward movement" is that the program executed forward once is executed backward by turning a manual handle in the negative direction.
The program can be executed backward only for the block executed forward. And, the number of blocks for it is about 190 blocks. This block number changes by the content of the commanded program.
The program is executed backward rapidly when a manual handle is turned to the negative direction rapidly. And the program is executed backward slowly when a manual handle is turned to the negative direction slowly. The distance traveled per pulse from manual handle can switch magnification as well as a usual manual handle feed.

> **NOTE**
> In the system which exceeds 4 paths and 20 axes, the maximum number of blocks which can move backward becomes about 97 blocks.

Explanation

- Control by the manual handle

Program execution start

The checking mode signal MMOD<Gn067.2> is set to 1 in the MEM mode in order to change the checking mode. Then, the program execution is begun by turning ST signal from 1 to 0.
If the manual handle check signal MCHK <Gn067.3> is set to 1 at this time, the execution of the program is controlled by a manual handle. The program is executed synchronizing with rotation of a manual handle.
When a manual handle check signal MCHK<Gn067.3> is set to 0, it is controlled as usual execution.
When check mode signal MMOD<Gn067.2> is set to 1 during the operation of the program, it is enabled a check mode from the block that next buffering is done.
That is, even if check mode signal set to 1, check mode is not always enabled at once.

When check mode is enabled, check mode confirmation signal MMMOD<Fn091.3> is set to 1.

> **NOTE**
> After the signal MMOD is turned to 0 during the execution of the program, the program cannot be executed forward and backward.

Control with the manual handle

The value of the parameter No.6410 and the scale factors decide the moving speed of the machine by one pulse generated by a manual handle.
When a manual handle is turned, the actual movement speed of the machine is as follows.
[Feedrate command value] × [Number of the handle pulse per a second]× [Handle magnification] × ([Parameter setting value]/100) × (8/1000) (mm/min or inch/min)
Example)

When feedrate command value is 30mm/min, handle magnification is 100, parameter No.6410 is set to 1 and manual pulse generator is rotated at 100 pulse/rev, the feedrate of axis is decided as follow.
[Feedrate]=30[mm/min] × 100[pulse/s] × 100 × (1/100) × (8/1000)[s]=24[mm/min]

When the feedrate exceeds the override 100% feedrate by turning a manual handle rapidly, the feedrate is clamped at the speed of override 100%. That is, if the pulse of the following formula exceeds 1, the feedrate is clamped.

[Number of the handle pulse per a second]× [Handle magnification] ×
([Parameter setting value]/100) × (8/1000)

The rapid traverse feedrate is clamped at 10%. However, the feedrate of the rapid traverse is clamped at 100% when the bit 0 (RPO) of parameter No. 6400 is set to 1.
And if parameter No.6405 is set to an optional value, it can be clamped to override by nearly optional value.
When the parameter No.6405 is set to larger value than "100", it is clamped to nearly 100%.
When parameter No.6405 is set to 0, the setting of bit 0 (RPO) of parameter No. 6400 becomes valid.
The single block signal and the feed hold signal are effective in the checking mode. When the execution of a program is stopped by the single block stop or the feed hold stop, it is necessary to turn ST signal from 1 to 0 in order to restart the program.
In the block with the movement and the block of dwell, the execution speed of the program can be controlled by turning a manual handle. As for the block of neither movement nor dwell such as the block of only address M, S, T, and F, the program advances to the following block even if a manual handle does not turn.
The rotation of the spindle does not synchronize with a pulse of a manual handle. During the checking mode, the spindle rotates at the specified rotation speed. As for the feed per revolution, a program is executed at the feedrate which was converted from the rotation speed of the spindle to the corresponding feed per minute inside CNC.

> **NOTE**
> The manual handle used by this function is always the first. The 2nd and 3rd manual handle cannot be used in this function.

Forward movement and backward movement with a manual handle

The program is executed forward when a manual handle is turned to the positive direction. And, the program is executed backward when a manual handle is turned to the negative direction.
The program is executed backward if a manual handle is turned to the negative direction in executing the program forward.
When a manual handle keeps being turned in a negative direction, the program is executed backward and the execution stops in the block of O number. Then, if a manual handle is turned to the positive direction, the program is executed forward again.
Even if a manual handle controls the program execution, the program is executed forward in no relation to a pulse generated by a manual handle on setting the manual handle check signal to 0.

The rotation amount of the manual handle is not accepted as an amount of the movement while changing forward movement and backward movement.

Program end

When the block of M2 or M30 is executed, the manual handle retrace ends. Execute backward movement from the block of M2 or M30 is not possible.
When the execution of the program ends, the checking mode signal and the manual handle check signal must be set to 0.
In 2 path control system, FIN signal must not be set to 1 when the block of M2 or M30 is executed in only one of paths. After the block of M2 or M30 has been executed in both paths, FIN signal is set to 1. (Except for the block of waiting M code is commanded before M2 or M30 in both paths.)

- Notice of the operation

- Dry-run can not operate during the checking mode. Dry-run signal must be set to 0.
- Automatic operation starts immediately with the feedrate commanded by the program, when the checking mode signal or the synchronous operation with handle signal is turned off during executing the program in the checking mode.
- While a program is executing, the edit of the program and the change of the parameter and the offset must not be done.
- While the program is being executed backward or blocks once executed backward are being executed forward again, do not change the checking mode signal MMOD <Gn067.2>.
- The single block operation is also possible. However, even if the manual handle is operated in single block stop state, neither forward movement nor backward movement is done. If cycle start is done, the continuation of the program is executed in the same direction before a single block stop, and the manual handle becomes effective.

- Backward movement of each code

All modal information of G, T, and S-code is memorized in executing the program forward. And, the memorized data of the modal G, T, and S-code are used in executing the program backward.
As for M-codes, they are grouped and the modal information is managed by parameter No.6411 to 6490. Therefore, M-code can be executed backward according to the information. As for the modal information of the M-code, a change in each group is memorized in the execution data.
As for the codes except for G, M, S, and T, the same code is output between forward movement and backward movement.

- G-code

If G-code that changes modal information is commanded in backward movement, the modal information of previous block is executed.
Example)

```
N1G99;
N2G01X_F_;
N3X_Z_;
N4G98;    .................... backward movement starts from this block
N5X_Y_Z_;
```

If backward movement starts from N4 block, the modal information is changed from G98 to G99 and G99 is executed from N3.
G-code with a movement is traced along the route opposite to forward movement.
G-code that can be command in executing the program backward is as follows.
The other G-codes cannot be command in executing the program backward.
The G-codes in the G-code system B and C also can be used.

Lathe system

G00 G01 G02 G03 G04 G10 G11
G22 G23 G25 G26 G27 G28 G30
G40 G41 G42 G50 G53 G61 G63
G64 G65 G68 G70 G71 G72 G73
G75 G80 G83 G85 G87 G89 G90
G94 G96 G97 G98 G99
(G-code system A)

Machining center system

G00 G01 G02 G03 G04 G10 G11
G22 G23 G25 G26 G27 G28 G30
G40 G41 G42 G43 G44 G49 G53
G61 G63 G64 G65 G73 G76 G80
G81 G82 G83 G85 G86 G87 G88
G89 G92 G94 G95 G96 G97

NOTE

1. In Small-Hole Pecking Drilling Cycle(G83), backward movement is prohibited.
2. In forward movement of Boring Cycle(G88), the sequence of actions at bottom of hole is shown as follows (dwell → stop of spindle motor → hold state). But in backward movement, that is (rotation of spindle → hold state → dwell after restart).
3. G68 for the lathe system means mirror image for double turret.

- M-code

If there is M-code in the same group is commanded in previous blocks, modal information of the M-code, commanded at the last in previous blocks, is output.
If no M-code is commanded in previous blocks, the M-code set to the first parameter in the same M-code group is output.
If M-code is not set to group M-code in parameter, the same M-code is output in backward movement.
If the bit 5 (RVN) of parameter No. 6400 is set to 1, the backward movement is prohibited when the M-code, which is not set to group M-code, is commanded in backward movement.

NOTE

When setting the bit 5 (RVN) of parameter No. 6400, backward movement prohibition is enabled except the M-code which was set in the grouping but backward movement can be enabled for the following M-code exceptionally.

1. Subprogram Call by M98/M99.
2. Subprogram Call using an M code
3. Macro Call using an M code
4. Waiting M code
5. M0

Example)

Output of M-codes that are set to groups by parameters in backward movement
Setting of parameters:
No.6400#2=1, #3=0 (5 M-codes/group and 16 groups)

No.6411=100
No.6412=101
No.6413=102 Group A
No.6414=103
No.6415=104
No.6416=200
No.6417=201
No.6418=202 Group B
No.6419=203
No.6420=204

Program O10 is executed in forward movement from N1 to N15 and backward movement is executed from N15. In backward movement, the output of M-codes is show as next table.

	Forward movement	**Backward movement**
O10;		
N1G4X1.;		
N2M101;	M101	M100 (*1)
N3G4X1.;		
N4M204;	M204	M200 (*1)
N5G4X1.;		
N6M104;	M104	M101 (*2)
N7G4X1.;		
N8M300;	M300	M300 (*3)
N9G4X1.;		
N10M200;	M200	M204 (*2)
N11G4X1.;		
N12M0;	M0	M0 (*3)
N13G4X1.;		
N14M102;	M102	M104 (*2)
N15G4X1.;	Backward movement starts from this block	
M2;		

*1 No M-code in the same group is commanded before this block, so the M-code, which is set in the 1st. parameter of the same group, is output.
*2 M-code in the same group is commanded before this block, so the M-code, which is commanded at the last before this block, is output.
*3 M-code is not set to group M-code, so the same M-code is output.

- S and T-code

A modal value of the previous block is output.
When movement command and S-code or T-code is commanded in the same block, the timing of the output of the S-code and T-code is different. Because, the timing where S-code and T-code are output at the forward movement is different from that at the backward movement. By setting the bit 7 (STO) of parameter No. 6401 to 1, the timing of the output of S and T code at the forward movement is the same as the one at the backward movement.

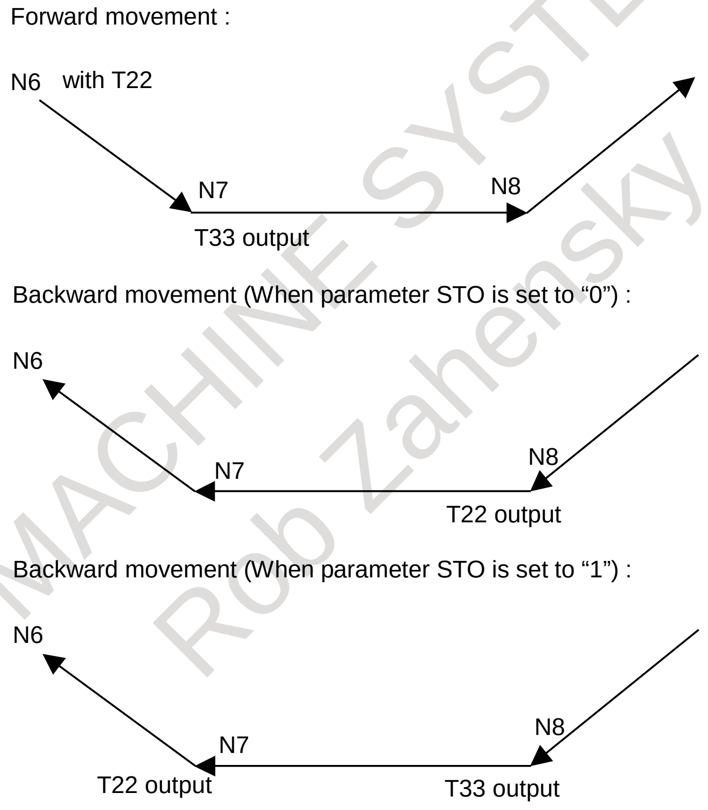
Example)

T-code output timing at the backward movement
T-code is output as follows when the program proceeds backward after the forward movement to N8 block.

	Forward movement	Backward movement	
		Parameter STO=0	Parameter STO=1
O1000;			
N1G98G00X0Z0;			Default T output
N2G00X-10.T11;	T11 output	Default T output	
N3G00X100.;			T11 output
N4G00X10.Z20.T22;	T22 output	T11 output	No T code output
N5G00X30.Z30.;			
N6G00X-10.Z-20.;			T22 output
N7G00X50.Z40.T33;	T33 output	T22 output	T33 output
N8G04X5.;		(Backward start)	(Backward start)
M30;			

The “Default T” means a T-code status at N1 block in forward movement. If the status is T0, “T0” signal is output as “Default T” in the backward movement.

The timing of T-code output of N7 and N8 in O1000 shown in the example above is as follows.



- Direction change prohibition

The direction change prohibition is a state not changing the direction where the program is executed.
In the state, even if the rotating direction of a manual handle is reversed, the reversed rotation is ignored.
A manual handle must be rotate in the same direction as present direction for removing this state.
The direction change prohibition can be confirmed by output signal MNCHG<Fn091.1>.

It becomes the change prohibition state under the following condition.

- While the block with the code waiting for FIN is executing
- After a block has done and until the next block begins to operate
- During thread cutting
- Modal G code of G68.1, G68 and G51.2

- The block with the axis that ends movement earlier in the block with G02 or nonlinear type position etc.
- During a time wait due to block switching (in a multi-path system only. See "Time wait in a multi-path system".)

- Backward movement prohibition

The backward movement prohibition is a state that the program cannot be executed from a certain block backward. In this state, the negative rotation of a manual handle is ignored, and the only positive rotation is effective. The program must be executed forward by rotating a manual handle in the positive direction for removing this state.
The backward movement prohibition can be confirmed by output signal MRVSP<Fn091.2>.
If the following blocks are executed in backward movement, backward movement is prohibited.

- Program number block of main program (except subprogram and macro program)
- Over the maximum number of the blocks for reverse movement
- The block including backward movement prohibition G-code (which is not described in the paragraph "G-code")
- The block which is executed while in modal including backward movement prohibition G-code (which is not described in the paragraph "G-code")

- Status display

In manual handle retrace, the status of manual handle retrace is displayed on clock display of CNC state display line. This status display is displayed during the execution of manual handle retrace. The clock is displayed usually.

When the all condition is filled, "M.H.RTR" is displayed on clock display of CNC state display line. This status is displayed by the color of color number 3 (Title, Axis name and O/N No. are the same color). The screen display is as shown in Fig. 5.3.5 (a). When the following conditions are not full, the clock is displayed.

- When bit 2 (CHS) of parameter No. 6401 is set to 0:
  1) Status display disable/enable bit 6 (HST) of parameter No. 6401 is set to 1.
  2) Check mode confirmation signal MMMOD<Fn091.3> is set to 1.

- When bit 2 (CHS) of parameter No. 6401 is set to 1:
  1) Status display disable/enable bit 6 (HST) of parameter No. 6401 is set to 1.
  2) Cycle start signal STL<Fn000.5> is set to 1.
  3) Check mode signal MMOD<Gn067.2> is set to 1.
  4) Manual handle check signal MCHK<Gn067.3> is set to 1.

Fig. 5.3.5 (a) "M.H.RTR." status display

Besides, when reverse movement prohibition signal MRVSP<Fn091.2> is set to 1, the "NO RVRS." is displayed. This status is displayed by blinking/reversing in the color of color number 1 (ALARM is the same color). The screen display is as shown in Fig. 5.3.5 (b). When reverse movement prohibition signal MRVSP<Fn091.2> is set to 0, the “M.H.RTR " is displayed again.

Fig. 5.3.5 (b) “NO RVRS." status display

Besides, when direction change prohibition signal MNCHG<F0091.1> is set to 1 and the direction of program’s execution is changed by manual handle, this status display changes from "M.H.RTR" to "NO.CHAG".

This status is displayed by blinking/reversing in the color of color number 3 (INPUT KEY, O/N NO. and STATUS are the same color). The screen display is shown as Fig. 5.3.5 (c). When the program is executed in the direction as the same as before by manual handle or direction change prohibition signal MNCHG<Fn091.1> is set to 0, the " M.H.RTR " is displayed again.

Moreover, when bit 1 (FWD) of parameter No. 6400 is set to 1 and the program is executed to change direction by manual handle, this status display changes from "M.H.RTR" to "NO.CHAG".

NOTE

When the improvement of direction change movement in auxiliary function output block is enabled, the state of direction change prohibition signal MNCHG<Fn091.1> is set to 1 and direction change is possible. Therefore please note that the status display of the direction change prohibition is displayed though it is possible to direction change.

Fig. 5.3.5 (c) "NO.CHAG." status display

Time constant for acceleration/deceleration after interpolation

The time constant for acceleration/deceleration after interpolation of the manual handle retrace mode (parameter No. 6495, No. 6496 or No. 6497) can be set.

When check mode confirmation signal MMMOD<Fn091.3> and handle available signal in checking mode MCHK<Gn067.3> are set to "1", and a manual handle is operated, these parameters are enabled.

NOTE

1. When effective and invalidity of handle of the manual handle retrace mode change, the distribution of the pulse is stopped once. Afterwards, a time constant for acceleration/deceleration after interpolation changes, and the distribution of the pulse is restarted. The change of enabled and disabled of handle of the manual handle retrace mode is disregarded between from the distribution stops of the pulse to a time constant for acceleration/deceleration after interpolation change. When a value is set even by one axis of parameters (No.6495-No.6497), it is sure to become the above-mentioned operation.
2. A time constant for acceleration/deceleration after interpolation for rigid tapping (parameter (No.5261-No.5264 and No.5271-No.5274)) is enabled in rigid tapping. A time constant for acceleration/deceleration after interpolation for this function is disabled.
3. A time constant for acceleration/deceleration after interpolation for the skip function for each axis is disabled when a time constant for acceleration/deceleration after interpolation for this function is enabled.

> **NOTE**
> 4 A linear acceleration/deceleration time constant(Parameter No.8192) in rapid traverse for each of the axes (master and slave axes) under superimposed control is disabled when a time constant for acceleration/deceleration after interpolation for this function is enabled.
> 5 A time constant for acceleration/deceleration after interpolation for positioning by optimum accelerations is disabled when a time constant for acceleration/deceleration after interpolation for this function is enabled.

Limitation

- Movement in automatic operation by DNC operation mode(RMT)

In the automatic operation by DNC operation mode(RMT), the backward movement is prohibited though the forward movement is enable.

- Movement in subprogram operation by external subprogram call

In M198 or M-code for subprogram operation by external subprogram call (parameter No.6030), the backward movement is prohibited though the forward movement is enable.

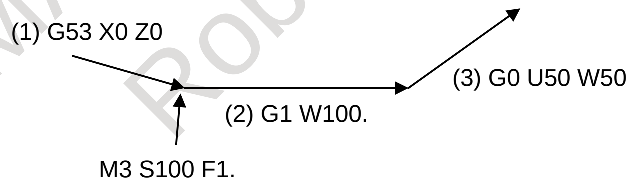
- Movement command and M,S,T-code

When M,S,T-codes and movement commands are in the same block, the timing outputting codes changes between in forward movement and backward movement. Therefore, M, S, T-codes should be commanded in backward movement after confirming that "DEN" signal is set to 1.

Example of executing the following programs with lathe system

```
O0001 ;
M5 S0 F0 ;
G53 X0 Z0 ; ............................................................................. (1)
G1 W100 M3 S100 F1. ; ................................................................ (2)
G0 U50. W50. ; ......................................................................... (3)
M2 ;
```

[Forward movement]



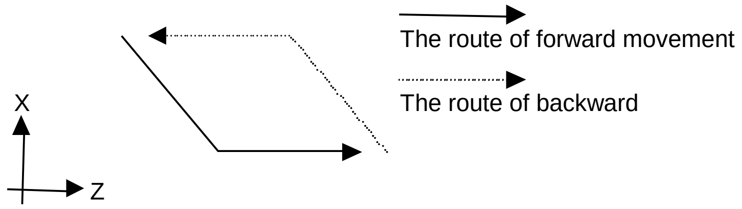
The block of (2) moves with M3 S100 F1.

[Backward movement]

The block of (2) moves with M5 S0 F1.

- Non linear interpolation type positioning

In the non-linear interpolation type positioning, the route is different between forward movement and backward movement.



Please use the interpolation type positioning to ward off danger. (Set the bit 1 (LPR) of parameter No. 1401 to 1)
If non-linear interpolation type positioning is used, direction change is prohibited at the end of movement along any axis.

- Threading

When bit 6 (HRG) of parameter No.6403 is set to 0, threading (G32,G76,G84,G88,G92)is always executed at 100% override speed. That is to say, a pulse generated by a manual handle is ignored in executing a threading block. In thread cutting cycle, the pulse is invalid at the time actually cutting thread, but the one are valid in the other movements.
When bit 6 (HRG) of parameter No.6403 is set to 1, it is possible to move backward and re-forward in the block of threading. However, threading cycle (G92) and multiple threading cycle (G76) are excluded.

> ⚠ **WARNING**
> When the parameter HRG is set to 1, detach the work if you execute the program including the threading because the synchronization of the spindle and the feed axis is not maintained at threading block. The machining of work is impossible.

- Rigid tapping (lathe system)

When bit 6 (HRG) of parameter No.6403 is set to 1, it is possible to move backward and re-forward in the block of rigid tapping. However, it is not possible to move backward by passing an on-off command of the rigid tapping mode.

> ⚠ **WARNING**
> When the parameter HRG is set to 1, detach the work if you execute the program including the rigid tapping. The machining of work is impossible.

- Tapping mode (G63)

When bit 6 (HRG) of parameter No.6403 is set to 1, it is possible to move backward and re-forward in the tapping mode.

> ⚠ **WARNING**
> When the parameter HRG is set to 1, detach the work if you execute the program including the tapping mode because the synchronization of the spindle and the feed axis is not maintained. The machining of work is impossible.

- Macro variable

In macro statement, the setting, operation, and so on of the macro variable is executed in only first forward movement. That is to say, the setting, operation, and so on of the macro variable is never executed in the block executing them once.

- Macro modal call

Manual handle retrace function is effective to macro modal call (G66,G66.1).

- Macro executor (execution macro)

Manual handle retrace function is effective while the execution macro of macro executor is called.

- Interruption type custom macro

Do not execute backward movement or re-forward movement after executing the interruption program of interruption type custom macro.

- Manual handle interrupt

Do not operate the manual handle interrupt simultaneously with manual handle retrace function.

- PMC axis control

The movement of PMC axis control cannot be controlled by this function.

- Time wait in a multi-path system

In a multi-path system, control is performed in such a way that during forward movement, the sum of the handle pulses input from the start and end of each block is memorized and during backward movement, the tool does not move to the previous block until as many handle pulses as the number of handle pulses memorized during forward movement are input. Any handle pulses input in an in-position check are also memorized as part of the pulses mentioned above, and if the speed of the handle (i.e., rate of movement along an axis) during forward movement differs from that during backward movement, the time required for an in-position check fluctuates, so that the sum of the handle pulses memorized during forward movement differs from the sum of the handle pulses during backward movement.
In this case, it can happen that even if a block ends during backward movement (the display of the remaining amount of travel becomes 0), the tool does not move to the previous block until the handle is rotated in the backward movement direction for the handle pulses memorized during forward movement. Also, at this time, the system is in the direction change prohibition state, and it is not possible to switch to forward movement until the tool continues backward movement to move to the previous block.

- Check of path unit by multi-path system

In the multi-path system, the program check of an arbitrary path is possible. In the path not to check, please select the mode excluding the MEM mode. If the bit 4 (HDMPH) of parameter No. 6400 is set to 1, it is possible to execute the check of forward movement, direction change and backward movement.
If waiting M code exist in the program, please set No-wait signal of two path NOWT <G0063.1>, or No-wait signal of three path NMWT<Gn063.9> to 1.

- Modal display

In the backward movement with manual handle, the modal display is updated according to the operation condition of the program.

- Modal information

In the backward movement with manual handle, the state of modal information is updated according to the operation condition of the program.

- Change in operation mode

When you change to EDIT mode during the checking mode, the backward movement and the re-forward movement cannot be executed in the blocks which have been already executed.

- ON/OFF of Manual Handle Retrace mode

When checking mode signal MMOD<Gn067.2> is set to 0 and handle available signal in checking mode MCHK<Gn067.3> is set to 0, the checking mode might not be turned off at once.
Basically, in the middle of block, the checking mode doesn't switch from ON to OFF or from OFF to ON. After the block is ended, the checking mode switches from ON to OFF or from OFF to ON.

- AI contour control

If the checking mode signal MMOD<Gn067.2> is 1, AI contour control mode is canceled. If AI contour control is canceled, forward movement and backward movement can be executed.

Furthermore, when checking mode signal MMOD<Gn067.2> is set to 1 in AI contour control mode, it is enabled a checking mode from the block that next buffering is done. Then, AI contour control is canceled. When bit 1 (FWD) of parameter No.6400 and bit 7 (HAI) of parameter No.6403 are 1, AI contour control is effective in the checking mode. Even if it is already AI contour control mode, the checking mode is effective.

- Multi-spindle control

During the backward movement, both TYPE-A and TYPE-B multi spindle control may not be operated exactly.

- Handle-synchronous feed

When manual handle retrace and a handle-synchronous feed are operated at the same time, forward movement and backward movement are done according to the operation of the first manual handle, and the feedrate of a handle-synchronous feed becomes effective.

- Execution of measurement G-code with the speed of override 100%

When the bit 6 (MGO) of parameter No. 6400 is set to 1, a handle pulse is invalid and it is always executed at a speed of 100% override while measurement G-code is executed. When the bit 6 (MGO) of parameter No. 6400 is set to 0, this function is invalid and a handle pulse is valid.
In the multi-path system, this function is not effective in the execution of another path and handle pulse is valid in another path. The measurement G code to which this function is effective is as follows.

1) G31 for skip
2) G31, G31P1, G31P2, G31P3, G31P4, G04, G04Q1, G04Q2, G04Q3 and G04Q4 for multistage skip
3) G31P99 and G31P98 for torque limit skip

When the measurement by G36 and G37 (G37.1 and G37.2. if bit 3 (G36) of parameter No.3405 is set to 1) of automatic tool compensation is executed, a handle pulse is invalid and it is always executed at a speed of 100% override regardless of setting the bit 6 (MGO) of parameter No. 6400. At the rapid traverse before measurement, handle pulse is valid.

When the bit 7 (SKF) of parameter No. 6200 is set to 0 and the bit 2 (SFN) of parameter No. 6207 is set to 0, handle pulse at G31 is invalid and it is always executed at a speed of 100% override regardless of setting the bit 6 (MGO) of parameter No. 6400.

When the bit 7 (MG4) of parameter No. 6400 is set to 1 and the multistage skip is enabled and the setting of parameter from No.6202 to No.6206 is enabled, the backward movement prohibition is enabled in G04 block for multistage skip.
The G code to which this function is effective is as follows.

1) G04, G04Q1, G04Q2, G04Q03 and G04Q4 for multistage skip

- Skip function, Multi-step skip function, High-speed skip function and Torque limit skip function

When bit 5 (HRF) of parameter No.6403 is set to 1, it is possible to move backward and re-forward in the block of G31.
During the backward movement or the re-forward movement, any skip signal and torque limit are ignored and it moves backward or re-forward on the path that moved first time forward movement.
The system variables #100151 to #100182 and #5061 to #5080 of custom macro are not updated during the backward movement and the re-forward movement.

- Reference position return check (G27)

The reference position return end signals ZP1 to ZP8 <Fn094> is not output in the backward movement.

- Polar coordinate interpolation
- Cylindrical interpolation
- 3-dimensional coordinate system conversion

It is not possible to move backward by passing an on-off block of these modes though it is possible to move backward and re-forward in these modes.

- Relation to another function

This function cannot coexist with the following functions

- Retrace

- Time constant for acceleration/deceleration after interpolation

A time constant for acceleration/deceleration after interpolation for manual handle retrace is disabled with the following functions.

- Spindle control with servo motor
- PMC axis control
- Threading (While executing the block of threading)
- Electronic gear box (EGB)
- Polygon turning
- Servo/spindle synchronous control
- Spindle of arbitrary speed threading

Message

The messages below will be displayed if direction change is prohibited during manual handle retrace operation.

Message	Description
PXX NO RVRS : PARAM OR SIGNAL	Direction change is prohibited because of the setting of bit 1 of parameter No. 6400 or signal G531.1.
PXX NO RVRS : IN AUXILIARY FUNCTION	Direction change is prohibited because an auxiliary function is being executed.
PXX NO RVRS : NON-LINEAR POSITIONING	Direction change is prohibited because non-linear positioning is in progress.
PXX NO RVRS : PROGRAM ENDING	Direction change is prohibited because of an M02 or M30 block.
PXX NO RVRS : FEED HOLD PROHIBITED	Direction change is prohibited because feed hold is prohibited due to, for example, threading.
PXX NO RVRS : ACC AFTER INTERPOLATION	Direction change is prohibited because an axis stop is awaited due to acceleration/deceleration after interpolation.
PXX NO RVRS : IN NO RVRS FUNCTION	Direction change is prohibited because of a modal code that does not allow direction change, such as polygon, balance cut, and 3-dimensional coordinate conversion.
PXX NO RVRS : WAITING M CODE	Direction change is prohibited because a waiting M code is being executed.
PXX NO RVRS : IN NO RVRS BLOCK	Direction change is prohibited because a block that does not allow backward movement is being executed.
PXX NO RVRS	Direction change is prohibited for another reason.
PXX IS TOP OF THE PROGRAM	The reverse movement of the program has ended.

XX: Path number 1 to 10

NOTE

If direction change is prohibited on two or more paths, the message for the path on which direction change is prohibited last will be displayed.

Parameter

	#7	#6	#5	#4	#3	#2	#1	#0
6400	MG4	MGO	RVN	HMP	MC8	MC5	FWD	RPO

[Input type] Parameter input
[Data type] Bit path

#0 RPO With the manual handle retrace function, the rapid traverse rate is clamped, assuming that:
0: An override of 10% is used.
1: An override of 100% is used.

#1 FWD With the manual handle retrace function, program execution can be performed:
0: In both forward and backward directions.
1: In the forward direction only. Execution in the backward direction is not permitted.

#2 MC5
#3 MC8 These parameters set the number of M code groups and the number of M codes per group. (See explanations of parameters Nos. 6411 to 6490.)

MC5	MC8	M code group setting
0	0	Standard (20 groups of four)
1	0	16 groups of five
0	1	10 groups of eight

When 16 groups of five are used, the meanings of parameters are changed as follows:
Group A No. 6411(1) to No. 6415(5)
Group B No. 6416(1) to No. 6420(5)
:
Group P No. 6486(1) to No. 6490(5)
When 10 groups of eight are used, they are changed as follows:
Group A No. 6411(1) to No. 6418(8)
Group B No. 6419(1) to No. 6426(8)
:
Group J No. 6483(1) to No. 6490(8)

#4 HMP When inversion or backward movement is inhibited in other paths:
0: Inversion or backward movement is not inhibited for the currently executed path.
1: Inversion or backward movement is inhibited also for the currently executed path.

#5 RVN When the manual handle retrace function is used, M codes other than grouped M codes:
0: Do not disable backward movement.
1: Disable backward movement.

When this parameter is set to 1, M codes other than grouped M codes disable backward movement in general. Exceptionally, however, the following M codes allow backward movement:
1. Subprogram call based on M98/M99
2. Subprogram call based on an M code
3. Macro call based on an M code
4. Waiting M code
5. M0

#6 MGO When the manual handle retrace function is used, handle pulses during execution of a G code related to measurement are:
0: Valid.
1: Invalid. A speed with an override of 100% is used for execution at all times.

#7 MG4 In the manual handle retrace function, for blocks for which multi-step skip G04 is enabled (when the multi-step skip is used, and the settings of parameters Nos. 6202 to 6206 are valid):
0: Backward movement is not prohibited.
1: Backward movement is prohibited.

	#7	#6	#5	#4	#3	#2	#1	#0
6401	STO	HST				CHS		

[Input type] Parameter input
[Data type] Bit path

#2 CHS In manual handle retrace:
0: The status is displayed if the following conditions are all satisfied:
(1) Bit 6 (HST) of parameter No. 6401, which specifies whether to enable or disable status display, is set to 1.
(2) Check mode output signal MMMOD<Fn091.3> is set to 1.
1: The status is displayed if the following conditions are all satisfied:
(1) Bit 6 (HST) of parameter No. 6401, which specifies whether to enable or disable status display, is set to 1.
(2) Cycle start lamp signal STL<Fn000.5> is set to 1.
(3) Checking mode input signal MMOD<Gn067.2> is set to 1.
(4) Handle input signal MCHK<Gn067.3> is set to 1 in the checking mode.

#6 HST When the manual handle retrace function is used, the time display field on the status display line of the CNC screen:
0: Does not display status.
1: Displays status.

#7 STO In the manual handle retrace function, the timing for outputting an S code and T code during backward movement is:
0: Different from the timing during forward movement:
1: The same as during forward movement.

	#7	#6	#5	#4	#3	#2	#1	#0
6402			MWR					

[Input type] Parameter input
[Data type] Bit path

#5 MWR When the manual handle retrace function is used, for a handle operation placed in the wait state by a waiting M code during backward movement:
0: Inversion is prohibited.
1: Inversion is permitted.

	#7	#6	#5	#4	#3	#2	#1	#0
6403	HAI	HRG	HRF					

[Input type] Parameter input
[Data type] Bit path

#5 HRF In skip function, multi-step skip function, high-speed skip function and torque limit skip function, with the manual handle retrace function, program execution in the backward and re-forward direction :
0: Cannot be performed.
1: Can be performed.

> **NOTE**
> 1 Any skip signal and torque limit are ignored and it moves backward and re-forward in the distance that moved first time forward movement during the backward movement and the re-forward movement.
> 2 The system variables #100151 to #100182 and #5061 to #5080 of custom macro are not updated during the backward movement and the re-forward movement.

#6 HRG In rigid tapping (lathe system) and threading, with the manual handle retrace function, program execution in the backward and re-forward direction :
0: Cannot be performed.
1: Can be performed.

> ⚠ **WARNING**
> 1 When the parameter HRG is set to 1, detach the work if you execute the program including the rigid tapping. The machining of work is impossible.
> 2 When the parameter HRG is set to 1, detach the work if you execute the program including the threading because the synchronization of the spindle and the feed axis is not maintained at the threading block. The machining of work is impossible.

#7 HAI In manual handle retrace mode, AI contour control is:
0: Disabled.
1: Enabled.

> **NOTE**
> This parameter is enabled when bit 1 (FWD) of parameter No.6400 is set to 1.

	#7	#6	#5	#4	#3	#2	#1	#0
6404								HMD

[Input type] Parameter input
[Data type] Bit

#0 HMD In manual handle retrace, when inversion or backward movement is inhibited:
0: Cause is not displayed.
1: Cause is displayed.

6405	**Override value (equivalence) for clamping the rapid traverse rate used with the manual handle retrace function**

[Input type] Parameter input
[Data type] Word path

[Unit of data] %
[Valid data range] 0 to 100
This parameter sets an override value (equivalence) for clamping the rapid traverse rate used with the manual handle retrace function. If a value greater than 100 is set in parameter No. 6405, the rapid traverse rate is clamped to an override of 100%. This function is invalid if 0 is set in parameter No. 6405. In this case, the setting of bit 0 (RPO) of parameter No. 6400 is used.

6410	**Travel distance per pulse generated from the manual pulse generator**

[Input type] Parameter input
[Data type] Word path
[Unit of data] %
[Valid data range] 0 to 100
Set the travel distance per pulse generated from the manual pulse generator in terms of the override value.
The distance traveled by the machine when the manual handle is actually turned can be found by the following expression:
[Specified speed] × [Handle magnification] × ([Setting of this parameter]/100) × (8/60000) (mm or inch)

[Example] When a specified feedrate is 30mm/min, the manual handle magnification is 100, and parameter No. 6410 is set to 1, the travel distance per pulse generated from the manual pulse generator is calculated as follows:
[Travel distance per pulse]=30[mm/min] × 100 × (1/100) × (8/60000)[min]= 0.004mm
When this parameter is set to 0, the amount of the movement becomes 0. Moreover, it is equivalent to 100 in case of 100 or more.

6411	**M code of group A in manual handle retrace (1)**
to	**to**
6414	**M code of group A in manual handle retrace (4)**
6415	**M code of group B in manual handle retrace (1)**
to	**to**
6418	**M code of group B in manual handle retrace (4)**
6419	**M code of group C in manual handle retrace (1)**
to	**to**
6422	**M code of group C in manual handle retrace (4)**
6423	**M code of group D in manual handle retrace (1)**
to	**to**

6427	**M code of group E in manual handle retrace (1)**
to	**to**
6430	**M code of group E in manual handle retrace (4)**
6431	**M code of group F in manual handle retrace (1)**
to	**to**
6434	**M code of group F in manual handle retrace (4)**
6435	**M code of group G in manual handle retrace (1)**
to	**to**
6438	**M code of group G in manual handle retrace (4)**
6439	**M code of group H in manual handle retrace (1)**
to	**to**
6442	**M code of group H in manual handle retrace (4)**

6443	M code of group I in manual handle retrace (1)
to	to
6446	M code of group I in manual handle retrace (4)

6447	M code of group J in manual handle retrace (1)
to	to
6450	M code of group J in manual handle retrace (4)

6451	M code of group K in manual handle retrace (1)
to	to
6454	M code of group K in manual handle retrace (4)

6455	M code of group L in manual handle retrace (1)
to	to
6458	M code of group L in manual handle retrace (4)

6459	M code of group M in manual handle retrace (1)
to	to
6462	M code of group M in manual handle retrace (4)

6463	M code of group N in manual handle retrace (1)
to	to
6466	M code of group N in manual handle retrace (4)

6467	M code of group O in manual handle retrace (1)
to	to
6470	M code of group O in manual handle retrace (4)

6471	M code of group P in manual handle retrace (1)
to	to
6474	M code of group P in manual handle retrace (4)

6475	M code of group Q in manual handle retrace (1)
to	to
6478	M code of group Q in manual handle retrace (4)

6479	M code of group R in manual handle retrace (1)
to	to
6482	M code of group R in manual handle retrace (4)

6483	M code of group S in manual handle retrace (1)
to	to
6486	M code of group S in manual handle retrace (4)

6487	M code of group T in manual handle retrace (1)
to	to
6490	M code of group T in manual handle retrace (4)

[Input type] Parameter input
[Data type] 2-word path
[Valid data range] 0 to 9999

Set a group of M codes output during backward movement.
For backward movement for an M code, the modal M code in the same group set by the parameter is output.
The first M code in each group is set as the default.
When the number of M codes in a group is 3 or less, set the parameter corresponding to an unused M code to 0.
For backward movement for "M0", "M0" is output regardless of which M code is set for the parameter. 0 set in the parameter is ignored.

For an M code which is not set in any group by any of the above parameters, the M code for forward movement is output.
With these parameters, an M code in the same group can be output in backward movement only when the M code is the first M code in each block. When a block contains two or more M codes, the same M codes as output in forward movement are output as a second M code and up.

> **NOTE**
> The above explanation of M code groups applies to the standard settings. The number of M codes in each group and the number of M code groups vary depending on the settings of bits 2 (MC5) and 3 (MC8) of parameter No. 6400.

6495	Time constant T or T1 used for linear acceleration/deceleration or bell-shaped acceleration/deceleration in rapid traverse for each axis for manual handle retrace

[Input type] Parameter input
[Data type] Word axis
[Unit of data] msec
[Valid data range] 0 to 4000

Specify a time constant used for acceleration/deceleration in rapid traverse for manual handle retrace. For an axis with 0 set in this parameter, a time constant for acceleration/deceleration of parameter (No.1620) is enabled.

6496	Time constant T_2 used for bell-shaped acceleration/deceleration in rapid traverse for each axis for manual handle retrace

[Input type] Parameter input
[Data type] Word axis
[Unit of data] msec
[Valid data range] 0 to 1000

Specify time constant T_2 used for bell-shaped acceleration/ deceleration in rapid traverse for each axis for manual handle retrace. For an axis with 0 set in this parameter, a time constant for acceleration/deceleration of parameter (No.1621) is enabled.

6497	Time constant of acceleration/deceleration in cutting feed for each axis for manual handle retrace

[Input type] Parameter input
[Data type] Word axis
[Unit of data] msec
[Valid data range] 0 to 4000

Set the time constant used for exponential acceleration/deceleration in cutting feed, bell-shaped acceleration/deceleration after interpolation or linear
acceleration/deceleration after interpolation in cutting feed for each axis for manual handle retrace. Which type to use is selected with bits 1 (CTBx) and 0 (CTLx) of parameter No. 1610. Except for special applications, the same time constant must be set for all axes in this parameter. If the time constants set for the axes differ from each other, proper straight lines and arcs cannot be obtained. For an axis with 0 set in this parameter, a time constant for acceleration/deceleration of parameter (No.1622) is enabled.

18060	M code that prohibits backward movement

[Input type] Parameter input
[Data type] Word path
[Valid data range] 1 to 999

When an M code that prohibits backward movement is specified during backward movement, backward movement of blocks before the M code is prohibited. In this case, backward movement prohibition signal MRVSP<Fn091.2> is output.

The M code that prohibits backward movement is not output to the PMC as an M code. As the M code that prohibits backward movement, set an M code that is not used by auxiliary functions and macros.

18065	M code 1 that prohibits backward movement and is output as an M code
18066	M code 2 that prohibits backward movement and is output as an M code

[Input type] Parameter input
[Data type] Word path
[Valid data range] 1 to 999

When an M code that prohibits backward movement is specified during backward movement, backward movement of blocks before the M code is prohibited. In this case, backward movement prohibition signal MRVSP<Fn091.2> is output.

Such M codes that prohibit backward movement are output to the PMC as M codes. As the M codes that prohibit backward movement, set M codes that are not used by auxiliary functions and macros.

Signal

Checking mode signal MMOD<Gn067.2>

[Classification] Input signal
[Function] The status of the manual handle retrace mode is changed.
[Operation] In case that the automatic operation is executed in the MEM mode when this signal is 1, the mode of the manual handle retrace becomes "ON".
In the MDI operation, the mode becomes "OFF".
Moreover, when this signal is set to 1 in the automatic operation in the MEM mode, the mode will become "ON" from the block executed next.
When this signal is set to 0 in the automatic operation, the mode will become "OFF" from the block executed next.

Handle available signal in checking mode MCHK<Gn067.3>

[Classification] Input signal
[Function] Enabling/disabling of the manual handle operation in the manual handle retrace mode is changed.
[Operation] When this signal is set to 1 in the manual handle retrace mode, the program is executed with the speed corresponding to the rotating speed of a manual handle. Moreover, when the manual handle is rotated to the opposite direction, the program is executed to the opposite direction.
When this signal is set to 0, the program is executed with the speed instructed in the program to the direction of the forward movement as same as a usual automatic operation.
When this signal is changed from 1 to 0 during the program, the program is executed as well.

Forward movement prohibition signal FWSTP<Gn531.0>

[Classification] Input signal

[Function] The forward movement in the manual handle retrace mode is prohibited.

[Operation] When this signal is set to 1 in the manual handle retrace mode, the forward movement of the program is prohibited. If this signal is set to 1 during the status of direction change prohibition or the status of the backward movement prohibition, both of the forward movement and the backward movement cannot be done.

Reverse movement prohibition signal MRVM<Gn531.1>

[Classification] Input signal

[Function] The backward movement in the manual handle retrace mode is prohibited.

[Operation] When this signal is set to 1 in the manual handle retrace mode, the backward movement of the program is prohibited. The backward movement is not done and the program stops even if a manual handle is rotated to the opposite direction.

Check mode confirmation signal MMMOD<Fn091.3>

[Classification] Output signal

[Function] This signal indicates the manual handle retrace mode.

[Operation] This signal becomes 1 when the manual handle retrace mode is "ON".
When the manual handle retrace mode is turned off, this signal becomes 0.

Reverse movement signal MRVMD<Fn091.0>

[Classification] Output signal

[Function] This signal indicates that program is being backward movement.

[Operation] This signal becomes 1 in the manual handle retrace mode when the backward movement is executed.
It becomes 0 during the forward movement and the re-forward movement.

Direction change prohibition signal MRNCHG<Fn091.1>

[Classification] Output signal

[Function] This signal indicates that direction change is being prohibited.

[Operation] It becomes 1 when the direction to which the program is executed cannot be changed(The status of the direction change prohibition) in the manual handle retrace mode.
When the backward movement of the program can be done, it becomes 0.

Reverse movement prohibition signal MRVSP<Fn091.2>

[Classification] Output signal

[Function] This signal indicates that the backward movement is being prohibited.

[Operation] It becomes 1 when the backward movement can be executed no more (The status of the backward movement prohibition) from a certain block in the manual handle retrace mode.
When the backward movement of the program can be executed, it becomes 0.

Signal address

	#7	#6	#5	#4	#3	#2	#1	#0
Gn067					MCHK	MMOD		
Gn531							MRVM	FWSTP

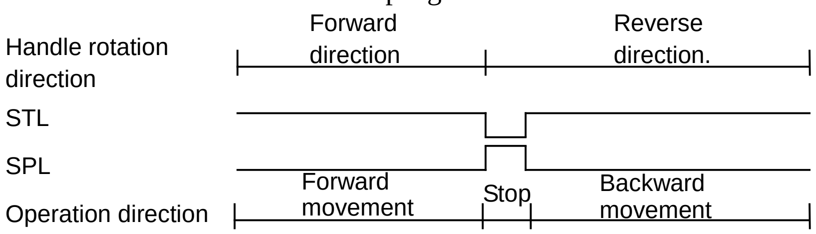
	#7	#6	#5	#4	#3	#2	#1	#0
Fn091					MMMOD	MRVSP	MNCHG	MRVMD

Notes

1) In manual handle retrace function, when checking mode signal MMOD<Gn067.2> is set to 0 and handle available signal in checking mode MCHK<Gn067.3> is set to 0, the check mode might not be turned off at once.

Basically, in the middle of block, the check mode doesn't switch from ON to OFF or from OFF to ON. After the block is ended, the check mode switches from ON to OFF or from OFF to ON.

2) When the rotate direction of the manual handle is changed, the timing chart of the cycle start lamp signal STL<Fn000.5> and the feed hold lamp signal SPL<Fn000.4> are shown in the figure below.



4) When manual handle retrace function is executed at the same time in two or more paths, some gaps might be caused in operation between each paths by repetition of forward movement and backward movement or rotational speed of manual handle. Waiting M codes are used for the synchronized block between each paths.

5.3.6 Auxiliary Function Output Block Reverse Movement for Manual Handle Retrace

Overview

This function enables reverse movement during manual handle retrace even if a move command and an auxiliary function (M/S/T/B code) are specified in the same block.

Explanation

Reverse movement is enabled for an auxiliary function output block if all the conditions and sequences described below are met.

<1> The function is effective when bit 0 (ADC) of parameter No. 6401 (auxiliary function output block reverse movement enable parameter) is set to 1.

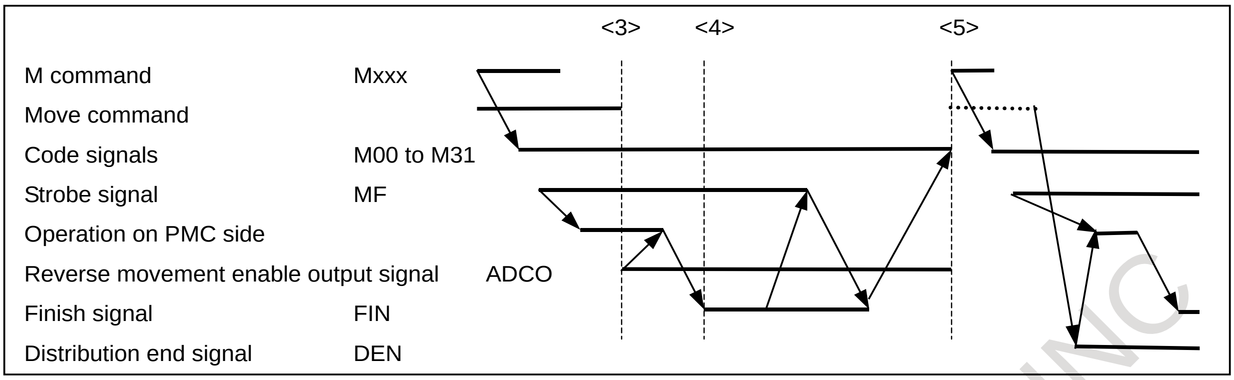
<2> The function is effective when a move command and an auxiliary function (M/S/T/B code) are specified in the same block.

<3> If the rotation of the manual pulse generator is reversed when all the conditions mentioned in <1> and <2> are met, the NC sets auxiliary function output block reverse movement enable output signal ADCO<Fn091.5> to 1.

<4> When auxiliary function output block reverse movement enable output signal ADCO<Fn091.5> is set to 1, the PMC performs the corresponding operation with a ladder language program. After that, set finish signal FIN<Gn004.3> to 1. This enables the NC to move the axis in reverse direction (move it backward or move it forward again).

<5> When finish signal FIN<Gn004.3> is set to 1, the NC sets ADCO<Fn091.5> to 0 and starts to move the axis in reverse direction (move it backward or move it forward again).
As for parameter-grouped M codes or S or T codes, those of the previous one block are output. As for M codes that are not grouped by parameter or B codes, the same codes as for the forward movement are also output for the reverse movement.

The figure below presents a timing chart depicting this process. The chart shows an example of M codes.
This example describes how an auxiliary function is executed after waiting for the move command to complete (distribution end signal DEN) following the reverse movement.
It is also possible to execute an auxiliary function without waiting for the move command to complete after the reverse movement.



Signal

Auxiliary function output block reverse movement enable output signal ADCO<Fn091.5>

[Classification] Output signal

[Function] Indicates that the manual handle has reversed during manual handle retrace in a block where a move command and an auxiliary function (M/S/T/B code) are specified together.

[Output cond.] This signal is set to 1 if all the conditions described below are met.

1) Bit 0 (ADC) of parameter No. 6401 (auxiliary function output block reverse movement parameter) is set to 1.
2) A move command and an auxiliary function (M/S/T/B code) are specified in the same block.
3) Finish signal FIN is being awaited after the rotation of the manual pulse generator has reversed.

Signal address

	#7	#6	#5	#4	#3	#2	#1	#0
Fn091			ADCO					

Parameter

	#7	#6	#5	#4	#3	#2	#1	#0
6401								ADC

[Input type] Parameter input
[Data type] Bit path

#0 ADC If a move command and an auxiliary function (M/S/T/B code) are specified in the same block when the manual handle retrace function is used, the block:

0: Disables reverse movement.
1: Does not disable reverse movement.

Notes

NOTE

1 When a single auxiliary function is specified individually, carry out the regular auxiliary function completion sequence. Reverse movement becomes possible after moving to the next (or previous) block.

2 If a move command and an auxiliary function are specified in the same block and if no travel distance remains after movement, carry out the regular auxiliary function completion sequence. Reverse movement becomes possible after moving to the next (or previous) block.

NOTE

3 To enable reverse movement using this function when an M code other than grouped M codes and a move command are specified in the same block, set bit 5 (RVN) of parameter No. 6400 to 0.
4 This function is not supported for M02 or M30.
5 If an auxiliary function is specified in a block having no move command, such as G70, carry out the regular auxiliary function completion sequence.
Reverse movement becomes possible after moving to the next (or previous) block.

Manual name	Item name
OPERATOR'S MANUAL (B-64694EN)	Manual handle retrace

5.3.7 Manual Handle Retrace Function for Multi-path

Overview

In the manual handle retrace function for multi-path systems, when the operation of re-forward movement is performed, the movement timing of all-path movement can be made identical to that of forward movement.

Explanation

In the manual handle retrace function for multi-path systems, when a certain path stopped with the backward movement prohibited and the other paths continue the backward movement, if re-forward movement is performed after that, all paths start the re-forward movement immediately, so the timing of block movement of each path is different from the original forward movement.
In this function, during re-forward movement, the path that stopped with backward movement prohibited doesn't start re-forward movement immediately. After other paths reach the position the path stopped with backward movement prohibited, the re-forward movement of this path is performed. Therefore, in multi-path systems, it is possible to perform re-forward movement in which the timing of block movement of each path is made identical to that of forward movement.
This function is enabled when bit 1 (RTW) of parameter No.18000 is set to 1.

For information on basic movement (forward, backward, re-forward) of the manual handle retrace function and the settings, refer to Subsection, "Manual Handle Retrace".

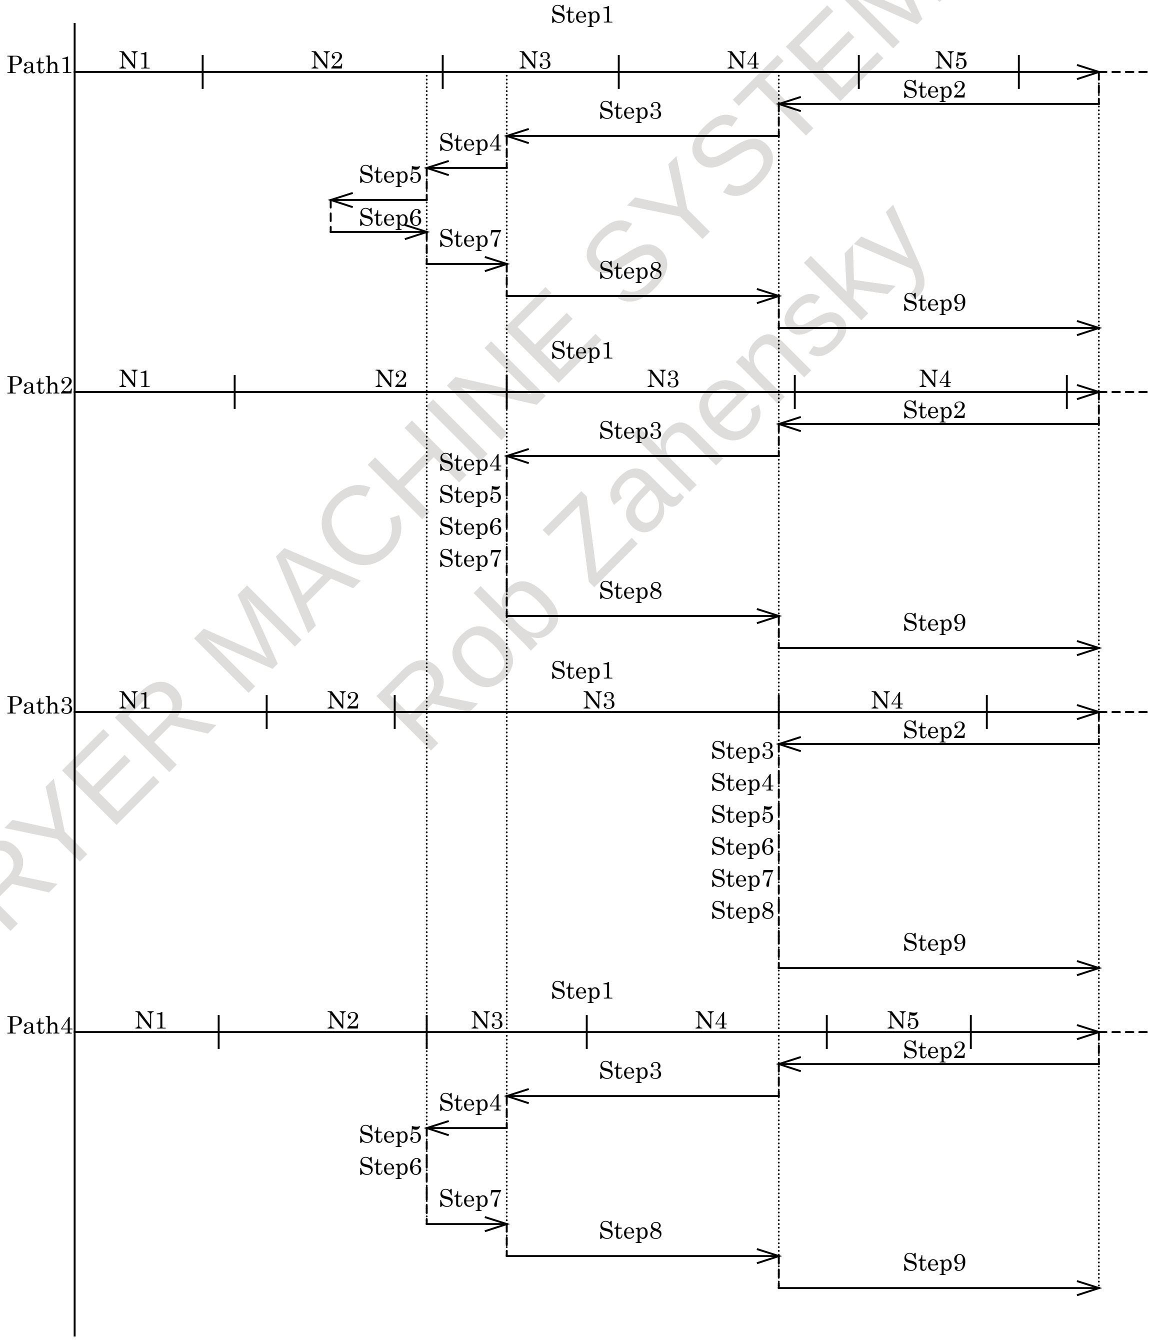
NOTE

Even when this function is enabled, the timing of block movement of each path may differ slightly due to the repetition of forward and backward movement and the rotation speed of the manual handle. Therefore, when synchronization is necessary, use the waiting M code.

Example) Re-forward movement of manual handle retrace in a 4-path system

Path1	Path2	Path3	Path4
O1001	O1001	O1001	O1001
N1 G1 X5.0 F1	N1 G1 Z6.0 F1	N1 G1 X7.0 F1	N1 G1 Z5.0 F1
N2 X12.0	N2 G31 Z14.0	N2 X10.0	N2 G31 Z11.0
N3 X22.0	N3 Z28.0	N3 G31 X27.0	N3 Z18.0
N4 X30.0	N4 Z36.0	N4 X33.0	N4 Z29.0
N5 X34.5	N5 Z50.0	N5 X50.0	N5 Z32.0
N6 X50.0	M30	M30	N6 Z50.0
M30			M30

When the above programs are operated in each path, the operation states of individual steps (in forward, backward, and re-forward movement) are shown below.



STEP	1	2	3	4	5	6	7	8	9
Command state	Forward	Backward	Backward	Backward	Backward	Re-forward	Re-forward	Re-forward	Re-forward
Execution state in Path1	Forward	Backward	Backward	Backward	Backward	Re-forward	Re-forward	Re-forward	Re-forward
Execution state in Path2	Forward	Backward	Backward	Stop	Stop	Wait P1	Wait P1,4	Re-forward	Re-forward
Execution state in Path3	Forward	Backward	Stop	Stop	Stop	Wait P1	Wait P1,4	Wait P1,2,4	Re-forward
Execution state in Path4	Forward	Backward	Backward	Backward	Stop	Wait P1	Re-forward	Re-forward	Re-forward

However, when bit 4 (HMP) of parameter No. 6400 is 0 (even if a path is prohibited from changing movement direction, the other paths can still change it), if operation is performed in the condition shown in the example below, re-forward movement may not keep the same motion as in forward movement.

Example)

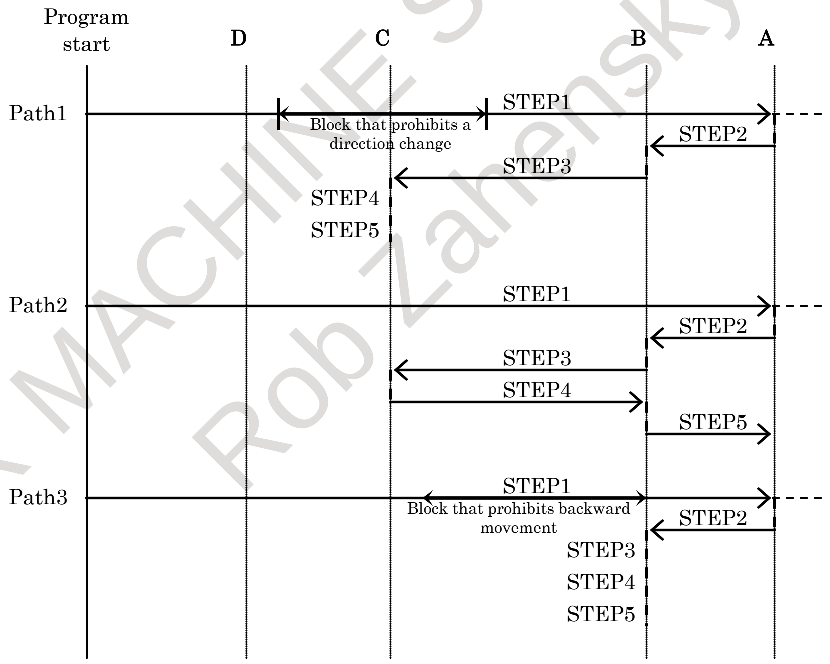
Conditions of the programs of the individual paths

Path1... In backward movement, there is a block that prohibits a change to forward movement.

Path2... In backward movement, there is neither block that prohibits backward movement nor block that prohibits a change to forward movement.

Path3... In backward movement, there is a block that prohibits backward movement.

In the above conditions, the following operation is performed.

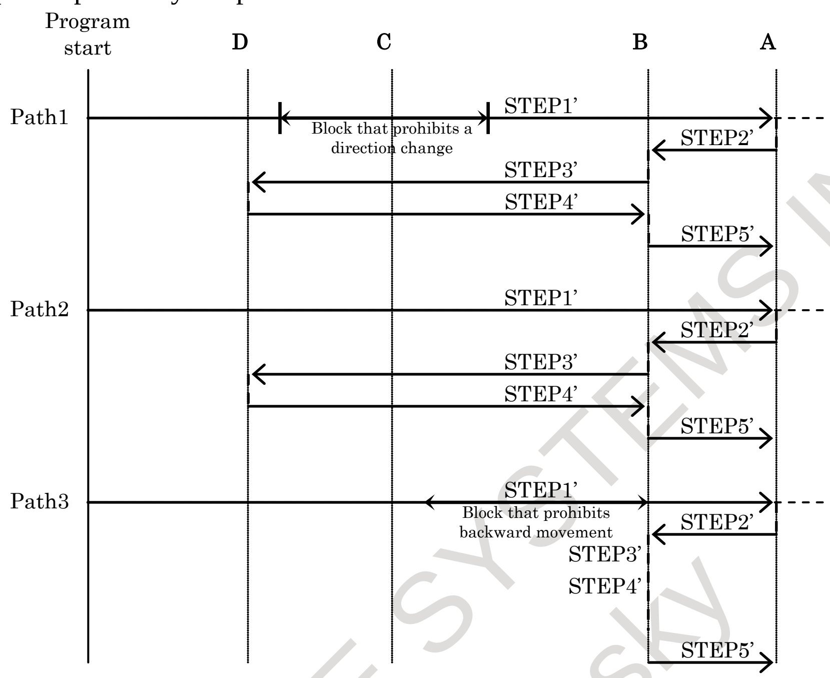


STEP1: Forward movement is performed to position A in the figure.

STEP2, STEP3: Backward movement is performed to position C in the figure. Path 3 is prohibited from moving backward at position B.

STEP4, STEP5: Re-forward movement is performed to position A in the figure. Since path 1 is prohibited from changing its direction, only path 2 performs re-forward movement. Even when path 2 performs re-forward movement to position B, path 3 does not start re-forward movement.

To keep synchronization in re-forward movement, perform backward movement of path 1 until path 1 passes by block D, which prohibits a direction change, and start re-forward movement of path 1.
In this case, if bit 4 (HMP) of parameter No.6400 is set to 1 (if a path is prohibited from changing its movement direction, the other paths cannot also change their direction), the other paths cannot change their direction until path 1 passes by the position D.



STEP1': Forward movement is performed to position A in the figure.
STEP2',STEP3': Backward movement is performed to position D in the figure. Path 3 is prohibited from moving backward at position B.
STEP4',STEP5: Re-forward movement is performed to position A in the figure. When path 1 and path 2 perform re-forward movement to position B, path 3 starts re-forward movement.

Parameter

	#7	#6	#5	#4	#3	#2	#1	#0
6400				HMP				

[Input type] Parameter input
[Data type] Bit path

#4 HMP When inversion or backward movement is inhibited in other paths:
0: Inversion or backward movement is not inhibited for the currently executed path.
1: Inversion or backward movement is inhibited also for the currently executed path.

	#7	#6	#5	#4	#3	#2	#1	#0
18000							RTW	

[Input type] Parameter input
[Data type] Bit

#1 RTW At the start of a re-forward movement operation of the manual handle retrace function in a multi-path system,
0: The re-forward movement operation is performed immediately on each path.
1: Those paths for which reverse movement are prohibited are synchronized at the stop position.

5.3.8 Extension of the Manual Handle Retrace Function

Overview

In manual handle retrace function, the following operations that were impossible so far become available.
(1) Forward movement of rigid tapping
(2) Forward movement of threading
(3) Forward movement of PMC axis control
(4) Backward movement of the orientation by the G00 command on the Cs contour control axis
(5) Backward movement of polygon turning with two spindles
(6) Backward movement of balance cutting
This function is included in the multi-path manual handle retrace function.

Explanation

- Rigid tapping

- When the bit 0 (HRA) of parameter No.6403 is set to 0 (Conventional specification)
  (1) When rigid tapping starts during forward movement, handle operation is disabled and rigid tapping is executed at a speed of 100% override.
  (2) Backward movement cannot be performed in the rigid tapping mode. In addition, when the rigid tapping block is reached after rigid tapping is completed in forward movement, backward movement cannot be done any more.
- When the bit 0 (HRA) of parameter No.6403 is set to 1 (Extensional specification)
  (1) In tapping during forward movement, the operation is performed at a speed according to handle operation.
  (2) Backward movement in rigid tapping is the same movement as in the case where bit 0 (HRA) of parameter No. 6403 is 0.

- Thread cutting

- When the bit 0 (HRA) of parameter No.6403 is set to 0 (Conventional specification)
  (1) When the threading block is reached during forward movement, handle operation become disabled and the operation is performed at a speed of 100% override.
  (2) Backward movement cannot be performed during threading. In addition, when the threading block is reached during backward movement after threading is completed in forward movement, backward movement cannot be done any more.
- When the bit 0 (HRA) of parameter No.6403 is set to 1 (Extensional specification)
  (1) In threading during forward movement, the operation is performed at a speed according to handle operation.
  (2) Backward movement in threading is the same movement as in the case where bit 0 (HRA) of parameter No. 6403 is 0.

> ⚠ **WARNING**
> In rigid tapping or threading during manual handle retrace, the workpiece cannot be actually machined.

- PMC axis control

- When the bit 1 (HRB) of parameter No.6403 is set to 0 (Conventional specification)
  (1) The PMC axis operates independently of handle operation.
- When the bit 1 (HRB) of parameter No.6403 is set to 1 (Extensional specification)
  (1) In PMC axis control during forward movement, the PMC axis is operated at a speed according to handle operation but, backward movement cannot be performed.

NOTE

1 Even when the axis specified by the program moves backward, the axis specified by PMC axis control cannot move backward. Therefore, the relative position between the axis specified by the program and the axis specified by PMC axis control changes when backward movement is performed while the axis that is specified by PMC axis control is operating. In this case, it is necessary to add the following PMC ladder process.
   - When the axis specified by PMC axis control is operating, prohibit the backward movement of the axis specified by the program using reverse movement prohibition signal MRVM <Gn531.1>.

2 Alarm PS0130 occurs when one of the following operations is executed.
   (1) In the backward movement, when PMC axis control is specified for the axis specified by the program in the previous block.
   (2) During PMC axis control, when a direction change is performed for the axis specified by the program in the previous block.

3 In the skip (03h), continuous feed (06h), speed command (10h), torque control (11h), and auxiliary function (12h,13h,14h) of PMC axis control, even if bit 1 (HRB) of parameter No. 6403 is set to 1, the axis operates independently of handle operation.

⚠ **WARNING**

During the manual handle retrace, if a reset is made when a command by PMC axis control is not completed, the command by the program stops, but the command by PMC axis control continues. In this case, even if bit 1 (HRB) of parameter No. 6403 is set to 1, the command by PMC axis control operates independently of handle operation. Make a reset after confirming that the command by the PMC axis control is completed.

- Orientation of Cs contour control axis

- When the bit 2 (HRC) of parameter No.6403 is set to 0 (Conventional specification)
  (1) Backward movement cannot be performed in orientation movement by the first G00 command after the Cs contour control mode is turned on. Therefore, when the above G00 command is reached during backward movement, backward movement cannot be done any more.
  (2) Backward movement can be performed in the reference point return command (G28) of the Cs contour control axis, but the processing proceeds to the previous block without performing orientation movement.
- When the bit 2 (HRC) of parameter No.6403 is set to 1 (Extensional specification)
  (1) Backward movement can be performed in the orientation operation by the G00 command, but the processing proceeds to the previous block without performing orientation movement as in G28 command.
  (2) The reference point return command (G28) of the Cs contour control axis performs the same movement as in the case where bit 2 (HRC) of parameter No. 6403 is 0.

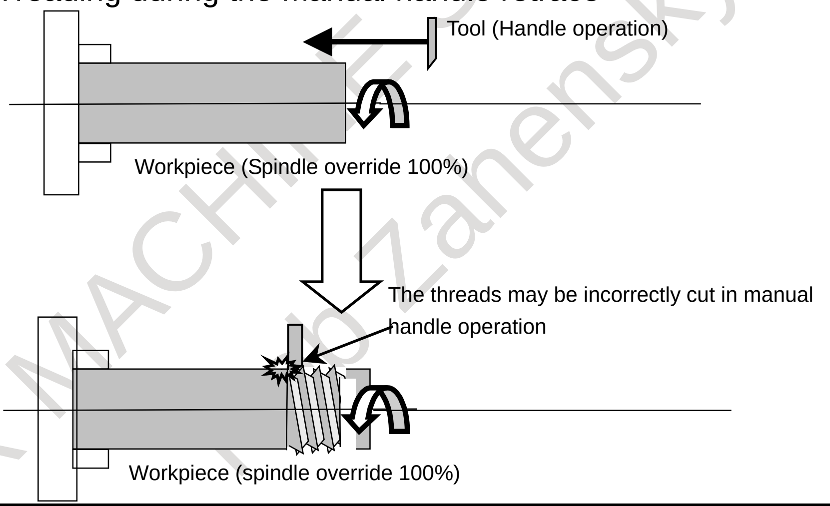
⚠ **WARNING**

The workpiece cannot be actually machined because the orientation movement of G00 and G28 is not executed during backward movement in Cs contour control.

- Polygon machining with two spindles

- When the bit 3 (HRD) of parameter No.6403 is set to 0 (Conventional specification)
  (1) Axes other than the polygonal synchronization axes operate at the speed according to handle operation even in the polygon machining mode. However, backward move cannot be performed in the block specified in the polygonal machining mode.
  (2) When the polygon machining block (G50.2) is reached in backward movement after the polygon machining is completed in forward movement, backward movement cannot be done any more.
- When the bit 3 (HRD) of parameter No.6403 is set to 1 (Extensional specification)
  (1) It is possible to move backward or re-forward in the block specified in the polygonal machining mode. When backward movement is performed during polygon machining, however, if the polygon machining-on block (G51.2) is reached, backward movement cannot be done any more.
  (2) The operation when the polygon machining block (G50.2) is reached in backward movement after the polygon machining is completed in forward movement the same as in the case where bit 3 (HRD) of parameter No. 6403 is 0.

> ⚠ **WARNING**
> In the threading and polygon machining between two spindles, the spindle operates at a speed of override 100% instead of the speed according to handle operation. Therefore, the workpiece cannot be actually machined.
>
> (Example) Treading during the manual handle retrace

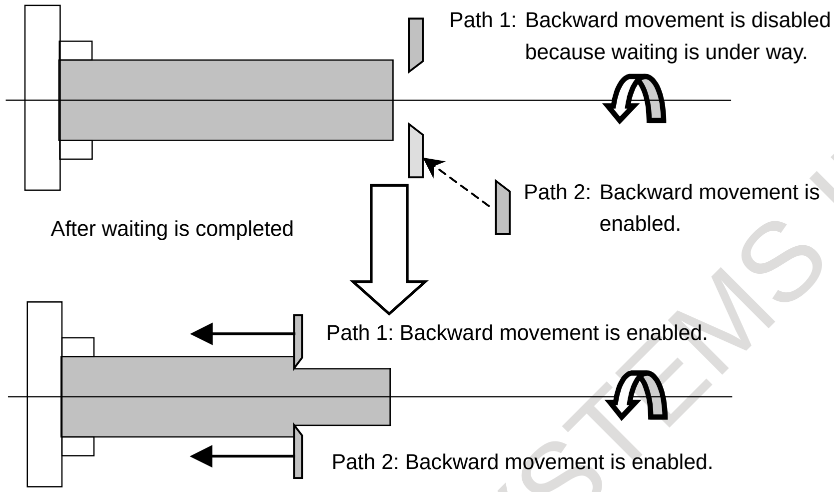


- Balanced cutting

- When the bit 4 (HRE) of parameter No.6403 is set to 0 (Conventional specification)
  (1) In the balance cutting mode, axes operate at the speed according to handle operation, but backward movement cannot be performed.
  (2) When the balance cutting block (G69) is reached in backward movement after the balance cutting is completed in forward movement, backward movement cannot be done any more.
- When the bit 4 (HRE) of parameter No.6403 is set to 1 (Extensional specification)
  (1) It is possible to move backward or re-forward in the block specified in the balance cutting mode. When backward movement is performed in the balance cutting mode, if the balance cut-on block (G68) is reached, backward movement cannot be done any more.
  (2) The operation when the balance cutting block (G69) is reached in the backward movement after the balance cutting was completed in forward movement is the same operation as in the case where bit 4 (HRE) of parameter No. 6403 is 0.

NOTE

1 In the balance cutting mode, waiting is done so that the block starts at the same time in each path. Backward movement cannot start during the waiting. After the waiting is completed and the next block starts, backward movement becomes possible.



2 In all paths that uses balance cutting, set bit 4 (HRE) of parameter No. 6403 to 1.

Parameter

	#7	#6	#5	#4	#3	#2	#1	#0
6403				HRE	HRD	HRC	HRB	HRA

[Input type] Parameter input
[Data type] Bit path

#0 HRA In rigid tapping and thread cutting, with the manual handle retrace function, program execution in the forward direction:
0: Cannot be performed.
1: Can be performed.

#1 HRB In PMC axis control, with the manual handle retrace, program execution in the forward direction:
0: Cannot be performed.
1: Can be performed.

#2 HRC During orientation operation according to G00 for a Cs contour control axis, with the manual handle retrace function, program execution in the backward direction:
0: Cannot be performed.
1: Can be performed.

#3 HRD In polygon machining with two spindles, with the manual handle retrace function, program execution in the backward direction:
0: Cannot be performed.
1: Can be performed.

#4 HRE In balanced cutting, with the manual handle retrace function, program execution in the backward direction:
0: Cannot be performed.
1: Can be performed.

5.4 MANUAL ABSOLUTE ON/OFF

Overview

Whether the distance by which the tool is moved by manual operation (such as jog feed or manual handle feed) is reflected in the absolute coordinate system can be selected.

- When manual absolute turns on

When manual intervention is performed during automatic operation, the distance by which the tool is moved by manual intervention is reflected in the absolute coordinate system. For this reason, the absolute and machine coordinate systems are the same before and after manual intervention.
The tool path after manual intervention is determined according to the setting of bit 1 (ABS) of parameter No. 7001 as follows.

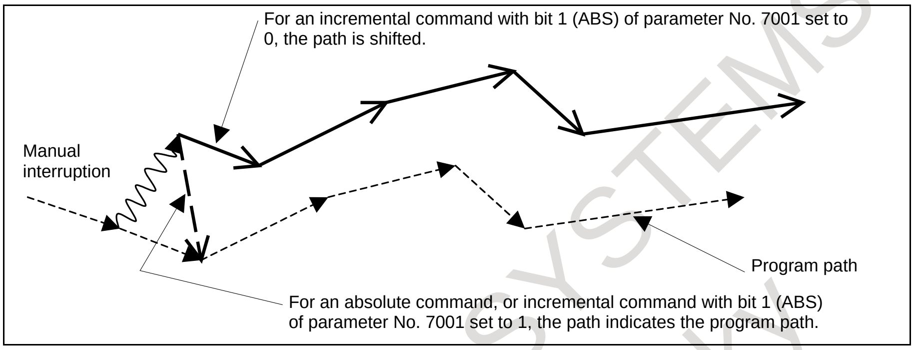


Fig. 5.4 (a)

- When manual absolute turns off

The distance by which the tool is moved is reflected in the absolute position display during manual operation.
When the system is reset or restarted in the automatic operation mode after manual operation, however, the absolute position display indicates the position before manual intervention and the absolute coordinate system after manual intervention is shifted from the machine coordinate system by the amount of manual intervention. The tool path after manual intervention is as follows.

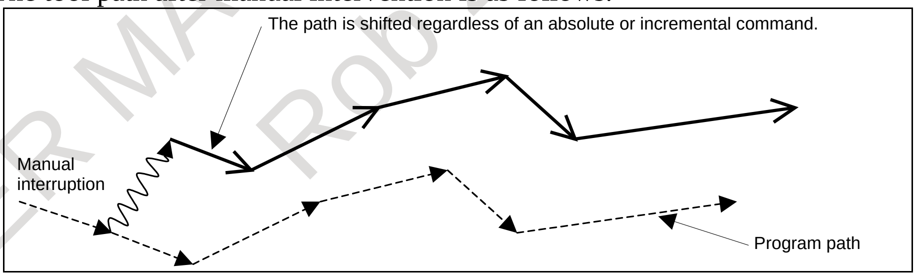

Fig. 5.4 (b)

Signal

Manual absolute signal *ABSM<Gn006.2>

[Classification] Input signal
[Function] Turns the manual absolute function on or off.
[Operation] When this signal is set to 0, turns on the manual absolute function.
When this signal is set to 1, turns off the manual absolute function.

Manual absolute check signal MABSM<Fn004.2>

[Classification] Output signal

[Function] Notifies the state of the manual absolute signal.

[Output cond.] This signal is set to 1 in the following case:

- When the manual absolute signal *ABSM is set to 0

This signal is set to 0 in the following case:

- When manual absolute signal *ABSM is set to 1

Signal address

	#7	#6	#5	#4	#3	#2	#1	#0
Gn006						*ABSM		
Fn004						MABSM		

Parameter

	#7	#6	#5	#4	#3	#2	#1	#0
7001							ABS	

[Input type] Parameter input

[Data type] Bit path

#1 ABS For the move command after manual intervention in the manual absolute on state:

0: Different paths are used in the absolute (G90) and incremental (G91) modes.

1: The same path (path in the absolute mode) is used in the absolute (G90) and incremental (G91) modes.

5.5 OPTIONAL BLOCK SKIP/ADDITION OF OPTIONAL BLOCK SKIP

Overview

When a slash followed by a number (/n, where n = 1 to 9) is specified at the head of a block, and optional block skip signals BDT1 to BDT9 are set to 1 during automatic operation, the information contained in the block for which /n, corresponding to signal BDTn, is specified is ignored (from /n to the end of the block).

(Example)

/2 N123 X100.0 Y200.0 ;

Table 5.5 (a)

Input signal	Code specified at the head of a block
BDT1	/ or /1 (Note)
BDT2	/2
BDT3	/3
BDT4	/4
BDT5	/5
BDT6	/6
BDT7	/7
BDT8	/8
BDT9	/9

NOTE

Number 1 for /1 can be omitted. However, when two or more optional block skip switches are used in one block, number 1 for /1 cannot be omitted.

(Example)

//3 N123 X100.0 Y200.0 ; Invalid

/1 /3 N123 X100.0 Y200.0 ; Valid

The following figures show the relationship between the timing, when optional block skip signals (BDT1 to BDT9) are set to 1, and the ignored information:

1. When BDTn is set to 1 before the CNC starts reading a block containing /n, the block is ignored.

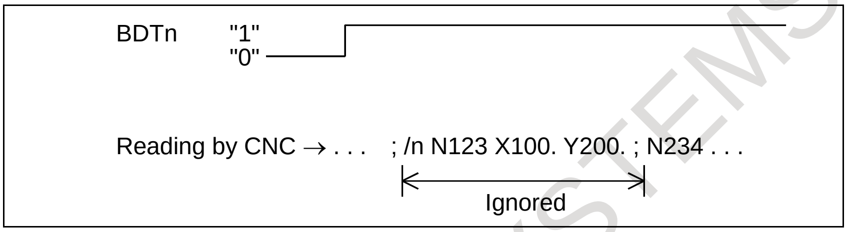

Fig. 5.5 (a)

2. When BDTn is set to 1 while the CNC is reading a block containing /n, the block is not ignored.

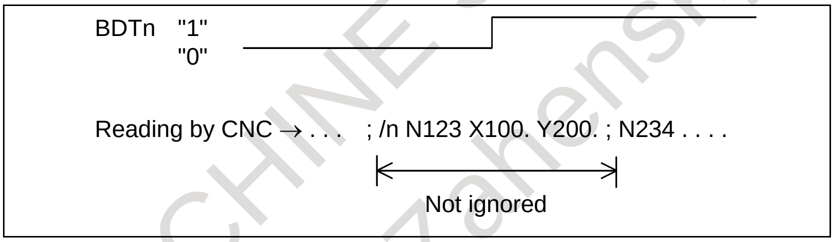

Fig. 5.5 (b)

3. When BDTn, currently set to 1, is set to 0 while the CNC is reading a block containing /n, the block is ignored.

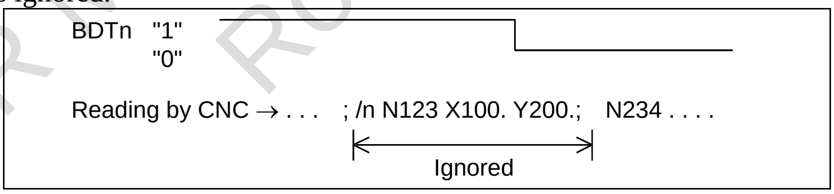

Fig. 5.5 (c)

4. Two or more optional block skip switches can be specified in a block and the block is ignored when BDTn corresponding to one of them is set to 1.

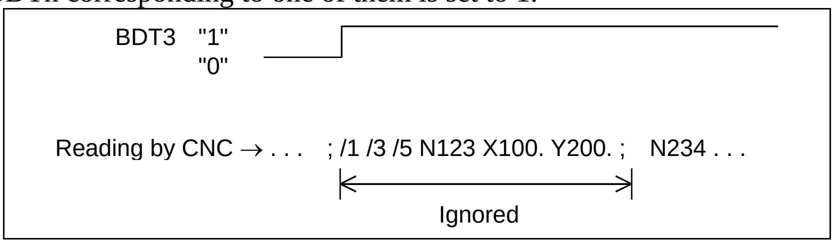

Fig. 5.5 (d)

Note

> **NOTE**
> 1. This function is ignored when programs are loaded into memory. Blocks containing /n are also stored in memory, regardless of how the optional block skip signal is set.
>   Programs stored in memory can be output, regardless of how the optional block skip signals are set.
>   Optional block skip is effective even during sequence number search operation.
> 2. Position of a slash
>   A slash (/) must be specified at the head of a block. If a slash is placed elsewhere, the information from the slash to immediately before the EOB code is ignored.
> 3. TV and TH check
>   When an optional block skip signal is 1. TH and TV checks are made for the skipped portions in the same way as when the optional block skip switch is 0.
> 4. When bit 6 (BDA) of parameter No.11504 is 0 and the optional block skip is invalid and /2 to /9 is specified, the specifying of optional block skip is ignored and the block is executed. When bit 6 (BDA) of parameter No.11504 is 1 and the optional block skip is invalid and /2 to /9 is specified, the alarm PS0004 "INVALID BREAK POINT OF WORDS" is generated.

Signal

Optional block skip signals BDT1<Gn044.0>, BDT2 to BDT9<Gn045>

[Classification] Input signal

[Function] Select whether a block containing /n is to be executed or ignored.

[Operation] During automatic operation, a block containing /n in the program is ignored when the corresponding optional block skip signal is set to 1. It is executed normally when the signal is set to 0.

Optional block skip check signals MBDT1<Fn004.0>, MBDT2 to MBDT9<Fn005>

[Classification] Output signal

[Function] Notify the PMC of the states of the optional block skip signals BDT1 to BDT9. Nine signals are provided, corresponding to the nine optional block skip signals. Signal MBDTn corresponds to signal BDTn.

[Output cond.] Signal MBDTn is set to 1 in the following case:
- When the corresponding optional block skip signal (BDTn) is set to 1

Signal MBDTn is set to 0 in the following case:
- When the corresponding optional block skip signal (BDTn) is set to 0

Signal address

	#7	#6	#5	#4	#3	#2	#1	#0
Gn044								BDT1
Gn045	BDT9	BDT8	BDT7	BDT6	BDT5	BDT4	BDT3	BDT2

	#7	#6	#5	#4	#3	#2	#1	#0
Fn004								MBDT1
Fn005	MBDT9	MBDT8	MBDT7	MBDT6	MBDT5	MBDT4	MBDT3	MBDT2

Parameter

Parameters which are used for this function are as follows.

	#7	#6	#5	#4	#3	#2	#1	#0
11504		BDA						

[Input type] Parameter input
[Data type] Bit

#6 BDA When the optional block skip is disabled and /2 to /9 is specified:
0: Alarm is not generated.
1: Alarm PS0004 "INVALID BREAK POINT OF WORDS" is generated.

> **NOTE**
> 1 This parameter is disabled to sequence number search operation.
> 2 This parameter is disabled to macro executor (conversational macro, auxiliary macro).

OPERATOR'S MANUAL (B-64694EN)	Optional block skip/addition optional block skip

5.6 PROGRAM RESTART

Overview

When the tool is broken during automatic operation, or when a machining operation interrupted by a holiday is to be restarted after the holiday, you can restart machining from a desired block by specifying the sequence number of the block or the number of blocks from the beginning of the program to the block where machining is to restart.
This function can also be used as a high-speed program check function.
There are two types of restarting methods as follows.
P type: Restart after a tool is broken down
Q type: Restart after the power is turned off (after a holiday, etc.) or after emergency stop is canceled

Explanation

- Outputting M, S, T, and B (second auxiliary function) codes on the program restart screen

By setting bit 7 (MOU) of parameter No. 7300, the M, S, T, and B (second auxiliary function) codes can be output after a block where the program is to restart is searched for.

1 Before a movement to the machining restart point

<1> The last M, S, T, and B (2nd auxiliary function) codes can be output to the PMC automatically. The last S code is output as the maximum spindle speed if the S code is specified together with G92 in one block; otherwise, the S code is output as a specified spindle speed. On the program restart screen, only the S code specified last is indicated regardless of whether it is specified together with G92 in one block or not.

<2> All M codes sampled during the search for the block where the program is to restart and the last S, T, and B (second auxiliary function) codes can be output to the PMC automatically.
Up to 35 M cods can be sampled. If there are more than 35 M codes to be sampled, the latest 35 M codes are output to the PMC.

<1> or <2> above can be selected by setting bit 6 (MOA) of parameter No. 7300.

2 Until the machining restart point is reached (over store mode)
On the program restart screen, you can specify M, S, T, and B (second auxiliary function) codes through MDI key input while maintaining the MEM mode or DNC mode.

- Movement to the restart point

No.7310 sets the ordinal number of an axis along which a movement is made in dry run after program restart. When No.7310 is not set, alarm SR5020 “PARAMETER OF RESTART ERROR” or the warning “ORDINAL NUMBER ERROR (RESTART)” is displayed.

- Presetting the relative coordinate values after the search

If bit 3 (RPR) of parameter No.7301 is 1, relative coordinate values are preset by absolute coordinate values after the search in program restart.

Limitation

- P type Restart

In the following conditions, P type restart cannot be performed:

- Bit 7 (SQP) of parameter No. 13117 is set to 1.
- Automatic operation has not been performed since power-on.
- Automatic operation has not been performed since emergency stop was released.
- Automatic operation has not been performed since the coordinate system was changed or shifted (change of the external workpiece origin offset value).

The block that can be restored properly by P type program restart is a block for which coordinate system setup or change was performed most recently before machining was interrupted.

- Block number specification Restart

In the following conditions, the block number specification restart cannot be performed:

- Bit 6 (SQB) of parameter No. 13117 is set to 1.
- Specified block number could not be found. (Alarm PS0071 “DATA NOT FOUND” occurs.

- Restart block

The block where the program is to restart is not necessarily be the block at which the program was interrupted. You can restart the program from any block. For P-type restart, however, the block where the program is to restart must use the same coordinate system as when program execution was interrupted.

- Single block

When the single-block operation is enabled at the time of a movement to the restart point, a single-block stop occurs each time an axis operation takes place. In this case, no MDI operation is allowed.

- Manual intervention

During movement to the restart point, manual intervention is allowed for an axis for which a return operation has not yet been performed. However, manual operations do not cause any movement along axes for which a return operation has already been completed.

- MDI

When the search operation has ended, no move command can be specified by MDI before axis movement.

- Reset

Do not perform a reset operation during the time from the start of the search operation of the restart sequence until machining is restarted.
If a reset operation is performed, the restart steps must be performed again from the beginning.

- Feed hold
If a feed hold operation is performed during the search, the restart steps must be performed again from the beginning.

- Manual absolute
Every manual operation must be performed with the manual absolute mode turned on regardless of whether the manual operation is performed before or after machining.

- Reference position return
Unless an absolute position detector (absolute pulse coder) is provided, be sure to perform reference position return after power-up, then perform restart operation.

- Program restart signal
When program restart signal SRN <Gn006.0> is set to "1", pressing the cycle start does not cause a start.

- Blocks specifying a macro statement, macro call, and subprogram call
Blocks specifying a macro statement, macro call, and subprogram call are not searched for even when they have a sequence number. In such a case, search for a block previously preceding such a block.

- Interruption type custom macro
During movement to the machining restart point at a dry run feedrate, no interruption type custom macro can be started. If an interruption type custom macro is started, alarm DS0024 is issued.

- Commands that prevent program restart
Program restart cannot be performed for blocks placed in the following modes:
- Polar coordinate interpolation (G12.1)
- Threading (G32, G33), Circular threading (G35, G36), Threading cycle (G92), Multiple repetitive threading cycle (G76)
- Polygon turning (G50.2)
- Balance cutting (G68)
- Rigid tapping
- Spindle positioning

If any of the following commands is included between the beginning of a program and the block where the program is to restart, program restart cannot be performed:
- Workpiece coordinate system preset (G92.1, G50.3)
- Commands for enabling and disabling synchronous/mixture control and superimposed control
- Commands for enabling and disabling axis synchronous control

- M, S, and T commands not usable in over store mode
The M, S, and T functions listed below, unlike the other M, S, and T functions, have special meanings within the CNC. These M, S, and T commands cannot be specified from the over store screen. To specify these commands, cancel the over store mode, and execute them in MDI operation.
Example:
- Spindle positioning
- Rigid tapping
- Tool management
- Tool offset for lathe system (T code)

- Tool radius / Tool nose radius compensation
When bit 4 (INT) of parameter No. 13117 is set to 1, the interference check on Tool radius/tool nose radius compensation can be disabled during search.

- Cs contour control

Usually, before a program restart operation can be started, it is necessary to enter Cs contour control mode and establish the origin of the Cs contour controlled axis.
By using the Cs axis coordinate establishment function and setting bit 5 (CCS) of parameter No. 7300 to 1, however, it is no longer necessary to enter Cs contour control mode or establish the origin of the Cs contour controlled axis before starting a program restart operation.
In this case, it is possible to change to Cs contour control mode, if necessary, after the end of the search for the block subject to the restart.
If the system enters Cs contour control mode, the origin of the Cs contour controlled axis is established with the Cs axis coordinate establishment function. And, the "DISTANCE TO GO" of the Cs contour controlled axis is recalculated.

> **NOTE**
> To use Cs contour control axis coordinate establishment, perform reference position return for the Cs contour control axis at least once after power on.
> For details, refer to “Cs Contour Control Axis Coordinate Establishment” in this manual.

- Flexible synchronization control

Setting bit 0 (FRS) of parameter No. 13421 to 1 enables program restart in a program containing an M code for turning the flexible synchronization mode on or off.

1. Before starting program restart, set the flexible synchronization control mode selection signal MTA <Gn197.0>, MTB <Gn197.1>, MTC <Gn197.2>, or MTD <Gn197.3> to set the synchronization mode specified in the program command in the block where the program is to restart (the state specified by an M code for turning the flexible synchronization mode on or off).
   If the signal setting is inconsistent with the state specified by the M code, alarm PS5374 occurs. The synchronization mode is assumed to be off in the program from the beginning of the program until the first M code for turning the flexible synchronization mode on or off is specified.
2. The flexible synchronization mode cannot be changed during the execution of program restart (when signal SRNMV <Fn002.4> is set to "1"). If an attempt is made to change the mode, alarm PS5375 occurs.
3. When a block in the flexible synchronization mode is specified as the restart block, 0 is displayed for DISTANCE TO GO for the slave axis. In addition, “********” is displayed as the restart position for the slave axis.
4. To restart a program from a block after the flexible synchronization mode is canceled, an absolute command must be specified for the slave axis after the mode is canceled. If no absolute command is specified for the slave axis, alarm PS5378 occurs.

- 3-dimensional coordinate system conversion / Tilted working plane command

When the block where the program is to restart is in 3-dimensional coordinate system conversion mode G68 (machining center system) or G68.1 (lathe system) or Tilted working plane command, bit 1 (3DD) of parameter No. 7301 can be set to select whether to move the tool to the restart position along each axis according to the program coordinate system or workpiece coordinate system. When the bit (3DD) is set to 0, the tool moves to the restart position along each axis according to the program coordinate system; when it is set to 1, the tool moves according to the workpiece coordinate system.
The “DESTINATION” and “DISTANCE TO GO” values are displayed according to the setting of this bit (3DD).
The "ABSOLUTE" values are displayed according to the setting of bit 6 (DAK) of parameter No. 3106.

- Setting to prevent movement to restart position

When there are two or more axes which has the same setting value in parameter No.7310, the movement to the restart position is not executed in the second or more axis.

Signal

Program restart signal SRN<Gn006.0>

[Classification] Input signal

[Function] Selects program restart.

[Operation] When the program restart signal is set to "1" to search for the sequence number of the block to be restarted, the screen changes to the program restart screen. When the program restart signal is set to "0", and automatic operation is activated, the tool is moved back to the machining restart point at dry run speed along the axes one by one in the sequence specified in parameter No. 7310. When the tool is set to the restart point, machining restarts.

Program restart under way signal SRNMV<Fn002.4>

[Classification] Output signal

[Function] Indicates the program is being restarted.

[Output cond.] The program restart under way signal becomes "1" when:

- The program restart signal is set to "0" after the screen changes to the program restart screen.

The signal is set to "0" when:

- The program restart sequence ends (the tool has been moved to the restart point on all controlled axes).

Signal address

	#7	#6	#5	#4	#3	#2	#1	#0
Gn006								SRN
Fn002				SRNMV				

Parameter

	#7	#6	#5	#4	#3	#2	#1	#0
7300	MOU	MOA	CCS					

[Input type] Parameter input

[Data type] Bit path

#5 CCS When the Cs contour control axis is used in the spindle mode or when the origin of the Cs contour control axis is not established, program restart is:

0: Disabled.

1: Enabled.

#6 MOA In program restart operation, before movement to a machining restart point:

0: The last M, S, T, and B codes are output.

1: All M codes and the last S, T, and B codes are output.

This parameter is enabled when the bit 7 (MOU) of parameter No.7300 is set to 1.

#7 MOU In program restart operation, before movement to a machining restart point after restart block search:

0: The M, S, T, and B codes are not output.

1: The last M, S, T, and B codes are output.

	#7	#6	#5	#4	#3	#2	#1	#0
7301					RPR		3DD	ROF

[Input type] Parameter input

[Data type] Bit path

#0 ROF When the coordinates for restarting are displayed on the program restart screen:

0: Tool length compensation (M series), tool position compensation (T series), cutter compensation (M series), and tool-nose radius compensation (T series) are considered.

1: Whether these compensation values are considered depends on the settings of bit 6 (DAL) of parameter No. 3104, bit 7 (DAC) of parameter No. 3104, and bit 1 (DAP) of parameter No. 3129 (parameters for specifying whether to consider each compensation value).

#1 3DD In program restart operation, when the restart block is in 3-dimensional coordinate conversion mode G68 (machining center system) or G68.1 (lathe system), the tool moves to the restart point along each axis:

0: According to the program coordinate system in dry run.

1: According to the workpiece coordinate system in dry run.

The restart coordinates and restart travel distance are also displayed in the coordinate system set in this parameter.

> **NOTE**
> The change made to this parameter in program restart operation is ignored.

#3 RPR When the search is completed in program restart or quick program restart, relative coordinate values are:

0: Not preset.

1: Preset by absolute coordinate values.

> **NOTE**
> This parameter is invalid in direct jump method of quick program restart.

7310	Ordinal number of an axis along which a movement is made in dry run after program restart

[Input type] Setting input
[Data type] Byte axis
[Valid data range] 1 to (Number of controlled axes)

This parameter sets the ordinal number of an axis along which a movement is made in dry run after the program is restarted.

> ⚠ **WARNING**
> 1 When there is two or more axes which has the same setting value in this parameter, the movement to the restart point is not executed in the second or more axis.
> 2 When the quick program restart is effective and bit 6 (SAV) of parameter No.11250 is set to 1, the movement to the restart point is not done in the axis which this parameter is set negative value(-1 to -(Number of controlled axes)).

> **NOTE**
> When this parameter is 0, alarm SR5020, "PARAMETER OF RESTART ERROR" or the warning "ORDINAL NUMBER ERROR (RESTART)" is displayed.

	#7	#6	#5	#4	#3	#2	#1	#0
13117	SQP	SQB		INT				

[Input type] Parameter input
[Data type] Bit path

#4 INT During a program restart, the interference check on cutter/tool nose radius compensation is:
0: Enabled.
1: Disabled.

#6 SQB A program restart with a block number specification is:
0: Enabled.
1: Disabled.

#7 SQP A program restart with the P type is:
0: Enabled.
1: Disabled.

	#7	#6	#5	#4	#3	#2	#1	#0
13421								FRS

[Input type] Parameter input
[Data type] Bit path

NOTE
Set these parameters for the first path only. It will be effective to all paths.

#0 FRS In a program containing an M code for turning the flexible synchronization mode on/off, a program restart is:
0: Disabled.
1: Enabled.

Alarm and message

Number	Message	Description
PS0060	SEQUENCE NUMBER NOT FOUND	In the program restart sequence number specification, the specified sequence number could not be found. Check the restart block.
PS0071	DATA NOT FOUND	In the program restart block number specification, the specified block number could not be found. Check the restart block.
PS0094	P TYPE NOT ALLOWED (COORD CHG)	P type cannot be specified when the program is restarted. (After the automatic operation was interrupted, the coordinate system setting operation was performed.) Perform the correct operation according to the Operator's Manual.
PS0095	P TYPE NOT ALLOWED (EXT OFS CHG)	P type cannot be specified when the program is restarted. (After the automatic operation was interrupted, the external workpiece offset amount changed.) Perform the correct operation according to the Operator's Manual.
PS0096	P TYPE NOT ALLOWED (WRK OFS CHG)	P type cannot be specified when the program is restarted. (After the automatic operation was interrupted, the workpiece offset amount changed.) Perform the correct operation according to the Operator's Manual.

Number	Message	Description
PS0097	P TYPE NOT ALLOWED (AUTO EXEC)	P type cannot be directed when the program is restarted. (After power ON, after emergency stop or alarms PS0094 to 0097 reset, no automatic operation is performed.) Perform automatic operation.
PS0098	G28 FOUND IN SEQUENCE RETURN	A command of the program restart was specified without the reference position return operation after power ON or emergency stop, and G28 was found during search. Perform the reference position return.
PS0099	MDI EXEC NOT ALLOWED AFT. SEARCH	After completion of search in program restart, a move command is given with MDI.
PS5374	FSC MODE MISMATCH IN RESTART	The current flexible synchronization mode differs from the flexible synchronization mode specified in a programmed command in the program restart block. Check the restart block.
PS5375	FSC MODE CAN NOT CHANGED	The flexible synchronization mode was changed during the execution of program restart. Check the restart block.
PS5378	INVALID RESTART BLOCK	The block specified as the restart block after the flexible synchronization mode was canceled was not a block after an absolute command for the axis specified as the slave axis. Check the restart block.
SR5020	PARAMETER OF RESTART ERROR	An invalid value is set in parameter No. 7310, which specifies the axis order in which the tool is moved along axes to the machining restart position in dry run. A value ranging from 1 to the number of controlled axes may be set in this parameter.
DS0024	UINT SIGNAL WAS ILLEGALLY INPUT	An interruption type custom macro was called during movement to the program restart position. Please do not call the interruption type custom macro.

Warning

⚠ **WARNING**

As a rule, the tool cannot be returned to a correct position under the following conditions.

Special care must be taken in the following cases since none of them cause an alarm:

- Manual operation is performed when the manual absolute mode is OFF.
- Manual operation is performed when the machine is locked.
- When the mirror image is used. However, P type return is possible for a block that switched between ON and OFF most recently or a subsequent block. In this case, the mirror image signal status present when the program was interrupted must be maintained.
- When no coordinate system is set up at the beginning of a program in which main commands are executed in the incremental mode.
- When manual intervention is performed in the course of axis movement for returning operation.
- When the program restart is commanded for a block between the block for skip cutting and subsequent absolute command block.
- When program restart is specified in the machine lock state, then the machine lock is canceled.
- When program restart specified for an intermediate block for a multiple repetitive canned cycle
- In general, when a coordinate system is set up, changed, or shifted after the search operation ends, the tool cannot be returned to a correct position.

Caution

> ⚠ **CAUTION**
> 1 Keep the following in mind when restarting a program including macro variables.
> - Common variable
>   When the program is restarted, the previous values are inherited as common variables without being preset automatically. Before restarting the program, initialize the appropriate variables to the original values used at start of the previous automatic operation.
> - System variable
>   The following system variables are not updated during search for restart:
>   #5021 to #5040 and #100051 to #100100 ABSMT
>   #5041 to #5060 and #100101 to #100150 ABSOT
>   #5061 to #5080 and #100151 to #100200 ABSKP
> - DI/DO
>   At restart of the program, DI can be read by a system variable, but DO cannot be output.
> - Clock
>   When the program is being restarted, the clock time can be obtained by a system variable, but the time cannot be preset.
> - Tool offset and workpiece origin offset
>   When the program is being restarted, the offset can be read by a system variable, but change of the offset is allowed only for the Q type.
>
> 2 The M, S, T, and B (second auxiliary function) codes specified in the over store mode are not displayed on the program restart screen.
> 3 In the over store mode, the over store mode is not cancelled even though the operation mode is changed to a mode other than the MEM mode or RMT mode, but a value cannot be input in the over store item.

Manual name	Item name
OPERATOR’S MANUAL (B-64694EN)	Program restart

5.6.1 Auxiliary Function Output in Program Restart Function

Overview

This function provides the following features for program restart:

- M/S/T/B codes found during a search through a block to be restarted for operation are output to the program restart screen and an MDI program. Then the M/S/T/B functions can be executed from the MDI program.
- On a system having the M-code grouping feature, M codes are grouped. When they are output to the above MDI program, only the M code specified last, among the M codes in the same group, is output to the program restart screen and MDI program.
- M codes for calling subprograms/custom macros and their arguments are also output to the MDI program.
- The order in which individual axes move the tool to the machining restart position can be not only conventionally parameter-set but also set from the program restart screen.

Explanation

- Program restart procedure

Follow the procedure below to restart a program using this function:

1. Turn on the program restart switch. (Set program restart signal SRN <Gn006.0> to 1.)
2. Display a program you want to restart and search for the beginning of the program.
3. Enter the sequence number (Nxxxx) or block number (Bxxxx) of a block you want to restart, then press the soft key [P TYPE] or [Q TYPE].
4. Upon completion of searching the block, the program restart screen will be displayed.
5. The M/S/T/B codes found by the search are output to the MDI program. At this time, program restart MDI program output completion signal SQMPR <Fn316.6> becomes 1. (For details, see "M/S/T/B code output to the MDI program".)
6. On the program restart screen, set the order in which individual axes moves the tool to the machining restart position.
   (For details, see "Specifying the order in which axes move the tool to the machining restart position".)
7. Turn off the program restart switch. (Set program restart signal SRN <Gn006.0> to 0.) At this time, the number to the left of each axis name under "DISTANCE TO GO" blinks, and the program restart underway signal <Fn002.4> becomes 1.
8. Switch to MDI mode and check the MDI program. Fix the MDI program as required, then execute cycle start. When the execution of the MDI program is started, the program restart MDI program output completion signal SQMPR <Fn316.6> becomes 0. (When program restart signal SRN <Gn006.0> is 0 and program restart MDI program output completion signal SQMPR <Fn316.6> is 1, the PMC ladder can be used to switch to MDI mode and execute cycle start.)
9. When the execution of the MDI program is completed, return to MEM mode. (Upon completion of MDI program execution, program restart MDI program execution completion signal SQMPRE <Fn316.7> becomes 1. When SQMPRE is 1, the PMC ladder can be used to return to MEM mode.)
10. Check whether the distance in "DISTANCE TO GO" is correct and whether the tool does not hit the workpiece or any other object when moving to the machining restart position. If the tool hits anything, move the tool manually to a position free from interference.
11. Press the cycle start button. The tool moves on each axis in the order set in step 6 to the machining restart position at the dry run feedrate, then restarts machining.

> **NOTE**
> 1. In steps 4, 7, and 11, the warning "ORDINAL NUMBER ERROR (RESTART)" is displayed if the order in which individual axes move the tool is set incorrectly.
> 2. If the warning occurs in step 4 or 7, you can perform the step that follows.
> 3. If the warning occurs in step 11, cycle start cannot be executed.
>   In this case, correct the order in which axes move the tool to the program restart position, then perform step 11 again.

- Protecting the MDI program

If you set bit 5 (PMP) of parameter No. 13117 to 1 and memory protect signal KEY3 <G0046.5> or KEY1 <G0046.3> to 0, the output MDI program remains protected until switching to MEM mode after the execution of the MDI program is completed. (That is, the MDI program is protected after the program restart MDI program output completion signal SQMPR <Fn316.6> becomes 1 until the program restart MDI program execution completion signal SQMPRE <Fn316.7> becomes 0.) You cannot edit the MDI program being protected. If you press INSERT, DELETE, or CALC ALTER, the warning "WRITE PROTECT" is displayed.

NOTE

1. When bit 7 (KEY) of parameter No. 3290 is set to 0, KEY3 is used to protect the MDI program. When the bit is set to 1, KEY1 is used instead.
2. When the 8-level data protection function is enabled, whether MDI program editing is allowed or not depends on the setting of that function. (It does not depend on the memory protect key setting.)

Signal

Memory protect signals KEY3 <G0046.5>, KEY1 <G0046.3>

[Classification] Input signal

[Function] Enables MDI program editing.

[Operation] KEY1 or KEY3 enables editing of the MDI program of MSTB code output by the "auxiliary function output in program restart" function.
When bit 7 (KEY) of parameter No. 3290 is 0, KEY3 is enabled. When the bit 1, KEY1 is enabled instead.

Program restart MDI program output completion signal SQMPR <Fn316.6>

[Classification] Output signal

[Function] Reports that M/S/T/B code output to the MDI program for program restart has been completed.

[Operation] 1) This signal becomes 1 when:

- M/S/T/B code output to the MDI program for program restart has been completed.

NOTE

If there is no M/S/T/B code to be output, no MDI program is created. In that case, SQMPR does not become 1.

2) This signal becomes 0 when:

- The execution of the MDI program is started.
- Program restart operation terminates before the execution of the MDI program is started.
- A reset occurs before the execution of the MDI program is started.

Program restart MDI program execution completion signal SQMPE <Fn316.7>

[Classification] Output signal

[Function] Reports that the execution of the MDI program output upon program restart has terminated.

[Output cond.] 1) This signal becomes 1 when:

- The execution of the MDI program output upon program restart has terminated.

2) This signal becomes 0 when:

- The machine switches to MEM mode after the MDI program output upon program restart has been executed.
- A reset occurs after the MDI program output upon program restart has been executed.

NOTE

To use the SQMPR and SQMPRE signals, the "auxiliary function output in program restart" function is required.

Signal address

	#7	#6	#5	#4	#3	#2	#1	#0
G0046			KEY3		KEY1			

	#7	#6	#5	#4	#3	#2	#1	#0

3290	KEY							

[Input type] Parameter input
[Data type] Bit path

#7 KEY For memory protection keys:
0: The KEY1, KEY2, KEY3, and KEY4 signals are used.
1: Only the KEY1 signal is used.

> **NOTE**
> 1 The functions of the signals depend on whether KEY=0 or KEY=1.
> When KEY = 0:
> - KEY1: Enables a tool offset value, workpiece zero point offset value, and workpiece shift value to be input.
> - KEY2: Enables setting data, macro variables, and tool life management value to be input.
> - KEY3: Enables program registration and editing.
> - KEY4: Enables PMC data (counter and data table) to be input.
>
> When KEY = 1:
> - KEY1: Enables program registration and editing, and enables PMC parameter input.
> - KEY2 to KEY4: Not used
>
> 2 When a multi-path system is used, the setting for path 1 is followed.

	#7	#6	#5	#4	#3	#2	#1	#0
13117			PMP					

[Input type] Parameter input
[Data type] Bit path

#5 PMP To the MDI program that is output due to a program restart, the memory protection signals KEY1 and KEY3 are:
0: Not effective.
1: Effective.

> **NOTE**
> When 0 is set in bit 7 (KEY) of parameter No. 3290, KEY3 is used to protect the MDI program. When 1 is set in the parameter, KEY1 is used.

Notes

To use this function, be sure to set bit 7 (MOU) of parameter No. 7300 to 0.

OPERATOR'S MANUAL (B-64694EN)	"Auxiliary function output in program restart" function

5.6.2 Approach for Each Arbitrary Axis in Program Restart

Overview

For the approach to the program restart position in program restart, the following functions are implemented. These functions allow the operator to sequentially determine the order in which the tool moves along axes with operations on the screen according to the situation including obstacles.

- On the program restart screen, enter the axis name of an arbitrary axis and press soft key [MOVE AXIS] to set an axis along which to move the tool to the program restart position. Then, execute cycle start. The tool moves to the program restart position along the target axis at the dry run feedrate. After the tool moves to the program restart position along all axes, executing cycle start restarts machining.
- When the tool has moved to the program restart position along not all of axes (including the case where the tool does not move along any axis), executing cycle start moves the tool to the program restart position at the dry run feedrate. At this time, the tool moves sequentially along the axes in the order specified in parameter No. 7310. Machining is then restarted.

Parameter

7310	Ordinal number of an axis along which a movement is made in dry run after program restart

[Input type] Setting input
[Data type] Byte axis
[Valid data range] 1 to (Number of controlled axes)

This parameter sets the ordinal number of an axis along which a movement to the restart point is made in dry run after the program is restarted.

> ⚠ **WARNING**
> 1 When there is two or more axes which has the same setting value in this parameter, the movement to the restart point is not executed in the second or more axis.
> 2 When the quick program restart is effective and bit 6 (SAV) of parameter No.11250 is set 1, the movement to the restart point is not done in the axis which this parameter is set negative value(-1 to -(Number of controlled axes)).

> **NOTE**
> When this parameter is 0, alarm SR5020, "PARAMETER OF RESTART ERROR" or the warning "ORDINAL NUMBER ERROR (RESTART)" is displayed.

	#7	#6	#5	#4	#3	#2	#1	#0
11250	OAA							

[Input type] Parameter input
[Data type] Bit path

 # 7 OAA In the program restart function, the approach to the program restart position for each arbitrary axis is:
0: Not used.

1: Used.

Warning and message

Warning message	Description
THERE IS NO SPECIFIED NAME OF AXIS	An invalid axis was specified as an input value. Enter a correct axis name.
WRONG MODE	The CNC mode is invalid. In the MEM or DNC mode, set or cancel an axis.
COMMAND ILLEGAL USE	1 The program restart coordinates are not set. 2 The tool starts moving to the program restart position along another axis. 3 No axis is set. (only for cancellation)

Manual name	Item name
OPERATOR'S MANUAL (B-64694EN)	Program Restart

5.7 QUICK PROGRAM RESTART

Overview

Generally, the following operations are required when machining is interrupted due to a reason such as a damaged tool and is restarted:

1. Removes the cause which interrupted the machining.
2. Locates the interrupted point in the program.
3. Restores the machine to the suitable status (including the auxiliary function status and spindle status).
4. Moves the tool to the position suitable for restarting the machining.
5. Resumes automatic operation from the interrupted block or before several blocks.

This function helps to perform the above operations from 2 to 5 more easily.

- For this function, a screen for restart operation is available. This screen is called “program restart setting screen”. To perform program restart, first specify a target block on the program restart setting screen, next press soft key [SEARCH EXEC]. Then, program restart is executed.
- The program restart setting screen is also used to locate the interrupted point in the program. On the program restart setting screen, information (including the program name and sequence number) on the last executed block is displayed as primary information. This information can be checked to locate the interrupted point in the program.
- On the program restart setting screen, in addition to the information on the last executed block, information on some blocks executed before that can be displayed. This information is automatically stored in CNC memory during the operation of a program. This memory is called “program restart memory”.
  Block information stored in program restart memory is called “restart block information”.
- You can select an arbitrary block in restart block information and press soft key [SEARCH EXEC] to restart automatic operation from that block.

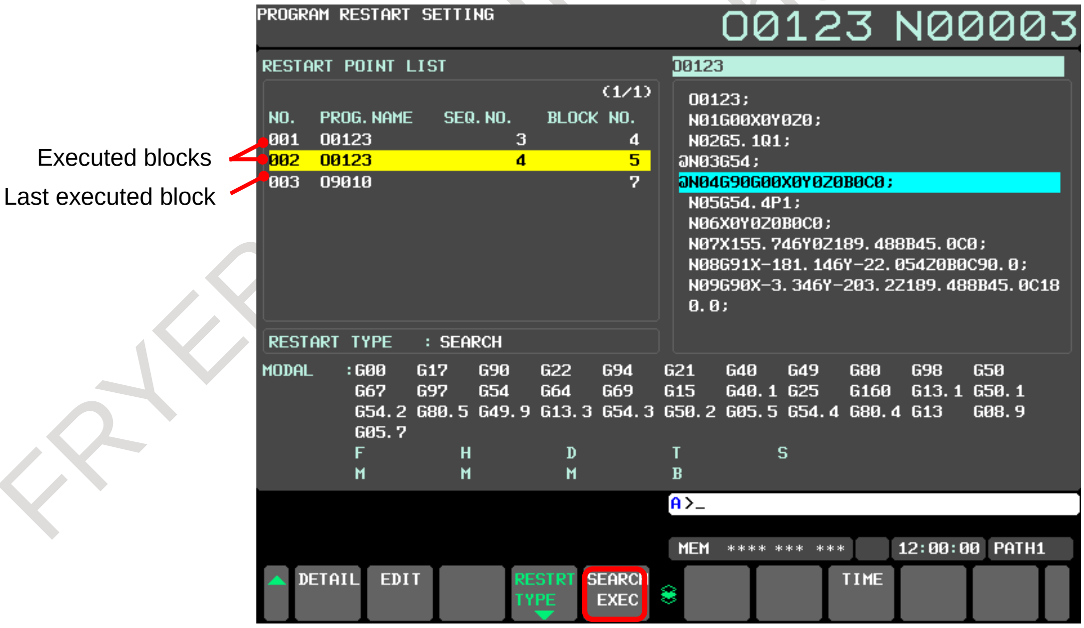

Fig. 5.7 (a) Program restart setting screen

- By changing a displayed block number or sequence number using the MDI unit and pressing [SEARCH EXEC] on the program restart setting screen, the program is restarted according to the data after change. With this operation, the program can be restarted from a position shifted relatively from the block stored in the program restart memory.
- To restore the machine to the suitable status (including the auxiliary function status and spindle status), use the “auxiliary function output in program restart” function. By using this function, any

auxiliary function found during search is output to the MDI program. This MDI program can be executed to restore the machine status easily.

- For this function, either of the following two types of restart methods can be selected.

  <1> Search method

  Use this type when it is difficult to restore the status of modal information and auxiliary functions manually. This type can be selected to restart a program not only from the block stored in the program restart memory, but also from another block. When this method is selected, the modal information and position information of the block from which to restart the program can be restored automatically.

  Application cases : When the power is turned off after machining is interrupted
  When another workpiece is machined after machining is interrupted, and the restart block information on the previous workpiece is not stored
  When the program is to be restarted from a block which is not stored in the program restart memory

  Function : By using the “auxiliary function output in program restart” function, the auxiliary function status can be restored.
  The tool automatically moves to the restart position along each axis when the program is restarted.

  Operation : Restores modal information and coordinate values while performing the simulated execution of the program until the block specified in the program restart setting screen is found. (Updates modal information and coordinate values without moving the tool along any axis.)
  Mainly updates the following data:
  - Modal information including G, F, D, and H codes
  - Absolute coordinate values
  - Auxiliary function output in the program restart

  <2> Direct jump method

  Use this type when the operator restores the status of modal information and auxiliary functions manually and restarts the machining. This method can be selected only when the program is to be restarted from the block stored in the program restart memory.
  When this method is selected, program restart is performed at high speed, though the modal information and position information of the restart block are not restored. Restart operation will be completed in a short time compared with the search method, in particular, when the restart block is in the middle of a long program.

  Application cases : When the operator can easily restore the machine status because changes in the machine status are few when, for example, machining is interrupted, and is to be restarted immediately)
  When a program is to be restarted from a block where operation can be started without restoring the machine status, such as a block on a machining process boundary

  Function : The “auxiliary function output in program restart” function cannot be used.
  The operator must determine whether to specify required auxiliary functions and specify them.
  The machine must be positioned at the restart position manually before operation is restarted because the tool does not move to the restart position along any axis when the program is restarted.
  Modal G codes and other modal information must be set to the suitable status by MDI operation before operation is restarted.

  Operation : Moves only the program cursor to the specified block at high speed without restoring modal information or coordinate values.

- Executing cycle start after the block specified in the program restart setting screen is found restarts operation from that block. When the search method is selected, the auxiliary function status is restored by the “auxiliary function output in program restart” function and the tool is moved to the restart position before operation is restarted.

Notes

- Program restart memory

1. The following blocks are stored in the program restart memory:
   a. Last executed block
   b. Blocks of positioning (When some blocks are consecutive, the first block is stored)
   c. Blocks of subprogram calls (including M98, M198, G65, G, and M code macro calls and subprogram calls)
   d. Other blocks judged to be suitable for restarting a program (blocks for turning each mode on or off and others that function as a breakpoint in a program)
2. If the program restart memory becomes full, block information is deleted from the older one and the information on a new block is overwritten.
3. The program restart memory is cleared when operation is started in the MEM or RMT mode after a reset.
   The memory is also cleared when the program is changed and restart operation using the search method starts.
4. When a program is restarted with specifying a new restart point, the information on the blocks stored before restart operation is not cleared. After the program is restarted, block information after restart is added following the block information stored before restart.

- Search method

1. Any sequence number in the programmable parameter input (G10L52 or G10L50) mode is not searched for when a search is executed with specifying a sequence number.
2. When a short cut is specified for a rotary axis, the tool also uses a short cut to the machining restart position.
3. If the single-block operation is enabled when the tool moves to the restart position, a single-block stop occurs each time the tool moves along an axis. During this operation, however, no MDI operation is allowed.
4. While the tool is moving to the restart position, manual intervention is allowed for an axis along which the tool does not move to the restart position. The tool does not move manually along any axis along which it has moved to the restart position, however.
5. During movement to the machining restart position at a dry run feedrate, no interruption type custom macro can be started. If an attempt is made to start an interruption type custom macro, alarm DS0024 "UINT SIGNAL WAS ILLEGALLY INPUT" occurs.

- Direct jump method

There are the following limitations.

1. A direct jump may not be able to be selected depending on the block. (Example: Block in the cutter or tool nose radius compensation mode)
   If an attempt is made to select “JUMP” as the restart type for such a block, the warning message, “ILLEGAL DATA”, is displayed and the setting is not accepted.
2. A direct jump can be selected to restart a program from a block stored in the program restart memory. It cannot be used to restart a program from a block which is not stored in the program restart memory. If an attempt is made to use a direct jump for the above block, the warning message, “ILLEGAL DATA”, is displayed.
3. When a direct jump is selected, the status of items including position information, modal information, and macro variables is not restored. The “auxiliary function output in program restart” function is not also executed. For this reason, the operator must restore the status manually with considering the status of the restart block.
4. In the following cases, a direct jump can be selected for a block in a subprogram or external subprogram call:
   a. Subprogram call using M98
   b. Subprogram call using G65
   c. Block in a subprogram on the Data Server operating by M198
   d. Block in a program on the Data Server operating in the RMT mode

In other cases, a direct jump cannot be selected for a block in a subprogram or external subprogram call.
That is, a direct jump cannot be selected for the following blocks:

e. Block in a subprogram specified by an M or G code or a program called by a macro call
f. Block operating in the RMT mode (other than the Data Server)
g. Block in an execution macro

5. Note that there are the following limitations for blocks described in c. and d. above:
   (1) It is not possible to jump to the right position when there is a branch instruction of the custom macro.
   (2) It may take 1 to a few minutes to move the cursor to the restart block in a long program longer than 20 MB.
6. The jump position is shifted if the number of lines in the program is changed by editing the program after interrupted.
7. When a direct jump is selected, the auxiliary function status is not restored by the “auxiliary function output in program restart” function. Restore the status of auxiliary functions by MDI operation before starting subsequent machining if necessary.
8. When a direct jump is selected, modal information is not restored and the tool does not move to the restart position. The status must be restored by MDI operation or manual operation before starting subsequent machining.

- Stop at the restart position

Change single block operation to stop at the restart position. Setting the bit 1 (RPS) of parameter No.7331 to 1 enables to stop at the restart position even for continuous operation.

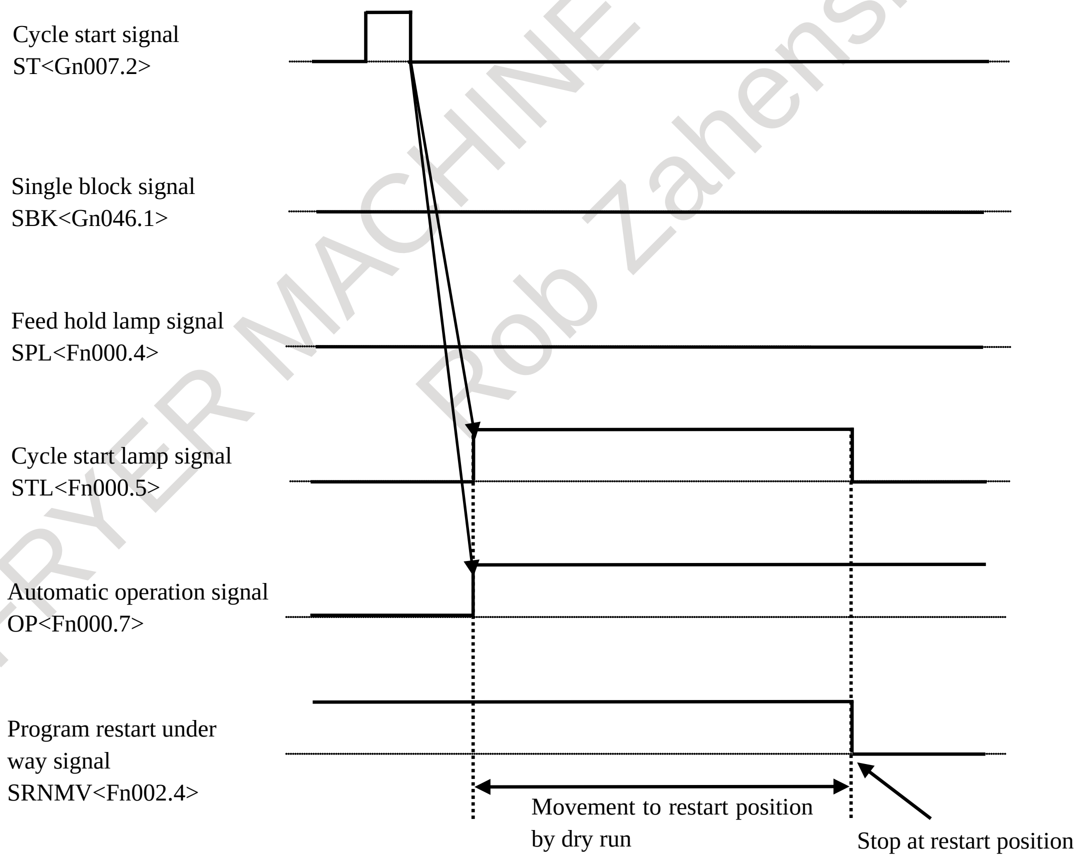

Fig. 5.7 (b) Operation in setting bit 1 (RPS) of parameter No.7331 to 1

- Execution macro (macro executor)

A program cannot be restarted from a block in an execution macro.

- Modal display on the program restart setting screen
The modal display on the program restart setting screen indicates the status before the execution of the stored block. That is, data specified in the stored block is not displayed.

- Reset
Do not perform reset operation from the start of a search for restart to the restart of machining.
If reset operation is performed, perform restart operation from the beginning again.

- Feed hold
If performing feed hold operation during search, perform restart operation from the beginning again.

- Manual absolute
Perform every manual operation with the manual absolute mode turned on regardless of whether the manual operation is performed before or after machining.

- Reference position return
When no absolute position detector (absolute pulse coder) is provided, be sure to perform reference position return after power-on, then perform restart operation.

- System variable
With a custom macro made by a machine tool builder, different operations between normal operation and program restart operation may be required. For this case, the operator can check the running state of program restart with system variable #3008.

#3008 = 0 : Normal operation
#3008 ≠ 0 : Program restart operation

- Relation to other functions
The symbols in the table are described below:

A : Can restart a program from a block in the mode of each function.
NA : Cannot restart a program from a block in the mode of each function. Also cannot restart a program when any of these commands is specified in the first block of the program to the restart block.
*1 : There are some limitations. See Remarks.
*2 : Can restart a program after the status of items including modal information, macro variables, and auxiliary functions is restored by MDI operation or manual operation.
*3 : May restart a program using the “auxiliary function output in program restart” function in some cases.
*4 : Cannot restart a program from a block in the mode of each function.
Can restart a program from a block in which the mode is off when the program contains a block for turning the mode on or off.
*5 : Coordinate values are calculated on the assumption that the block is executed to the end point. Therefore, if the program is restarted from a block without specifying an absolute command at least once following this command, the positioned coordinate values may be different from those actually executed.

Function name	Search method	Direct jump method	Remarks
Automatic operation (Memory operation)	A	A	
DNC operation	A	*1	Only the DNC operation of the Data Server is available on the direct jump method. When the program restart is executed excluding the Data Server, the warning of "ILLEGAL DATA" is displayed and the restart is not started.

Function name	Search method	Direct jump method	Remarks
DNC operation with memory card	A	NA	In the direct jump method, the warning of "ILLEGAL DATA" is displayed and the restart is not started.
Schedule function	NA	NA	In the search method, alarm SR1968 is generated. In the direct jump method, the warning of "ILLEGAL DATA" is displayed and the restart is not started.
Optional block skip	*1	*1	The optional block skip signal cannot be changed while executing the program restart. The program restart cannot be correctly executed, and restarts in a wrong block when the signal is changed.
Positioning	A	A	
Single direction positioning (G60)	A	A	
Linear interpolation	A	A	
Circular interpolation	A	A	
Helical interpolation	A	A	
Dwell	A	A	
Thread cutting, synchronous cutting	*4	*4	The thread shifts when restarting on the way of the threading blocks continuously commanded.
Multi threading	*4	*4	Same as the above-mentioned
Continuous threading	*4	*4	Same as the above-mentioned
Variable lead thread cutting	*4	*4	Same as the above-mentioned
Circular thread cutting	*4	*4	Same as the above-mentioned
Skip	*5	*2	
High-speed skip	*5	*2	
Multi-step skip	*5	*2	
Continuous high-speed skip	*5	*2	
Torque limit skip	*5	*2	
Polar coordinate interpolation	*4	*4	In the search method, tool position might shift by operating after the program restarts. In the direct jump method, the warning of "ILLEGAL DATA" is displayed and the restart is not started.
Cylindrical interpolation	*4	*4	Alarm PS176 is generated and restart is not available in both search methods and the direct jump methods.
Polar coordinate command	A	*4	In the direct jump method, the warning of "ILLEGAL DATA" is displayed and the restart is not started.
Normal direction control	A	*4	In the direct jump method, the warning of "ILLEGAL DATA" is displayed and the restart is not started.
Mirror image	NA	*2	In the search method, tool position might shift by operating after the program restarts.
Programmable mirror image	A	*4	In the direct jump method, the warning of "ILLEGAL DATA" is displayed and the restart is not started.
Mirror image for double turret	A	*4	In the direct jump method, the warning of "ILLEGAL DATA" is displayed and the restart is not started.
Figure copying	A	*4	In the direct jump method, the tool path might shift by operating after the program restarts.

Function name	Search method	Direct jump method	Remarks
Coordinate system rotation	A	*4	In the direct jump method, the tool path might shift by operating after the program restarts.
3-dimensional coordinate system conversion	A	*2	If G68(G68.1) is commanded with MDI operation and 3-dimensional coordinate system conversion mode is restored, the direct jump method is available.
Tilted working plane indexing	A	*2	See item “Tilted working plane indexing” for details when a direct jump is selected. See item “Workpiece setting error compensation (or tilted working plane indexing + tool center point control)” to use tool center point control simultaneously.
Workpiece coordinate system	A	*2	
Workpiece coordinate system preset (G92.1/G50.3)	NA	*2	In the search method, tool position might shift by operating after the program restarts.
Coordinate system setting (G92/G50)	A	*2

Reference position return check	A	A	
2nd reference position return	A	A	
3rd/4th reference position return	A	A	
Tool length offset	A	*2	
Tool offset (G45 to G48)	A	*2	
Tool functions (T code on lathe system)	A	*2	
Tool radius / Tool nose radius compensation	A	*4	In the direct jump method, the warning of "ILLEGAL DATA" is displayed and the restart is not started.
Tool offset for Milling and Turning function	A	*2	
Automatic tool length measurement (M series) / Automatic tool offset (T series)	*5	*2	
Plane selection	A	*2	
Balanced cutting	*4	*4	Synchronization between paths might shift by operating after the program restarts. In the direct jump method, the warning of "ILLEGAL DATA" is displayed and the restart is not started.
Programmable data input	A	A	
Programmable parameter input	A	A	For the blocks between G10L52 and G11, program restart with specifying a sequence number is disabled.
Sub program call (M98)	A	A	
Sub program call (M198)	A	*1	Only a program call on the Data Server is available for a direct jump.
Inch/metric conversion	A	*2	
Direct drawing dimension programming	A	*4	
Chamfering/Corner R	A	*4	
Optional chamfering corner R	A	*4	
Custom macro	A	*2	
Interruption type custom macro	A	*2	
Canned cycle	*4	*4	Tool path might shift by operating after the program restarts.
Multiple repetitive canned cycles	*4	*4	Tool path might shift by operating after the program restarts.

Function name	Search method	Direct jump method	Remarks
Multiple repetitive canned cycles II	*4	*4	Tool path might shift by operating after the program restarts.
Canned cycles for grinding	*4,*5	*4	Tool path might shift by operating after the program restarts.
Canned cycle for drilling (except rigid tapping)	A	*4	In the direct jump method, the warning of "ILLEGAL DATA" is displayed and the restart is not started.
Small-hole peck drilling cycle	*4	*4	In the search method, operation is restarted from the beginning of the hole machining. In the direct jump method, the warning of "ILLEGAL DATA" is displayed and the restart is not started.
Rigid tapping	*4	*4	In the search method, an alarm PS0200 is generated after restart. In the direct jump method, the warning of "ILLEGAL DATA" is displayed and the restart is not started.
PMC axis control	*3	*2	
Real time custom macro	NA	*4	The real time custom macro is not executed while restarting. Therefore, the real time custom macro might not operate correctly after the program restarts. (both search methods and the direct jump methods)
Polygon turning	*4	*4	
Polygon turning by Cs contour control	*4	*4	
Polygon machining with two spindles	*4	*4	
High-speed HRV3 control (G5.4)	*4	*2	On/off of this function is not restored as for the search method either. If G05.4Q1 or Q0 is commanded by MDI operation and the state is restored after restarted, operation can be restarted. (both search methods and the direct jump methods)
Optimum torque acceleration/deceleration	A	A	
Jerk control	A	A	
AI contour control I	A	A	
AI contour control II	A	A

Tool management function	*3	*2	When the search method is selected and a tool exchange macro is executed after search, the amount of tool offset may be incorrect. (For a macro using a command such as H#8409D#8410)
Tool life management	*3	A	
Embedded macro	A	A	
Arbitrary angular axis control	A	A	

Function name	Search method	Direct jump method	Remarks
Axis synchronous control	NA	*4	In the search method, program restart can be restarted if the synchronization is always ON. If on/off of synchronization is changed by M code etc. in the program, the position of the master axis and the slave axis might shift after restart.
Synchronous/Composite control	NA	*4	If on/off is changed by M code etc. in the program, the position of the master axis and the slave axis might shift after restart.
Superimposed Control	NA	*4	If on/off is changed M code etc. in the program, the position of the master axis and the slave axis might shift after restart.
Synchronous/Composite/Superimposed control by program command	NA	*4	If on/off is changed in the program, the position of the master axis and the slave axis might shift after restart.
Flexible synchronization control	*1	*1	See item “Flexible synchronization control”.
Hobbing/Electric gear box	NA	*4	The machining is executed with the function is invalid after restarted.
Electric gear box 2 pair	NA	*4	Same as the above-mentioned
Electric gear box automatic phase synchronization	NA	*4	Same as the above-mentioned
Spindle electric gear box	NA	*4	Same as the above-mentioned
Machining condition selecting function	A	*2	
Spindle positioning	*4	*4	The spindle must be positioned to the restart position by MDI operation in advance.
Cs contouring control	*3	*2	See item “Cs contour control” for details when the search method is selected.
Spindle speed fluctuation detection	A	*2	
Spindle synchronous control	*3	*2	
Live tool control with servo motor	*3	*2	
Servo/spindle synchronous control	*3	*2	
Macro executor	*4	*4	A program cannot be restarted from a block in an execution macro.

- Tool radius / Tool nose radius compensation

When bit 4 (INT) of parameter No. 13117 is set to 1, the interference check on cutter/tool nose radius compensation can be disabled during search by search method.

- Cs contour control

For details, see Item, “Cs contour controlled” in Section, “PROGRAM RESTART”.

- Flexible synchronization control

Setting bit 0 (FRS) of parameter No. 13421 to 1 enables program restart by search method in a program containing an M code for turning the flexible synchronization mode on or off.

1. Before starting program restart, set the flexible synchronization control mode selection signal MTA <Gn197.0>, MTB <Gn197.1>, MTC <Gn197.2>, or MTD <Gn197.3> to set the synchronization mode specified in the program command in the block where the program is to restart (the state specified by an M code for turning the flexible synchronization mode on or off). If the signal setting is inconsistent with the state specified by the M code, alarm PS5374 occurs. The synchronization mode is assumed to be off in the program from the beginning of the program until the first M code for turning the flexible synchronization mode on or off is specified.
2. When program restart is executed (when signal SRNMV <Fn002.4> is set to “1”), the flexible synchronization mode cannot be changed. If an attempt is made to change the mode, alarm PS5375 occurs.

3. When a block in the flexible synchronization mode is specified as the restart block, the restart travel distance for the slave axis is set to 0. In addition, "********" is displayed as the restart position for the slave axis.
4. To restart a program from a block after the flexible synchronization mode is canceled, an absolute command must be specified for the slave axis after the mode is canceled. If no absolute command is specified for the slave axis, alarm PS5378 occurs.

- 3-dimensional coordinate system conversion / Tilted working plane command

When the block where the program is to restart is in 3-dimensional coordinate system conversion mode G68 (machining center system) or G68.1 (lathe system) or Tilted working plane command, bit 1 (3DD) of parameter No. 7301 can be set to select whether to move the tool to the restart position along each axis according to the program coordinate system or workpiece coordinate system. When the bit (3DD) is set to 0, the tool moves to the restart position along each axis according to the program coordinate system; when it is set to 1, the tool moves according to the workpiece coordinate system.
The "DESTINATION" and "DISTANCE TO GO" values are displayed according to the setting of this bit (3DD).
The "ABSOLUTE" values are displayed according to the setting of bit 6 (DAK) of parameter No. 3106.

- Tilted working plane indexing

To restart a program from a block in the tilted working plane indexing mode using a direct jump, follow the procedure below:

1. Return the tool to the restart position.
2. Execute a direct jump.
3. Specify the tilted working plane indexing mode using the MDI unit after the program has been restarted (blinking RSTR disappears).
4. If the program is restarted from block after tool axis direction control, please command tool axis direction control.
5. The present absolute coordinate is matched to the absolute coordinates of the restart block.

- Presetting the relative coordinate values after the search

If bit 3 (RPR) of parameter No.7301 is 1, relative coordinate values are preset by absolute coordinate values after the search in quick program restart. However, this preset function is invalid in direct jump method of quick program restart.

Signal

Program restart under way signal SRNMV<Fn002.4>

[Classification] Output signal
[Function] Indicates the program is being restarted.
[Output cond.] The program restart under way signal becomes "1" when:
- The program restart signal is set to "0" after the screen changes to the program restart screen.

The signal is set to "0" when:
- The program restart sequence ends (the tool has been moved to the restart point on all controlled axes).

Quick program restart under way signal SRNEX<Fn534.1>

[Classification] Output signal
[Function] Indicates the quick program restart is executing.
[Output cond.] The program restart under way signal becomes "1" when:
- Press the soft key [SEARCH EXEC], and quick program restart is begun.

The signal is set to "0" when:
- The quick program restart sequence ends (the tool has been moved to the restart point on all controlled axes).

Signal address

	#7	#6	#5	#4	#3	#2	#1	#0
Fn002				SRNMV				
Fn534							SRNEX	

Parameter

	#7	#6	#5	#4	#3	#2	#1	#0
3106		DAK						

[Input type] Setting input
[Data type] Bit

#6 DAK Specifies whether to display coordinates in the program coordinate system or workpiece coordinate system as absolute coordinates when the 3-dimensional coordinate conversion mode or the tilted working plane indexing mode is set.
0: Display coordinates in the program coordinate system.
1: Display coordinates in the workpiece coordinate system.

	#7	#6	#5	#4	#3	#2	#1	#0
3712						CSF		

[Input type] Parameter input
[Data type] Bit

#2 CSF In the Cs contour control mode, the function for setting machine coordinates and absolute coordinates based on the machine position of the spindle if the origin is already set up is:
0: Disabled.
1: Enabled.

	#7	#6	#5	#4	#3	#2	#1	#0
4353			CSP					

[Input type] Parameter input
[Data type] Bit

#5 CSP The function for transferring Cs axis positional data is:
0: Disabled.
1: Enabled.
When this parameter is used, set the bit 7 (RFCHK3) of parameter No.4016 is to 0.

	#7	#6	#5	#4	#3	#2	#1	#0
7300			CCS					

[Input type] Parameter input
[Data type] Bit path

#5 CCS When the Cs contour control axis is used in the spindle mode or when the origin of the Cs contour control axis is not established, program restart is:
0: Disabled.
1: Enabled.

	#7	#6	#5	#4	#3	#2	#1	#0
7301					RPR		3DD	ROF

[Input type] Parameter input
[Data type] Bit path

#0 ROF When the coordinates for restarting are displayed on the program restart screen:
- 0: Tool length compensation (M series), tool position compensation (T series), cutter compensation (M series), and tool-nose radius compensation (T series) are considered.
- 1: Whether these compensation values are considered depends on the settings of bit 6 (DAL) of parameter No. 3104, bit 7 (DAC) of parameter No. 3104, and bit 1 (DAP) of parameter No. 3129 (parameters for specifying whether to consider each compensation value).

#1 3DD In program restart operation, when the restart block is in 3-dimensional coordinate conversion mode G68 (machining center system) or G68.1 (lathe system), the tool moves to the restart point along each axis:
- 0: According to the program coordinate system in dry run.
- 1: According to the workpiece coordinate system in dry run.

The restart coordinates and restart travel distance are also displayed in the coordinate system set in this parameter.

> **NOTE**
> The change made to this parameter in program restart operation is ignored.

#3 RPR When the search is completed in program restart or quick program restart, relative coordinate values are:
- 0: Not preset.
- 1: Preset by absolute coordinate values.

> **NOTE**
> This parameter is invalid in direct jump method of quick program restart.

7310	Ordinal number of an axis along which a movement is made in dry run after program restart

[Input type] Setting input
[Data type] Byte axis
[Valid data range] 1 to (Number of controlled axes)

This parameter sets the ordinal number of an axis along which a movement to the restart point is made in dry run after the program is restarted.

> ⚠ **WARNING**
> 1 When there is two or more axes which has the same setting value in this parameter, the movement to the restart point is not executed in the second or more axis.
> 2 When the quick program restart is effective and bit 6 (SAV) of parameter No.11250 is set to 1, the movement to the restart point is not done in the axis which this parameter is set negative value(-1 to -(Number of controlled axes)).

> **NOTE**
> When this parameter is 0, alarm SR5020, "PARAMETER OF RESTART ERROR" or the warning "ORDINAL NUMBER ERROR (RESTART)" is displayed.

	#7	#6	#5	#4	#3	#2	#1	#0
7331							RPS	

[Input type] Setting input
[Data type] Bit

#1 RPS In moving to the restart point of quick program restart, when the single block operation is invalid, the axes
0: do not stop by the restart point.
1: stop in state of the single block by the restart point.

> **NOTE**
> When this parameter is set to 1, the axes stop once in state of the single block in starting after restart operation even if these don't move to the restart point.

	#7	#6	#5	#4	#3	#2	#1	#0
11250	OAA							

[Input type] Parameter input
[Data type] Bit path

#7 OAA In the program restart function, the approach to the program restart position for each arbitrary axis is:
0: Not used.
1: Used.

	#7	#6	#5	#4	#3	#2	#1	#0
11251				NPN				

[Input type] Parameter input
[Data type] Bit

#4 NPN In Quick Program Restart Function, when an interrupted program is restarted from the block in the subprogram, the subprogram name is :
0: specified.
1: not specified.

	#7	#6	#5	#4	#3	#2	#1	#0
13117				INT				

[Input type] Parameter input
[Data type] Bit path

#4 INT During a program restart, the interference check on cutter/tool nose radius compensation is:
0: Enabled.
1: Disabled.

	#7	#6	#5	#4	#3	#2	#1	#0
13421								FRS

[Input type] Parameter input
[Data type] Bit path

> **NOTE**
> Set these parameters for the first path only. It will be effective to all paths.

#0 FRS In a program containing an M code for turning the flexible synchronization mode on/off, a program restart is:
0: Disabled.
1: Enabled.

Alarm and message

Number	Message	Description
PS0060	SEQUENCE NUMBER NOT FOUND	In the program restart sequence number specification, the specified sequence number could not be found. Check the restart block.
PS0071	DATA NOT FOUND	In the program restart block number specification, the specified block number could not be found. Check the restart block.
PS0098	G28 FOUND IN SEQUENCE RETURN	A command of the program restart was specified without the reference position return operation after power ON or emergency stop, and G28 was found during search. Perform the reference position return.
PS5374	FSC MODE MISMATCH IN RESTART	The current flexible synchronization mode differs from the flexible synchronization mode specified in a programmed command in the program restart block. Check the restart block.
PS5375	FSC MODE CAN NOT CHANGED	The flexible synchronization mode was changed during the execution of program restart. Check the restart block.
PS5378	INVALID RESTART BLOCK	The block specified as the restart block after the flexible synchronization mode was canceled was not a block after an absolute command for the axis specified as the slave axis. Check the restart block.
DS0024	UINT SIGNAL WAS ILLEGALLY INPUT	An interruption type custom macro was called during movement to the program restart position. Please do not call the interruption type custom macro.

Warning

⚠ WARNING

1 In principle, the tool cannot return to a correct position in the following cases. Special care must be taken in the following cases since none of them cause an alarm.
   - Manual operation is performed when the manual absolute mode is off.
   - Manual operation is performed when the machine is locked.
   - The mirror image is used. The tool can be returned by P type program restart, however, when the program is restarted from a block after the mode is turned on or off last. At this time, keep the state of the mirror image signal when the machining is interrupted.
   - A program in which main commands are executed in the incremental mode does not begin with coordinate system setting.
   - Manual intervention is performed while the tool is returning to the restart position along an axis.
   - Program restart is specified for a block between the block for skip cutting and subsequent absolute command block.
   - After program restart is specified in the machine lock state, the machine lock state is canceled.
   - In general, if a coordinate system is set up, changed, or shifted after search, the tool cannot return to the correct position.

2 When macro variable #3008 (indicating the status of program restart) is used and the behavior of the program during restart operation is different from that during normal operation, the program cannot be restarted from the correct position using the search method.

Example)

Program O0002 performs different operations between normal operation and program restart operation. In the following examples, this program cannot be restarted from the block of N998 or N999 using the search method. A main program including such a subprogram can be restarted, however. In this example, the program can be restarted from the block of N1.

```
O0001(MAIN)             O0002(SUB)
M98P0002                IF[#3008NE0]GOTO999
N1G00X100.Y100.         G53Z0
  :                     T#500
                        N998G00Z0
                        N999
                        M99
```

Caution

> ⚠ **CAUTION**
> Keep the following in mind when restarting a program including a macro variable.
> - Common variable
>   When a program is restarted, the previous values are inherited as common variables without being preset automatically. For this reason, before restarting the program, initialize the required variables to the original values used at the start of the previous automatic operation.
> - System variable
>   The following system variables are not updated during search for restart:
>   #5021 to #5028 ABSMT
>   #5041 to #5048 ABSOT
>   #5061 to #5068 ABSKP
> - DI/DO
>   During the restart of a program, DI can be read by a system variable, but DO cannot be output.
> - Clock
>   During the restart of a program, the clock time can be obtained by a system variable, but the time cannot be preset.

Reference item

Manual name	Item name
OPERATOR'S MANUAL (B-64694EN)	Quick program restart

5.7.1 Suppress Motion of Quick Program Restart

Overview

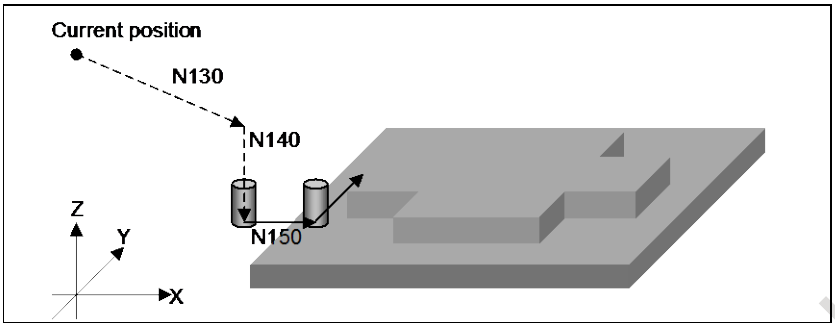
Suppress motion is a function which prohibits the approach to the start point of the specified restart block. In the conventional specification, the approach is performed to the start point of the restart block. To perform the approach to the end point of the restart block, the next block must be specified as the restart block. This function enables the tool to be moved to the end point of the specified restart block.
For example, when a block for approach is inserted in the machining program, the block for approach can be specified as the restart block and the tool can be moved to the end point of the block.

> **NOTE**
> An approach block is used for moving the tool closer to the workpiece from an arbitrary position (such as a tool change position). Normally, all axes used for the interrupted machining are specified. An approach block may consist of more than one block. In this case, select the first approach block as the restart block.

Example) Operation example

```
O1234;
:
N100 G91G28Z0.;
N110 G28X0.Y0.;
N120 T01M6;
N130 G90G00X-50.Y0;          Approach block for the X- and Y-axes
N140 Z-10.;                  Approach block for the Z-axis
N150 G41G01X-50.F1000.D1;
N160 Y50.;
:
```

When N130 is specified as the restart block, the tool moves from the current position to the end point of N130.



Explanation

Bit 5 (SPR) of parameter No. 11250 can be used to select whether to use suppress motion. To use suppress motion, press soft key [SET SUPRES] on the program restart information screen.

- Block for which suppress motion is available

To perform suppress motion, select a block which satisfies conditions (1) to (3) below:

(1) An absolute command is specified in the block.
If an incremental command is specified in the restart block, alarm PS1930, "ILLEGAL COMMAND AFTER RESTART", occurs.

(2) The G00 or G01 command is specified in the block.
If a command other than G00 or G01 is specified in the block, alarm PS1930 occurs.

(3) The block is not a modal block listed below.
If the restart block is a modal block listed below, suppress motion is not available even when the G00 or G01 command is specified in that block. If suppress motion is performed for a modal block listed below, alarm PS1931, "ILLEGAL MODE AFTER RESTART", occurs.

- Programmable mirror image
- 3-dimensional coordinate system conversion
- Coordinate system rotation
- Tilted working plane indexing
- Tilted working plane indexing by tool axis direction
- Tilted working plane indexing (incremental multiple command)
- Scaling
- Polar coordinate interpolation
- Normal direction control
- Canned cycle for drilling
- Canned cycle

- Saving the suppress motion status

By setting bit 6 (SAV) of parameter No. 11250 to 1, the suppress motion status can be saved. With this function, when suppress motion is always executed, once suppress motion setting is performed, the setting can be omitted after that.

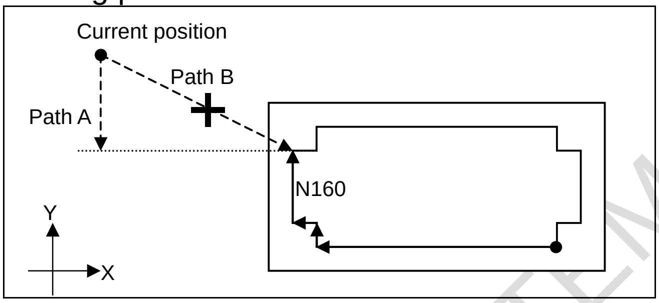
The suppress motion status can be checked using parameter No. 7310. When suppress motion is used, a negative value is set in parameter No. 7310.

For an axis for which an invalid value is set in parameter No. 7310, the suppress motion status is not saved.

Caution

⚠ **CAUTION**

When suppress motion is used, the tool moves to the end point of the restart block only along the axis specified in the restart block. For this reason, the tool does not move to the end point of the restart block along any axis that is not specified in the restart block.
When N160 in the example is specified for the restart block, the tool moves not along path B, but along path A as shown below:



Along any axis that is not specified in the restart block, move the tool to a position where it will not hit anything when it moves during restart operation, in the manual mode in advance.

Note

NOTE

1 While the tool is moving along another axis, suppress motion cannot be set or canceled. If suppress motion is set or canceled while the tool is moving along another axis, the warning message, “COMMAND ILLEGAL USE”, is displayed.
2 Performing approach for each arbitrary axis in the suppress motion status cancels the suppress motion.

Parameter

7310	Ordinal number of an axis which a movement is made in dry run after program restart

[Input type] Setting input
[Data type] Byte axis
[Valid data range] 1 to (Number of controlled axes)

This parameter sets the ordinal number of an axis along which a movement is made in dry run after the program is restarted.

⚠ **WARNING**

1 When there is two or more axes which has the same setting value in this parameter, the movement to the restart point is not executed in the second or more axis.
2 When the quick program restart is effective and bit 6 (SAV) of parameter No.11250 is set to 1, the movement to the restart point is not done in the axis which this parameter is set negative value(-1 to -(Number of controlled axes)).

NOTE

When this parameter is 0, alarm SR5020, "PARAMETER OF RESTART ERROR" or the warning "ORDINAL NUMBER ERROR (RESTART)" is displayed.

	#7	#6	#5	#4	#3	#2	#1	#0
11250		SAV	SPR					

[Input type] Parameter input
[Data type] Bit path

#5 SPR Suppress motion is:
0: Disabled.
1: Enabled.

#6 SAV The suppress motion state is:
0: Not saved to a parameter.
1: Saved to a parameter.

Alarm and message

Number	Message	Description
PS1930	ILLEGAL COMMAND AFTER RESTART	The restart block does not satisfy either of the following conditions: (1) An absolute command is specified in the block. (2) The G00 or G01 command is specified in the block. Select a block satisfying conditions (1) and (2) as the restart block.
PS1931	ILLEGAL MODE AFTER RESTART	Suppress motion is specified in a mode in which suppress motion is not available. Select a block in a mode in which suppress motion is available as the restart block.

OPERATOR'S MANUAL (B-64694EN)	Suppress motion of quick program restart

5.7.2 Quick program restart for multi path system

Overview

When the machining was restarted by quick program restart in multi path system, it has been necessary to operate the program restart every one path.
In this function, when the program restart is operated in one path, the program restart is automatically operated as for other paths. As a result, the program restart can be executed by an easy operation in the machine with a multi path system.

Explanation

When the program restart is operated in certain one path, it is automatically operated in the multi path system as for other paths.
This operation is called "multi path quick program restart" ("multi path restart" at the following).
As for this function, only the program restart of the search method is possible. It cannot be used with the direct jump method.

Setting

In the path that sets the same group number as parameter No.7337, Multi path restart is available.
When the program restart is operated in a certain path, it is operated at the same time in the path that belongs to the same group.
In the path that sets 0 to parameter No.7337, Multi path restart is not available.

Blocks in which restart is possible

It is the following blocks that can restart the machining by the multi path restart.

(1) Block that is memorized in program restart memory, and was interrupted machining

(2) Block of waiting M code that was memorized in program restart memory, or arbitrary waiting M code specified on program restart setting screen

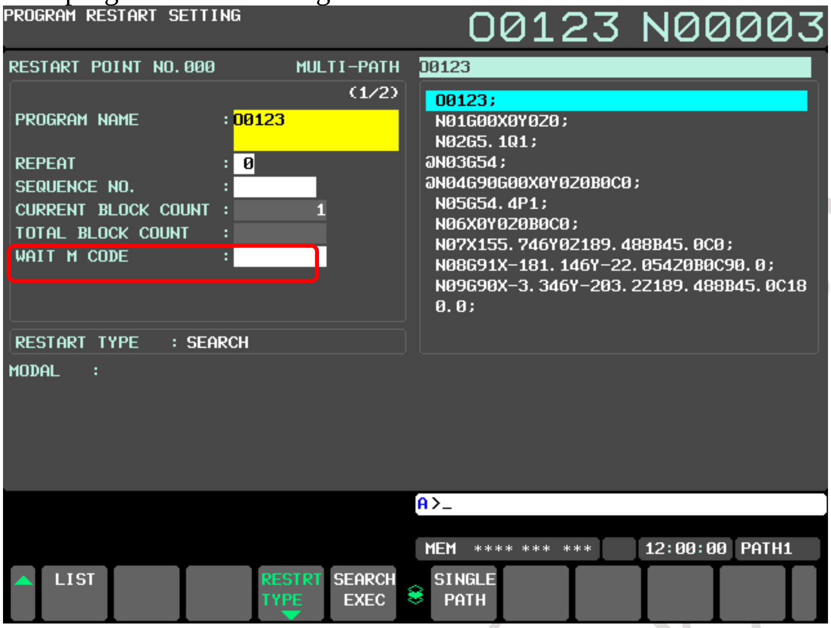

Fig. 5.7.2 (a) Screen for specify waiting M code

(3) Block of arbitrary sequence number specified on program restart setting screen without using program restart memory

When the program restart is executed to the block like the above-mentioned in certain one path, an operation of the program restart is automatically started as for other paths. When an operation of the program restart is started, each path starts the search of a target block severally.

Operation when the block of above-mentioned (1) - (3) is specified is as follows.

(a) Block where machining was interrupted
The block where machining is interrupted is searched for in each path and the search stops at the block.

(b) Block of the waiting M code
A block of the specified waiting M code is searched in each path, and the search stops in a block in which it was found. However, if the subprogram call is commanded in the same block as the waiting M code, the search stops at a first block of the subprogram. (Machining is restarted from a head of subprogram.)

(c) Block of arbitrary sequence number
A block of the specified sequence number is searched in each path, and the search stops in a block in which it was found. This method can be used in case that the same sequence number is put on the program in each path as a sign of the delimitation of the machining.

When the block that corresponds to above-mentioned (a)-(c) is specified as a restart block, the following method to specify are possible.

Fig. 5.7.2 (a) Search that restart for multi path system is possible

Method to specify / Kind of restart block	Select in list or detail screen	Select in list or detail screen and edit	Direct specification by newly edit
(a) Block where machining was interrupted	Available	Not available	Not available
(b) Block of the waiting M code	Available	Not available	Available
(c) Block of arbitrary sequence number	Not available	Not available	Available

NOTE

1. Warning "CAN NOT RESTART IN MULTI PATH MODE" is displayed when multi path restart is executed with specifying blocks other than the above-mentioned (a) to (c).
2. No-wait signal NOWT <G0063.1> and NMWT <Gn063.7> can be used as well as normal automatic operation when searching a waiting M code. It is not searched in a path which the waiting M code is disable.
   However, warning "CAN NOT RESTART IN MULTI PATH MODE" is displayed in the following cases.
   - It is ignoring waiting in operation path
   - The path that can be searched by ignoring waiting is below one path.
3. When the alarm is issued in a path executing the multi path restart, alarm (PS0060) "SEQUENCE NUMBER NOT FOUND" or alarm (PS0071) "DATA NOT FOUND" is issued in other paths of the same group.

Operation after search is completed

The target path of dry run movement after search is specified by bit 0 (MPD) of parameter No.7331.

- When parameter MPD is set 0 :

The order in the path which dry run movement is executed after search can be specified by parameter No.7338.

It enters the state of STRT after the axes move to the machining restart position with dry run and the machining program becomes waiting for execution.

When all paths of the same group enter the state of STRT, the waiting state is released and the machining program is executed.

In the path that 0 is set to parameter No.7338, the dry run movement and the machining program are executed without waiting for other path.

- When parameter MPD is set 1 :

Dry run is executed in the path that has been selected by the path selection signal HEAD<G0063.0>, HEAD2<G0062.7>.

It is necessary to do cycle start in each path whenever the selected path is changed by the path selection signal.

It enters the state of STRT after the axes move to the machining restart position with dry run and the machining program becomes waiting for execution.

When all paths of the same group enter the state of STRT, the waiting state is released and the machining program is executed.

NOTE

1. In case of bit 0 (MPD) of parameter No.7331 is set 0, when one path enters in the state of STRT, the movement of a dry run of next path is automatically started.
2. In case of bit 0 (MPD) of parameter No.7331 is set 1, the path has not been selected by the path selection signal does not accept the cycle start to a dry run movement after search.
3. Program restart under way signal SRNMV<Fn002.4> becomes "1" until the movement of a dry run in all paths that belong to the same group is completed. However, when the movement of a dry run in the path is completed, signal SRNMV<Fn002.4> becomes "0" as for the path set to parameter MPD=0 and parameter No.7338=0.

⚠ **WARNING**

The path of the same group to restart a multi path begins the execution of the machining program after waiting for other paths, but it does not synchronize with the path that is not the same group.

Single path restart

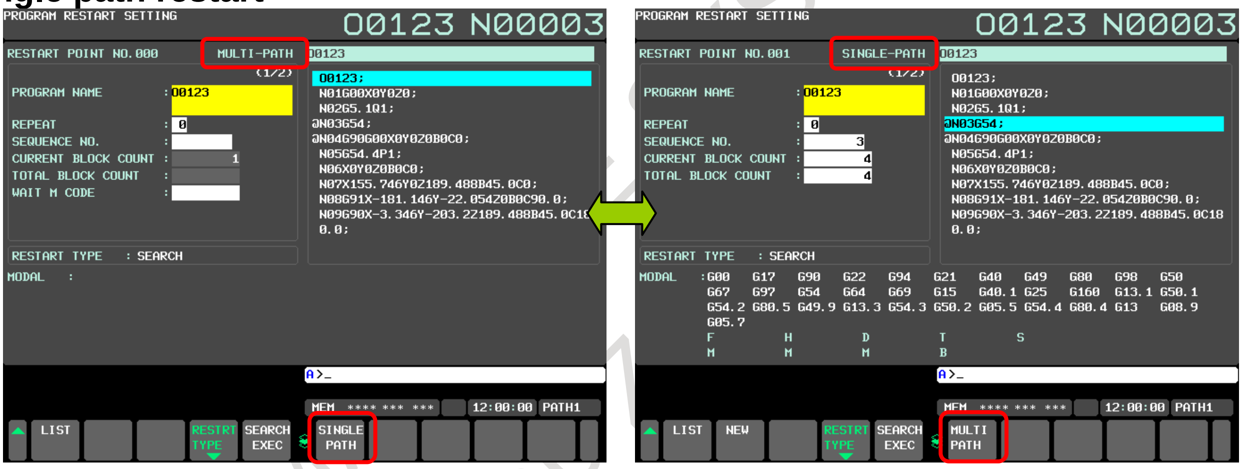

Fig. 5.7.2 (b) Program restart screen

When a soft key [SINGLE PATH] is pushed, it is change in the single path restart mode.

In the single path restart mode, it can be done the program restart operation only in the path under the display.

"SINGLE PATH" is displayed on the right of a left screen like showing in Fig. 5.7.2 (b) the single system restart mode inside.

The single path restart mode is canceled by either of the following operations.

- Program restart operation is executed.
- Another screen was selected.
- Soft key [MULTI PATH] is pushed.

Limitation

- Miscellaneous function

The miscellaneous function under the search is not output to PMC.

Please restore the state of the miscellaneous function by MDI operation before restarting the machining after the search ends.

- Synchronous / Composite / Superimposed control

On/off command of the synchronous control, the composite control, and the superimposed control by the miscellaneous function or G code under the search is invalid.

Please restore the state of the synchronous control, the composite control, and the superimposed control by MDI operation before restarting the machining after the search ends.

- Flexible path axis assignment

In the command of the flexible path axis assignment under the search, the flexible path axis assignment is not operated.
Please restore the state of the flexible path axis assignment by MDI operation before restarting the machining after the search ends.

Parameter

The parameter used by this function is shown as follows.

	#7	#6	#5	#4	#3	#2	#1	#0
7331								MPD

[Input type] Setting input
[Data type] Bit

#0 MPD In the multi path quick program restart function, the target path for a dry run movement after restart search is :
0: Specified by parameter No.7338.
1: Specified by path select signal HEAD<G0063.0> and HEAD2<G0062.7>.

> **NOTE**
> When MPD is set 1, do the cycle start further after the axes moves to the machining restart position to make each path stand-by in the STRT state. In the multi path quick program restart, all paths in the same group should be these stand-by states for an automatic operation to be executed.

7337	Group number of multi path quick program restart

[Input type] Setting input
[Data type] Byte path
[Valid data range] 0 to (Number of controlled paths)
Please set the group number to this parameter in the path which the multi path quick program restart is effective.

Example) In the four paths system, when path1 to 3 and path4 are made each group, please set this parameter as follows.

Path	Setting value of parameter No.7337
1	1
2	1
3	1
4	2 (or 0)

In this setting, the program restart is automatically executed in path2 and path3 set to the same group when the program restart is executed in path1.
Similarly, when the program restart is executed in path2 or path3, the program restart is automatically executed in two remaining paths.
When the program restart is executed in path4, the program restart is executed only in path4.

> **NOTE**
> If a value that is bigger than the number of controlled paths is set, warning "CAN NOT RESTART IN MULTI PATH MODE" is displayed at the search.

7338	Ordinal number of a path when moving by dry run in multi path quick program restart

[Input type] Setting input
[Data type] Byte path
[Valid data range] 0 to (Number of controlled paths)

Set the order of the path when moving to the restart point by a dry run after it begins to restart. When the same number is set, it moves at the same time. The path to which 0 is set does not wait for other paths, and the movement of a dry run and the machining program are executed.

Example) In the four paths system, to move a dry run in order in the first path2, in the second path1 and path3, at the end path4, set this parameter as follows.

Path	Setting value of parameter No.7338
1	2
2	1
3	2
4	3

> **NOTE**
> This parameter is effective at bit 0 (MPD) of parameter No.7331 is set 0.

5.7.3 Improvement of Quick program restart for non-machining program

Overview

In Quick Program Restart function, when a program is executed in MEM or RMT mode, restart block information is automatically memorized in the program restart memory.
After a machining program is interrupted, another program, which is not related to machining, is sometimes executed for the purpose of tool retract and the preparation of the machining in MEM or RMT mode. In this case, restart the block information is newly memorized, and the restart block information on the machining program memorized till then is overwritten. (It is not overwritten when a non-machining program is executed in MDI mode.)
By this improvement, restart block information is not memorized in the case of a certain specific program.
As a result, even when programs of tool retract and machining preparation are executed during the machining, restart block information related to machining can be kept.

Explanation

When the parameter to activate this function is set and the following programs are executed, restart block information is not memorized.

(1) Program with specific program number
Specify the range of the program number by the parameter No.7335 and No.7336. When the program with the program number specified here is selected as a main program, restart block information is not memorized.
Moreover, restart block information of a subprogram called from this main program is not

memorized. When the program specified here is called from the main program whose restart block information is memorized, restart block information is memorized.

NOTE
The folder cannot be used. Restart block information is not memorized when the program number is within the range, regardless of a folder.

(2) One touch macro call
Restart block information is not memorized by setting bit 0 (OMC) of parameter No.7330=1 while a one-touch macro is being executed. Restart block information of a subprogram called from one touch macro is not memorized, either.

Example

If parameter No.7335=7900 and No.7336=20 are set when program O7900-O7919 is used as a program for the tool retract, the relation between the main program number and the memorization of restart block information is as follows.

Main program number	Restart block information
O0001 — O7988	Memorized
O7900 — O7919	Not memorized
O7920 — O9999	Memorized

For instance, when O0001 is executed, restart block information about O0001 is memorized.
Restart block information about O0001 is kept, even if O0001 is interrupted on the way and O7901 for tool retract is selected as a main program and executed.
The program can be easily restarted by using kept restart block information if O0001 is selected again as a main program after the tool retract program is executed.
Restart block information about O0001 is overwritten, when O0001 is interrupted on the way and O0002 is newly executed as a main program, and restart block information on O0002 is memorized.

Parameter

	#7	#6	#5	#4	#3	#2	#1	#0
7330								OMC

[Input type] Parameter input
[Data type] Bit path

#0 OMC While executing One-touch macro, restart block information on Quick program restart is :
0: Memorized.
1: Not memorized.

7335	The first O number of program not memorized in program restart memory

[Input type] Parameter input
[Data type] 2-word path
[Valid data range] 1 to 99999999

Set the first number of the program that is not memorized as restart block information in quick program restart function.

7336	The number of programs not memorized in program restart memory

[Input type] Parameter input
[Data type] 2-word path
[Valid data range] 1 to 32767

Set the number of the programs that is not memorized as restart block information in quick program restart function.

Example)
When parameter No.7335=7900 and No.7336=20 are set, the program of O7900-O7919 (20 programs) is treated as a program not memorized in the program restart memory. When these programs are executed as the main program, restart block information is not memorized.

5.7.4 Improvement of Storing in Program Restart Memory

Overview

In Quick program restart, the storing the block information in the program restart memory can be disabled by the input signal of PMC or the system variable.

Explanation

In this function, the storing the block information in the program restart memory can be disabled by the input signal of PMC or the system variable. Therefore, the storing of useless block information as a restart point can be controlled, and useful restart points can be stored in the program restart memory more.

Signal

The storing the block information in the program restart memory can be disabled by program restart memory storing disabled signal QRSTD<Gn517.6>.
When this signal is set to “0”, block information is stored in the program restart memory.
When this signal is set to “1”, block information is not stored in the program restart memory.
If the state of QRSTD is “1” when an automatic operation begins, the program restart memory is not cleared and the storing in the program restart memory is disabled until end of the automatic operation.

System variable

The storing the block information in the program restart memory can be disabled by the system variable #151171 of custom macro.
When #151171 is set to 0, the block information is stored in the program restart memory.
When #151171 is set to 1, the block information is not stored in the program restart memory.
#151171 is cleared to 0 by a reset operation. When an automatic operation begins, the program restart memory is cleared without depending on #151171.

System variable number	System variable name	Attribute	Description
#151171	[#_QRSTD]	R/W	The control to store the block information in the program restart memory.

Use program restart memory storing disabled signal QRSTD<Gn517.6> in an automatic operation that should not use program restart function.
The system variable #151171 is effective when the storing the block information in the program restart memory temporarily is disabled while the program execution.

Example

<When you would like to execute the program restart after another program is executed once after the processing interrupts>

1. Set program restart memory storing disabled signal QRSTD<Gn517.6> to “1”.
2. Another program O1000 is selected, and executed.
3. Set program restart memory storing disabled signal QRSTD<Gn517.6> to “0”.
4. Program O0001 when the processing interrupts is selected because restart block information when the processing interrupts remains,
   and program restart is executed.

This usage is effective for the program name (Program name is not a number or DNC operation) that cannot be set to parameter No.7335 and No.7336.

<When you would like to disable to store in the program restart memory partially of a program>

In program O0002, when you would like to disable to store in the program restart memory during executing program O9001 called by a macro call, the program is made as follows.

```
O0002 ;                         O9001 ;
G28 X0.0 ;                      #151171=1 ;      It disables to store in the program restart memory.
Mxx ;                           #100=#1+#2 ;
:                               G00 G91 X#100 ;
G65 P9001 L2 A1.0 B2.0 ;              :          This section is not stored in the program restart memory.
:                               Myy ;
M30 ;                           G00 G91 Y#100 ;
                                #151171=0 ;      It enables to store in the program restart memory.
                                M99 ;
```

It is possible to substitute by program restart memory storing disabled signal QRSTD<Gn517.6>, but the program can be executed at high speed or more by using the system variable if storing and not storing restart memory are switched in the program.

Signal

Program restart memory storing disabled signal QRSTD <Gn517.6>

[Classification] Input signal
[Function] It is selected whether to store a block information in the program restart memory.
[Operation] When this signal is set to "0", block information is stored in the program restart memory.
When this signal is set to "1", block information is not stored in the program restart memory.

Signal address

	#7	#6	#5	#4	#3	#2	#1	#0
Gn517		QRSTD						

Alarm and message

Number	Message	Description
PS0110	OVERFLOW :INTEGER	The tolerance of the system variable was exceeded.

Note

- Use M code without buffering when you change program restart memory storing disabled signal QRSTD <Gn517.6 > during an automatic operation. Moreover, whether the block of this M code is stored in program restart memory is decided by the state of the signal when read in advance.
- System variable #151171 can be written only 0 or 1. When other values are written, the alarm (PS0110) "OVERFLOW :INTEGER" occurs.

5.7.5 Manual Intervention in Quick Program Restart

Overview

In Search method of Quick program restart, tool moves to the restart position automatically. This movement is executed in the specified order of axes one by one. Traditionally, if manual intervention is

executed in this movement to avoid interference with mechanical elements and others, reset and selection of restart block have to be executed again.
By manual intervention in Quick program restart, the movement to restart position can be continued without reset and selection of restart block even if operation mode change or manual intervention is executed before the movement is completed.

Explanation

Manual intervention in Quick program restart is enabled by setting the bit 5 (RMI) of parameter No.11251 to 1. If RMI is set to 0, Quick program restart works traditionally.

Traditional specifications (RMI is set to 0)

If RMI is set to 0, manual intervention is executed before the movement to restart position is completed, reset and selection of restart block have to be executed again.

Specifications when this function is enabled (RMI is set to 1)

If RMI is set to 1, operation mode is changed before the movement to restart position is completed, the movement to restart position is executed again from the first axis. Therefore, the movement can be continued without reset or selection of restart block, even if manual intervention is executed before the movement is completed.

Example

Example when this function is enabled is following.

(1) Assume that tool is retracted while N2 block is executing.
In this case, restart position is set to the starting position of N2 block when operation is restarted from interrupt position.

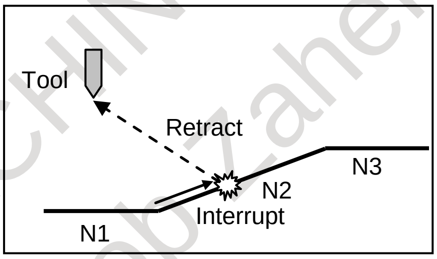

Fig. 5.7.5 (a) Starting of Quick program restart

(2) After reset is executed, N2 block is selected as the restart block and Quick program restart is executed. The movement to restart position is executed per axis in the specified order. Assume that operator notices possibility of interference when the movement of first axis is completed, and moves the tool to the other position by manual intervention.

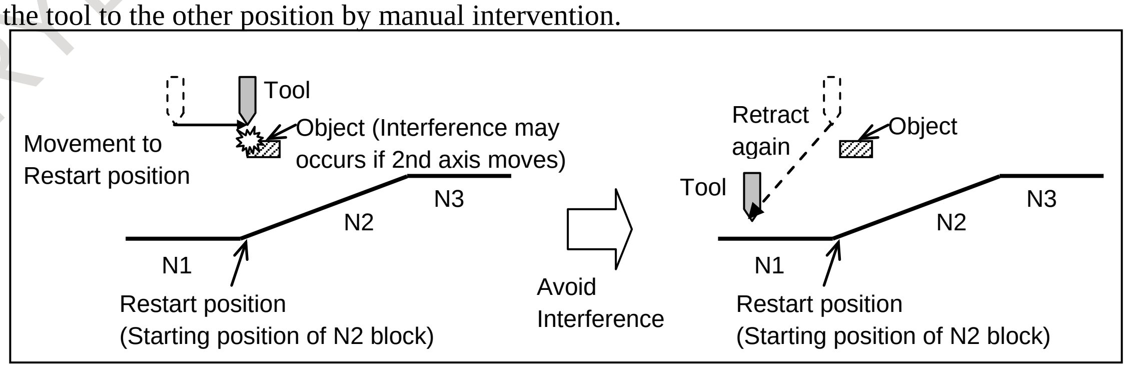

Fig. 5.7.5 (b) Interference avoidance by manual intervention

(3) After tool retraction of (2), the tool moves to the restart position correctly even if without reset because the movement to restart position is executed again from first axis.

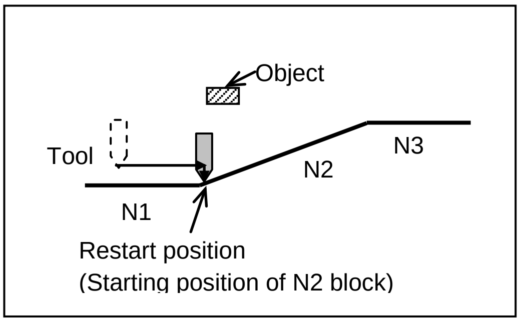

Fig. 5.7.5 (c) Movement to restart position after manual intervention

Parameter

	#7	#6	#5	#4	#3	#2	#1	#0
11251			RMI					

[Input type] Parameter input
[Data type] Bit

#5 RMI Manual intervention in Quick program restart is :
0: Disabled.
1: Enabled.

Restriction

In case that bit 5 (RMI) of parameter No.11251 is set to 1, modal information is not restored again if it is changed in MDI mode during interruption of movement to restart position. If modal information have to be restored again, reset and selection of restart block is needed again.

5.7.6 Tool axis direction approach at program restart

Overview

In Program restart and Quick program restart (Search type), when the program restart is done to the block of the following function executing, the restart operation of the tool axis direction becomes possible.
This function is valid by bit 2 (TLR) of parameter No.7301 is set to 1. By the parameter (No. 7311), the approach distance to restart operation starting position of the tool axis direction can be set.

NOTE
1. This function requires "Program restart" function or “Quick program restart” function. To enable "Program restart" function, set NSQ (bit 2 of parameter No.8135) to 0.
2. This function is possible only for the tool rotation or mix type machine (the parameter No. 19680 is set to 2 or 21).

Explanation

- Moved to the restart position

A series of operation example of restart operation of the tool axis direction is shown in Fig. 5.7.6 (a) and Fig. 5.7.6(b). Moreover, Table 5.7.6 (a) shows the order of restart operation and the content.

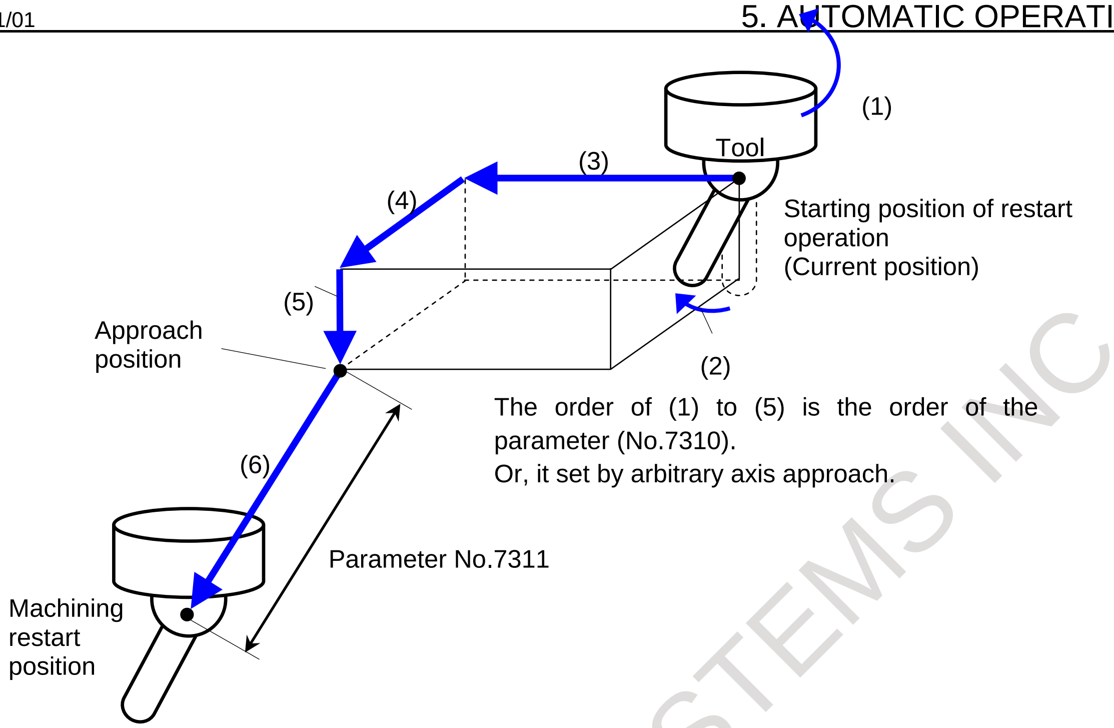

Fig. 5.7.6 (a) Restart movement of tool axis direction (parameter TLR=1) - example 1

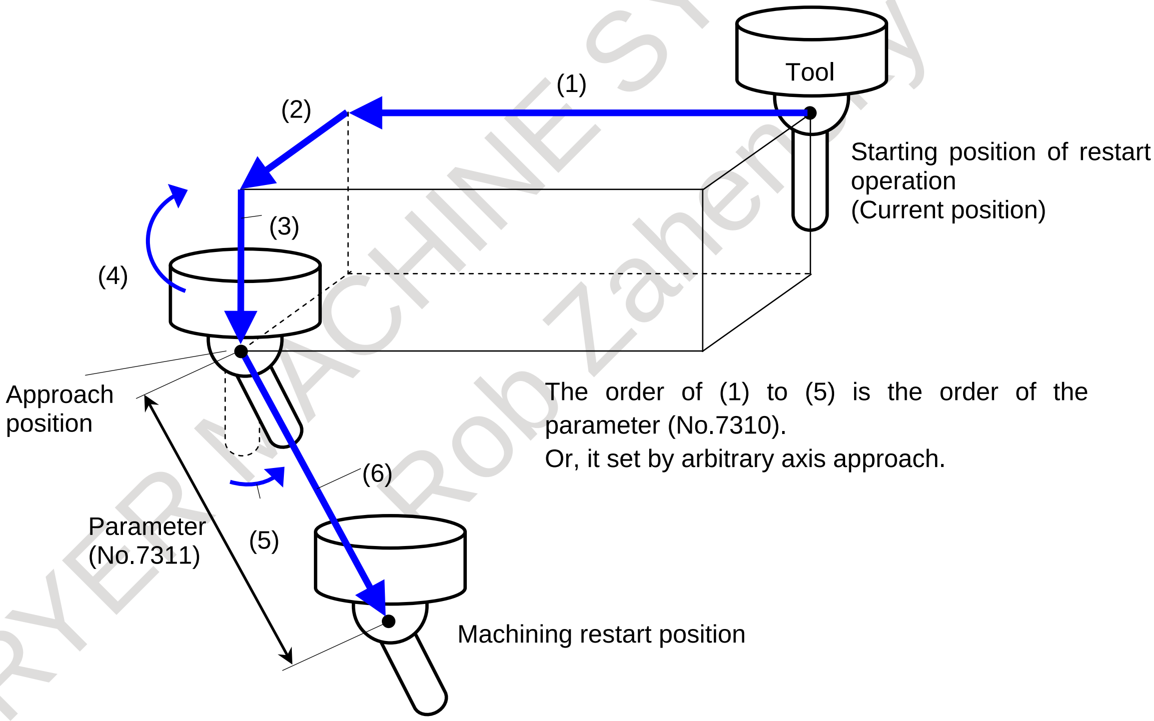

Fig. 5.7.6 (b) Restart operation of tool axis direction (parameter TLR=1) - example 2

Table 5.7.6 (a) Flow of restart movement of tool axis direction

Order	Contents of restart operation	Note
(1)-(5)	The following axes are positioned in order by the parameter (No. 7310) or arbitrary 1-axis approach	
	- Restart operation of rotary axis	- Positioning of the rotary axis becomes a base of the tool axis direction
	- Positioning to approach position with linear 3-axis	- The approach position is a point where the parameter (No. 7311) leaves the machining restart position for the tool axis direction
	- Restart operation of other axis	
(6)	Positioning to machining restart position as tool axis direction	

- Feedrate of restart operation

Restart operation is moved at the dry run rate.

- Tool axis direction approach

In case of that the tool position (position of rotary 2-axis and linear 3-axis) is already at the machining restart position when restart operation start, the tool axis direction approach is invalid.

- Single block

When the single block signal SBK <Gn046.1> set to 1, the single block stop is done in each of restart operation, approach position and machining restart position of each axis.

- Functions that cannot be used simultaneously

- Suppress motion of quick program restart
- Quick program restart for multi path system

Parameter

7310	Ordinal number of an axis along which a movement is made in dry run after program restart

[Input type] Setting input
[Data type] Byte axis
[Valid data range] 1 to (Number of controlled axes)

This parameter sets the ordinal number of an axis along which a movement is made in dry run after the program is restarted.

> ⚠ **WARNING**
> 1 When there is two or more axes which has the same setting value in this parameter, the movement to the restart point is not executed in the second or more axis.
> 2 When the quick program restart is effective and bit 6 (SAV) of parameter No.11250 is set to 1, the movement to the restart point is not done in the axis which this parameter is set negative value(-1 to -(Number of controlled axes)).

> **NOTE**
> When this parameter is 0, alarm SR5020, "PARAMETER OF RESTART ERROR" or the warning "ORDINAL NUMBER ERROR (RESTART)" is displayed.

19680	Mechanical unit type

[Input type] Parameter input
[Data type] Byte path
[Valid data range] 0 to 21

Specify the type of the mechanical unit.

Parameter No. 19680	Mechanical unit type	Controlled rotation axis	Master and slave
2	Tool rotation type	Two rotation axes of the tool	The first rotation axis is the master, and the second rotation axis is the slave.
21	Mixed type	One rotation axis of the tool + one rotation axis of the table	The first rotation axis is the tool rotation axis, and the second rotation axis is the table rotation axis.

5.8 TOOL RETRACT AND RECOVER

Overview

The tool can be retracted from a workpiece to replace the tool, if damaged during machining, or to check the status of machining. Then, the tool can be returned to restart machining efficiently.

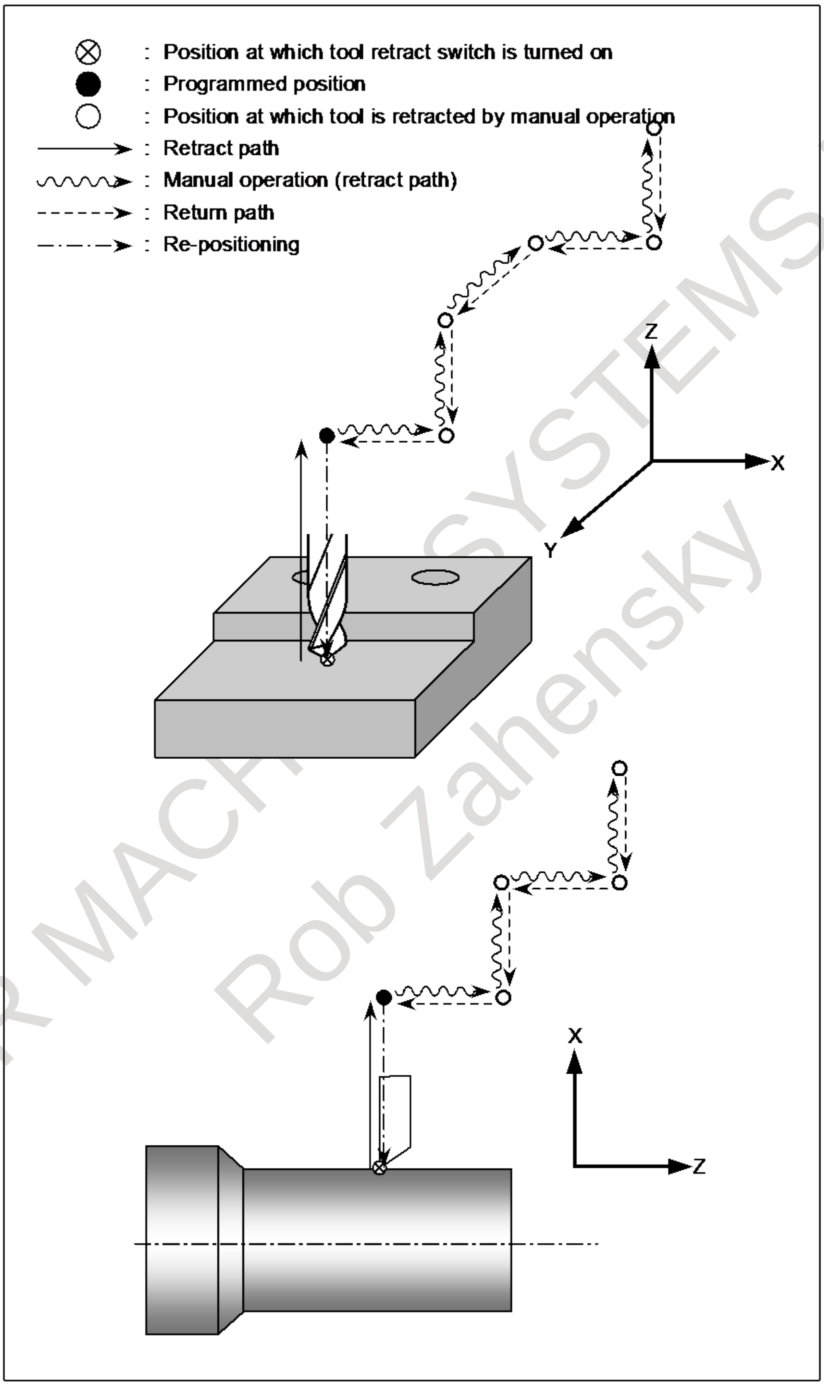

Fig. 5.8 (a) Path of tool retract and recover for milling machining

- Basic procedure for tool retract and recover

(1) When tool retraction signal TRESC <Gn059.0>, which is an input signal from the PMC, is set to 1 during automatic operation, in the automatic operation stopped state, or in the automatic operation halted state, the tool is retracted by a specified distance. This operation is called retraction. The position at which the retraction is completed is called the retract position.

The tool is retracted by linear interpolation at the minimum feedrate among the parameter (No.7042) values of moving axes.
If a block is being executed halfway when the TRESC signal is set to “1” during automatic operation, the execution of the block is interrupted immediately, then retraction is performed. After the retraction is completed, the automatic operation is halted. If G10.6 is not programmed, retraction does not take place, block execution is interrupted, and the automatic operation is halted or stopped.
The distance of retraction can also be specified in parameter No. 7041.
When the TRESC signal is set to “1”, it is said that the tool retraction mode is entered.
The tool retraction mode involves all of retraction, manual retraction, recovery, and re-positioning operations.
When the tool retraction mode is entered, tool retraction mode signal TRACT <Fn092.3> is set to “1”, notifying the PMC that the tool retraction mode is set.
When the tool starts moving to retract, tool retraction axis movement signal TRMTN <Fn092.4> is set to “1”. When the tool is stopped at the retract position, TRMTN is set to “0”, and tool retraction/return completion signal TRSPS <Fn092.5> is set to “1”.

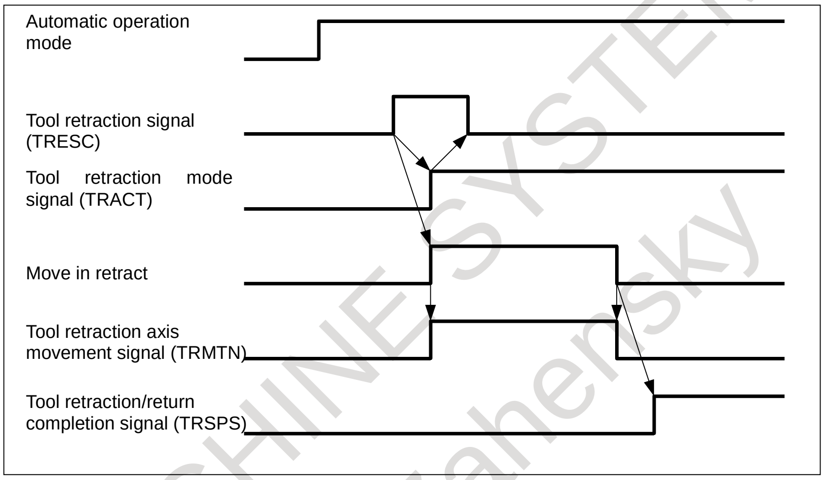

Fig. 5.8 (b) Timing chart of retraction operation (when movement is involved)

(2) Change the mode to the manual mode, and move the tool by a manual operation (jog feed, incremental feed, manual handle feed) for a purpose such as the purpose of changing the tool. This operation is called manual retraction. The CNC automatically records the retract path of the tool. Up to 20 points on the tool retract path are recorded automatically. When the tool is retracted manually, the TRSPS signal is set to “0”. While the tool is moving along an axis by manual operation, the TRMTN signal is “0”.

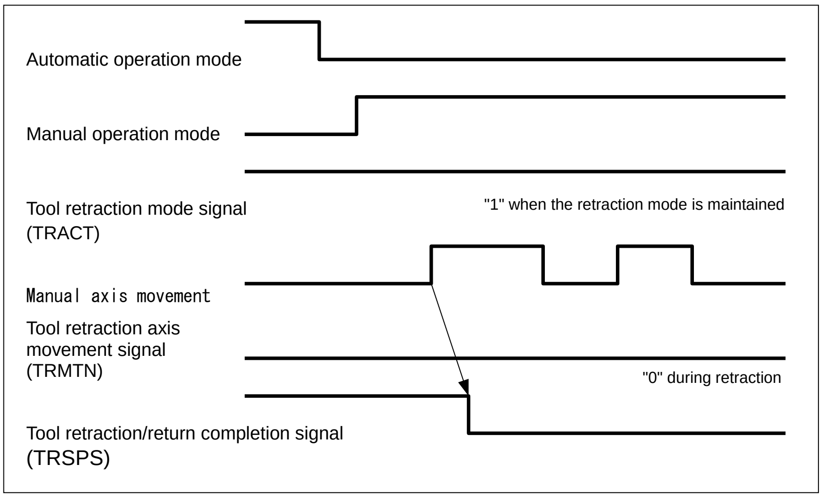

Fig. 5.8 (c) Timing chart of manual retraction

NOTE
If the path number is 5 or over, the maximum number of record points on the tool retract path is 10.

(3) Restore the automatic operation mode, and set tool return signal TRRTN <Gn059.1> to “1” then back “0”. The CNC then reverses the tool along the path of the manual movement to return the tool to the retract position. This operation is called recovery. When the tool starts moving for recovery, TRMTN is set to “1”. Upon completion of the recovery to the retract position, TRSPS is set to “1”. The recovery is performed at the feedrate specified by parameter No.7042 for each axis.

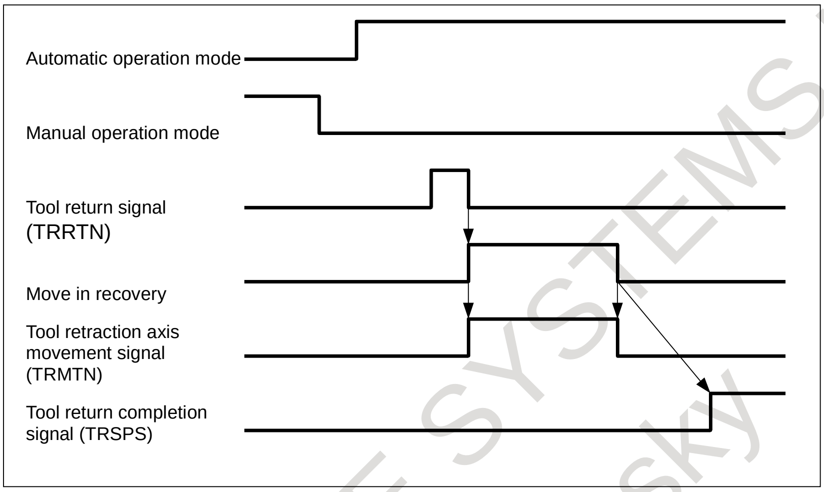

Fig. 5.8 (d) Timing chart of recovery (when the tool returns to the retract position without performing single block stop or feed hold stop during recovery)

(4) When a cycle start is directed at the retract position, the tool first moves to a position at which tool retraction signal TRESC was set to “1”. This operation is called re-positioning. As re-positioning starts, tool retraction/return completion signal TRSPS is set to “0”. During movement for re-positioning, tool retraction axis movement signal TRMTN is “1”.
The re-positioning movement is made by linear interpolation at the minimum feedrate among the parameter (No.7042) values of moving axes.
Upon completion of the re-positioning, tool retraction mode signal TRACT is set to “0”, notifying the PMC that the tool retraction mode ends. The subsequent operation varies depending on the automatic operation state present when the tool retraction mode was entered as follows:
<1> When the tool retraction mode was entered during automatic operation, the interrupted automatic operation is restarted continuously after re-positioning is completed.
<2> When the tool retraction mode was entered from the automatic operation stopped state or automatic operation halted state, the automatic operation stopped state or automatic operation halted state is once entered, respectively, after re-positioning is completed. Then, directing a cycle start restarts automatic operation.

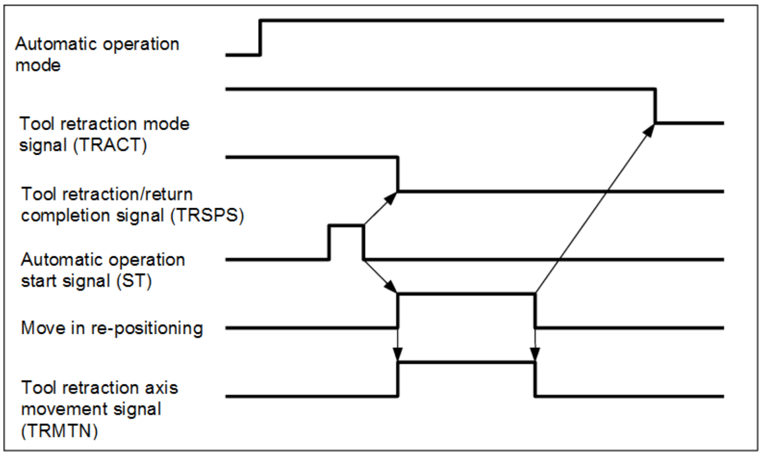

Fig. 5.8 (e) Timing chart of re-positioning (when movement is involved)

NOTE

1 If negative value or zero is set in parameter (No.7042) of moving axes, retract, recovery and re-positioning are performed at the dry run feedrate.

2 Manual feedrate override signal is effective for the feedrate of parameter (No.7042).

- Tool retract and recover for threading

Tool retract and recover for threading is different from ordinary tool retract and recover as follows

(1) During retraction, chamfering is performed between the specified retraction axis and threading axis. Furthermore, in this state, tool retraction axis movement signal TRMTN is not set to “1”

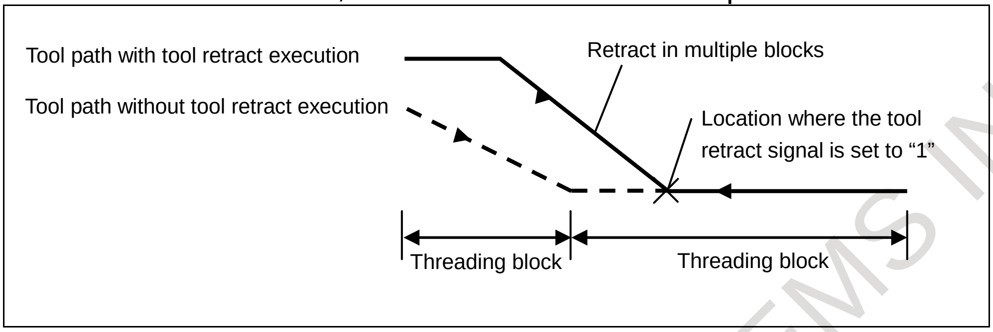
(2) After retraction, one block that does not specify threading is executed and the tool stops.

(3) When the major axis for threading is specified as the retraction axis, retraction is not performed by turning the TOOL WITHDRAW switch on. In this case, after a block that does not specify threading is executed, an alarm PS0429, “ILLEGAL COMMAND IN G10.6” is issued and the tool stops.

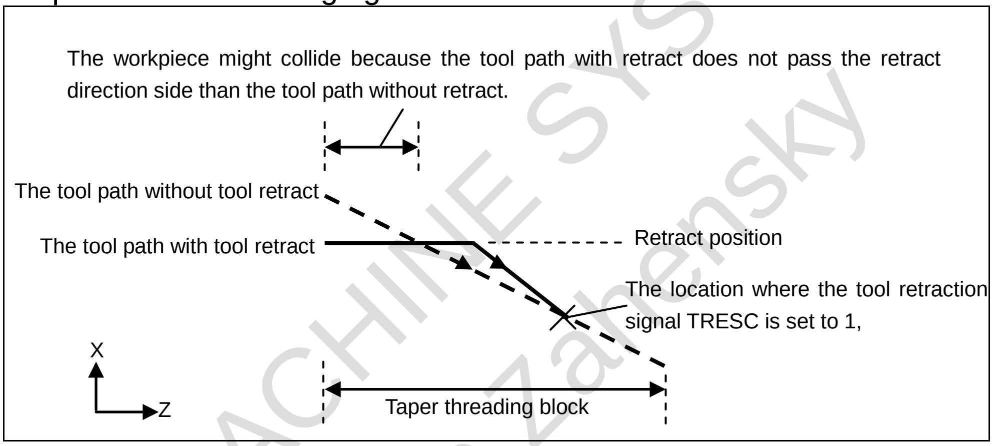
(4) As repositioning, the tool is returned to the position specified in the first block that does not specify threading.

NOTE

3 In threading cycle and multiple threading cycle, tool retract and recover is invalid.
4 In circular threading, tool retract and recover is invalid.
5 When dry run is executed, tool retract and recover for threading is invalid.
6 In continuous threading blocks other than last threading block, if retract start at a location near the block end, retract is executed in multiple blocks.



7 In taper threading, specify the retract position as the tool does not collide the workpiece surely because the tool might collide depending on specification of retract position as following figure.



Signal

Tool retraction signal TRESC<Gn059.0>

[Classification] Input signal

[Function] Tool retraction mode is selected.

[Operation] When this signal is turned to "1", the CNC retracts the tool by a pre-programmed distance.

Tool retraction mode signal TRACT<Fn092.3>

[Classification] Output signal

[Function] This signal reports that tool retraction mode is set. When the CNC is reset while the signal is "1", the signal is turned to "0", and tool retraction mode is canceled.

[Output cond.] The signal is turned to "1" when:
- Tool retraction mode is selected.

The signal is turned to "0" when:
- Tool retraction mode is not selected.

Tool return signal TRRTN<Gn059.1>

[Classification] Input signal

[Function] In tool retraction mode, a tool that has been retracted manually along an axis is returned to the retract position along the same axis.

[Operation] When this signal is turned from “1” to “0”, the CNC traces back the path of the manually moved tool to automatically return the tool to the retract position.

Tool retraction axis movement signal TRMTN<Fn092.4>

[Classification] Output signal

[Function] This signal reports that the tool is moving along an axis during retraction, recovery, or re-positioning.

[Output cond.] The signal is turned to “1” when:

- The tool moves along an axis during retraction, recovery, or re-positioning.

The signal is turned to “0” when:

- The tool does not move along any axis during retraction, recovery, or re-positioning.

Tool return completion signal TRSPS<Fn092.5>

[Classification] Output signal

[Function] This signal reports that the tool is in the retract position in tool retraction mode. When this signal is “0”, re-positioning cannot be performed by pressing the cycle start button.

[Output cond.] The signal is set to “1” when:

- Retraction has been completed.
- The tool has been returned to the retract position.

The signal is set to “0” when:

- The tool is not in the retract position in tool retraction mode.

Signal address

	#7	#6	#5	#4	#3	#2	#1	#0
Gn059							TRRTN	TRESC

	#7	#6	#5	#4	#3	#2	#1	#0
Fn092			TRSPS	TRMTN	TRACT			

Parameter

	#7	#6	#5	#4	#3	#2	#1	#0
7040					TRC	RPS	TRS	TRI

[Input type] Parameter input

[Data type] Bit path

#0 TRI The G10.6 command for tool retract and return is:

0: Assumed to be an absolute or incremental programming according to the absolute or incremental programming mode.

1: Always assumed to be an incremental programming.

#1 TRS After the completion of repositioning in tool retract and return:

0: Automatic operation is restarted.

1: Operation stops when the single block switch is on. When a cycle start is executed again, automatic operation is started.

#2 RPS When the tool retract signal TRESC <Gn059.0> is set to “1” after G10.6 is specified alone:

0: The tool is not retracted.

1: The tool is retracted with the value set for parameter No. 7041 or 11261 used as the incremental retraction distance.

#3 TRC When automatic operation is restarted after the tool retract and return is executed during the execution of a drilling canned cycle:

0: Machining of the same cycle is performed again (the same drilling is performed).

1: Machining of the next drilling cycle is performed (the next drilling is performed).

7041	Retraction distance in tool retract and return

[Input type] Setting input
[Data type] Real axis
[Unit of data] mm, inch, deg (input unit)
[Min. unit of data] Depend on the increment system of the applied axis
[Valid data range] 9 digit of minimum unit of data (refer to standard parameter setting table (A))
(When the increment system is IS-B, -999999.999 to +999999.999)

This parameter sets the retraction distance used when G10.6 is specified alone for the tool retract and return. The tool is retracted by the distance set for this parameter in the incremental mode. This data is valid only when bit 2 (RPS) of parameter No. 7040 is set to 1.

7042	Feedrate for each axis in tool retract and recover

[Input type] Parameter input
[Data type] Real axis
[Unit of data] mm/min, inch/min, deg/min (machine unit)
[Min. unit of data] Depend on the increment system of the applied axis
[Valid data range] Refer to the standard parameter setting table (C)

Set the feedrate for each axis in tool retract and recover. The recovery is performed at the feedrate specified by this parameter. The retract and repositioning are performed at the minimum feedrate among the parameter values of moving axes. Furthermore, if maximum number of record point in manual retract is exceeded, the tool move to last record point by linear interpolation at the minimum feedrate among the parameter values of moving axes. Manual feedrate override signal is effective for the feedrate of this parameter.

	#7	#6	#5	#4	#3	#2	#1	#0
10410								NRT

[Input type] Parameter input
[Data type] Bit axis

#0 NRT In tool retract and recover or manual intervention and return, the axis is:

0: Subject to tool retract and recover or manual intervention and return.

1: Not subject to tool retract and recover or manual intervention and return.

Limitation

Tool retract and recover cannot be performed along axes that are in the modes below.

- Superimposed control

Warning

> ⚠ **WARNING**
> The retraction axes and retraction distances specified with G10.6 need to be changed in appropriate blocks depending on the figure to be machined. An incorrectly specified retraction distance may damage a workpiece, the machine, or the tool. So, be very careful when specifying a retraction distance.

Alarm and message

Number	Message	Description
DS0310	NOT ON RETURN POINT	The return position recorded during retraction is not reached during recovery. The position may be displaced during recovery due to a machine lock or mirror image. Perform the operation again after making a reset.
PS0015	TOO MANY SIMULTANEOUS AXES	A move command was specified for more axes than can be controlled by simultaneous axis control. Either add on the simultaneous axis control extension, or divide the number of programmed move axes into two blocks.
PS0429	ILLEGAL COMMAND IN G10.6	When retraction was started in the threading block, the retract command was performed in the longitudinal direction of the threading.

5.8.1 Improvement of Tool Compensation for Tool Retract and Recover

Outline

In this function, when the recovery operation or re-positioning operation is started, the updated compensation value is used. Therefore the restart operation is performed with the updated compensation value.

Explanation

If this function is effective (the bit 7 (TRO) of parameter No.7002 is set to 1), when the recovery operation or re-positioning operation is started, the updated compensation value is used and the restart operation is performed with the updated compensation value. Thus, if the compensation value is updated after exchanging the tool at the manual retract position or the retract position, the tip point of tool becomes the same position as it of before exchanging tool in the restart operation thereafter.

The operation that updated compensation value is effective can be selected by the bit 6 (TNR) of parameter No.7002.

Example-1 (When the bit 6 (TNR) of parameter No.7002 is set to 0):
Assuming that the compensation value is updated from OFS_1 to OFS_2 after exchanging the tool at the manual retract position. When the recovery operation is started, the updated compensation value OFS_2 is used, the tip point of new tool and old tool is the same position in the retract position. (Refer to the figure Fig. 5.8.1 (a))

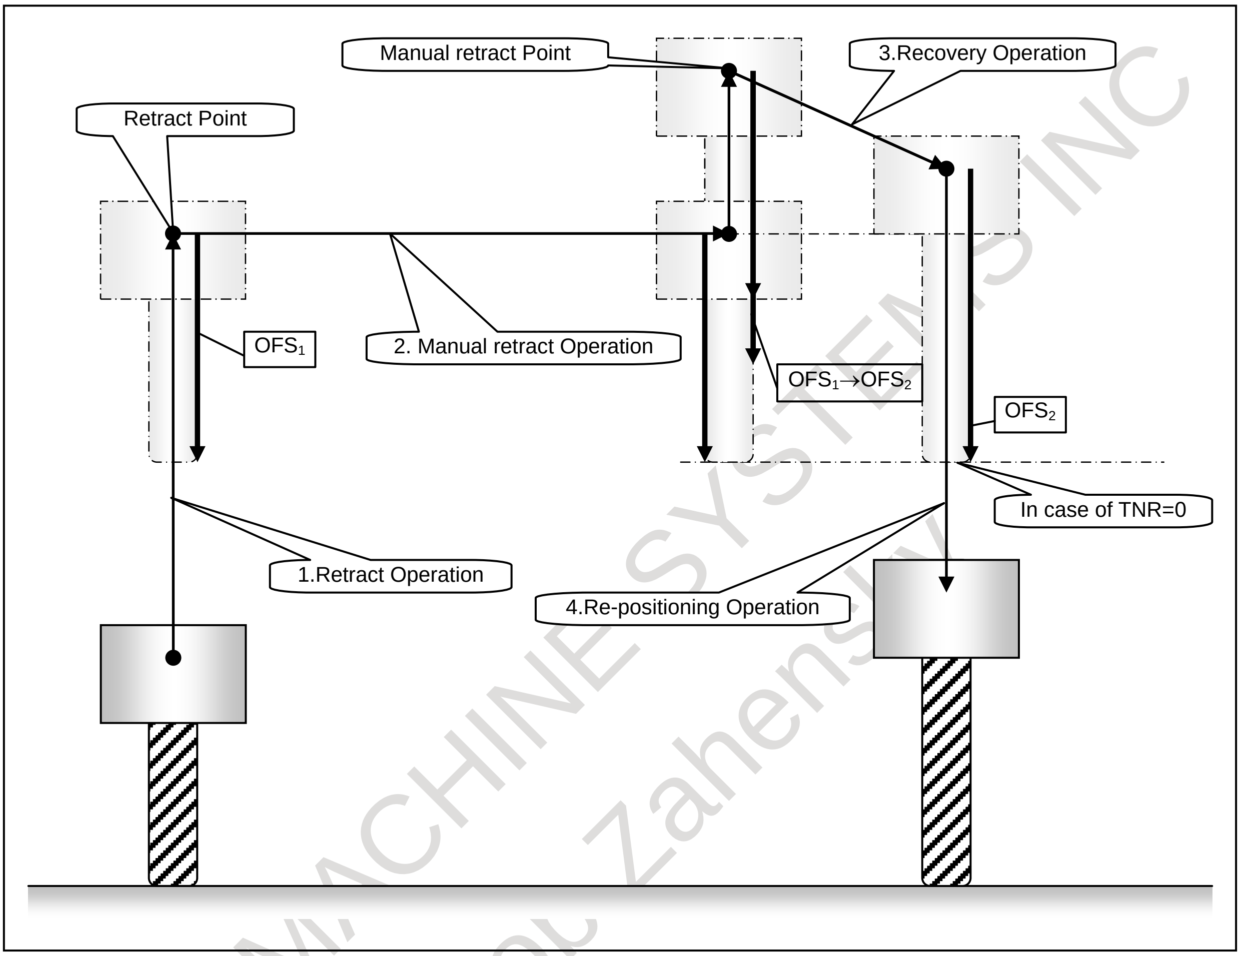

Fig. 5.8.1 (a)

Example-2 (When the bit 6 (TNR) of parameter No.7002 is set to 1):
Assuming that the compensation value is updated from OFS_1 to OFS_2 after exchanging the tool in the manual retract position. When the recovery operation is started, the updated compensation value OFS_2 is not used. After re-positioning operation, the updated compensation value OFS_2 is used (Refer to the figure Fig. 5.8.1 (b))

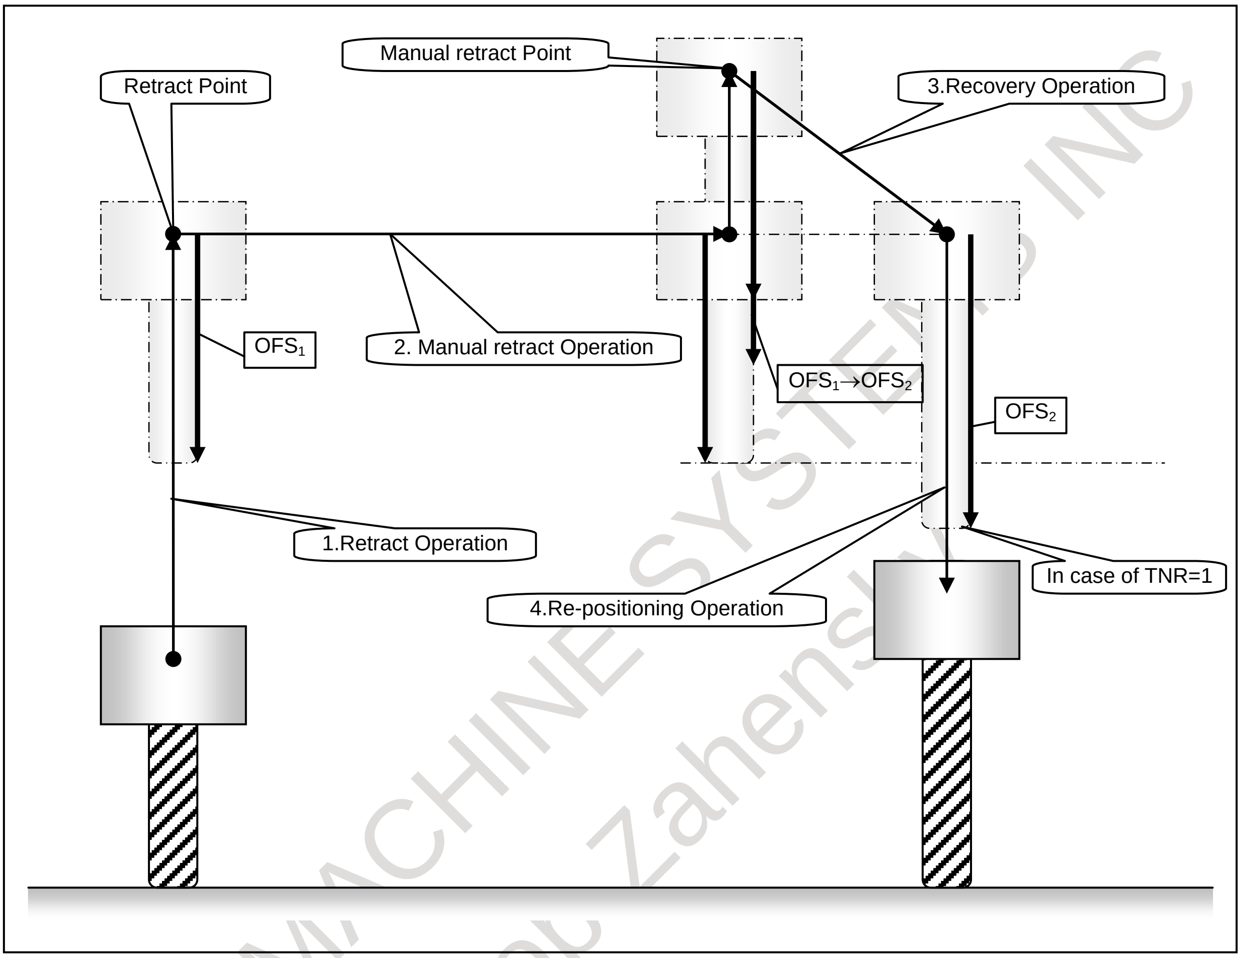

Fig. 5.8.1 (b)

Parameter

	#7	#6	#5	#4	#3	#2	#1	#0
7002	**TRO**	**TNR**						

[Input type] Parameter input
[Data type] Bit path

#6 TNR When the updated compensation value in the tool retract and recover function is effective (the bit 7 (TRO) of parameter No.7002 is set to 1)
0: The updated compensation value is effective in the recovery operation.
1: The updated compensation value is effective in the re-positioning operation.

#7 TRO When the compensation value is updated while the tool retract and recover function is executing,
0: The updated compensation value is invalid.
1: The updated compensation value is effective.

Notes

NOTE

1 The compensation considered by this function is as follows. Neither the cutter compensation nor the tool nose radius compensation is considered.
Machining system : Tool length compensation G43/G44 (wear/geometry),
Tool Offset G43.7/G44.7 (wear /geometry)
Lathe system : When the Extended Tool Selection is not used (the bit 3 (TCT) of parameter No.5040 is set to 0)
Tool compensation T code (wear /geometry)
When the Extended Tool Selection is not used (the bit 3 (TCT) of parameter No.5040 is set to 1)
Tool length compensation G43/G44 (wear /geometry),
Tool Offset G43.7/G44.7 (wear /geometry)

2 The compensation value can be changed only in the retract position or the manual retract position.

3 When the tool length compensation B is used, the vertical axis against the plane from which the tool retract and recover is executed is compensated. This plane is not a same plane when G43/G44 is instructed (In case machining system)

4 When the tool length compensation C is used and G43 or G44 is commanded, the compensated axis is indefinite. Therefore this function cannot be used in this case.

5 This function cannot be used during the movement to the reference position by the G28/G30 command or the G53 command is executing.

5.9 MANUAL INTERVENTION AND RETURN

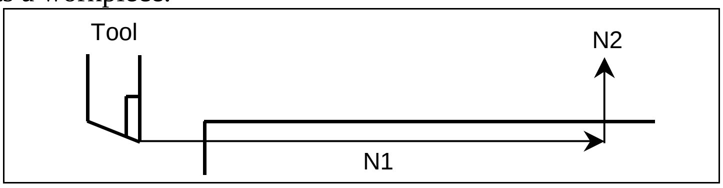
Overview

If you use feed hold to stop the tool from moving an axis during automatic operation and restarts the tool after manual intervention, for example, for checking a cutting surface, the tool can resume automatic operation after automatically returning to the pre-intervention position.
This function is optional.

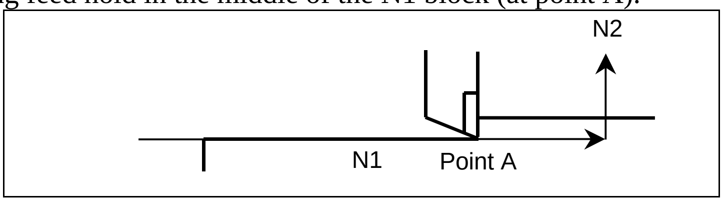
Explanation

Setting bit 0 (MIT) of parameter No. 7001 enables manual intervention and return.
The sequence of manual intervention and return is as follows:

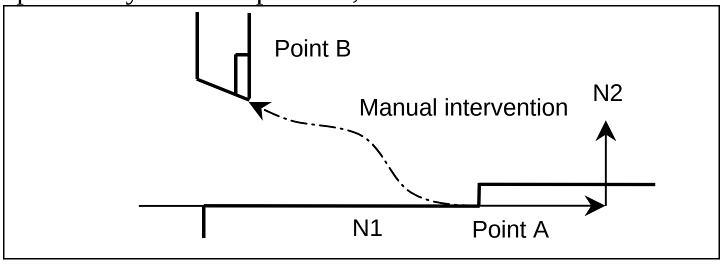
1. The N1 block cuts a workpiece.



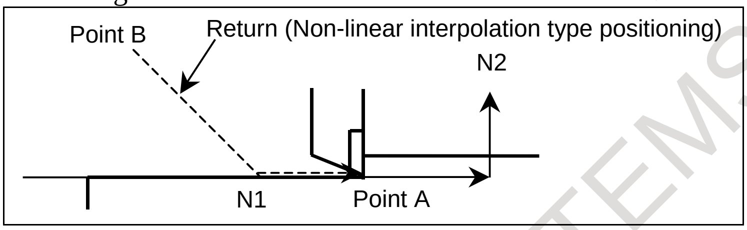
2. Stop the tool using feed hold in the middle of the N1 block (at point A).



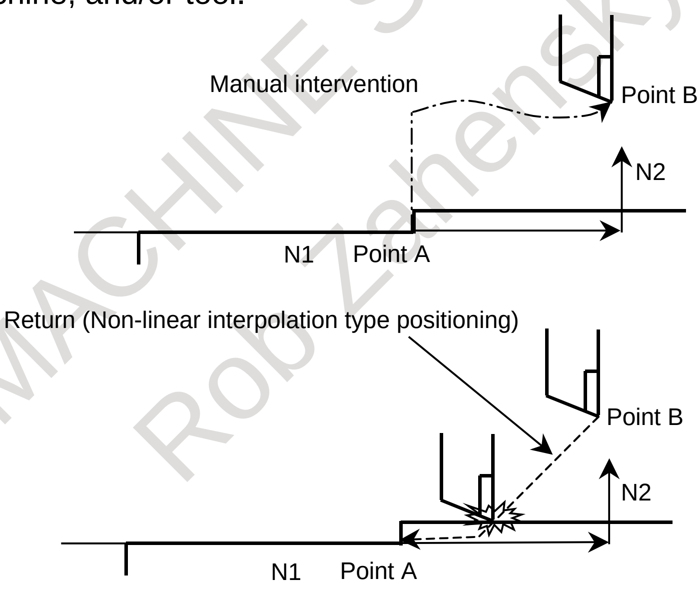
3. Retract the tool to point B by manual operation, then restart the machine.



4. After the tool automatically returns to point A by non-linear interpolation type positioning at the dry run feedrate, the remaining move command of the N1 block is executed.



> ⚠ **WARNING**
> Manual intervention must be performed correctly with meticulous care, following the machining direction and the shape of the workpiece, not to damage the workpiece, machine, and/or tool.



- Manual absolute on/off

In manual absolute off mode, the tool does not return to the stop position. Instead, the tool moves according to the manual absolute on/off function.

- Return feedrate

For the return operation, the dry run feedrate is used, and the jog feedrate override function is enabled. When manual rapid traverse selection signal RT <G019.7> is 1, the return feedrate is not dry run feedrate but rapid traverse rate.

- Return operation

Return operation is performed according to non-linear interpolation type positioning.

- Single block
If the single block stop switch is on during return operation, the tool stops at the stop position once and restarts movement when cycle start is executed again.

- Cancellation
If a reset, alarm, or emergency stop occurs during manual intervention or return operation, the manual intervention and return function is cancelled.

- MDI mode
The manual intervention and return function can be used in the MDI mode as well.

- Relation to other functions
In other functions such as canned cycle, the manual intervention and return function is effective.

- PMC axis control
If intervention is performed under PMC axis control after feed-holding of automatic operation, return operation does not apply to the axis moving under PMC axis control when the return operation starts.
If the return operation is started with the axis under PMC axis control being stopped after having completed the PMC axis control command, however, the return operation is performed by the amount of movement by PMC axis control.
When PMC axis control is used for an axis unrelated to the program command, set bit 0 of parameter No. 10410 to 1 to exclude the axis completely from return operation by the manual intervention and return function.

Parameter

	#7	#6	#5	#4	#3	#2	#1	#0
7001								MIT

[Input type] Parameter input
[Data type] Bit path

#0 MIT Manual intervention and return function is:
0: Disabled.
1: Enabled.

	#7	#6	#5	#4	#3	#2	#1	#0
10410								NRT

[Input type] Parameter input
[Data type] Bit axis

#0 NRT In tool retract and recover or manual intervention and return, the axis is:
0: Subject to tool retract and recover or manual intervention and return.
1: Not subject to tool retract and recover or manual intervention and return.

Alarm and message

Number	Message	Description
PS5219	CAN NOT RETURN	Manual intervention and return cannot be performed during execution of 3-dimensional coordinate system conversion, tilted working plane indexing.

Limitations

- Enabling/disabling of manual intervention and return function

Manual intervention and return function is enabled in the feed hold state (feed hold lamp signal SPL<Fn000.4> is set to "1").
Manual intervention and return function is disabled in automatic operation stop state (single block stop, feed hold stop with no travel distance remaining, etc.) and the operation is performed according to the manual absolute on/off function.

- Offset

When the tool is replaced using manual intervention for a reason such as tool damage, even if the amount of offset is changed when restarting in the middle of the interrupted block, the change is not reflected in machining.

- Machine lock, mirror image, and scaling

When performing manual intervention and return, never use the machine lock, mirror image, or scaling function.

- 3-dimensional coordinate system conversion, tilted working plane indexing

Alarm PS5129 is issued when manual intervention and the return is attempted during execution of 3-dimensional coordinate system conversion, tilted working plane indexing.

- Parking

Do not switch the parking signal during manual intervention and return (for example, after feed hold stop). The tool may not return in the right position when the parking signal is switched during manual intervention and return.

- Manual intervention and return by multi-path system

If cycle start is executed at the same time on two or more paths in a multi-path system, the path that performed manual intervention does return operation. However, the path that did not perform manual intervention restarts processing without doing return operation.

- Axis for which return operation is not performed

When the axis is in the following conditions, return operation of the axis is not performed.

- Spindle positioning
- Tapping
- Slave axis of axis synchronous control
- Slave axis of synchronous control
- Spindle control by servo motor
- Polygon axis

> **NOTE**
> Under synchronous control, manual intervention and return can be performed for the slave axis only when bit 2 (PKUx) of parameter No. 8162 is 1 and the master axis is parking.

- Feed hold during return operation

Feed hold is not effective during return operation.

5.10 RETRACE

M

Overview

The tool can retrace the path along which the tool has moved so far (reverse execution). Furthermore, the tool can move along the retraced path in the forward direction (forward reexecution). After forward reexecution is performed until the tool reaches the position at which reverse execution started, machining is continued as programmed.

> **NOTE**
> This function is optional.

Procedure

- Forward execution → reverse execution

To perform forward execution of a program, set the reverse execution signal RVS<Gn007.0> to "0", then perform a cycle start operation. If the reverse execution signal RVS is set to "1", reverse execution or the end of reverse execution results.

To perform reverse execution of a program, use one of the following methods:

1) Set the reverse execution signal RVS to "1" during forward execution of a block.
2) Perform a single block stop operation during forward execution, then set the reverse execution signal RVS to "1".
3) Perform a feed hold stop operation during forward execution, then set the reverse execution signal RVS to "1".

When method 1) is used, reverse execution starts after the end of the block being executed (after execution up to the single block stop position). Reverse execution does not start as soon as the reverse execution signal RVS is set to on.

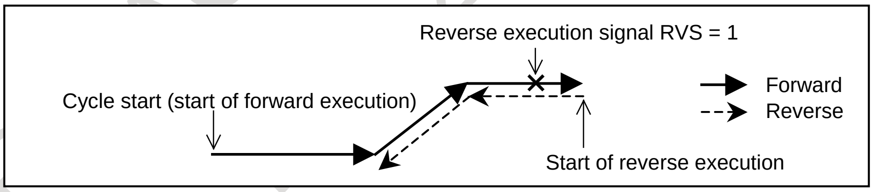


Fig. 5.10 (a)

When method 2) is used, performing a cycle start operation starts reverse execution from the position at which a single block stop takes place.

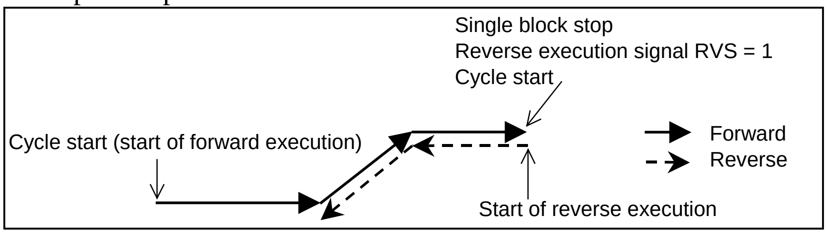

Fig. 5.10 (b)

When method 3) is used, performing a cycle start operation starts reverse execution from the position at which a feed hold stop takes place.

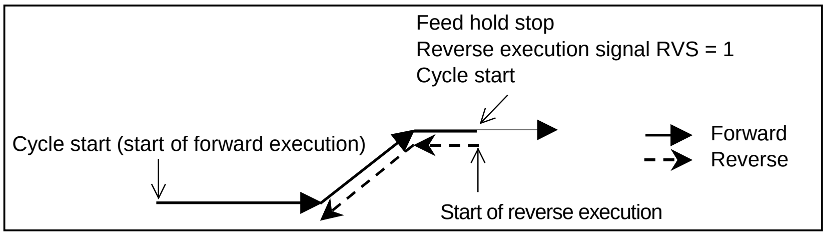

Fig. 5.10 (c)

- Reverse execution → forward reexecution

To perform forward reexecution of a program, use one of the following three methods:

1) Set the reverse execution signal RVS to 0 during reverse execution of a block.
2) Set the reverse execution signal RVS to 0 after a single block stop takes place during reverse execution.
3) Set the reverse execution signal RVS to 0 after a feed hold stop takes place during reverse execution.

When method 1) is used, forward reexecution starts after the block being executed ends (after execution up to the position at which a single block stop takes place). Forward reexecution does not start as soon as the reverse execution signal RVS is set to 0.

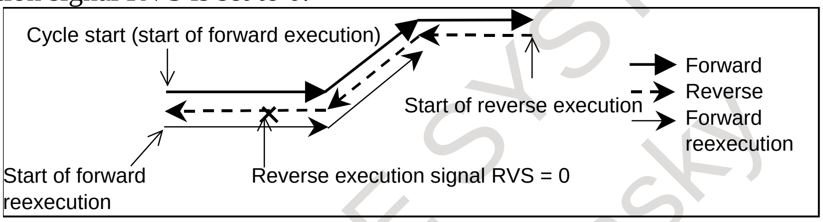

Fig. 5.10 (d)

When method 2) is used, performing a cycle start operation starts forward reexecution from the position at which a single block stop takes place.

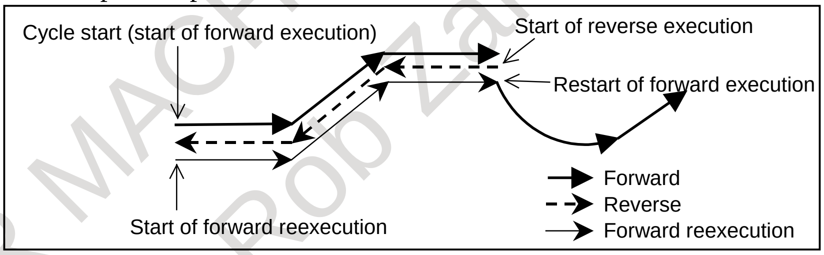

Fig. 5.10 (e)

When method 3) is used, performing a cycle start operation starts forward reexecution from the position at which a feed hold stop takes place.

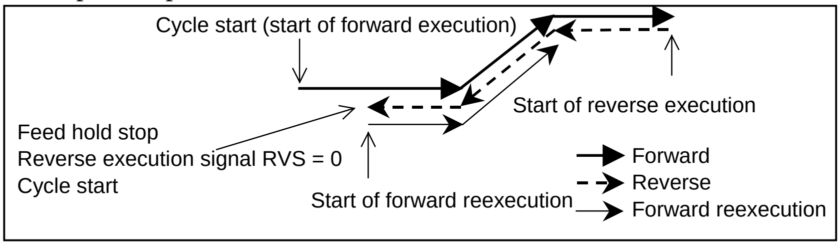

Fig. 5.10 (f)

- Reverse execution → end of reverse execution → forward reexecution

When a block to be executed is no longer present during reverse execution (when reverse execution has been performed up to the block where forward execution started, or when forward execution has not yet been performed), the reverse execution end state is entered, and operation stops.

Even when a cycle start operation is performed while the reverse execution signal RVS is held 1, operation is not performed, and the reverse execution end state is maintained. Forward reexecution (or forward execution) is started by setting the reverse execution signal RVS to 0 then performing a cycle start operation.

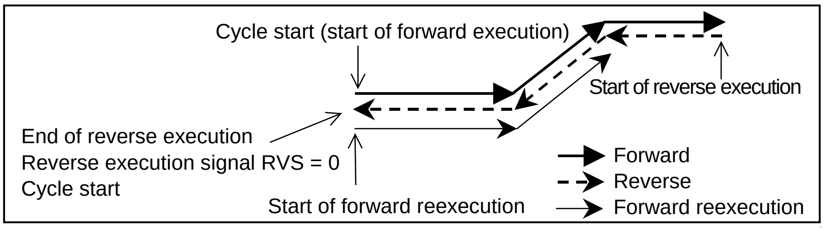

Fig. 5.10 (g)

- Forward reexecution → forward execution

After forward reexecution is performed up to the block at which reverse execution started, forward execution starts automatically, and commands are read from the program again and executed. No particular operation is required.

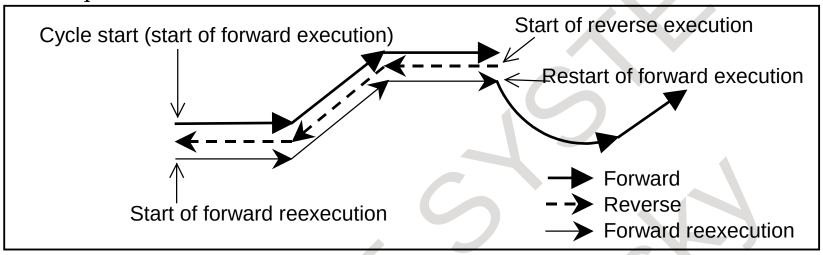

Fig. 5.10 (h)

If reverse execution was performed after feed hold stop, forward reexecution ends when the feed hold stop position is reached, then forward execution is performed. Also if single block operation was performed, forward reexecution ends at the single block stop position.

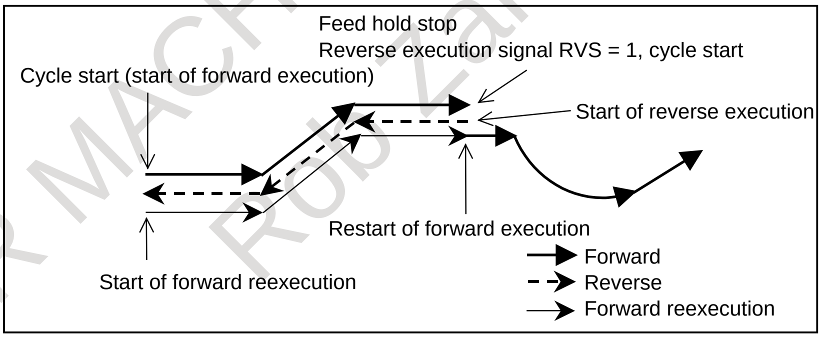

Fig. 5.10 (i)

Description

- Reverse execution and forward execution

Usually in automatic operation, a program is executed in the programmed order. This is called forward execution. This function allows a program executed by forward execution to be executed in the reverse direction. This is called reverse execution. Reverse execution allows the tool to retrace the path along which the tool has moved during forward execution.

Reverse execution of a program can be performed only for blocks that have been executed by forward execution.

Furthermore, in single block operation, reverse execution can also be performed on a block-by-block basis.

- Forward reexecution

Blocks that have been executed by reverse execution can be reexecuted in the forward direction up to the block from which reverse execution started. This is called forward reexecution. Forward reexecution allows the tool to retrace the same tool path as in forward execution until the position at which reverse execution started is reached.
After the block from which reverse execution started is reached, the program is executed again in the programmed order (forward execution).
Furthermore, in single block operation, forward reexecution can also be performed on a block-by-block basis.

- End of reverse execution

When a block to be executed is no longer present during reverse execution (when stored blocks have all been executed during reverse execution, or when forward execution has not yet been performed), operation stops. This is called the end of reverse execution.
